Septic subacromial bursitis caused by *Streptococcus pneumoniae*: A case report

Abir Bou Khalil, Ziad Hajj, Umayya M. Musharrafieh, Hassan Sidani, Dania Abdallah, Rima Abdallah Moghnieh

**ABSTRACT**

Introduction: Isolated infection of the subacromial bursa is a rare entity. Primary subacromial septic bursitis is uncommon compared to other superficial bursa because of its deep anatomic location. The potential for an underlying spread of infection to unusual sites has been reported in the setting of diabetes mellitus and can very easily be overlooked.

Case Report: We describe the clinical presentation, radiological investigations and strategies for the management of a 59-year-old diabetic male presented with subacromial bursitis as a result of *Streptococcus pneumoniae* infection. It resolved without sequelae using oral and parenteral antibiotics, incision and drainage, and surgical debridement. The range of motion improved gradually until full recovery.

Conclusion: Subacromial septic bursitis is rarely reported in medical literature. Its fast identification and treatment is needed to allow full recovery of range of motion.
Septic subacromial bursitis caused by *Streptococcus pneumoniae*: A case report

ABSTRACT

Introduction: Isolated infection of the subacromial bursa is a rare entity. Primary subacromial septic bursitis is uncommon compared to other superficial bursa because of its deep anatomic location. The potential for an underlying spread of infection to unusual sites has been reported in the setting of diabetes mellitus and can very easily be overlooked. Case Report: We describe the clinical presentation, radiological investigations and strategies for the management of a 59-year-old diabetic male presented with subacromial bursitis as a result of *Streptococcus pneumoniae* infection. It resolved without sequelae using oral and parenteral antibiotics, incision and drainage, and surgical debridement. The range of motion improved gradually until full recovery. Conclusion: Subacromial septic bursitis is rarely reported in medical literature. Its fast identification and treatment is needed to allow full recovery of range of motion.

Keywords: Subacromial, Bursitis, *Streptococcus pneumoniae*

INTRODUCTION

The subacromial bursa is the synovial membrane between the acromial process and the capsule of the shoulder joint. Primary subacromial septic bursitis is uncommon compared to other superficial bursa because of its deep anatomic location. We present a case of subacromial septic bursitis due to *Streptococcus pneumoniae* infection in an immunocompromised host.

CASE REPORT

A 59-year-old male, a hospital kitchen worker in-charge of dish washing, known to have non-insulin-dependent diabetes mellitus controlled on oral hypoglycemic agent, presented to the emergency room with one week history of pain, swelling and coldness of the right arm and shoulder. The pain was so severe that it had been preventing him from sleep, where it was exaggerated by movement. He had no previous history of antecedent trauma, injury, or any shoulder pain. He denied any systemic symptoms such as fever, anorexia, weight loss, sweating, cough or dyspnea.
The patient had undergone amputation of the right hallux and long toe as complication of diabetes mellitus several years ago. He had history of gastric cancer that was resected several years ago and is being followed-up, with no evidence for recurrence or metastasis. He was non-smoker and non-alcoholic. He had no travel history outside Lebanon and lives in a crowded area. He is married with two children, and denies any extramarital affairs.

On initial examination, vital signs were normal. No redness, hotness, or skin lesion of the right arm was observed. Yet, there was tenderness over deltoid muscle and stiffness in the range of motion (ROM) of the right shoulder. He had 10° external rotation, 10–15° abduction, 5° extension, 10° flexion and 0° internal rotation. He was moving freely his right elbow, wrist and fingers with no pain. He had intact neurovascular system. Otherwise, nothing was remarkable except that patient puts a denture, and there was no evidence of gingival inflammation, or any point of tenderness over the sinuses or mandibles. He had no meningeal signs, and no heart murmurs. His lungs were clear and, abdomen was soft. His laboratory tests showed white blood cell count 15,700/μL, neutrophils 83.1%, lymphocytes 9.7%, eosinophils 0.5%, platelets count 566,000/μL, hemoglobin 12.4 g/dL, hematocrit 39.6%, erythrocyte sedimentation rate (ESR) 28 mm/h, C-reactive protein (CRP) 25.7 mg/dL, serum blood urea nitrogen (BUN) 15 mg/dL, serum creatinine 0.8 mg/dL, serum lactate dehydrogenase (LDH) 129 U/L, serum alanine transaminase (SGPT/ALT) 36 U/L, serum creatine phosphokinase (CPK) 117 U/L, procalcitonin 0.41 ng/mL, microalbumin urine spot 249.4 mg/L, total protein 7.2 g/dL, albumin 3.7 g/dL, globulin 3.5 g/dL, Hba1c 10%, D-dimer 3.89 μg/mL. Blood cultures were taken on admission and grew Streptococcus pneumoniae, susceptible to penicillin with minimal inhibitory concentration (MIC) < 0.016 μg/mL after four days of incubation.

