Multiple Signal Classification Based Joint Communication and Sensing System

Xu Chen, Member, IEEE, Zhiyong Feng, Senior Member, IEEE, Zhiqing Wei, Member, IEEE, Xin Yuan, Member, IEEE, Ping Zhang, Fellow, IEEE, J. Andrew Zhang, Senior Member, IEEE, and Heng Yang, Member, IEEE

Abstract—Joint communication and sensing (JCS) has become a promising technology for mobile networks because of its higher spectrum and energy efficiency. Up to now, the prevalent fast Fourier transform (FFT)-based sensing method for mobile JCS networks is on-grid based, and the grid interval determines the resolution. Because the mobile network usually has limited consecutive OFDM symbols in a downlink (DL) time slot, the sensing accuracy is restricted by the limited resolution, especially for velocity estimation. In this paper, we propose a multiple signal classification (MUSIC)-based JCS system that can achieve higher sensing accuracy for the angle of arrival, range, and velocity estimation, compared with the traditional FFT-based JCS method. We further propose a JCS channel state information (CSI) enhancement method by leveraging the JCS sensing results. Finally, we derive a theoretical lower bound for sensing mean square error (MSE) by using perturbation analysis. Simulation results show that in terms of the sensing MSE performance, the proposed MUSIC-based JCS outperforms the FFT-based one by more than 20 dB. Moreover, the bit error rate (BER) of communication demodulation using the proposed JCS CSI enhancement method is significantly reduced compared with communication using the originally estimated CSI.

Index Terms—Joint communication and sensing, MUSIC-based range and velocity estimation, perturbation analysis.

I. INTRODUCTION

WIRELESS communication and sensing are both indispensable for critical machine-type applications, e.g., the 5th generation (5G) and the future 6th generation (6G) networks [1], [2], [3]. Nevertheless, the proliferation of wireless sensing and communication infrastructures and devices will result in severe spectrum congestion problems [4]. Joint communication and sensing (JCS) has emerged as one of the most promising 6G key techniques due to its potential in improving spectrum and energy efficiency. It aims to achieve wireless sensing and communication simultaneously using unified spectrum and transceivers, sharing the same transmitted signals [5].

B. Related Works

Since orthogonal frequency-division multiplexing (OFDM) is the most popular physical-layer signal solution for broadband wireless networks, the JCS techniques based on OFDM signals have been widely researched. Sturm and Wiesbeck [6] proposed a fast Fourier transform (FFT)-based frequency-domain OFDM JCS signal processing method, realizing both active range estimation and communication. By utilizing the FFT-based JCS signal processing method, Zhang et al. [5] proposed a practical OFDM JCS system based on the time-division-duplex (TDD) mobile network, which is suitable for downlink (DL) echo sensing. In [7], the authors proposed an IEEE 802.11ad-based OFDM JCS vehicle-to-vehicle (V2V) system exploiting the preamble of a single-carrier physical layer frame to achieve V2V communication and full-duplex radar in the 60 GHz band. In [8], the authors proposed a code-division OFDM JCS system by introducing code-division multiplex into FFT-based OFDM JCS processing to improve the JCS sensing performance. As pointed out in [9], the full-duplex (FD) is the critical enabler for implementing DL JCS, which can simultaneously transmit JCAS signals and receive reflections. Seyed Ali et al. [10] realized an FD JCS platform that detects targets while communicating with another node by canceling the self-leakage interference with analog and digital self-leakage canceler.

Despite the above studies, there is a huge obstacle to utilizing the FFT-based OFDM JCS method in real applications. This method has to use consecutive OFDM subcarriers and symbols to estimate the range and velocity on the fixed grid, while the grid interval determines the resolution. Therefore, the range and velocity resolutions are determined by the number of used subcarriers and OFDM symbols, respectively. Thus, for mobile networks that typically have limited subcarriers and OFDM symbols, e.g., 14 OFDM symbols in each DL time slot, the sensing accuracy, especially the velocity accuracy,
is largely restricted. Besides, in [11], the author showed that overlapped interference deteriorates sensing performance in a networking situation. Therefore, it is also important for a sensing method that can still work effectively under a low signal to interference plus noise ratio (SINR).

C. Our Contributions

To resolve the aforementioned problems, we propose a multiple signal classification (MUSIC)-based sensing scheme for OFDM JCS systems that can achieve accurate estimation of the angle of arrival (AoA), range, and velocity, adapting to various OFDM communication signals with limited OFDM subcarriers and symbols. We also propose a JCS channel state information (CSI) enhancement method that exploits the JCS sensing results for refining CSI estimation with a Kalman filter. Furthermore, we provide some theoretical lower bound of mean square error (MSE) for the proposed MUSIC-based JCS sensing algorithms.

The main contributions of this paper are summarized as follows.

1. We propose a novel MUSIC-based JCS range and velocity estimation scheme, which consists of expanded two-dimensional (2D) MUSIC algorithms and two-step descent searching algorithms. The proposed scheme can use communication signals to achieve accurate range and velocity estimation.

2. We propose a JCS CSI enhancement method based on the Kalman filter, which exploits the JCS sensing parameters to construct the state transfer model and refines the CSI estimation using the JCS sensing results. This method can improve the bit error rate (BER) in the case of imperfect CSI.

3. We derive the theoretical MSEs for the proposed MUSIC-based JCS range and velocity estimation scheme using perturbation analysis. The theoretical MSEs of range and velocity estimation match the simulation MSEs well in the high SINR regime.

4. Extensive simulations are conducted to validate the proposed JCS sensing and CSI enhancement schemes and the theoretical MSEs. The results show that the proposed sensing scheme outperforms the conventional 2D-FFT method in terms of range and Doppler estimation MSEs by more than 20 dB, and the JCS CSI enhancement method can significantly improve communication performance.

D. Organization and Notations

The remaining parts of this paper are organized as follows. In Section II, we describe the DL JCS model and transmitting signal model, and propose the JCS channel model. Section III proposes the MUSIC-based JCS AoA, range and velocity estimation method. Section IV provides a theoretical analysis of the proposed estimation method. In Section V, the simulation results are presented. Section VI concludes this paper.

Notations: Bold uppercase letters denote matrices (e.g., $M$); bold lowercase letters denote column vectors (e.g., $v$); scalars are denoted by normal font (e.g., $\gamma$); the entries of vectors or matrices are referred to with brackets, for instance, the $q$th entry of vector $v$ is $[v]_q$, and the entry of the matrix $M$ at the $n$th row and $q$th column is $[M]_{n,m}$; $(\cdot)^H$, $(\cdot)^*$ and $(\cdot)^T$ denote Hermitian transpose, complex conjugate and transpose, respectively; $\|v_k\|_l$ represents the $l$-norm of $v_k$; $E(\cdot)$ represents the expectation of random variables; $M_1 \in \mathbb{C}^{M \times N}$ and $M_2 \in \mathbb{R}^{M \times N}$ represent that $M_1$ and $M_2$ are $M \times N$ complex-value and real-value matrices, respectively, and $v \sim \mathcal{CN}(m, \sigma^2)$ means $v$ follows a complex Gaussian distribution with mean $m$ and variance $\sigma^2$.

II. System Model

A. DL JCS Model

As shown in Fig. 1, we consider the DL JCS process between the BS and the machine-type user equipment (MUE), such as a road-side infrastructure and a vehicle. Millimeter-wave (mmWave) signal is considered for DL JCS. It is particularly suitable for JCS given its potential high resolution. The BS and MUEs are equipped with uniform plane arrays (UPAs). The BS is equipped with two spatially well-separated UPAs and a self-leakage canceler to realize the FD capability, as detailed in [10]. Therefore, the self-leakage between arrays is ignored and not considered in the signal model in this paper. One BS array is used for transmitting the DL JCS signal, and the other is used for consistently receiving echoes of the JCS signal. MUE receives the JCS signal to demodulate the communication data, while BS receives the echoes to estimate the AoAs, ranges, and velocities. Moreover, we consider that both BS and MUE receive the superimposed co-channel interference from multiple reflected interference sources (ISs). The MUE is equipped with one UPA for receiving the communication signal. The array sizes of the BS and MUEs are $P_t \times Q_t$ and $P_r \times Q_r$, respectively.

B. UPA Model

Fig. 2 demonstrates the model of UPAs. The uniform interval between the neighboring antenna elements is denoted by $d_u$. The size of the UPA is denoted by $P \times Q$. The two-dimensional (2D) AoA for receiving or the angle-of-departure (AoD) for transmitting the $k$th far-field signal is $p_k = (\varphi_k, \theta_k)^T$, where $\varphi_k$ is the azimuth angle, and $\theta_k$ is...
the elevation angle. We use $A_{p,q}$ to denote the $(p,q)$th antenna element, and $A_{0,0}$ to represent the reference antenna element. Then, the phase difference between $A_{p,q}$ and $A_{0,0}$ is expressed as

$$a_{p,q}(p) = \exp \left[ -j \frac{2\pi}{\lambda} d_p \cos \phi \sin \theta + q \sin \phi \sin \theta \right], \quad (1)$$

where $\lambda = c/f_c$ is the wavelength of the carrier, $c$ is the speed of light in vacuum, and $f_c$ is the carrier frequency.

The steering vector for the array is

$$a(p_k) = [a_{p,q}(p_k)]_{p=0,1,...,P-1; q=0,1,...,Q-1}, \quad (2)$$

where $a(p_k)$ is a $PQ \times 1$ vector, and $[v_{p,q}]_{(p,q)\in S_1 \times S_2}$ denotes the vector stacked by $v_{p,q}$ satisfying $p \in S_1$ and $q \in S_2$.

The steering matrix for $K$ far-field signals is then represented as

$$A = [a(p_1), a(p_2), \ldots, a(p_K)], \quad (3)$$

which is a matrix of dimension $PQ \times K$.

