Observers for Invariant Systems on Lie Groups with Biased Input Measurements and Homogeneous Outputs

Alireza Khosravian, Jochen Trumpf, Robert Mahony, Christian Lageman

Abstract

This paper provides a new observer design methodology for invariant systems whose state evolves on a Lie group with outputs in a collection of related homogeneous spaces and where the measurement of system input is corrupted by an unknown constant bias. The key contribution of the paper is to study the combined state and input bias estimation problem in the general setting of Lie groups, a question for which only case studies of specific Lie groups are currently available. We show that any candidate observer (with the same state space dimension as the observed system) results in non-autonomous error dynamics, except in the trivial case where the Lie-group is Abelian. This precludes the application of the standard non-linear observer design methodologies available in the literature and leads us to propose a new design methodology based on employing invariant cost functions and general gain mappings. We provide a rigorous and general stability analysis for the case where the underlying Lie group allows a faithful matrix representation. We demonstrate our theory in the example of rigid body pose estimation and show that the proposed approach unifies two competing pose observers published in prior literature.

Keywords: Observers, Nonlinear systems, Lyapunov stability, Lie groups, Symmetries, Adaptive control, Attitude control

1. Introduction

The study of dynamical systems on Lie groups has been an active research area for the past decade. Work in this area is motivated by applications in analytical mechanics, robotics and geometric control for mechanical systems [2,5]. Many mechanical systems carry a natural symmetry or invariance structure expressed as invariance properties of their dynamical models under transformation by a symmetry group. For totally symmetric kinematic systems, the system can be lifted to an invariant system on the symmetry group \[ \mathfrak{g} \]. In most practical situations, obtaining a reliable measurement of the internal states of such physical systems directly is not possible and it is necessary to use a state observer.

Systematic observer design methodologies for invariant systems on Lie groups have been proposed that lead to strong stability and robustness properties. Specifically, Bonnabel et al. [7,9] consider observers which consist of a copy of the system and a correction term, along with a constructive method to find suitable symmetry-preserving correction terms. The construction utilizes the invariance of the system and the moving frame method, leading to local convergence properties of the observers. The authors propose methods in [10,12] to achieve almost globally convergent observers. A key aspect of the design approach proposed in [10,12] is the use of the invariance properties of the system to ensure that the error dynamics are globally defined and are autonomous. This leads to a straightforward stability analysis and excellent performance in practice. More recent extensions to early work in this area was the consideration of output measurements where a partial state measurement is generated by an action of the Lie group on a homogeneous output space \[ \mathfrak{g} \] [6,8,11-13]. Design methodologies exploiting symmetries and invariance of the system can be applied to many real world scenarios such as attitude estimation on the Lie group \[ \text{SO}(3) \] [8,14-18], pose estimation on the Lie group \[ \text{SE}(3) \] [19-22], homography estimation on the Lie group \[ \text{SL}(3) \] [23], and motion estimation of chained systems on nilpotent Lie groups [24] (e.g. front-wheel drive cars or kinematic cars with k trailers).

All asymptotically stable observer designs for kinematic systems on Lie groups depend on a measurement of system input. In practice, measurements of system input are often corrupted by an unknown bias that must be estimated and compensated to achieve good observer error performance. The specific cases of attitude estimation on \[ \text{SO}(3) \] and pose estimation on \[ \text{SE}(3) \] have been studied independently, and methods have been proposed for the concurrent estimation of state and input measurement bias [14,17,20]. These methods strongly depend on particular properties of the specific Lie groups \[ \text{SO}(3) \] or \[ \text{SE}(3) \] and do not directly generalize to general Lie groups. To the authors’ knowledge, there is no existing work on combined state and input bias estimation for general classes of invariant systems.

In this paper, we tackle the problem of observer design for general invariant systems on Lie groups with homogeneous outputs when the measurement of system input is corrupted by an unknown constant bias. The observer is required to be implementable based on available sensor measurements; the system

---

Preprint submitted to Automatica July 15, 2015
input in the Lie algebra, corrupted by an unknown bias, along with a collection of partial state measurements (i.e., outputs) that ensure observability of the state. For bias free input measurements, it is always possible to obtain autonomous dynamics for the standard error [10,13], and previous observer design methodologies for systems on Lie groups rely on the autonomy of the resulting error dynamics. However, for concurrent state and input measurement bias estimation, we show that any implementable candidate observer (with the same state space dimension as the observed system) yields non-autonomous error dynamics unless the Lie group is Abelian (Theorem 4.1). This result explains why the previous general observer design methodologies for the bias-free case do not apply and why the special cases considered in prior works [20,21] do not naturally lead to a general theory.

We go on to show that, despite the nonlinear and non-autonomous nature of the error dynamics, there is a natural choice of observer for which we can prove exponential stability of the error dynamics (Theorems 5.1 and 5.3). The approach taken employs a general gain mapping applied to the differential of a cost function rather than the more restrictive gradient-like innovations used in prior work [10,13]. We also propose a systematic method for construction of invariant cost functions based on lifting costs defined on the homogeneous output spaces (Proposition 6.1). To demonstrate the generality of the proposed approach we consider the problem of rigid body pose estimation using landmark measurements when the measurements of linear and angular velocity are corrupted by constant unknown biases. We show that for specific choices of gain mappings the resulting observer specializes to either the gradient-like observer of [21] or the non-gradient pose estimator proposed in [20], unifying these two state-of-the-art application papers in a single framework that applies to any invariant kinematic system on a Lie-group. Stability of estimation error is proved for the case where the Lie group allows a faithful matrix representation.

The paper is organized as follows. After briefly clarifying our notation in Section 2, we formulate the problem in Section 3. A standard estimation error is defined and autonomy of the resulting error dynamics is investigated in section 4. We introduce the proposed observer in Section 5 and investigate the stability of observer error dynamics. Section 6 is devoted to the systematic construction of invariant cost functions. A detailed example in Section 7 and brief conclusions in Section 8 complete the paper. A preliminary version of this work was presented at the CDC 2013 [13]. This manuscript was published in Automatica [1]. In addition to the material presented in [1], this paper contains detailed proof of theorems as well as detailed mathematical derivations of application examples.