X-ray of right shoulder revealed calcific tendinitis at the rotator cuff insertion with no bony lesion (Figure 1). Computed tomography (CT) scan of the right shoulder showed similar results along with minimal acromioclavicular arthrosis with minimal inferior spurring and acromial enthesopathy. A gadolinium-enhanced magnetic resonance imaging (MRI) scan of the right shoulder (Figure 2) revealed acromioclavicular and glenohumeral degenerative osteoarthritic changes showing no osteomyelitis. With respect to the supraspinatus and subscapularis tendon, findings suggest severe tendinitis and partial tearing. There was mild to moderate synovial hyperplasia and remarkable distension and fluid filling of the subacromial/subdeltoid bursa. Mild synovial enhancement was noticed following injection of contrast where findings suggested synovitis/bursitis most likely to be reactive. Nothing was remarkable on CT scan of chest and upper extremity venous Doppler ultrasound. Echocardiography showed global hypokinesia with an ejection fraction (EF) 42% ruling out any endocardial vegetation. Serum protein electrophoresis was done and showed no abnormalities.

The patient was empirically started on antibiotic treatment with ceftriaxone (2 g IV daily), and then changed to penicillin G (2 MIU IV every 4 hours for 4 weeks), based on culture and antibiogram results. Anti-inflammatory and analgesic drugs were prescribed to the patient for pain management. Three weeks after the intravenous antibiotic therapy, the patient underwent arthroscopic synovectomy with resection of subacromial bursa. Intraoperatively, a thick purulent material was drained from the subacromial space. Pus removed from the bursa and sent to culture did not grow any organism. Histological analysis of the removed synovial tissue from the subacromial bursa was consistent with a diagnosis of bursitis showing thick fibrous membrane infiltrated by mononuclear inflammatory cells with granulation tissue formation and fibrinous deposition (Figure 3).

Physical examination few days postoperatively showed that the patient could freely move his arm. Intravenous penicillin G was stopped after completion of four weeks in total. The patient was discharged on good condition on oral cefadroxil and rifampicin for two weeks. The patient underwent physiotherapy for four weeks after discharge. His range of motion, in the follow-up visit at third month post-discharge, revealed up to 90° abduction, 30° external rotation, 40° internal rotation and full flexion.

DISCUSSION

The subacromial bursa is a fluid-filled sac or saclike cavity between the acromion and the insertion of the supraspinatus muscle, extending between the deltoid and greater tubercle of the humerus [1]. Septic bursitis is commonly seen in superficial bursae, such as the olecranon or the bursae around the
knee since they are easily inoculated transcutaneously through minor trauma [2]. Deep bursal infections such as subacromial and subdeltoid septic bursitis occur much more rarely than superficial ones [2] with only a few cases reported in literature, mostly due to immunosuppression involved in the onset of infection. Routes of infection into the subacromial bursa are associated with three main risk factors: immunocompromised state [2], injection into the subacromial bursa [3], and hematogenous spread [4, 5]. *Staphylococcus aureus* is the most common pathogen and has been reported in approximately 80% of cases [5]. Other pathogens have also been reported [2, 5–9].

Ultrasnonography or MRI scan can be used to identify fluid collection in the subacromial space. A large fluid collection with surrounding tissue edema suggesting cellulitis is usually consistent with septic bursitis but should always be clinically correlated [10]. Needle aspiration will confirm the diagnosis and identify the pathogen with appropriate analysis and culture of the bursal fluid [10]. Since hematogenous spread is one of the main risk factors so blood cultures should be taken.

Depending on the severity of the illness, treatment of subacromial/subdeltoid bursitis includes oral and parenteral antibiotics, needle aspiration, incision and drainage, and surgical debridement [10]. All of the cases reported in literature were treated similarly through surgical and medical interventions. After treatment range of motion usually improves until full recovery as given in Table 1.

We conducted literature search from January 2004 to January 2014 in the following electronic databases: Pubmed, Sciverse (Science Direct), Springer, Wiley, and Ovid MD. Case reports of septic subacromial bursitis published in English language were only included. Only nine cases have been reported in literature in last ten years (Table 1).