C. DL JCS Signal and Channel Model

In this paper, we consider the JCS system using OFDM-based signals. The transmitting signal is

$$s_D(t) = \sum_{m=0}^{M_r-1} \sum_{n=0}^{N_c-1} \sqrt{P_t} d_{n,m} e^{j2\pi (f_c + \Delta f) t} \text{Rect}\left( \frac{t - mT}{T} \right), \quad (4)$$

where $P_t$ is the DL transmit power, $d_{n,m}$ is the $m$th baseband OFDM symbol of the $n$th subcarrier, $\Delta f$ is the subcarrier interval, $T = T_s + T_g$, $T_s = 1/\lambda$ is the duration of OFDM symbol, $T_g$ is the guard interval, $M_s$ and $N_c$ are the number of OFDM symbols and subcarriers, respectively, and $\text{Rect}(t/T)$ is the rectangular window function of duration $T$. When the DL preamble signal for beam alignment and CSI estimation is transmitted, $d_{n,m}$ is replaced by the preamble symbols, denoted by $d_{n,m}^a$, which is known and deterministic to both BS and MUE. When the DL data signal is transmitted, $d_{n,m} \in \Theta_{QAM}$ is a random symbol, where $\Theta_{QAM}$ is the constellation of quadrature amplitude modulation (QAM). Note that $d_{n,m}$ is known to BS but unknown to MUE.

Next, we present the JCS channel model. As illustrated in Fig. 1, the DL JCS channel comprises a communication channel and an echo sensing channel.

- The JCS communication channel consists of a line-of-sight (LoS) path and several non-line-of-sight (NLoS) scattering paths.
- The JCS echo sensing channel consists of the echo path from MUE as a scatterer, and the echo paths from other scatterers which may or may not contribute to the communication channel. Since the signals after multiple reflections are much smaller than those with only one reflection, we only consider echoes directly reflected from scatterers.

Then, the JCS echo sensing and communication channels at the $n$th subcarrier of the $m$th OFDM symbol are defined as [8] and [5]

$$H_{i,n,m} = \sum_{l=0}^{L-1} \alpha_{i,n,m,l} \alpha^*(p_{RX,l}) a^T(p_{TX,l}), \quad (5)$$

where $p_{RX,l}$ is the AoD of BS’s JCS transceivers, $[\alpha_{p,q}]_{(p,q)\in S_1 \times S_2}$ is the corresponding transmit steering vectors as given in (2), $L$ is the number of scatterers, $l = 0$ for the direct path between BS and MUE, $l = 1, \ldots, L - 1$ for the reflected paths involved the $l$th scatterer. Moreover, $i = S$ and $i = C$ represent the echo sensing and communication channels, respectively; $p_{RX,l}^S$ and $p_{RX,l}^C$ are the AoD of BS’s echo receiver and the MUE’s communication receiver, respectively; and $\alpha_{S,n,m,l}$ and $\alpha_{C,n,m,l}$ are the channel fading for the $l$th echo sensing path and communication path, respectively.

1) JCS Echo Sensing Channel: When $i = S$, $a(p_{RX,l}^S) \in C^{P_r Q_s \times 1}$ is the receive steering vector for the $l$th echo path, as given in (2). Since the mmWave array is typically small, $p_{RX,l}^S = p_{TX,l}$. Moreover, $\alpha_{S,n,m,l}$ is the fading factor for the $l$th echo (when $l = 0$, MUE acts as a scatterer), which is given by

$$\alpha_{S,n,m,l} = b_{S,l} e^{2\pi m T f_{r,l+1}} e^{-j2\pi m T f_{r,l}}, \quad (6)$$

where $f_{r,0,l} = \frac{2\pi \nu_{r,0,l}}{c}$ and $f_{r,0,l} = \frac{2\pi \nu_{r,0,l} - 1}{c}$ are the echo Doppler frequency shifts and time delay between BS and MUE, with $\nu_{r,0,l}$ and $d_{0,l}$ being the corresponding radial relative velocity and the distance, respectively; $f_{s,l+1} = \frac{2\pi \nu_{s,l}}{c}$ and $f_{s,l} = \frac{2\pi \nu_{s,l} - 1}{c}$ are the echo Doppler frequency shifts and time delay between BS and the $l$th scatterer, with $\nu_{s,l}$ and $d_{l}$ being the corresponding radial relative velocity and distance, respectively. Moreover, $b_{S,l} = \sqrt{\frac{\tilde{\gamma}^2}{4\pi^2 d_{l}^2}}$ and $\beta_{S,l}$ is the random reflection fading factor of the $l$th scatterer, following the complex Gaussian distribution with zero mean and variance $\sigma_{S,l}^2$.

2) JCS Communication Channel: When $i = C$, $a(p_{RX,l}^C) \in C^{P_q Q_t \times 1}$ is the receive steering vector for the $l$th communication path, as given in (2). Moreover, $\alpha_{C,n,m,l}$ is the fading factor for the $l$th path, and is expressed as

$$\alpha_{C,n,m,l} = \begin{cases} \frac{b_{C,0} e^{2\pi m T f_{s,0} d_{0,l}} e^{-j2\pi m T f_{r,0,l}}}{b_{C,1} e^{2\pi m T f_{s,1} + f_{s,2} d_{1,l}} m T} & , l = 0 \frac{b_{C,1} e^{2\pi m T f_{s,1} + f_{s,2} d_{1,l}} m T}{b_{C,2} e^{2\pi m T f_{s,2} d_{2,l}} + m T} & , l > 0. \end{cases} \quad (7)$$

Authorized licensed use limited to the terms of the applicable license agreement with IEEE. Restrictions apply.
where \( f_{c,d,0} = \frac{v_{r,d,0}}{X} \) and \( \tau_{c,0} = \frac{d_{c}}{c} \) are the Doppler frequency shift and time delay of the LoS path; \( f_{d,l,1} = \frac{v_{r,d,1}}{X}, \tau_{d,l,1} = \frac{d_{l}}{c} \) and \( \tau_{d,l,2} = \frac{d_{c}}{c} \) are the Doppler frequency shifts and time delay between BS and scatterer, and between the scatterer and MUE of the \( l \text{th} \) NLoS path, respectively, with \( \tau_{d,l,2} \) and \( d_{l} \) being the radial relative velocity and distance between the \( l \text{th} \) scatterer and MUE, respectively; \( b_{C,0} = \sqrt{\frac{\lambda^2}{(4\pi d_{0})^2}} \) is the propagation loss of the LoS path, and \( b_{C,l} = \sqrt{\frac{(4\pi d_{l})^2}{(4\pi d_{0})^2}} \) is the path fading factor of the \( l \text{th} \) NLoS path with \( \beta_{C,l} \) being the scattering factor of the \( l \text{th} \) path. Here, \( \beta_{C,l} \) is the random reflecting factor of the scatterer in the \( l \text{th} \) path, which is assumed to follow the complex Gaussian distribution with zero mean and variance \( \sigma^2_{C,l} \). Due to the existence of \( b_{C,l} \), the LoS path is much stronger than the NLoS path for mmWave.

Note that \( H_{C,n,m} \) is unknown and needs to be estimated by utilizing the DL preambles, \( d_{n,m} \). The parameters of \( H_{S,n,m} \) are unknown, and BS has to estimate the AoA, range and Doppler in \( H_{S,n,m} \). Since BS acts as both the sensing transmitter and receiver, both \( d_{n,m} \) and \( n_{d,m} \) can be used for DL sensing. Moreover, \( l = 0 \) represents a special path, for which the echo time delay and Doppler are twice of those in the communication channel, which is the theoretical basis for the JCSI enhancement method to be introduced in Section III-B.

### D. JCSI Received Signal Model

In this subsection, we present the expressions for DL JCSI received signals.

1) DL Communication Received Signal: The frequency-domain DL communication signal received by MUE at the \( m \text{th} \) OFDM symbol of the \( s \text{th} \) subcarrier is expressed as

\[
y_{C,n,m} = \sqrt{P_{d,n,m}}(w_{RX})^H H_{C,n,m} w_{TX} + n_{C,n,m}^X,
\]

where \( w_{TX} \in \mathbb{C}^{P_{TX} \times 1} \) and \( w_{RX} \in \mathbb{C}^{P_{RX} \times 1} \) are the JCSI transmit and communication receive beamforming (BF) vectors, respectively; \( \|w_{TX}\|^2 = \|w_{RX}\|^2 = 1 \). In this paper, the low-complexity least-square (LS) method is used to generate \( w_{TX} \) and \( w_{RX} \) for BF. BS utilizes the known DL preambles, i.e., \( d_{n,m} = \overline{d}_{n,m} \), to conduct beam alignment with MUE. When beam alignment is completed, \( w_{TX} = c_1[a^T(\overline{p}_{TX,0})]^\dagger \) and \( w_{RX} = c_2[a(\overline{p}_{RX,0})]^\dagger \), where \( c_1 \) and \( c_2 \) are both arbitrary complex values with modulus 1, \([\cdot]^\dagger \) is the pseudo-inverse operation, \( \overline{p}_{TX,0} \approx p_{TX,0} \) and \( \overline{p}_{RX,0} \approx p_{RX,0} \) \( \dagger \). Simultaneously, the unknown communication CSI, \( (w_{RX})^H H_{C,n,m} w_{TX} \), can be estimated by processing the received preambles.

Moreover, \( n_{C,n,m} = n_{C,n,m} + \xi_{C,n,m} \) is the sum of noise and interference, \( n_{C,n,m} = (w_{RX})^H n_{C,n,m} \) and \( \xi_{C,n,m} = (w_{RX})^H x_{C,n,m} \) are transformed noise and interference, the dimensions of \( n_{C,n,m} \) and \( x_{C,n,m} \) are both \( P_{TX} \times 1 \), \( n_{C,n,m} \) is Gaussian noise vectors with each element following \( \mathcal{CN}(0, \sigma_{n,m}^2) \), and \( x_{C,n,m} \) is the reflected interference signals from other network devices. We assume there are \( N_c \) ISs, and the reflected fading for each IS follows a Gaussian distribution. Since the superimposed one of multiple random OFDM signals is noise-like, the \( p \text{th} \) element of \( x_{C,n,m} \) can be given as

\[
x_{C,n,m,p} = \sum_{i=0}^{P_{TX}} \sqrt{P_{TX}} \gamma_{p,i} \beta_{p,i} \phi_p, \quad \text{where } P_{TX} \text{ is the power of incident signal from the } i\text{th IS, and } \beta_{p,i} \sim \mathcal{CN}(0, 1). \]

Let \( P_{IC} = \sum_{i=0}^{N_c} P_{TX} \). The interference to noise power ratio (INR) is \( \gamma_{IN} = \frac{P_{TX}}{P_{IC} + \sigma_{N}^2} \). Further, we define the communication SINR (C-SINR) as

\[
\gamma_{C,n,m} = \frac{P_{TX}^2 \|h_{C,n,m}\|^2}{P_{IC} + \sigma_{N}^2},
\]

where \( h_{C,n,m} = (w_{RX})^H H_{C,n,m} w_{TX} \) is the gain of DL communication signal.