2. Notations and Definitions

Let $G$ be a finite-dimensional real connected Lie group with associated Lie algebra $\mathfrak{g}$. Denote the identity element of $G$ by $I$. Left (resp. right) multiplication of $X \in G$ by $S \in G$ is denoted by $LS X = SX$ (resp. $RS X = XS$). The Lie algebra $\mathfrak{g}$ can be identified with the tangent space at the identity element of the Lie group, i.e. $\mathfrak{g} \cong T_I G$. For any $u \in \mathfrak{g}$, one can obtain a tangent vector at $S \in G$ by left (resp. right) translation of $u$ denoted by $S \mathcal{T}[u] := T_I L_S [u] \in T_S G$ (resp. $u S \mathcal{T} := T_I R_S [u] \in T_S G$). The element inside the brackets $[\cdot]$ denotes the vector on which a linear mapping (here the tangent map $T_I L_S : \mathfrak{g} \to T_S G$ or $T_I R_S : \mathfrak{g} \to T_S G$) acts. The adjoint map at the point $S \in G$ is denoted by $\mathcal{A}_S : \mathfrak{g} \to \mathfrak{g}$ and is defined by $\mathcal{A}_S [u] := S^{-1} S \mathcal{T}[S^{-1} [T_I L_S [u]]] = T_S R_{S^{-1}} \circ T_I L_S [u]$ where $o$ denotes the composition of two maps. For a finite-dimensional vector space $V$, we denote its corresponding dual and bidual vector spaces by $V^*$ and $V^{**}$ respectively. A linear map $F : V^* \to V$ is called positive definite if $v^* [F(v^*)] > 0$ for all $0 \neq v^* \in V^*$. The dual of $F$ is denoted by $F^*: V^* \to V^{**}$ and is defined by $F^*[v^*] = v^* \circ F$. The linear map $F$ is called symmetric (resp. anti-symmetric) if $v^* [F(w^*)] = w^* [F(v^*)]$ (resp. $v^* [F(w^*)] = -w^* [F(v^*)]$) for all $v^*, w^* \in V^*$, and it is called symmetric positive definite if it is symmetric and positive definite. We can extend the above notion of symmetry and positive-definiteness to linear maps $H : V \to W$ as well. Defining $V := W^*$, $H$ is called positive definite if $H^*: V^* \to V$ is positive definite and it is called symmetric if $H^*$ is symmetric. Positive definite cost functions on manifolds are also used in the paper and should not be mistaken with positive definite linear maps.

3. Problem Formulation

We consider a class of left invariant systems on $G$ given by

$$
\dot{X}(t) = X(t)u(t), \quad X(t_0) = X_0,
$$

(1)

where $u \in \mathfrak{g}$ is the system input and $X \in G$ is the state. Although the ideas presented in this paper are based on the above left invariant dynamics, they can easily be modified for right invariant systems as was done for instance in [10]. We assume that $u : \mathbb{R}^+ \to \mathfrak{g}$ is continuous and hence a unique solution for (1) exists for all $t \geq t_0$ [23]. In most kinematic mechanical systems, $u$ models the velocity of physical objects. Hence, it is reasonable to assume that $u$ is bounded and continuous.

Let $M_i, i = 1, \ldots, n$ denote a collection of $n$ homogeneous spaces of $G$, termed output spaces. Denote the outputs of system (1) by $y_i, i \in M_i$. Suppose each output provides a partial measurement of $X$ via

$$
y_i = h_i(X, \hat{y}_i)
$$

(2)

where $\hat{y}_i \in M_i$ is the constant (with respect to time) reference output associated with $y_i$ and $h_i$ is a right action of $G$ on $M_i$, i.e. $h_i(I, y_i) \equiv y_i$ and $h_i(XS, y_i) = h_i(S, h_i(X, y_i))$ for all $y_i \in M_i$ and all $X, S \in G$. To simplify the notation, we define the combined output $y := (y_1, \ldots, y_n)$, the combined reference output $\hat{y} := (\hat{y}_1, \ldots, \hat{y}_n)$, and the combined right action $h(X, \hat{y}) := (h_1(X, \hat{y}_1), \ldots, h_n(X, \hat{y}_n))$. The combined output $y$ belongs to the orbit of $G$ acting on the product space $M_1 \times M_2 \times \ldots \times M_n$ containing $\hat{y}$, that is $M := \{ y \in M_1 \times M_2 \times \ldots \times M_n | y = h(X, \hat{y}), X \in G \} \subset M_1 \times M_2 \times \ldots \times M_n$. Note that the combined action $h$ of $G$ defined above is transitive on $M$. Hence, $M$ is a homogeneous space of $G$ while $M_1 \times M_2 \times \ldots \times M_n$ is not necessarily a homogeneous space of $G$ [24].
We assume that measurements of the system input are corrupted by a constant unknown additive bias. That is
\[ u_t = u + b \] (3)
where \( u_t \in \mathfrak{g} \) is the measurement of \( u \) and \( b \in \mathfrak{g} \) is the unknown bias. In practice, bias is slowly time-varying but it is common to assume that \( b \) is constant for observer design and analysis.

We investigate the observer design problem for concurrent estimation of \( X \) and \( b \). The observer should be implementable based on sensor measurements. This is important since the actual state \( X \in G \) and the actual input \( u \in \mathfrak{g} \) are not available for measurement and only the partial measurements \( y_1, \ldots, y_n \) and the biased input \( u_t \) are directly measured. We consider the general class of implementable observers with the same state space dimension as the observed system.

\[ \dot{X} = \gamma(X, y, \hat{b}, u_t, t) \] (4a)
\[ \dot{b} = \beta(X, y, \hat{b}, u_t, t) \] (4b)

where \( \dot{X} \) and \( \dot{b} \) are the estimates of \( X \) and \( b \), respectively, and \( \gamma: G \times M \times \mathbb{R}^q \times \mathbb{R} \to TG \) and \( \beta: G \times M \times \mathbb{R} \to \mathfrak{g} \) are parameterized vector fields on \( G \) and \( \mathfrak{g} \), respectively. Note that \( \dot{X}, y, \hat{b}, u_t \), and \( t \) are all available for implementation of the observer in practical scenarios. We refer to (4a) and (4b) as the group estimator and the bias estimator, respectively.

**Example 3.1** (Pose Estimation on \( SE(3) \)). Estimating the position and attitude of a rigid body has been investigated by a range of authors during the past decades, see, e.g., [3, 23, 27]. The full 6-DOF pose kinematics of a rigid body can be modeled as an invariant system on the special Euclidean group \( SE(3) \) [20, 22, 23]. The Lie group \( SE(3) \) has a representation as a semi-direct product of \( SO(3) \) and \( \mathbb{R}^3 \) given by \( SE(3) = \{(R, p) \mid R \in SO(3), p \in \mathbb{R}^3\} \). Consider the group multiplication on \( SE(3) \) given by \( L_{(R, p)}(S, q) = (RS, p + Rq) \) for any \( (R, p), (S, q) \in SE(3) \). The identity element of \( SE(3) \) is represented by \( (I_{3 \times 3}, 0) \) and the inverse of an element \( (R, p) \in SE(3) \) is given by \( (R, p)^{-1} = (R^{-1}, -R^{-1}p) \). The Lie algebra of \( SE(3) \) is identified with \( \mathfrak{se}(3) = \{[\Omega, V] \mid \Omega \in \mathfrak{so}(3), V \in \mathbb{R}^3\} \) where \( \mathfrak{so}(3) \) denotes the Lie algebra of \( SO(3) \) represented as the set of skew-symmetric \( 3 \times 3 \) matrices with zero trace.