*Streptococcus pneumoniae* is a known cause of otitis media and severe community-acquired pneumonia with invasive pneumococcal disease occurring in many forms to include bacteremia, meningitis, endocarditis and joint infections such as septic arthritis [11]. Although most cases of septic arthritis are caused by *Staphylococcus aureus*, *Staphylococcus epidermidis*, and *Streptococcus pneumoniae* have been noted to cause up to 10% of reported cases [12, 13]. This is the second case to report *Streptococcus pneumoniae* induced septic subacromial bursitis. The first one was reported by Mukerji et al. [8] who described a case of a 68-year-old male diagnosed for septic subacromial bursitis with extra-articular involvement, pneumococcal endocarditis. Septic bursitis is an unusual presenting complaint in pneumococcal endocarditis. A high index of suspicion with a thorough physical examination and supportive investigations should be considered in patients with septic bursitis or pneumococcemia and persistent fever. In this case, echocardiography ruled out any endocardial vegetation.

Diabetes is a well-known risk factor for invasive pneumococcal infection [14, 15] and our patient is diabetic and had pneumococcemia. The MRI scan of the right shoulder showed fluid filling of the subacromial/subdeltoid bursa and revealed the presence of tendinitis thus facilitating the seeding of the infection to the patient’s shoulder. Yet, the bursal pus culture, drained intraoperatively, did not grow any microorganism since the patient was already on antibiotic therapy. Costantino et al. reported a 52-year-old female who had a history of diabetes mellitus with concomitant *Staphylococcus aureus* induced septic glenohumeral arthritis and subacromial bursitis of her shoulder [16]. Lan et al. described another diabetic case of purulent subacromial/

subdeltoid bursitis and abscess formation in the rotator cuff muscles as a result of viridans *Streptococcus* infection [6].

**CONCLUSION**

In conclusion, subacromial septic bursitis is rarely reported in medical literature. Its fast identification and treatment is needed to allow full recovery of range of motion. The potential for an underlying spread of infection to unusual sites has been reported in the setting of diabetes mellitus and can very easily be overlooked. A high index of suspicion is required in such cases because any delay in diagnosis can be serious consequences.

**KEY CLINICAL MESSAGE**

Isolated infection of the subacromial bursa is a rare entity. We describe the clinical presentation, radiological investigations and strategies for the management of a 59-year-old diabetic male presented with subacromial bursitis as a result of *Streptococcus pneumoniae* infection, which resolved without sequelae.

Edorium Journals: An introduction

Edorium Journals Team

About Edorium Journals
Edorium Journals is a publisher of high-quality, open-access, international scholarly journals covering subjects in basic sciences and clinical specialties and subspecialties.

Invitation for article submission
We sincerely invite you to submit your valuable research for publication to Edorium Journals.

But why should you publish with Edorium Journals?
In less than 10 words - we give you what no one does.

Vision of being the best
We have the vision of making our journals the best and the most authoritative journals in their respective specialties. We are working towards this goal every day of every week of every month of every year.

Exceptional services
We care for you, your work and your time. Our efficient, personalized and courteous services are a testimony to this.

Editorial Review
All manuscripts submitted to Edorium Journals undergo pre-processing review, first editorial review, peer review, second editorial review and finally third editorial review.

Peer Review
All manuscripts submitted to Edorium Journals undergo anonymous, double-blind, external peer review.

Early View version
Early View version of your manuscript will be published in the journal within 72 hours of final acceptance.

Manuscript status
From submission to publication of your article you will get regular updates (minimum six times) about status of your manuscripts directly in your email.

Our Commitment

Six weeks
You will get first decision on your manuscript within six weeks (42 days) of submission. If we fail to honor this by even one day, we will publish your manuscript free of charge.

Four weeks
After we receive page proofs, your manuscript will be published in the journal within four weeks (31 days). If we fail to honor this by even one day, we will publish your manuscript free of charge and refund you the full article publication charges you paid for your manuscript.

Mentored Review Articles (MRA)
Our academic program “Mentored Review Article” (MRA) gives you a unique opportunity to publish papers under mentorship of international faculty. These articles are published free of charges.

Favored Author program
One email is all it takes to become our favored author. You will not only get fee waivers but also get information and insights about scholarly publishing.

Institutional Membership program
Join our Institutional Memberships program and help scholars from your institute make their research accessible to all and save thousands of dollars in fees make their research accessible to all.

Our presence
We have some of the best designed publication formats. Our websites are very user friendly and enable you to do your work very easily with no hassle.

Something more...
We request you to have a look at our website to know more about us and our services.

We welcome you to interact with us, share with us, join us and of course publish with us.