2) DL Echo Sensing Received Signal: The echo signal that BS receives for the \( m \text{th} \) OFDM symbol at the \( s \text{th} \) subcarrier is given by

\[
y_{S,n,m} = \sqrt{P_{d,n,m}} H_{S,n,m} w_{TX} + n_{S,n,m}^X = \sqrt{P_{d,n,m}} \sum_{l=0}^{L-1} \left( \alpha_{S,n,m,l} |\chi_{TX,l}| \right) X_{TX,l} \left( \alpha_{S,n,m,l} |\chi_{RX,l}| \right) + n_{S,n,m}^X. \]

where \( \chi_{TX,l} = a^T(p_{TX,l}) w_{TX} \) represents the gain of the DL JCSI transmit BF, \( n_{S,n,m} = n_{S,n,m} + x_{S,n,m} + n_{S,n,m} \) is the sum of noise and interference, \( n_{S,n,m} \) is the Gaussian noise vector with each element following \( \mathcal{CN}(0, \sigma_{n,m}^2) \), \( x_{S,n,m} \) is the superimposed interference vector for \( N_s \) reflected ISs, and the dimensions of \( x_{S,n,m} \) and \( x_{S,n,m} \) are \( P_{TX} \times 1 \). Similar to \( x_{C,n,m} \), the \( p \text{th} \) element of \( x_{S,n,m} \) can be given as

\[
x_{S,n,m,p} = \sum_{i=0}^{N_c} \sqrt{P_{TX}} \beta_{p,i}, \quad \text{where } P_{TX} \text{ is the incident power of the } i\text{th IS, and } \beta_{p,i} \sim \mathcal{CN}(0, 1). \]

The aggregate power of each element of \( x_{S,n,m} \) is \( P_{s} = \sum_{i=0}^{N_c} P_{TX} \). The sensing INR is defined as \( \gamma_{S} = P_{s}/\sigma_{N}^2 \). Further, the sensing SINR (S-SINR) is defined as

\[
\gamma_{S,n,m} = \frac{P_{TX}^{2} \|h_{S,n,m}\|^2}{P_{s} + \sigma_{N}^2},
\]

where \( h_{S,n,m,l} = \alpha_{S,n,m,l} |\chi_{TX,l}| \) is the gain of DL echo sensing signal at each antenna element.

By defining \( s_{n,m,l} = \sqrt{P_{d,n,m}} \alpha_{S,n,m,l} |\chi_{TX,l}| \) and \( s_{n,m,l} = [s_{n,m,l}]_{l=0,1,...,L-1} \),

\[
y_{S,n,m} = A_{S,RX} s_{n,m} + n_{S,n,m}^X,
\]

where \( A_{S,RX} = [a(p_{TX,l})]^T \) is the steering matrix stacked by steering vectors of \( L \) echoes, \( A_{S,RX} \in \mathbb{C}^{P_{RX} \times L} \), and \( s_{n,m,l} \in \mathbb{C}^{L \times 1} \). By stacking all the \( M_s \) OFDM symbols with \( N_c \) subcarriers, we have

\[
Y_S = A_{S,RX} S + N_{S,n,m}^X,
\]

where \( S = [s_{n,m,l}([m, n])_{l=0}^{N_n} \in \mathbb{C}^{L \times N_s} \times [0, \cdots, M_s] \in \mathbb{C}^{L \times N_s} \), and \( Y_S \in \mathbb{C}^{P_{RX} \times N_s M_s} \).

### III. DL JCSI Signal Processing

In this section, we demonstrate the signal processing for DL JCSI sensing and communication, which is shown in Fig. 3. We first present the sensing signal processing scheme, and then elaborate on the JCSI CSI enhancement method.
A. JCS Sensing Signal Processing

In this subsection, we first present the conventional MUSIC method for estimating the 2D AoAs, and then introduce the novel MUSIC-based range and Doppler estimation method.

1) JCS MUSIC 2D Angle Detection: First, the correlation matrix of \( Y_S \) is obtained as

\[
R_X = \frac{1}{M_N} Y_S Y_S^H. \tag{14}
\]

By applying eigenvalue decomposition to \( R_X \), we have

\[
[U_x, \Sigma_x] = \text{eig} (R_X), \tag{15}
\]

where \( \Sigma_x \) is the real-value eigenvalue diagonal matrix in descending order, and \( U_x \) is the orthogonal eigen matrix. Calculate the average of eigenvalues and denote it as \( \bar{U} \), where \( \bar{U} \) is the real-value eigenvalue diagonal matrix in descending order. Let \( \alpha \) be a preset threshold, which is determined as elaborated in Appendix A. Then, the number of echo paths is determined by the number of eigenvalues no smaller than \( \alpha \), denoted by \( N_x \).

Construct \( U_N = U_x(:, N_x + 1 : P_t Q_r) \) as the noise subspace basis. We then use it to obtain the spatial angular spectrum function as [12]

\[
f_a(p; U_N) = a^H(p) U_N (U_N)^H a(p), \tag{16}
\]

where \( p = (\varphi, \theta) \) is the 2D angle, and \( a(p) \) is given in (2). The spatial spectrum is represented as [12]

\[
S_a(p; U_N) = [a^H(p) U_N (U_N)^H a(p)]^{-1}. \tag{17}
\]

The maximum points of \( S_a(p; U_N) \), i.e., the minimum points of \( f_a(p; U_N) \) are the estimated AoAs [13]. We first find \( N_x \) local maximum points of \( S_a(p; U_N) \) using a grid searching method with relatively large granularity, then we use the Newton descent method to identify the accurate minimum point of \( f_a(p; U_N) \) by inputting the above local maximum points as initial points for iteration.

2) JCS Range and Doppler Detection: After the AoAs are obtained, through BF at the AoA of interest, the filtered received signal at the \( n \)th subcarrier of the \( m \)th OFDM symbol can be expressed as

\[
\bar{y}_{S,n,m,k} = (w_{RX,S,k})^H y_{S,n,m} = \sqrt{P_t} d_{n,m} \sum_{l=0}^{L-1} [\tilde{a}_{S,n,m,l} c_{T X,l} (\omega_{RX,l,k}) + w_{t,n,m,k}],
\]

where \( w_{t,n,m,k} = (w_{RX,S,k})^H n_{S,n,m} \) is the transformed noise and interference with zero mean and variance \( \sigma_w^2 \), \( \omega_{RX,l,k} = (w_{RX,S,k})^H a(p_{RX,l,k}) \) is the receive BF gain, and \( w_{RX,S,k} \) is the receive BF vector for the \( k \)th AoA, \( k \in \{0, 1, \ldots, N_x - 1\} \). Note that \( \omega_{RX,l,k} \) is typically larger than \( \omega_{RX,l,k} (l \neq k) \) due to the narrow beam feature of mmWave.

By substituting (6) into (18), we obtain (19), shown at the bottom of the page. In (19), there are independent complex exponential functions for range and Doppler, i.e., \( e^{-j2\pi n \Delta f_{1}} \) and \( e^{j2 \pi f_{s,l,i,mT}} \), respectively. Here, we define the range and Doppler steering vectors as

\[
a_r(r) = [e^{-j2 \pi n \Delta f_{1}}]_{n=0,1,..,N_x-1}, \tag{20}
\]

\[
a_f(f) = [e^{j2 \pi mT f}]_{m=0,1,..,M_s-1}, \tag{21}
\]

respectively. The range and Doppler steering matrices are defined as

\[
A_r = [a_r(r)]_{|r|=0,1,..,L-1}, \tag{22}
\]

\[
A_f = [a_f(f)]_{|f|=0,1,..,M_s-1}, \tag{23}
\]

where \( A_r \in \mathbb{C}^{N_x \times L} \) and \( A_f \in \mathbb{C}^{M_s \times L} \).

Stack \( \bar{y}_{S,n,m,k} \) into a matrix \( \bar{Y}_S \) where \( [\bar{Y}_S]_{n,m} = \bar{y}_{S,n,m,k} \), then erase the communication symbol matrix \( D_s \) where \( D_s = d_{n,m} \). From \( \bar{Y}_S \), we obtain

\[
\bar{H}_S = \frac{\bar{Y}_S}{D_s}, \tag{24}
\]

where the division is element-wise, and \( \bar{H}_S \in \mathbb{C}^{N_x \times M_s} \).

According to (19), \( \bar{H}_S \) can be expressed by \( A_r \) as

\[
\bar{H}_S = A_r S_{r,s} + W_{tr}, \tag{25}
\]

where \( S_{r,s} = [s_{r,m}]_{m=0,1,..,M_s-1} \in \mathbb{C}^{L \times M_s}, \)

\[
s_{r,m} = [\sqrt{P_t} b_{S,l,k} c_{T X,l,k} c_{T X,l} e^{j2 \pi mT}]_{l=0,1,..,L-1}, \text{ and } W_{tr} = w_{t,n,m,k}. \]

On the other hand, the transpose of \( \bar{H}_S \), i.e., \( (\bar{H}_S)^T \), can be presented by \( A_f \) as

\[
(\bar{H}_S)^T = A_f S_{f,s} + W_{tf}, \tag{26}
\]

where \( S_{f,s} = [s_{f,n}]_{n=0,1,..,N_x-1} \in \mathbb{C}^{L \times N_x}, s_{f,n} = [\sqrt{P_t} b_{S,l,k} c_{T X,l,k} c_{T X,l} e^{-j2 \pi n \Delta f_{1}}]_{l=0,1,..,L-1}, \text{ and } W_{tf} = w_{t,n,m,k}. \)

Authorized licensed use limited to the terms of the applicable license agreement with IEEE. Restrictions apply.
The range and Doppler can be estimated via the autocorrelation of \( \mathbf{H}_S \) and \( (\mathbf{H}_S)^T \), which are given by

\[
\mathbf{R}_{x,r} = \frac{1}{M_s} \mathbf{H}_S (\mathbf{H}_S)^H, \\
\mathbf{R}_{x,f} = \frac{1}{N_c} (\mathbf{H}_S)^T (\mathbf{H}_S)^*,
\]

respectively. Denote the noise subspaces of \( \mathbf{R}_{x,r} \) and \( \mathbf{R}_{x,f} \) as \( \mathbf{U}_{x,r,N} \) and \( \mathbf{U}_{x,f,N} \), respectively.