Let \( R \) be a rotation matrix corresponding to the rotation from the body-fixed frame to the inertial frame and suppose that \( p \) represents the position of the rigid body with respect to the inertial frame and expressed in the inertial frame. The left-invariant kinematics of a rigid body on \( SE(3) \) is formulated as
\[ (\dot{R}, \dot{p}) = T_I L_{(R, p)}(\Omega, V) = (R\Omega, RV) \] (5)
where \( \Omega \) resp. \( V \) represent the angular velocity resp. linear velocity of the rigid body with respect to the inertial frame expressed in the body-fixed frame. Here, the group element is \( X = (R, p) \in SE(3) \) and the system input is \( u = (\Omega, V) \in \mathfrak{se}(3) \). Denote the measurement of the system input by \( (\Omega, V) \in \mathfrak{se}(3) \) and assume that it is corrupted by an unknown constant bias \( (b_\omega, b_v) \in \mathfrak{se}(3) \) such that \( (\Omega_t, V_t) = (\Omega + b_\omega, V + b_v) \). Suppose that positions of \( n \) points with respect to the body-fixed frame are measured by on-board sensors and denote these measurements by \( y_1, \ldots, y_n \in \mathbb{R}^3 \). Denote the positions of these points with respect to the inertial frame by \( \tilde{y}_i, i = 1, \ldots, n \in \mathbb{R}^3 \) and assume these positions are known and constant. The output model for such a set of measurements is given by
\[ y_i = h_i((R, p), \tilde{y}_i) = R^T \tilde{y}_i - R^T p, \quad i = 1, \ldots, n \] (6)
where \( h_i \) is a right action of \( SE(3) \) on the homogeneous output space \( M_i := \mathbb{R}^3 \). A practical example of measurements modeled by (6) is vision based landmark readings where the landmarks are fixed in the inertial frame, leading to constant \( \tilde{y}_i, i = 1, \ldots, n \). The pose estimation problem is to estimate \( R \) and \( p \) together with the input biases \( b_\omega \) and \( b_v \).

4. Error Definition and Autonomy of Error Dynamics

We consider the following right-invariant group error,
\[ E = \tilde{X}X^{-1} \in G, \] (7)
where \( \tilde{X} \) and \( X \) are right invariant in the sense that \( E = \tilde{X}X^{-1} \) as was proposed in [3, 10]. The above error resembles the usual error \( x - \hat{x} \) used in classical observer theory when \( x, \hat{x} \) belong to a vector space. We have \( \tilde{X} = X \) if and only if \( E = I \). We also consider the following bias estimation error
\[ \hat{b} = \hat{b} - b \in \mathfrak{g}. \] (8)

We are interested to see when an observer of the general form [4] produces autonomous error dynamics since that would enable straightforward stability analysis. When the measurement of system input is bias free, implementable observers of the form (4a) have been proposed that produce autonomous group error dynamics \( E \in \mathfrak{g} \). In this section, we show that when the measurement of system input is corrupted by bias, any implementable observer of the form (4) produces non-autonomous error dynamics for general Lie groups, and it can only produce autonomous error dynamics for Abelian Lie groups. To prove this result, we note that the observer (4) can be rewritten into the form
\[ \dot{X} = \hat{X}[u_t - \hat{b}] - \alpha_3(\hat{X}, y, \hat{b}, u_t, t), \] (9a)
\[ \dot{b} = \beta_3(\hat{X}, y, \hat{b}, u_t, t), \] (9b)
where \( \alpha_3: G \times \mathbb{R} \to \mathfrak{g} \) and \( \beta_3: G \times \mathbb{R} \to \mathfrak{g} \) are parameterized vector fields on \( G \) and \( \mathfrak{g} \). respectively, and \( \dot{y} \) is now interpreted as a parameter for \( \alpha_3 \) and \( \beta_3 \).

**Theorem 4.1.** Consider the observer (9) for the system (7)–(4).

The error dynamics \( \dot{E}, \dot{b} \) is autonomous if and only if all of the following conditions hold:

(a) \( \alpha_3 \) and \( \beta_3 \) do not depend on \( \hat{b}, u_t \), and \( t \).

(b) The vector field \( \alpha_3 \) is right equivariant in the sense that \( T_R Q_3 \alpha_3(\hat{X}, y) = \alpha_3(Q_3 \hat{X}, h(Z, y)) \) for all \( \hat{X}, Z \in G \) and all \( y \in M \).

(c) The vector field \( \beta_3 \) is right invariant in the sense that \( \beta_3(\hat{X}, y) = \beta_3(Q_3 \hat{X}, h(Z, y)) \) for all \( \hat{X}, Z \in G \) and all \( y \in M \).
For all $Z \in G$ the adjoint map $Ad_Z : g \to g$ is the identity map. □

Proof: In view of (11) and (13b), differentiating $E = \dot{X}X^{-1}$ and $\hat{b} = b - \beta$ with respect to time yields

$$
\dot{E} = -T_{\dot{X}} X^{-1} \alpha(y, \hat{b}, u, t) - T_{\dot{E}} R E \dot{A} \hat{b} \tag{10a}
$$

$$
\hat{b} = \beta(x, y, \hat{b}, u, t). \tag{10b}
$$

If the conditions (a) to (d) of the Theorem hold, the error dynamics will be simplified to

$$
\dot{E} = -\alpha(y, \dot{X}X^{-1}, y) - T_{\dot{R}E} \hat{b} = -\alpha(y, \hat{b} - \alpha(y, y) - T_{\dot{E}} R \dot{E} \hat{b}, \tag{11a}
$$

$$
\hat{b} = \beta(x, \dot{X}X^{-1}, y) = \beta(x, y), \tag{11b}
$$

which are autonomous.

Conversely, assume that the error dynamics (10) are autonomous. Then there exist functions $F_i : G \times g \to TG$ and $H_i : G \times g \to g$ such that for all $X, \dot{X} \in G$, $y \in M$, $u, t \in g$,

$$
\dot{E} = -T_{\dot{X}} X^{-1} \alpha(y, \hat{b}, u, t) - T_{\dot{E}} R E \dot{A} \hat{b} = F_i(E, \hat{b}) \tag{12a}
$$

$$
\hat{b} = H_i(E, \hat{b}). \tag{12b}
$$

It immediately follows that $\alpha_i$ and $\beta_i$ are independent of $u$ and $t$. Moreover, since the error $E = \dot{X}X^{-1}$ is invariant with respect to the transformation $(\dot{X}, X) \mapsto (\dot{X}, XZ)$ for all $Z \in G$ and the error $\hat{b} = b - b$ is invariant with respect to the transformation $(\hat{b}, b) \mapsto (\hat{b} + d, b + d)$ for all $d \in g$, we have

$$
\begin{split}
- T_{\dot{X}} X^{-1} \alpha_i((X, y), \hat{b}) - T_{\dot{E}} R E \dot{A} \hat{b} &= F_i(E, \hat{b}) \tag{13a} \\
&= -T_{\dot{X}Z} X^{-1} \alpha_i((XZ, h(Z), y), \hat{b} + d) - T_{\dot{E}} R E \dot{A} \hat{b}, \\
\beta_i((X, y), \hat{b}) &= H_i(E, \hat{b}) = \beta_i((XZ, h(Z), y, \hat{b} + d)). \tag{13b}
\end{split}
$$