**Theorem 1:** The minimum of \( \| \mathbf{U}_{x,r,N}^H \mathbf{a}_r (r) \|_2^2 \), denoted by \( r_{s,l} \), is linked to the range via \( r_{s,l} = 2d_{l,1} \). The minimum of \( \| \mathbf{U}_{x,f,N}^H \mathbf{a}_f (f) \|_2^2 \) corresponds to the Doppler value, \( f_{s,l,1} \).

**Proof:** The proof is presented in Appendix C.

By applying eigenvalue decomposition to \( \mathbf{R}_{x,r} \) and \( \mathbf{R}_{x,f} \), we have

\[
[\mathbf{U}_{x,r}, \Sigma_{x,r}] = \text{eig} (\mathbf{R}_{x,r}), \\
[\mathbf{U}_{x,f}, \Sigma_{x,f}] = \text{eig} (\mathbf{R}_{x,f}),
\]

where \( \Sigma_{x,r} \) and \( \Sigma_{x,f} \) are the real-value diagonal matrices of eigenvalues in the descending order, and \( \mathbf{U}_{x,r} \) and \( \mathbf{U}_{x,f} \) are the corresponding eigenvector matrices.

We use \( m_{x,r} \) to denote the mean value of \( \Sigma_{x,r} \), and then set the threshold \( \alpha_{x,r} \) using the method in Appendix A by replacing \( \Sigma_{x,r} \) with \( \Sigma_{x,r} \). The number of targets in the AoA of interest, \( N_{x,r} \), is determined as the number of eigenvalues no smaller than \( \alpha_{x,r} m_{x,r} \). Then, the noise subspace basis for range estimation is derived as \( \mathbf{U}_{x,r,N} = \mathbf{U}_{x,r}(:, N_{x,r} + 1 : N_c) \). Since the number of targets is the same for both Doppler and range estimation, the noise subspace basis for the Doppler estimation can be derived as \( \mathbf{U}_{x,f,N} = \mathbf{U}_{x,f}(:, N_{x,r} + 1 : N_s) \).

We use \( \mathbf{U}_{x,r} \) and \( \mathbf{U}_{x,f} \) to derive the range and Doppler spectrum functions as

\[
f_r (r; \mathbf{U}_{x,r,N}) = \mathbf{a}_r (r)^H \mathbf{U}_{x,r,N} (\mathbf{U}_{x,r,N})^H \mathbf{a}_r (r), \\
f_f (f; \mathbf{U}_{x,f,N}) = \mathbf{a}_f (f)^H \mathbf{U}_{x,f,N} (\mathbf{U}_{x,f,N})^H \mathbf{a}_f (f),
\]

respectively. The range and Doppler spectra can be given by

\[
S_r (r; \mathbf{U}_{x,r,N}) = [\mathbf{a}_r (r)^H \mathbf{U}_{x,r,N} (\mathbf{U}_{x,r,N})^H \mathbf{a}_r (r)]^{-1}, \\
S_f (f; \mathbf{U}_{x,f,N}) = [\mathbf{a}_f (f)^H \mathbf{U}_{x,f,N} (\mathbf{U}_{x,f,N})^H \mathbf{a}_f (f)]^{-1},
\]

respectively.

The maximum points of \( S_r (r; \mathbf{U}_{x,r,N}) \) and \( S_f (f; \mathbf{U}_{x,f,N}) \), i.e., the minimum points of \( f_r (r; \mathbf{U}_{x,r,N}) \) and \( f_f (f; \mathbf{U}_{x,f,N}) \), are the range and Doppler estimation values, denoted by \( \hat{r}_{s,l} \) and \( \hat{f}_{s,l} \), respectively. The distance, \( d_{l,1} \), and radial velocity, \( v_{r,0,1} \), between BS and the target are estimated as \( \hat{d}_{l,1} = \frac{r_{s,l}}{2} \) and \( \hat{v}_{r,0,1} = \frac{\Delta f_r}{2} \).

The minimum of \( f_r (r) \) and \( f_f (f) \) can be identified using a two-step Newton descent method. We first find the local maximum points of \( S_r (r) \) and \( S_f (f) \) with large-granularity grid searching. Then, we use the Newton descent method to find the accurate minimum points of \( f_r (r) \) and \( f_f (f) \) using the above local maximum points as the initial points. The iterative expression for the Newton descent method is derived as follows.

By applying the Taylor series decomposition to \( f_r (r) \) and \( f_f (f) \), and taking their first order derivative over \( r \) and \( f \), respectively, we obtain

\[
\frac{\partial f_r (r)}{\partial r} = \frac{\partial f_r (r_0)}{\partial r} + \frac{\partial^2 [f_r (r_0)]}{\partial^2 r} (r - r_0),
\]

and

\[
\frac{\partial f_f (f)}{\partial f} = \frac{\partial f_f (f_0)}{\partial f} + \frac{\partial^2 [f_f (f_0)]}{\partial^2 f} (f - f_0).
\]

By setting the above first-order derivative to be 0, the iterative descent expression for range and Doppler estimation can be given by

\[
r^{(k)} = r^{(k-1)} - \left[ \frac{\partial^2 f_r (r^{(k-1)})}{\partial^2 r} \right]^{-1} \frac{\partial f_r (r^{(k-1)})}{\partial r},
\]

\[
f^{(k)} = f^{(k-1)} - \left[ \frac{\partial^2 f_f (f^{(k-1)})}{\partial^2 f} \right]^{-1} \frac{\partial f_f (f^{(k-1)})}{\partial f},
\]

respectively. From (29), the first-order and second-order derivatives of \( f_f (f) \) and \( f_r (r) \) are expressed as

\[
\frac{\partial f_f (f)}{\partial f} = 2 \text{Re} \left[ \mathbf{a}_f^{(1)} (f)^H \mathbf{U}_{x,f,N} (\mathbf{U}_{x,f,N})^H \mathbf{a}_f (f) \right],
\]

\[
\frac{\partial^2 f_f (f)}{\partial^2 f} = 2 \text{Re} \left[ \mathbf{a}_f^{(2)} (f)^H \mathbf{U}_{x,f,N} (\mathbf{U}_{x,f,N})^H \mathbf{a}_f (f) \right],
\]

\[
\frac{\partial f_r (r)}{\partial r} = 2 \text{Re} \left[ \mathbf{a}_r^{(1)} (r)^H \mathbf{U}_{x,r,N} (\mathbf{U}_{x,r,N})^H \mathbf{a}_r (r) \right],
\]

\[
\frac{\partial^2 f_r (r)}{\partial^2 r} = 2 \text{Re} \left[ \mathbf{a}_r^{(2)} (r)^H \mathbf{U}_{x,r,N} (\mathbf{U}_{x,r,N})^H \mathbf{a}_r (r) \right],
\]

where \( \mathbf{a}_r^{(1)} (r) \) and \( \mathbf{a}_f^{(1)} (f) \) are the first-order and second-order derivatives of \( \mathbf{a}_r (r) \) and \( \mathbf{a}_f (f) \), respectively.

The JCS Communication Signal Processing

By substituting (5) into (8), and taking into consideration that \( w_{TX} \) and \( w_{RX} \) in (8) generate beams pointed at the AoD and AoA of the LoS communication path, respectively, we obtain the communication received signal as

\[
y_{C,n,m} = \sqrt{T_d} d_{n,m} h_{C,n,m} + \eta_{C,n,m},
\]

where \( h_{C,n,m} = b_{C,0} \mathbf{w}_{RX,0} \mathbf{x}_{TX,0} e^{j2\pi m T_d \phi_{C,0}} e^{-j2\pi n \Delta f_{c,0}} \) is the real communication channel response, and \( \mathbf{w}_{RX,0} = (\mathbf{w}_{RX})^H \mathbf{P}_{RX,0} \) and \( \mathbf{x}_{TX,0} = \alpha^T (\mathbf{p}_{TX,0}) \mathbf{w}_{TX} \) are the BF receive and transmit gains, respectively. In the CSI estimation, \( d_{n,m} = d_{n,m} \), and we denote \( y_{C,n,m} = \hat{y}_{C,n,m} \) as the received signal. The CSI estimated with the LS method is expressed as \([14]\)

\[
\hat{h}_{C,n,m} = \frac{\hat{y}_{C,n,m}}{\sqrt{T_d} d_{n,m}} = \hat{h}_{C,n,m} + w_{C,n,m}.
\]
Algorithm 1 JCS CSI Enhancement Method

Input: The observation variance $\sigma^2_p$. The variance of the initial estimation $p_{w,0}$. The initial observation $h_{C,0,m}$; The transfer factor $A = e^{-j2\pi \Delta f t_e}$; The observation sequence $\Phi$.

Output: Filtered sequence $[\hat{h}_{C,n,m}]_{n=0,\ldots,N_c-1}$.

Step 1: $\hat{h}_{C,0,m} = h_{C,0,m}$.

Step 2: for $n = 1$ to $N_c - 1$ do

\[ h_{n,m} = Ah_{C,n-1,m}; \]

\[ p_{w,n} = Ap_{w,n-1}A^*; \]

\[ K_k = (p_{w,n})^*(p_{w,n} + \sigma^2_p)^{-1}; \]

\[ \hat{h}_{C,n,m} = h_{n,m} + (\hat{h}_{C,n,m} - h_{n,m})K_k; \]

\[ p_{w,n} = (1 - K_k)p_{w,n}; \]

end

return $[\hat{h}_{C,n,m}]_{n=0,\ldots,N_c-1}$.

where $w_{C,n,m} = \frac{1}{N} \sum_{k=1}^{N} h_{n,m}^* h_{C,n,m}$ is the transformed noise plus interference and follows $\mathcal{C}\mathcal{N}(0, \sigma^2_p)$. $\sigma^2_p = (P_I + \sigma^2_0)/P$. The estimated communication response matrix at $M$ BS OFDM symbols is denoted by $H_C$, where $[H_C]_{n,m} = h_{C,n,m}$. The method for estimating $\sigma^2_p$ based on $H_C$ is presented in Appendix B.

The conventional communication uses $\hat{H}_C$ to demodulate the communication data. On the other hand, $f_{c,d,0}$ and $\tau_{c,0}$ can be estimated by JCS as $f_{c,d,0} = \tilde{f}_{c,d,0}/2$ and $\tau_{c,0} = \tilde{\tau}_{c,0}/(2c)$, respectively. Based on the prior information obtained by JCS sensing, we propose a Kalman filter-based JCS enhancement method to improve CSI by leveraging the sensing estimation results of JCS.

For the $m$th OFDM symbol, $\hat{h}_{C,n,m}$ can be regarded as the observation of $h_{C,n,m}$ as given in (41). Since $h_{C,0}$ is unchanged for the same OFDM symbol. The state transfer of $h_{C,n,m}$ is given by

\[ h_{C,n+1,m} = e^{-j2\pi \Delta f t_{\tau_{c,0}}} \hat{h}_{C,n,m}; \]

(42)

The Kalman filter algorithm that utilizes $\hat{\Phi} = [\hat{h}_{C,n,m}]_{n=0,\ldots,N_c-1}$ to recursively derive the estimation of $\Phi$ is presented in Algorithm 1, with the details of the Kalman Filter algorithm referenced to [15]. Note that we obtain $h_{C,n,m} = e^{-j2\pi n \Delta f \tau_{c,0}} \hat{h}_{C,0,m}$ from (42), based on which we can further estimate the initial observation variance as

\[ p_{w,0} = \frac{1}{N_c-1} \sum_{n=1}^{N_c-1} \| e^{-j2\pi n \Delta f \tau_{c,0}} \hat{h}_{C,n,m} - \bar{h}_{C,0,m} \|^2/(N_c-1), \]

(43)

After $[\hat{h}_{C,n,m}]_{n=0,\ldots,N_c-1}$ for $m = 0, \ldots, M_s - 1$ are all derived via Algorithm 1, we can form the enhanced CSI matrix $\tilde{H}_C$, where $[\tilde{H}_C]_{n,m} = h_{C,n,m}$, to demodulate the data symbols. First, $y_{C,n,m}$ given in (8) is equalized as $\tilde{r}_{C,n,m} = y_{C,n,m}/(\sqrt{T_I}h_{C,n,m})$, then we use the maximum likelihood (ML) method to estimate $\tilde{d}_{n,m}$ as $\tilde{d}_{n,m} = \arg \min_{d \in \Theta_{QAM}} \| \tilde{r}_{C,n,m} - d \|^2_2$, where $\Theta_{QAM}$ is the constellation.

IV. PERFORMANCE ANALYSIS OF THE JCS PROCESSING

In this section, the analytical MSE results of AoAs, range, Doppler, and location estimation of the proposed MUSIC-based JCS processing are derived using the perturbation method.

A. Analysis of 2D Angle Detection MSE

From (13), the noise term $N_t$ can be treated as the perturbation to the useful signal, which is expressed as

\[ Y_S = Y_{S,R} + N_t, \]  

(44)

where $Y_{S,R} = A_{S,RX}$ is the useful signal. The singular value decomposition of $Y_{S,R}$ can be expressed as

\[ Y_{S,R} = U_{S,R} \Sigma_{R,S} V_{S,R}^H, \]

(45)

where $U_0$ is the noise subspace basis, and $U_{0}^H Y_{S,R} = 0$. Further, we have $U_{0}^H A_{S,RX} = 0$.

With noise as perturbation, $Y_S$ can be expressed as

\[ Y_S = [\tilde{U}_S, \tilde{U}_0] \begin{bmatrix} \Sigma_S & 0 \\ 0 & \Sigma_0 \end{bmatrix} \begin{bmatrix} \tilde{V}_S^H \\ \tilde{V}_0^H \end{bmatrix}, \]

(46)

where $\Sigma_0 = \Delta \Sigma_0$, $\tilde{\Sigma}_S = \Sigma_S + \Delta \Sigma_S$, and $\tilde{U}_0 = U_0 + \Delta U_0$. Here, $\tilde{U}_0$ and $\tilde{U}_S$ are both orthogonal unitary matrices, and $U_0^H Y_{S,R} = \Delta \Sigma_0 \tilde{V}_0^H$. In the high SINR regime, solving the perturbation problem is equivalent to seeking the optimal $\Delta U_0$ to minimize $\| \tilde{U}_0^H Y_{S,R} \|_2$ subject to the constraint $\tilde{U}_0^H \tilde{U}_0 = I$ [13]. By substituting (44) into $\| \tilde{U}_0^H Y_{S,R} \|_2$, we have

\[ \| \tilde{U}_0^H Y_{S,R} \|_2 = \| (U_0 + \Delta U_0)^H (Y_{S,R} + N_t^X) \|_2. \]

(47)

The second-order perturbation $(\Delta U_0)^H N_t$ and $U_{0}^H Y_{S,R} = 0$ can be discarded. By using the LS method [13], $\Delta U_0$ can be presented as

\[ \Delta U_0 = -U_{S} \Sigma_{S}^{-1} V_{S}^H N_t \]  

(48)

The MUSIC 2D angle estimation result is distorted by the noise perturbation, which is expressed as $\tilde{p}_k = p_k + \Delta p_k$, where $p_k$ is the actual value of AoA. Apply Taylor series decomposition to $f_a(\tilde{p}_k; \tilde{U}_0)$ in (16), and take the first three terms. Applying first-order derivative to the truncated Taylor series, we have

\[ \frac{\partial f_a(\tilde{p}_k; \tilde{U}_0)}{\partial p_k} = \frac{\partial f_a(p_k; \tilde{U}_0)}{\partial p_k} + \frac{\partial^2 f_a(p_k; \tilde{U}_0)}{\partial p_k^2} \Delta p_k. \]

(49)

By setting (49) to be 0, we can obtain

\[ \Delta p_k = -H^{-1}_p (p_k; \tilde{U}_0) G_p(p_k; \tilde{U}_0), \]

(50)

where $H_p(p_k; \tilde{U}_0) = \frac{\partial^2 f_a(p_k; \tilde{U}_0)}{\partial p_k^2} \in C^{2 \times 2}$ is the Hessian matrix of $f_a$, and $G_p(p_k; \tilde{U}_0) = \frac{\partial f_a(p_k; \tilde{U}_0)}{\partial p_k} \in C^2$ is the gradient vector of $f_a$.

With the perturbation expression, we can obtain

\[ G_p(p_k; \tilde{U}_0) = G_p(p_k; U_0) + \Delta G_p, \]

(51)

\[ H_p(p_k; \tilde{U}_0) = H_p(p_k; U_0) + \Delta H_p. \]

(52)
From (16), we have
\[ G_p(p_k; U) = \frac{\partial f_p(p; U)}{\partial p} = 2\text{Re}\{a_p(p)H U U^H a(p)\}, \]
(53)
\[ \text{vec}[H_p(p; U)] = 2\text{Re}\left\{ \text{vec}\left[ a_p(p)^H H U U^H a(p)\right]\right\}, \]
(54)
where \text{vec}(\cdot) is to vectorize a matrix, \( a_p^{(1)}(p) \) and \( a_p^{(2)}(p) \) are the first-order and second-order derivatives of \( a(p) \) over \( p \), respectively, which can be derived from (2).

Since \( U_0^H A_{S,RX} = 0 \), we can obtain
\[ G_p(p_k; U_0) = 0, \]
(55)
\[ H_p(p_k; U_0) = 2\text{Re}\{a_p^{(1)}(p_k)^H U_0 U_0^H a_p^{(1)}(p_k)\}. \]
(56)
We use \( H_{p0} \) to represent \( H_p(p_k; U_0) \). By substituting (55) and (56) into (51) and (52), (50) can be rewritten as
\[ \Delta p_k = -(H_{p0} + \Delta H_{Gp})^{-1}(\Delta G_p) \]
(57)
\[ = - \left( I - H_{p0}^{-1}\Delta H_{Gp} + (H_{p0}^{-1}\Delta H_{Gp})^2 + \ldots \right) H_{p0}^{-1}\Delta G_p. \]
(58)
Discarding the perturbation terms that are higher than second-order in (57), we can rewrite (58) as
\[ \Delta p_k = -H_{p0}^{-1}\Delta G_p. \]
(59)
By substituting (59) and (56) into (58), we can obtain \( \Delta p_k \) as shown in (60), at the bottom of the page. The MSE of angle estimation can be expressed as
\[ \text{MSE}(p_k) = E\{\text{diag}(\Delta p_k[\Delta p_k]^H)\}. \]
(61)

B. Analysis of Range and Doppler Detection MSE

1) Analysis of Range Detection MSE: The noisy signal for the range estimation, as shown in (25), is rewritten as
\[ \tilde{H}_S = \tilde{H}_{S,p} + W_r, \]
(62)
where \( \tilde{H}_{S,p} = A_r S_{r,s} \) is the useful signal. The singular value decomposition of \( \tilde{H}_{S,p} \) is
\[ \tilde{H}_{S,p} = [U_{r,s} U_{r,0}] \begin{bmatrix} V_{r,s}^H & 0 \\ 0 & V_{r,0}^H \end{bmatrix} = U_{r,s} \Sigma_{r,s} V_{r,s}^H, \]
(63)
where \( U_{r,s} \) and \( U_{r,0} \) are orthogonal unitary matrices, and \( U_{r,0}^H \tilde{H}_{S,p} = 0 \). We further obtain \( U_{r,0}^H A_r = 0 \).

By treating \( W_r \) as a perturbation term, \( \tilde{H}_S \) can be decomposed as
\[ \tilde{H}_S = \begin{bmatrix} \tilde{U}_{r,s} & \tilde{U}_{r,0} \end{bmatrix} \begin{bmatrix} \tilde{V}_{r,s}^H & 0 \\ 0 & \tilde{V}_{r,0}^H \end{bmatrix}, \]
(64)
where \( \tilde{S}_{r,0} = \Delta \Sigma_{r,0} \) and \( \tilde{U}_{r,0} = U_{r,0} + \Delta U_{r,0} \). Because \( \tilde{U}_{r,s} \) and \( \tilde{U}_{r,0} \) are orthogonal unitary matrices, we have
\[ \tilde{U}_{r,s}^H S_r = \Delta \Sigma_{r,0} V_{r,0}^H, \]
and the second-order perturbation \( \Delta U_{r,0}^H \tilde{H}_{S,p} = 0 \) and the second-order perturbation \( \Delta U_{r,0}^H W_r = 0, \)
(65)
Using the LS method and substituting (63) into (65), we can obtain \( \Delta U_{r,0} \) as
\[ \Delta U_{r,0} = -U_{r,s} \Sigma_{r,s}^{-1} V_{r,0}^H (W_r H_{r,0}) U_{r,0}. \]
(66)

Next, we derive the expression for the perturbation of range estimation, i.e., \( \Delta r = r - r_k \), where \( r_k \) is the actual value of range, and \( r \) is the estimation value.