From (13b) it follows that $\beta_i$ is independent of $\hat{b}$ since the right hand side of (13b) depends on $d$ while the left hand side is independent of this variable. This establishes condition (a) for $\beta_i$. It also follows that $\beta_i$ satisfies the invariance condition $\beta_i((X, y), \hat{b}) = \beta_i((X, Z, h(Z), y))$ (condition (c) in the Theorem). We can rearrange (13b) to obtain

$$
\begin{split}
- T_{\dot{X}} X^{-1} \alpha_i((X, y), \hat{b}) - T_{\dot{E}} R E \dot{A} \hat{b} + T_{\dot{R}E} R \dot{E} \dot{A} \hat{b} &= T_{\dot{X}} X^{-1} \alpha_i((XZ, h(Z), y), \hat{b} + d), \tag{14} \\
&= -T_{\dot{X}Z} X^{-1} \alpha_i((XZ, h(Z), y), \hat{b} + d). \tag{15}
\end{split}
$$

The right hand side of (14) is a function of $d$ while the left hand side is not. This implies that $\alpha_i$ is independent of $\hat{b}$ (establishing condition (a) for $\alpha_i$). We can then rearrange (14) again to obtain

$$
- T_{\dot{X}} X^{-1} \alpha_i((X, y), \hat{b}) + T_{\dot{X}} X^{-1} \alpha_i((XZ, h(Z), y)) = T_{\dot{R}E} R \dot{E} \hat{b} - T_{\dot{R}E} R \dot{E} \dot{A} \hat{b}. \tag{15}
$$

The right hand side of (15) is a linear function acting on $\hat{b} \in g$ while the left hand side is completely independent of the variable $\hat{b}$. Since $\hat{b}$ is arbitrary, this implies that both sides of (15) are zero. In particular, $T_{\dot{X}} X^{-1} \alpha_i((X, y), \hat{b}) = T_{\dot{X}} X^{-1} \alpha_i((XZ, h(Z), y))$ and $T_{\dot{R}E} R \dot{E} \dot{A} \hat{b} = T_{\dot{R}E} R \dot{E} \dot{A} \hat{b} \in g$ for all $\hat{b} \in g$ and all $X, Z \in G$. These equations imply $T_{\dot{X}} X^{-1} \alpha_i((X, y), \hat{b}) = \alpha_i((XZ, h(Z), y))$ and $AdZ \hat{b} = \hat{b}$ to obtain conditions (b) and (d) imposed in the theorem, respectively. This completes the proof.

Remark 4.2. If $G$ is a real, finite-dimensional, connected Lie group then condition (d) of Theorem 4.1 implies that $G$ is Abelian [28, Proposition 1.91]. By the structure theorem for connected Abelian Lie groups [28, Proposition III.6.4.11], this means that $G$ is isomorphic to a product $R^n \times (S^m)^n$ where $R^n$ is additive and $(S^m)^n$ denotes the $n$-dimensional torus. This class of Lie groups is far more specific than the Lie groups that are encountered in many practical applications. For robotics applications, the Lie groups typically considered are $SO(3)$ and $SE(3)$ both of which are non-Abelian. Theorem 4.1 in particular implies that all implementable geometric bias estimators on $SO(3)$ and $SE(3)$ proposed in the literature produce non-automous standard error dynamics (see [14] and [24]). □

5. Observer Design and Analysis

We propose the following implementable group estimator,

$$
\dot{X} = \dot{X}(u, \hat{b}) = K_i((\dot{X}, \hat{b}, \hat{u}, t])[D_i \phi_i(\hat{X}, \hat{y})], \tag{16}
$$

where $\dot{X}(\hat{u}) = \hat{X}_0$ where $\phi_i : G \times M \to R^*$ is a $C^2$ cost function, $D_i \phi_i(\hat{X}, \hat{y}) \in T^{\ast}_G \Gamma_i$ denotes the differential of $\phi_i$ with respect to its first argument evaluated at the point $(\hat{X}, \hat{y})$ and $K_i((\hat{X}, \hat{b}, \hat{u}, t))$ is a linear gain mapping from $T^{\ast}_G \Gamma_i$ to $T^{\ast}_G \Gamma_i$. Note that $\hat{y}$ is considered to be a parameter for $K_i$ and $\phi_i$. The above group estimator matches the structure of (22) where the innovation $\alpha_i$ is generated by applying the gain mapping $K_i$ to the differential $D_i \phi_i$. By Theorem 4.1 we already know that the above estimator cannot produce autonomous error dynamics for a general Lie group. Hence, there is no reason to omit the arguments $\hat{b}, \hat{u}$, and $t$ of the gain mapping. If the gain mapping $K_i$ is symmetric positive definite and independent of $\hat{b}, \hat{u}$, and $t$, the above estimator simplifies to the gradient-like observers proposed in (10) for the bias free case, and in (13) for the case including bias.

We consider the following bias estimator,

$$
\hat{b} = \Gamma \circ T_{\dot{L}_i} : g \to g = \hat{b}, \tag{17}
$$

where $T_{\dot{L}_i} : R^* \to g$ is the dual of the map $T_{\dot{L}_i}$ (see Section 3 and $\Gamma : g \to g$ is a constant gain mapping.

We will require the following assumptions for statement of results.

(A1) Lie group $G$ has a faithful representation as a finite-dimensional matrix Lie group. That is, there exist a positive integer $m$ and an injective Lie group homomorphism $\Phi : G \to GL(m)$ into the group $GL(m)$ of invertible $m \times m$ matrices. Note that $\Phi(G)$ is a matrix subgroup of $GL(m)$.

(A2) [boundedness conditions] $\Phi(X), \Phi(X)^{-1}$ and $K(X, \hat{b}, \hat{u}, t)$ are bounded along the system trajectories.

(A3) [differentiability conditions] $\dot{u}(t)$, the first differentials of $h_i(\hat{X}, \hat{y})$ and $K(\hat{X}, \hat{b}, \hat{u}, t)$, as well as the first and the second differential of $\phi_i(\hat{X}, \hat{y})$ with respect to all of their arguments are bounded along the system trajectories.

Remark 1. Second differential of $\phi$ is either in the sense of embedding the Lie group into $R^{m_{	ext{max}}}$ or in the sense of employing a Riemannian metric.
Theorem 5.1. Consider the observer (16)-(17) for the system (17)-(18). Suppose that assumptions (A1) and (A3) hold. Assume moreover that the gain mappings $K$ and $\Gamma$, and the cost function $\phi$ satisfy the following properties:

(a) The gain mapping $K: T^*_X \to T_X$ is uniformly positive definite (not necessarily symmetric). That is, there exist positive constants $\underline{k}$ and $\bar{k}$ and a continues vector norm $|.|$ on $T^*_XG$ such that for all $v^* \in T^*_XG$ we have $k|v^*|^2 \leq |v^*|^2 \leq \bar{k}|v^*|^2$.

(b) The gain mapping $\Gamma, g^*: \R^+ \to \R^+$ is symmetric positive definite.

(c) The cost function $\phi$ is right invariant, that is $\phi(\hat{X}Z,h(Z,y)) = \phi(\hat{X},y)$ for all $\hat{X}, Z \in \mathcal{G}$ and all $y \in M$.

(d) The cost $\phi(\cdot,\cdot, \cdot): G \to \R^+$, $E \mapsto \hat{\phi}(E, \hat{y})$ is locally positive definite around $E = I$ and it has an isolated critical point at $E = I$.

Then the error dynamics $(\hat{E}, \hat{b})$ is uniformly locally asymptotically stable at $(I, 0)$. $\square$

Proof: The following result is used in the development later in this proof.