Apply Taylor series decomposition to (29) at \( r_k \), and keep the first three terms. Applying the first-order derivative to the truncated series with respect to \( r \), we obtain the range perturbation as
\[ \frac{\partial f_r(r; \tilde{U}_{r,0})}{\partial r} = \frac{\partial f_r(r_k; \tilde{U}_{r,0})}{\partial r} + \frac{\partial^2 f_r(r_k; \tilde{U}_{r,0})}{\partial^2 r} \Delta r. \]
(67)
Because the Newton descent method identifies the optimal point with \( \frac{\partial f_r(r_k; \tilde{U}_{r,0})}{\partial r} = 0 \), the range perturbation can be expressed as
\[ \Delta r = -[H_r(r_k; \tilde{U}_{r,0})]^{-1} G_r(r_k; \tilde{U}_{r,0}). \]
(68)
where
\[ G_r(r; U) = \frac{\partial f_r(r; U)}{\partial r} = 2\text{Re}\{a_r^{(1)}(r)^H U U^H a_r(r)\}, \]
(69)
and
\[ H_r(r; U) = \frac{\partial^2 f_r(r; U)}{\partial^2 r} \]
(70)
Using the perturbation form to express \( G_r(r_k; \tilde{U}_{r,0}) \) and \( H_r(r_k; \tilde{U}_{r,0}) \), we have
\[ G_r(r_k; \tilde{U}_{r,0}) = G_r(r_k; U_{r,0}) + \Delta G_r, \]
(71)
and
\[ H_r(r_k; \tilde{U}_{r,0}) = H_r(r_k; U_{r,0}) + \Delta H_r. \]
(72)
Because \( U_{r,0}^H A_r = 0 \), we have
\[ G_r(r_k; U_{r,0}) = 0, \]
(73)
and
\[ H_r(r_k; U_{r,0}) = 2\text{Re}\{a_r^{(1)}(r_k)^H U_{r,0} U_{r,0}^H a_r^{(1)}(r_k)\} = H_{r,0}. \]
(74)
By substituting (73) and (74) into (71) and (72), respectively, (68) becomes
\[ \Delta r_k = -(H_{r0} - (H_{r0})^{-1} H_{r})^{-1} \Delta H_r, \]
where the last equation is obtained by discarding the second-order perturbation terms. The perturbation expression of \( \Delta H_r \) is derived in Appendix D, given by
\[ \Delta H_r = 2Re[a_{(r)}(r^H U_{r0,0} - 0.0)^H a_{(r)}(r)], \]
where \( a_{(r)}(r) \) is given in (20), and \( a_{(r)}(r^H) \) is given in (39). The MSE of the MUSIC-based JCS range estimation can be expressed as
\[ MSE(r) = E[\Delta r_k^2]. \]

2) Analysis of Doppler Detection MSE: Similar to the range estimation, the perturbation of Doppler estimation can be derived as
\[ \Delta f_d = \frac{H_{r0} - (H_{r0})^{-1} H_{r}}{Re[a_{(f)}(f^H U_{f0,0} - 0.0)^H a_{(f)}(f)]}, \]
where \( f_k \) is the real Doppler value, and \( a_{(f)}(f^H) \) is given in (21). Furthermore, the perturbation of the radial velocity estimation is
\[ \Delta v = \lambda \Delta f_d. \]

C. Analysis of Location MSE
The location of the target can be obtained after the AoA, \( p_k = (\varphi_k, \theta_k) \), and the range, \( r_k \), are detected. The expression for the actual location is given by
\[ p_{loc}(r_k, \varphi_k, \theta_k) = (x_k, y_k, z_k) = (r_k \sin \theta_k \cos \varphi_k, r_k \sin \theta_k \sin \varphi_k, r_k \cos \theta_k). \]
With the AoA and range estimation perturbation, \( \Delta p_k = (\Delta \varphi_k, \Delta \theta_k) \) and \( \Delta r_k \), the location of the target is
\[ p_{loc}(r_k + \Delta r_k, \varphi_k + \Delta \varphi_k, \theta_k + \Delta \theta_k) = (r_k + \Delta r_k) \sin \theta_k + \Delta \theta_k \sin \varphi_k + \Delta \varphi_k, \]
\[ \frac{(r_k + \Delta r_k) \sin \theta_k + \Delta \theta_k \sin \varphi_k + \Delta \varphi_k,}{(r_k + \Delta r_k) \cos \theta_k + \Delta \theta_k} \]
Comparing (81) with (82) and discarding the second-order perturbation, we can represent the perturbation of \( x, y \), and \( z \) axes coordinates as
\[ \Delta x = \Delta r_k \sin \theta_k \cos \varphi_k + r_k \frac{\Delta \theta_k \cos \theta_k \cos \varphi_k - \Delta \varphi_k \sin \theta_k \sin \varphi_k}{\Delta r_k \sin \theta_k \sin \varphi_k + r_k \Delta \varphi_k \cos \theta_k \sin \varphi_k}, \]
\[ \Delta y = \Delta r_k \sin \theta_k \sin \varphi_k + r_k \frac{\Delta \varphi_k \cos \theta_k \cos \varphi_k - \Delta \theta_k \sin \theta_k \sin \varphi_k}{\Delta r_k \cos \theta_k \sin \varphi_k + r_k \Delta \varphi_k \cos \theta_k \cos \varphi_k}, \]
and
\[ \Delta z = \Delta r_k \cos \theta_k - r_k \Delta \theta_k \sin \theta_k. \]
Finally, the location error can be expressed as
\[ E[||\Delta p_{loc}||^2] = E[(\Delta x)^2 + (\Delta y)^2 + (\Delta z)^2]. \]

D. Cramer–Rao Bound of JCS Sensing
We further derive the Cramer–Rao bound (CRB) to characterize the minimum lower bound for sensing. Based on the signal model presented in Section II-D.2, the echo signal of the \( l \)th target received by the \( p, q \)th antenna element at the \( n \)th subcarrier of the \( m \)th OFDM symbol is
\[ y_{S,n,m,l}^p = \sqrt{P_I d_{n,m} a_{S,n,m,l} X,p,q(p)} + \eta_{S,n,m,l}^p, \]
where \( a_{S,n,m,l} = b_{S,n,m,l} e^{2\pi m T_2 v_s l / c} e^{-2\pi m v_s T_2 c} \) is given as (6), \( v_s \) is the relative velocity and distance between BS and the \( l \)th target, respectively; \( a_{p,q}(p) \) is given in (1), \( p = \tau_{X,l} \) is the 2D AoA of the \( l \)th target; \( \chi_{X,l} \) is the transmitting BF gain; \( n_{S,n,m,l}^p \) and \( x_{S,n,m,l}^p \) are the noise and interference at the \( p, q \)th antenna element. Let \( n_{X,p,q} = n_{S,n,m,l}^p + x_{S,n,m,l}^p \), then \( n_{X,p,q} \) is independent and identically distributed, following \( C \mathcal{N}(0, \sigma_n^2) \), where \( \sigma_n^2 = P_{IS} + \sigma_n^2 \).

Let \( \psi = (r_{s,l}, v_{s,t}, \varphi_l, \theta_l) \) be the set of estimation parameters. Then, the distribution of \( y_{S,n,m,l}^p \) is
\[ p(y; \psi) = \frac{1}{\pi \sigma_n^2} e^{-\|y - \sqrt{T d_{n,m} a_{S,n,m,l} X,p,q(p)}\|^2 / \sigma_n^2}, \]
Because there are \( N_s M_s P_q \) independent symbols used for estimation, the joint distribution of these symbols is
\[ p(y; \psi) = \rho e^{-\|y - \sqrt{T d_{n,m} a_{S,n,m,l} X,p,q(p)}\|^2 / \sigma_n^2}, \]
where \( \rho = (\frac{1}{\pi \sigma_n^2})^{N_s M_s P_q} \) and \( n_{S,n,m,l} = \sqrt{T d_{n,m} \chi_{X,l}} \). Note that \( a_{S,n,m,l} \) is independent and identically distributed with \( E[\|d_{n,m}\|^2] = 1 \). According to [16] and [17], the CRB of \( \psi \), \( \psi_i = (r_{s,l}, v_{s,t}, \varphi_l, \theta_l) \), is given by
\[ C_{\psi_i} = \left\{ E \left[ \frac{\partial^2 \ln p(y; \psi)}{\partial^2 \psi_i} \right] \right\}^{-1}. \]

With (89) and (90), the sensing CRBs are derived as
\[ C_{r_{s,l}} = \frac{c^2}{32 \pi^2 \gamma S M_s P_q T_{d}}, \]
\[ C_{v_{s,t}} = \frac{\lambda^2}{32 \pi^2 \gamma S N_s M_s \sum_{m=0}^{M-1} m^2 T^2}, \]
\[ C_{\varphi_l} = \frac{8 \pi^2 d_{\theta q}^2 \gamma S N_s M_s \sum_{j=0}^{J} (\cos \varphi_l \sin \theta_l - p \sin \varphi_l \cos \theta_l)^2}{\lambda^2}, \]
\[ C_{\theta_l} = \frac{8 \pi^2 d_{\theta q}^2 \gamma S N_s M_s \sum_{j=0}^{J} (p \cos \varphi_l \cos \theta_l + q \sin \varphi_l \cos \theta_l)^2}{\lambda^2}, \]
where \( \gamma S \) is the S-SINR as given in (11).
E. Complexity Analysis and Comparison

In this section, we analyze and compare the complexity of the proposed MUSIC-based JCS method with the conventional FFT-based methods. We consider three schemes: Scheme 1 is the proposed MUSIC-based method; Scheme 2 is the original FFT-based method in [6]; and Scheme 3 is the Code-division OFDM (CD-OFDM) FFT-based method in [8].

Scheme 1: The main complexity is associated with the eigenvalue decomposition of $R_{xx}$ and $R_{xf}$ and the derivation of detection spectra. Therefore, for range and Doppler estimation, the computation complexities are $O(\|N_c\|^3)$ and $O(\|M_f\|^3)$, respectively. Because the MUSIC-based JCS method can work in parallel, the total complexity is $O(\max\{\|M_s\|,\|N_c\|^3\})$.

Scheme 2: The complexity is mainly from two serial FFT operations for the $N_c \times M_s$ echo sensing channel matrix. Therefore, the complexity of Scheme 2 is $O(\|M_s\|\|N_c\|\log(\|M_s\|\|N_c\|))$.

Scheme 3: The complexity is mainly from code-division multiplex demodulation and two serial FFT operations for the $N_c \times M_s$ echo sensing channel matrix. Therefore, the complexity of Scheme 3 is $O(\|N_c\|^2\|M_s\|\|N_c\|\log(\|M_s\|\|N_c\|))$.

It can be seen that Scheme 2 has the lowest complexity. The complexity of Scheme 3 increases due to the additional code-division multiplex processing. The complexity of our proposed MUSIC-based JCS method has the highest complexity to achieve super-resolution detection.

V. NUMERICAL AND SIMULATION RESULTS

In this section, we present extensive simulation results for the proposed MUSIC-based JCS processing method, with comparison to the Schemes 2 and 3 as described in Section IV-E, and verify them against the analytical performance bounds derived in Section IV. We also compare the BER results of communication demodulation for the proposed JCS CSI enhancement method with those in conventional communication systems.

A. System Setup

The system setup largely follows the specification in the 3GPP Vehicular-to-Everything (V2X) applications [18]. The carrier frequency is 63 GHz, the antenna bandwidth, $d_a$, is half of the wavelength, the sizes of antenna arrays of BS and MUE are $P_t \times Q_t = 8 \times 8$ and $P_r \times Q_r = 1 \times 1$, respectively. The subcarrier interval is $\Delta f = 480$ kHz, the subcarrier number is set to $N_c = 256$, and the number of consecutive OFDM symbols is $M_s = 64$. Therefore, the bandwidth for JCS is $B = N_c\Delta f = 122.88$ MHz. The range and radial velocity resolutions are $\Delta r = \frac{\lambda}{2P_r} = 1.22$ m and $\Delta v = \frac{\lambda}{2\pi f_r} = 17.8571$ m/s, respectively [6]. The variance of the Gaussian noise is $\sigma^2_{N} = kTfb = 4.9177 \times 10^{-12}$ W, where $k = 1.38 \times 10^{-23}$ J/K is the Boltzmann constant, $F = 10$ is the noise factor, and $T = 290$ K is the standard temperature. The INRs for communication and sensing signals are $\gamma^{IN} = \gamma^{IS} = 3$ dB.

Moreover, the location of the BS transmitting array is $p_{loc, BS} = (50, 4.75, 7)$ m. MUE moves on the $x$-axis and its antenna’s location is $p_{loc, u} = (x, 0, 2)$ m, where $x$ follows uniform distribution from 50 m to 155 m. The scatterer is generated uniformly in a sphere centered at BS with a radius of 100 m. BS is static, while the velocity of MUE is $(-11.11, 0, 0)$ m/s. The reflection factors of the targets are $\sigma_{c,31}^2 = \sigma_{s,31}^2 = 1$. The BS array spins 45 degrees along the $z$-axis and has a downtilt angle of 20 degrees. For each test, the AoAs, ranges, and radial velocities between BS and MUE are then generated from the above parameters, and the JCS communication and echo sensing channels are further generated following the expressions in Section II-C.

The transmit power of BS for each test, $P_t$, is determined using (11) for the given values of S-SINR and INR.

The MSEs of AoA, range, velocity, and location estimation are defined as the mean values of the squared errors of all the estimates.

B. Sensing Performance

We first demonstrate the sensing spectra of schemes 1, 2, and 3. The normalized range spectrum and radial velocity spectrum are shown in Figs. 4(a) and 4(b), respectively. The S-SINR is $\gamma_{s,n,m} = -20$ dB. For range estimation as shown in Fig. 4(a), the peak to sidelobe ratio (PSLR) of scheme 1 is about 26 dB. By contrast, the PSLRs of schemes 2 and 3 are both around 10 dB. For radial velocity estimation as shown in Fig. 4(b), the PSLR of scheme 1 is about 33 dB, while the PSLRs of schemes 2 and 3 are around 10 dB. The improvement of PSLR of the proposed MUSIC-based JCS method is credited to the eigenvalue (or singular value) decomposition process, which separates the interference-plus-noise (IN) and signal subspace and reduces the influence of the noise on signal detection.

Fig. 5(a) presents the AoA estimation MSE of various S-SINRs. With the increase of S-SINR, the AoA estimation MSE decreases as the receiving signal power increases. As the S-SINR is larger than $-27$ dB, the AoA estimation MSE is less than 0.5 square degrees. Since the range of azimuth angle, $\varphi_k$, is larger than the elevation angle, $\theta_k$, the MSE of $\varphi_k$ is larger than $\theta_k$ at first. With S-SINR becoming large enough, the MSE of $\varphi_k$ approaches that of $\theta_k$.

Fig. 5(b) and Fig. 5(c) demonstrate the range and radial velocity estimation MSEs for schemes 1, 2, and 3 under various S-SINRs, respectively. The range and velocity estimation MSEs of scheme 3 outperform scheme 2 because the code-division multiplex processing in scheme 3 can suppress the interference to a certain extent. scheme 1 achieves much lower MSEs than both schemes 2 and 3, closer to the CRBs in the high SINR regime. This is because the resolutions of schemes 2 and 3 are constrained by FFT-based sensing, with $(\Delta r)^2 = 1.5 m^2$ and $(\Delta v)^2 = 318 (m/s)^2$ in this simulation setting. In contrast, our proposed MUSIC-based method can sample the consecutive range and velocity spectra and achieves range and velocity estimation MSEs lower than $10^{-3} m^2$ and $10^{-3} (m/s)^2$, respectively. The MSEs for scheme 1 is about 25 dB lower than those for scheme 3, closer to the range and velocity CRBs. These results demonstrate that the proposed MUSIC-based JCS method achieves super-resolution sensing. Moreover, the theoretical MSEs are shown to be close to the
Fig. 4. Detection spectra of schemes 1, 2 and 3.

Fig. 5. MSEs for sensing parameter estimation. In Fig. 5(a), the solid curves are for the MSEs and CRBs of azimuth and elevation angles obtained in simulation, and the dashed curves are for the numerical ones via the theoretical perturbation results; in Figs. 5(b), 5(c) and 5(d), the solid curves are for the MSEs and CRBs computed via simulation results, and the dashed curves are for theoretical perturbation results.

Simulation MSEs in the high SINR regime. The higher QAM order results in larger MSEs for scheme 1, because the increase of QAM order results in larger transformed noise as can be seen from (19) and (24).

Fig. 5(d) shows the location MSE versus S-SINR. With the estimated AoA and range, the location can be determined by (81). Given the sensing SINR, the MUSIC-based JCS method achieves lower localization MSE than scheme 3. The gaps between scheme 1 and scheme 3 are not so large in the high SINR regime. This is because the AoA estimation error dominates the localization MSE. More specifically, $E\{(\hat{r}_{s,l} - r_{s,l})^2\}$ is smaller than $10^{-1} \text{ m}^2$, while the errors of
achieve accurate AoA, range, and velocity estimation based on improved MUSIC algorithms, together with improved communication performance. Compared with the conventional FFT-based JCS sensing method, our proposed MUSIC-based sensing method can achieve much higher accuracy in range and radial velocity estimation. The proposed JCS CSI enhancement method exploits the JCS sensing results in the design of a Kalman filter for refining the CSI estimate. It is shown to significantly improve the communication performance at high SNRs, approaching the performance with perfect CSI. Moreover, we derived the theoretical lower bound MSEs for the proposed range and velocity estimators using perturbation analysis. Simulation results demonstrate that the theoretical results match the simulation results well, particularly at higher SNRs.

C. Communication Performance

In this section, we first present the BERs of demodulating communication signals using the CSI obtained by the JCS CSI enhancement method, compared with using the original CSI. For the simplicity of description, we predefine 4 cases for comparison: Cases A and B are for demodulating communication signals using the perfect CSI and original estimated CSI, respectively. Cases C and D are for demodulating communication signals with the CSI enhanced by the MUSIC-based JCS sensing results and the CSI processed with FFT-based JCS sensing results, respectively.

Fig. 6 shows the BER results when 64-QAM is used for communication. Note that when the detected target is the communication user, the relation between C-SINR and S-SINR is $\gamma_{c,m,n,m} = \frac{\|h_{c,m,n,m}\|^2}{\|h_{c,m,n,m}\|^2}$, according to (9) and (11) under the assumption $\gamma_{c}^{IN} = \gamma_{S}^{IN} = 3$ dB. Due to the CSI estimation error caused by noise and interference, the BER for case B is significantly larger than that for case A. As C-SINR increases, the BER for case C decreases rapidly and becomes lower than that for case B after C-SINR is larger than 20 dB. This is because the JCS CSI enhancement method exploits the accurate sensing results and improves the estimated CSI. By comparing case D with cases B and C, we can see that the BER for case D is much larger, which indicates that the FFT-based JCS sensing results are not helpful for improving the CSI and for communication. Referring to the sensing MSEs of the MUSIC-based and the FFT-based JCS in Fig. 5(b), we can see that the more accurate the sensing results are, the better CSI enhancement performance is, as the accuracy of range estimation directly determines the accuracy of the transfer factor in Algorithm 1. This is also the reason that the BER for case C decreases rapidly when the sensing MSE becomes sufficiently low.

VI. CONCLUSION

In this paper, we proposed a novel JCS system that can achieve accurate AoA, range, and velocity estimation based on improved MUSIC algorithms, together with improved communication performance. Compared with the conventional FFT-based JCS sensing method, our proposed MUSIC-based sensing method can achieve much higher accuracy in range and radial velocity estimation. The proposed JCS CSI enhancement method exploits the JCS sensing results in the design of a Kalman filter for refining the CSI estimate. It is shown to significantly improve the communication performance at high SNRs, approaching the performance with perfect CSI. Moreover, we derived the theoretical lower bound MSEs for the proposed range and velocity estimators using perturbation analysis. Simulation results demonstrate that the theoretical results match the simulation results well, particularly at higher SNRs.