Lemma 5.2. Let $\phi: G \times M \to \R^+$ be a right-invariant cost function in the sense defined in part (c) of Theorem 5.1. Then we have

$$D_t \phi(\hat{X}, \hat{y}) = T^*_X \phi(\hat{X}, \hat{y}) = \Gamma \phi(\hat{X}, \hat{y}) \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi$$

Now, considering the candidate Lyapunov function,

$$\mathcal{L}(E, \hat{b}) = \phi(\hat{E}, \hat{y}) + \frac{1}{2} \Gamma^{-1}[\hat{b}] [\hat{b}]$$

The Lyapunov candidate is at least locally positive definite due to conditions (b) and (d). The time derivative of $\mathcal{L}$ is given by

$$\dot{\mathcal{L}}(E, \hat{b}) = D_t \phi(\hat{E}, \hat{y}) \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi$$

Recalling that $\hat{b} = \hat{b}$ and substituting $\hat{E}$ form (20) in (22), we obtain

Now, replacing $\hat{b}$ with (17) we obtain

$$\mathcal{L}(E, \hat{b}) = -D_t \phi(\hat{E}, \hat{y}) \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi$$

Duality implies $D_t \phi(\hat{X}, \hat{y}) \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi$ simplifies to

$$\mathcal{L}(E, \hat{b}) = -D_t \phi(\hat{E}, \hat{y}) \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi$$

Since $K(\cdot)$ is assumed to be positive definite and the map $T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi$ is full rank, the map $T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi \circ T^*_X \phi$ is positive definite. This implies that $\mathcal{L}(E, \hat{b}) \leq 0$ and hence the Lyapunov function is non-increasing along the system trajectories. We adopt the proof of [50, Theorem 4.8] to prove uniformly local stability of error dynamics. Recalling assumption (A1) distance to the identity element of $G$ is denoted by $d(.)$ and is induced by Frobenius norm on $\mathcal{O}(G) \subset \R^{m \times n}$ via $d(E):= ||I - \phi(E)||$ where $I$ is the identity matrix. Define the compound error $x := (E, \hat{b}) \in \R^g \times \hat{b}$ and obtain the distance of $x$ to $(I, 0)$ by $l(x^2) := d(E^2) + [\hat{b}]^2$ where $||\hat{b}||_0$ denotes a norm on $\hat{b}$. Using assumption (A3) there exist a ball $B_{\hat{b}} := \{E \in G : d(E) \leq r\}$ such that $\phi_1(\hat{y})$ is positive definite on $B_{\hat{b}}$. Consequently $\mathcal{L}(\hat{x})$ is positive definite on $B_{\hat{b}} := \{E \in G : d(E) \leq r\}$ such that $\phi_1(\hat{y})$ is positive definite on $B_{\hat{b}}$. Consequently $\mathcal{L}(\hat{x})$ is positive definite on $B_{\hat{b}} \subset \R^g$. Since $\mathcal{L}(\hat{x}) \leq 0$, any solution starting in $\Omega_{\hat{x}}$ at $t_0$ remains in $\Omega_{\hat{x}}$ for all $t \geq t_0$. On the other hand, since $\mathcal{L}(\hat{x})$ is positive definite on $\Omega_{\hat{x}} \subset B_{\hat{b}}$, there exist class $\mathcal{K}$ functions $\eta_1$ and $\eta_2$ such that $\eta_1(\hat{x}(t)) \leq \eta_2(\hat{x}(t))$ for all $\hat{x} \in \Omega_{\hat{x}}$. Since $\mathcal{L}(\hat{x})$ is the only $\{x \in B_{\hat{b}} \in \mathcal{L}(\hat{x}) \leq c\}$, the equilibrium point $\hat{x} = (I, 0)$ is uniformly stable for all initial conditions starting in $\Omega_{\hat{x}}$. Moreover, the error $E$ is bounded by $d(E(t)) \leq l(\hat{x}(t)) \leq \eta^{-1}(\mathcal{L}(\hat{x}(t)))$ for such initial conditions. Boundeness of $\hat{x}(t)$ implies that $E(t)$ and $\hat{b}(t)$ are bounded with respect to $d(.)$ and $||\hat{b}||_0$, respectively. Differentiating (20) with respect to time and considering the boundedness of $(E(t), \hat{b}(t))$ together with assumptions (A2) and (A3) one can conclude that $\mathcal{L}(\hat{t})$ is bounded and hence $\mathcal{L}(\hat{t})$ is uniformly continuous. By invoking Barbacut’s lemma we conclude that $\mathcal{L}(\hat{t}) \to 0$. This together with condition (A3) implies that $D_t \phi(E, \hat{y}) \to 0$. Since $\phi(E, I)$ has an isolated critical point at $E = I$, there exist a ball $B_{\hat{b}} \subset \R^g$ such that $E = I$ is the only point in $B_{\hat{b}}$ where $D_t \phi(E, \hat{y})$ is zero. We proved before that $E(t) \in B_{\hat{b}}$ for all initial conditions starting in $\Omega_{\hat{x}}$. Choosing $c < min(\eta_1(\hat{x}), min(\eta_2(\hat{x})))$ ensures that $E = I$ is the only critical point in $B_{\hat{b}}$. This implies that $E(t) \to I$ for all initial conditions starting in $\Omega_{\hat{x}}$. Using (1), (22), and (20), recalling assumptions (A2) and (A3) and using a local coordinate representation, one can verify that $E(t)$ is bounded and hence $E(t)$ is uniformly continuous. This, by invoking Barbacut’s lemma we have $E(t) \to 0$. Considering $E(t), \hat{E}(t) \to 0$ together with error dynamics (20) implies that $\hat{b}(t) \to 0$ for all initial errors starting in $\Omega_{\hat{x}}$. This completes the proof of uniformly local asymptotic stability of the error dynamics.
The following theorem proposes additional conditions to guarantee local exponential stability of the error dynamics.

**Theorem 5.3.** Consider the observer (30)-(31) for the system (1)-(3). Suppose that assumptions (A1) and (A2) and conditions (a) and (b) of Theorem 5.1 hold. Assume moreover that:

(d) \( D_1 \phi_1(I, \tilde{y}) = 0 \) and \( \text{Hess}_1 \phi_1(I, \tilde{y}) : \mathfrak{g} \to \mathfrak{g}^* \) is symmetric positive definite.

(e) The condition number of \( \Phi(X(t)) \) is bounded for all \( t \geq t_0 \) (uniformly in \( t_0 \)).

Then, the error dynamics \( (E(t), \dot{b}(t)) \) is uniformly locally exponentially stable at \( (I, 0) \).