APPENDIX A
DERIVATION OF $\alpha_t$

First, we denote the eigenvalue vector as $v_x = \text{diag}(\Sigma_x)$, where $\text{diag}(X)$ denotes a vector taking the diagonal values of $X$. The mean value of $v_x$ is denoted by $m_x$, and $v_x \in \mathbb{R}^{N \times 1}$. We assume there are $L$ incident signals. According to the property of the MUSIC algorithm, the $i$th entry of $v_x$ can be expressed as

$$[v_x]_i = \begin{cases} P_i + \sigma^2_N, & i \leq L \\ \sigma^2_N, & i > L, \end{cases}$$

(92)

where $P_i$ is the power of the $i$th incident signal, $\sigma^2_N$ is the noise power. We define the differential vector of $v_x$ as $v_\Delta$, where $[v_\Delta]_i = [v_x]_i - [v_x]_{i+1}$, and $v_\Delta \in \mathbb{R}^{(N-1) \times 1}$. Obviously, $[v_\Delta]_i \approx 0$ when $i > L$, while $[v_\Delta]_i \gg 0$ when $i \leq L$. Since mmWave suffers from large propagation loss, $L$ is typically much smaller than $N$. Then, we represent the mean value of the latter half of $v_\Delta$ as $\bar{v} = \frac{1}{N-1} \sum_{k=\lfloor(N-1)/2\rfloor}^{N-1} [v_\Delta]_k / (N - \lfloor(N-1)/2\rfloor)$, and $\bar{v}$ is close to 0.

Therefore, the number of detected targets is determined as

$$\hat{L} = \arg\max_{i \in \{1, \ldots, N\}} [v_\Delta]_i > (1 + \varepsilon)\bar{v},$$

(93)

where $\varepsilon$ is a parameter used to avoid false detection caused by a small error. In the simulation, we set $\varepsilon = 1$.

Therefore, $\alpha_t$ is set as $\alpha_t = [v_x]_L / m_x$. It is a key parameter and has an important impact on sensing accuracy. When $\alpha_t$ is too large, the selected noise subspace will include part of the signal subspace, and thus the target may be missed; when $\alpha_t$ is too small, the noise subspace is not selected completely, and thus large noise may be taken into the signal space.

APPENDIX B
DERIVATION OF $\sigma^2_p$

We first derive the eigenvalue matrix of $\hat{H}_C (\hat{H}_C)^H$ as $\Sigma_p$, and obtain the eigenvalue vector as $v_p = \text{diag}(\Sigma_p)$. As the LoS signal dominates the communication channel, i.e., $L = 1$, from (92), we can estimate $\sigma^2_p$ as

$$\hat{\sigma}^2_p = \frac{1}{N_c} \sum_{i=2}^{N_c} [v_x]_i / (N_c - 1).$$

(94)
Appendix C
Proof of Theorem 1

$U_{x,r}$ can be divided as $U_{x,r} = [S_{x,r} U_{x,r}N]$. Because $U_{x,r}$ is an orthogonal matrix, $[S_{x,r}]^H U_{x,r}N = 0$ and $[U_{x,r}N]^H U_{x,r}N = I$ hold.

On the other hand, since $U_{x,r}N$ is the noise subspace of $R_{x,r}$, we have

$$R_{x,r} U_{x,r}N = \sigma W^2 U_{x,r}N,$$  \( (95) \)

where $\sigma W^2$ is the Gaussian noise variance.

On the other hand, we have

$$R_{x,r} = E[H_S[H_S]^H] = A_r E[S_{r,s}[S_{r,s}]^H][A_r]^H + \sigma W^2 I.$$  \( (96) \)

Therefore,

$$R_{x,r} U_{x,r}N = A_r E[S_{r,s}[S_{r,s}]^H][A_r]^H U_{x,r}N + \sigma W^2 U_{x,r}N.$$  \( (97) \)

By comparing (95) with (97), we obtain

$$A_r E[S_{r,s}[S_{r,s}]^H][A_r]^H U_{x,r}N = 0.$$  \( (98) \)

Thus,

$$[U_{x,r}N]^H A_r E[S_{r,s}[S_{r,s}]^H][A_r]^H U_{x,r}N = 0.$$  \( (99) \)

Since $E[S_{r,s}[S_{r,s}]^H]$ is full-rank, $[U_{x,r}N]^H A_r = 0$. Therefore, the multiplication between $[U_{x,r}N]^H$ and each column of $A_r$ is 0, i.e., $A_r x_0, r, N = 0$. Thus, the minimum points of $\|U_{x,r}N^H a_r(r)\|^2$ are the ranges.

Similarly, by comparing the two expressions of $R_{x,f} U_{x,f}N$, we obtain

$$[U_{x,f}N]^H A_f E[S_{f,s}[S_{f,s}]^H][A_f]^H U_{x,f}N = 0.$$  \( (100) \)

Because $E[S_{f,s}[S_{f,s}]^H]$ is full-rank, $[U_{x,f}N]^H A_f = 0$ holds. Hence, the multiplication between $[U_{x,f}N]^H$ and each column of $A_f$ is 0, i.e., $A_f x_0, r, N = 0$. Thus, the minimum points of $\|U_{x,f}N^H a_f(f)\|^2$ are the Doppler results.

The proof of Theorem 1 is completed.

Appendix D

1) The Derivatives for $\Delta G_p$: The expanded expression for $G_{p}(p_k; \hat{U}_0)$ can be given by

$$G_{p}(p_k; \hat{U}_0) = 2\Re\left\{a_p^{(1)}(p_k)^H U_{0} + \Delta U_0 \right\}.$$  \( (101) \)

Then, according to (51), $\Delta G_p$ can be expressed as

$$\Delta G_p = 2\Re\left\{a_p^{(1)}(p_k)^H U_{0} \Delta U_0^H \right\}.$$  \( (102) \)

By discarding the second-order perturbation $U_{0} \Delta U_0^H$ and $U_{0}^H a_p(p_k) = 0$, and substituting (48) into (102), we obtain

$$\Delta G_p = 2\Re\left\{a_p^{(1)}(p_k)^H U_{0} U_{0}^H [\mathbf{N}_1]^H \mathbf{V}_s S_1^{-1} U_{s}^H a_p(p_k)] \right\}.$$  \( (103) \)

2) The Derivatives for $\Delta G_r$: The expanded expression for $\Delta G_r$ can be given by

$$\Delta G_r = G_r(r; \hat{U}_0) - G_r(r; U_{0}) = 2\Re\left\{a_r^{(1)}(r)^H U_{0} + \Delta U_0 \right\}(U_{0} + \Delta U_0)^H a_r(r).$$  \( (104) \)

By discarding the second-order perturbation term, $U_{r,0}^H A_r = 0$, and substituting (66) into (103), we obtain

$$\Delta G_r = 2\Re\left\{a_r^{(1)}(r)^H U_{0} U_{0}^H [\mathbf{W}_r \mathbf{V}_s S_1^{-1} U_{s}^H a_r(r)] \right\}.$$  \( (105) \)

Xu Chen (Member, IEEE) received the B.S. degree from Southwest Jiaotong University in 2018. He is currently pursuing the Ph.D. degree with the Beijing University of Posts and Telecommunications. His research interests include wireless communication, machine-type communication, sensor networks, joint communication and sensing networks, and signal processing.

Zhiyong Feng (Senior Member, IEEE) received the B.E., M.E., and Ph.D. degrees from the Beijing University of Posts and Telecommunications (BUPT), Beijing, China. She is currently a Professor with BUPT and the Director of the Key Laboratory of the Universal Wireless Communications, Ministry of Education, China. Her main research interests include wireless network architecture design and radio resource management in fifth generation mobile networks (5G), spectrum sensing and dynamic spectrum management in cognitive wireless networks, and universal signal detection and identification. She is the Vice Chair of the Information and Communication Test Committee of the Chinese Institute of Communications (CIC). She is currently serving as an Associate Editors-in-Chief for China Communications and a Technological Advisor for international forum on NGMN.

Zhiqing Wei (Member, IEEE) received the B.E. and Ph.D. degrees from the Beijing University of Posts and Telecommunications (BUPT) in 2010 and 2015, respectively. He is currently an Associate Professor with BUPT. He has published one book, three book chapters, and more than 50 articles. His research interests include the performance analysis and optimization of mobile ad hoc networks. He was granted the Exemplary Reviewer of IEEE WIRELESS COMMUNICATIONS LETTERS in 2017 and the Best Paper Award of International Conference on Wireless Communications and Signal Processing (WCSP) 2018. He was the Registration Co-Chair of IEEE/CIC International Conference on Communications in China (ICCC) 2018 and the publication Co-Chair of IEEE/CIC ICCC 2019.

Ping Zhang (Fellow, IEEE) received the M.S. degree in electrical engineering from Northwestern Polytechnical University, Xi’an, China, in 1986, and the Ph.D. degree in electric circuits and systems from the Beijing University of Posts and Telecommunications (BUPT), Beijing, China, in 1990. He is currently a Professor with BUPT. His research interests include cognitive wireless networks, fourth-generation mobile communication, fifth-generation mobile networks, communications factory test instruments, universal wireless signal detection instruments, and mobile internet. He was a recipient of the First and Second Prize from the National Technology Invention and Technological Progress Awards and the First Prize Outstanding Achievement Award of Scientific Research in college. He is the Executive Associate Editor-in-Chief on information sciences for the Chinese Science Bulletin, a Guest Editor of IEEE Wireless Communications Magazine and an Editor of China Communications.

J. Andrew Zhang (Senior Member, IEEE) received the B.Sc. degree from Xi’an Jiaotong University, China, in 1996, the M.Sc. degree from the Nanjing University of Posts and Telecommunications, China, in 1999, and the Ph.D. degree from the Australian National University, in 2004. He is currently a Professor with the School of Electrical and Data Engineering, University of Technology Sydney, Australia. He has published more than 260 papers in leading international journals and conference proceedings. His research interests are in the area of signal processing for wireless communications and sensing and vehicular networks. He has won five best paper awards for his work.

Heng Yang (Member, IEEE) received the B.Sc. and M.Sc. degrees from the Chongqing University of Posts and Telecommunications, Chongqing, China, in 2016 and 2019, respectively. He is currently pursuing the Ph.D. degree with the School of Information and Communication Engineering, Beijing University of Posts and Telecommunications, Beijing, China. His current research interests include radio resource management, vehicular networks, and joint communication and sensing networks.