Proof: The group error dynamics \( \dot{E} \) can be rewritten as

\[
\dot{E} = -T_{X} R_K \circ K_1(\hat{X}, \hat{b}, u, I) \circ T_{X} R_K^{-1} [D_1 \phi_1(E, \hat{y})] - T_I L_E \text{Ad}_E \hat{b}.
\]  

(27)

Using (28) and (17), the bias error dynamics is obtained as

\[
\dot{b} = \Gamma_0 \circ T_I L_{\hat{E}} \circ T_{X} R_K^{-1} [D_1 \phi_1(E, \hat{y})]
\]

\[
\Gamma_0 \circ \text{Ad}_{E} \circ T_I L_{\hat{E}} [D_1 \phi_1(E, \hat{y})].
\]

(28)

Defining \( \epsilon, \delta \in \mathfrak{g} \) as the first order approximation of \( E \) and \( \hat{b} \) respectively, linearizing the error dynamics around \( (I, 0) \) and neglecting all terms of quadratic or higher order in \( (\epsilon, \delta) \) yields

\[
\dot{\epsilon} = -T_{X} R_K \circ K_1(\hat{X}, \hat{b}, u, I) T_{X} R_K^{-1} [D_1 \phi_1(E, \hat{y})] \epsilon
\]

\[
- \text{Ad}_{E} \delta,
\]

(29)

\[
\dot{\delta} = \Gamma_0 \circ \text{Ad}_{E} \circ \text{Hess}_1 \phi_1(I, \hat{y}) \epsilon,
\]

(30)

where \( \text{Hess}_1 \phi_1(I, \hat{y}) : \mathfrak{g} \to \mathfrak{g}^* \) denotes the Hessian operator which is intrinsically defined at the critical point of the cost function. In order to investigate the stability of the linearized error dynamics, we consider a basis for the involved tangent spaces and rewrite (29) in matrix format. To this end, consider a basis \( \{e_i\} \) for \( \mathfrak{g} \) and its corresponding dual basis \( \{\epsilon_i\} \). Obtain the basis \( \{e_i X\} \) for the vector space \( T_X G \) by right translating \( \{e_i\} \) and consider its corresponding dual basis \( \{\epsilon_i X^*\} \) for \( T_X G \). Denote by \( \|\epsilon_i\|, \|\delta_i\| \) the representation of the vectors \( \epsilon, \delta \) with respect to the basis \( \{e_i\} \). Denote the matrix representation of the maps \( K_1(\hat{X}, \hat{b}, u, I) : T_{X} G \to T_{X} G \), \( \Gamma_0 : \mathfrak{g} \to \mathfrak{g}^* \), \( \text{Hess}_1 \phi_1(I, \hat{y}) : \mathfrak{g} \to \mathfrak{g}^* \) and \( \text{Ad}_{E} \) respectively. Note that the matrix representation of \( T_{X} R_K^{-1} : T_{X} G \to \mathfrak{g} \) with respect to the corresponding basis for its domain and co-domain is the identity matrix. Hence, the matrix representation of the error dynamics is obtained as

\[
\begin{bmatrix}
\|\epsilon_i\| \\
\|\delta_i\|
\end{bmatrix} = \begin{bmatrix}
-\|K\| H & -\|\text{Ad}_E\| H \\
\|\Gamma\| \|\text{Ad}_E\| H & 0
\end{bmatrix}
\begin{bmatrix}
\|\epsilon_i\| \\
\|\delta_i\|
\end{bmatrix}.
\]

(31)

Since \( \Gamma \) is symmetric positive definite, there exists a full rank square matrix \( L \) such that \( \|\Gamma\| = L^T L \). Consider the change of coordinates \( \tilde{\epsilon} := L \epsilon \) and \( \tilde{\delta} := L^{-1} \delta \). Using (31), the dynamics of the new error coordinates are obtained as

\[
\begin{bmatrix}
\|\tilde{\epsilon}\| \\
\|\tilde{\delta}\|
\end{bmatrix} = \begin{bmatrix}
-L\|K\| H L^{-1} & -L\|\text{Ad}_E\| B L^T \\
\|L\| \|\text{Ad}_E\| H L^{-1} & 0
\end{bmatrix}
\begin{bmatrix}
\|\tilde{\epsilon}\| \\
\|\tilde{\delta}\|
\end{bmatrix}.
\]

(32)

Consider initial conditions \( X(t_0) \) for system (1) and \( (\hat{X}(t_0), \hat{b}(t_0)) \) for the estimator (16)-(17), respectively. Introducing the parameter \( \lambda = (t_0, X(t_0), \hat{X}(t_0), \hat{b}(t_0)) \in \mathcal{D} \) where \( \mathcal{D} := \mathbb{R} \times \mathbb{R} \times \mathbb{R} \times \mathbb{R} \), the trajectories of \( X, \hat{X}, \hat{b} \) and \( y \) can be viewed as functions of \( t \) and \( \lambda \). Define \( A(t, \lambda) := -L\|K\| H L^{-1}, B(t, \lambda) := -L\|\text{Ad}_E\| B L^T, \) and \( P := L^{-1}\|H\| L^{-1} \). The system (32) belongs to the following standard class of parameterized linear time-varying systems discussed extensively in the literature (33-34).

We can now verify the conditions of (34) Theorem 1) to prove the stability of system (32). Both \( B(t, \lambda) \) and its time derivative are bounded due to Assumption (A2). Since \( \text{Hess}_1 \phi_1(I, \hat{y}) \) is symmetric positive definite and \( L \) has full rank, the matrix \( P \) is symmetric positive definite and it is bounded by \( c_F(H)\|L\|^2 I \leq P \leq \bar{c}_F(H)\|L\|^2 I \) where \( c_F(H) \) and \( \bar{c}_F(H) \) denote the smallest and largest singular value of a matrix respectively. Define \( -Q := P + A(t, \lambda) P + P(t, \lambda) = (-\|H\| L^{-1}) \|K\| L^{-1} \). Using condition (a) of Theorem 5.1 and recalling assumption (A2) there exist positive constants \( k_1 \) and \( k_2 \) such that \( 2k_1 Id \leq \|K\| + \|\Gamma\| \leq 2k_2 Id \) where \( Id \) is the identity matrix. This ensures that \( Q \) is uniformly symmetric positive definite and we have \( 2k_1 \|H\|^2 \|\text{Ad}_E\|^2 \|L\|^2 \leq Q \leq 2\bar{c}_F(H)^2 k_2 \|L\|^2 \). It only remains to investigate whether \( B(t, \lambda) = \lambda \)-uniformly persistently exciting (34) equation (10)]. Embed the Lie algebra \( \mathfrak{g} \) into \( \mathbb{R}^{m_{max}} \). Invoking the property \( \text{vec}(\Phi(X) w) \Phi(X)^{-1}) = \Phi(X)^{-1} \otimes \Phi(X) \text{vec}(w) \) where \( \text{vec}(w) \in \mathbb{R}^{m_{max}} \) is the vectorization of the matrix \( w \in \mathfrak{g} \) and \( \otimes \) denotes the Kronecker product, one can conclude that the matrix representation of \( \text{Ad}_E : \mathbb{R}^{m_{max}} \to \mathbb{R}^{m_{max}} \) with respect to the standard basis for its domain and co-domain is given by \( \text{Ad}_E = \Phi(X)^{-1} \otimes \Phi(X) \). Thus \( \text{vec}(\text{Ad}_E) = \text{vec}(\Phi(X)^{-1} \otimes \Phi(X)) \) and \( \text{cond}(\Phi(X)^{-1}) \) denotes the condition number of \( \Phi(X) \in \mathbb{GL}(m) \). Since \( \mathbb{R}^{m_{max}} \) is the minimum singular value of \( \text{Ad}_E : \mathfrak{g} \to \mathfrak{g} \) is larger than or equal to the minimum singular value of \( \text{Ad}_E : \mathbb{R}^{m_{max}} \to \mathbb{R}^{m_{max}} \). Using condition (c) there exists a positive constant \( c_0 \) such that \( \text{cond}(\Phi(X) t) \leq c_0 \). Hence, \( \text{vec}(B(t, \lambda) B(t, \lambda)^T) = \text{vec}(\text{Ad}_E)^T \text{vec}(\text{Ad}_E) L^{-1} \text{vec}(\text{Ad}_E)^T \text{vec}(\text{Ad}_E) L^{-1} \geq \bar{c}_0 T Id \) which completes the requirements of (34) Theorem 1). Hence, the equilibrium \( (0, 0) \) of the system (32) is uniformly exponentially stable. This implies that the equilibrium \( (0, 0) \) of the linearized system (32) is uniformly exponentially stable and consequently the equilibrium \( (0, 0) \) of the nonlinear error dynamics (27)-(28) is uniformly locally exponentially stable (30) Theorem 4.1.5) (note that what is referred to as uniform exponential stability here is the same as exponential stability in the sense of (30)).

Owing to the parameter-dependent analysis, the obtained exponential stability is uniform with respect to the choice of all
initial conditions in $\lambda$ and not only with respect to the choice of $E(t_0)$ and $b(t_0)$ for a given $X$.

**Remark 5.4.** For the stability analysis, we assume that $G$ allows a matrix Lie group representation (by assumption (A1)). Nevertheless, the actual formulas of the proposed observer (16-17) can be computed without requiring any matrix structure for the Lie group, owing to the representation-free formulation of the proposed observer. We only require the matrix Lie group representation of $G$ to interpret the boundedness conditions on $\Phi(X)$, $\Phi(X^{-1})$, and $\text{cond}(\Phi(X))$. We will illustrate this point further with an example in section 2. Boundedness of $\Phi(X(t))$ and $\Phi(X^{-1}(t))$ are usually mild conditions in practice. Moreover, it is easy to verify that $\text{cond}(X(t))$ is uniformly bounded (uniformly in $t_0$) if $\Phi(X(t))$ and $\Phi(X^{-1}(t))$ are uniformly bounded (uniformly in $t_0$). For the special case where the considered Lie group is $\mathbb{SO}(3)$, all of these boundedness conditions are satisfied automatically since we have $\|\Phi(X(t))\|_2^2 = \text{tr}(\Phi(X)^T\Phi(X)) = \text{tr}(I) = 3$ for all $X \in \mathbb{SO}(3)$. In section 7 we interpret the boundedness requirements for the Lie group $\mathbb{SE}(3)$ as well.

It is possible to replace the requirement for boundedness of $\Phi(X(t))$, $\Phi(X^{-1}(t))$, and $\text{cond}(\Phi(X(t)))$ respectively with the boundedness of $\hat{\Phi}(X(t))$, $\Phi(X^{-1}(t))$, and $\text{cond}(\Phi(X(t)))$ in Theorems 5.1 and 5.3 and still prove the same stability results. Boundedness conditions on $\hat{X}$ are always verifiable in practice.

Theorem 5.1 does not necessarily require a symmetric gain mapping $K_1$. Also, we do not impose any invariance condition on this gain mapping. Condition (a) of Theorem 5.1 only requires the symmetric part of $K_1$, denoted by $K_1^s$, to be uniformly positive definite. Considering a basis for $T_X G$ and the corresponding dual basis for $T^*_X G$, condition (a) of Theorem 5.1 implies that the matrix representation of $K_1^s(X): T_X G \to T_X G$ with respect to these bases is uniformly symmetric positive definite. In practice, we will use this property to design a suitable gain mapping and obtain the innovation term of the observer. We will illustrate this method with an example in Section 7.

Condition (d) of Theorem 5.1 is milder than condition (d) of Theorem 5.3 or similar conditions imposed in [10] and [13]. This allows the choice of much larger class of cost functions to generate innovation terms that guarantee the asymptotic stability of error dynamics.

In the special case where $K_1$ is uniformly symmetric positive definite and is independent of the arguments $\hat{b}, u$, and $t$, the term $K_1(\hat{X}, \hat{y})[D \phi_1(\hat{X}, \hat{y})]$ simplifies to $\text{grad} \phi_1(\hat{X}, \hat{y})$ where $\text{grad}$ denotes the gradient with respect to the Lie-Riemannian metric on $G$ induced by the gain mapping. In this case, the observer (16-17) simplifies to the gradient-like observer discussed in [13] equations (7)-(8) where the gain mapping $F$ is a scalar, or the observer of [10] for the bias-free case. If in addition we assume that $K_1$ satisfies the invariance condition $T_{\hat{X}} R_Z \circ K_1(\hat{X}, \hat{y}) = K_1(\hat{XZ}, h(Z, y))$, the induced Riemannian metric on $G$ would be right-invariant. In this case, the error dynamics (27)-(28) correspond to the perturbed gradient-like error dynamics given by [13] equations (17)-(18)]. The larger class of gain mappings together with the larger class of cost functions proposed in this paper ensures that the proposed observer allows a much larger class of observers comparing to the authors’ previous work [10][12][13]. The discussion presented here shows also that a non-invariant Riemannian metric can be employed for the bias-free case to design the innovation term of the gradient-like observers in [11][12][13]. In this case, the resulting error dynamics would be stable as long as the conditions on the cost function are satisfied, but the error dynamics would be non-autonomous. Non-invariant gains also lead to observers that are not symmetry-preserving in the sense of [3].

6. Constructing Invariant Cost Functions on Lie Groups

In Section 5 we propose the observer (15-12) that depend on the differential of the cost function $\phi_1: G \times M \to \mathbb{R}^+$ as its innovation term. The cost function $\phi_1$ must be right invariant, and it should satisfy condition (d) of Theorem 5.1 (or condition (d) of Theorem 5.3) in order to guarantee asymptotic (or exponential) stability of the observer error. Designing such a cost function can be challenging since $M$ is an orbit in the product of different output spaces which can generally be a complicated manifold. In this section, based on the idea presented in [6], we propose a method for constructing a suitable cost function $\phi_1$ by employing single variable cost functions on the homogeneous output spaces $M_i$. Finding a suitable cost function on each output space is usually easy, especially when the output spaces are embedded in Euclidean spaces.

**Proposition 6.1.** Suppose $f_{i_1}, f_{i_2}, \ldots, f_{i_n}: M_i \to \mathbb{R}^+$, $y_i \to f_{i_1}(y)$ are single variable $C^\infty$ cost functions on $M_i$, $i = 1, \ldots, n$. Corresponding to each $f_{i_1}, \ldots, f_{i_n}$ construct a cost function $\phi_1: G \times M_i \to \mathbb{R}^+$ using $\phi_1(\hat{X}, y) := f_{i_1}(h_1(\hat{X}, y), \ldots, f_{i_n}(h_n(\hat{X}, y)))$. Obtain the cost function $\phi_1(\hat{X}, y) := \sum_{i=1}^n \phi_1^i(\hat{X}, y_i)$.

(a) The cost function $\phi_1$ is right invariant in the sense defined in part (c) of Theorem 5.7.

(b) Assume that each $f_{i_1}, i = 1, \ldots, n$ is locally positive definite around $\tilde{y}_i \in M_i$. Assume moreover that $\bigcap_{i=1}^n \text{stab}_{\tilde{y}_i}(\tilde{y}_i) = \{0\}$ where $\text{stab}_{\tilde{y}_i}(\tilde{y}_i)$ denotes the stabilizer of $\tilde{y}_i$ with respect to the action $h_i$ defined by $\text{stab}_{\tilde{y}_i}(\tilde{y}_i) := \{X \in G : h_i(\hat{X}, \tilde{y}_i) = \tilde{y}_i\}$. Then $\phi_1(\hat{X}, y) : G \to \mathbb{R}^+$ is locally positive definite around $\hat{X} \in G$.

(c) If $D f_{i_1}(\tilde{y}_i) = 0$ for all $i = 1, \ldots, n$ then $D_1 \phi_1(\hat{X}, y) = 0$. If additionally the Hessian operators $\text{Hess} f_{i_1}(\tilde{y}_i): T_{\tilde{y}_i} M_i \to T_{\tilde{y}_i} M_i$ are symmetric positive definite for all $i = 1, \ldots, n$ and $\bigcap_{i=1}^n T \text{stab}_{\tilde{y}_i}(\tilde{y}_i) = \{0\}$, then $\text{Hess} \phi_1(\hat{X}, y)$ is symmetric positive definite.

Proof of Proposition 6.1 is given in the Appendix. Proposition 6.1 suggests a systematic method to construct a cost function which satisfies the requirements of Theorem 5.1 or Theorem 5.3. The differential of this function can be employed to design the innovation term of the observer. We will illustrate this method with an example in section 7.

The method proposed by Proposition 6.1 to construct the cost function $\phi_1$ is basically different from the one presented in [13] Proposition 2. The method proposed in [13] employs invariant cost functions on $M_i \times M_i$ while the method presented here
only requires single variable cost functions on each $M_i$. Implement-
ability of the proposed observer in (13) is guaranteed when the
homogeneous output spaces are reductive. The method pre-
presented in this paper guarantees the implementability of resulting
observer without imposing any reductivity condition.

The condition $\cap_{i=1}^{n}\text{stab}_{b}(\hat{y}_i) = \{I\}$ (imposed in part [B] of
Proposition 6.1) is sufficient to ensure $\cap_{i=1}^{n}T_{i}\text{stab}_{b}(\hat{y}_i) = \{0\}$
(imposed in part [C] of the Proposition). This condition can be
interpreted as an observability criterion. In particular, for the
attitude estimation problem with vectorial measurements, this
condition is equivalent to the availability of two or more non-
collinear reference vectors $\{13\}$. As will be discussed in the
next section, for the pose estimation problem with landmark
measurements, this condition corresponds to the availability of
three or more landmarks which are not located on the same line.

The method presented in this paper suits the systems with
constant reference outputs. Time varying reference outputs
have been investigated in (18) and (20) for attitude estimation
problem on $SO(3)$. Nevertheless, in most practical cases, the
reference outputs are approximately constant $\{18\}$ and the proposed observer design methodology applies.

7. Example: Pose Estimation Using Biased Velocity Measure-
ments

Recalling the pose estimation problem discussed in Example
(3.1) here we employ our observer (16)-(17) to derive the pose
estimators proposed in (3.1) and (3.3) and we generalizem them.

Apart from the semi-direct product representation of $SE(3)$
 discussed in Example (3.1) it is known that $SE(3)$ has also a ma-
trix Lie group representation as a subgroup of $GL(4)$ (see e.g.
(21)). We use this matrix Lie group representation only to
interpret the required boundedness conditions (see Assump-
tion (A2)) but we employ the semi-direct product representation
to derive the observer formulas (see remark (5.3)). The Lie group
homomorphism $\Phi$ which maps an element $(R, p) \in SE(3)$ to its
Corresponding matrix representation in $GL(4)$ is given by: $\Phi :$

$$(R, p) \mapsto \begin{bmatrix} R & p \\ 0 & 1 \end{bmatrix}.$$ The Frobenius norm of $\Phi((R, p))$ is given by $||\Phi((R, p))||^2 = \text{tr}(\Phi((R, p))^T\Phi((R, p))) = 4 + ||p||^2.$ Hence, $\Phi((R(t), p(t)))$ is bounded if $p(t)$ is bounded. Similarly, one can verify that $\Phi((\dot{R}(t), p(t)))$ is bounded (uniformly in $t_0$). This characterization the boundedness conditions imposed by Assumption (A2) and part (C) of Theorem 5.3.

From here after, we only consider the semi-direct product representation of $SE(3) \cong SO(3) \times \mathbb{R}$. We aim to employ the
observer developed in section 5 and use the guidelines pre-
sent in section 5 to design an observer to estimate the pose
$X = (R, p)$ and the bias $b = (b_{x}, b_{y}).$ Let us first evaluate the
observability condition imposed by part [B] and [C] of Proposition
6.1. We have $\cap_{i=1}^{n}\text{stab}_{b}(\hat{y}_i) = \{(R, p) \in SE(3) : R^T\hat{y}_i - R^T p = \hat{y}_i, \ i = 1, \ldots, n\} = \{(R, p) \in SE(3) : R^T p = R^T \hat{y}_1 - \hat{y}_1, \hat{y}_i - \hat{y}_j = \hat{y}_i - \hat{y}_j, \ i, j = 1, \ldots, n, i \neq j\}$ which implies that $\hat{y}_i - \hat{y}_j$ is an eigenvector of $R$. Hence, a necessary and sufficient condition which guarantees $\cap_{i=1}^{n}\text{stab}_{b}(\hat{y}_i) = \{(R_{i33}, 0)\}$ (and consequently $\cap_{i=1}^{n}T_{i}\text{stab}_{b}(\hat{y}_i) = \{(0_{3 \times 3}, 0)\}$) is the existence of at least three reference outputs $\hat{y}_i, \hat{y}_j, \hat{y}_k$ such that $\hat{y}_i - \hat{y}_j$ is not parallel to $\hat{y}_j - \hat{y}_k.$ Note that this condition is independent of the choice of inertial frame. Specifically, when landmark mea-

in order to design the innovation terms of the estimator (16)-(17), we resort to choose a basis for each tangent space to obtain matrix representations for the linear mappings $K_i, \Gamma, T_{i}L^x_{i},$ and use simple matrix calculus. For the sake of clarity, we denote the matrix representation of a linear mapping $F : U \to W$ with respect to the basis $\{u\}$ for its domain and basis $\{w\}$ for its co-
domain by the notation $\|F\|_{\{u\}}$. Also, the $R^\perp$ representation of a vector $a \in U$ with respect to the basis $\{u\}$ is denoted by $\|a\|_u$. Denote the standard bases of $\mathbb{R}^3$ and $\mathbb{S}(3)$ by $\{e_1\}$ and $\{e_3\}$, respectively. Using these bases, one can obtain a standard basis for $\mathbb{S}(3)$ denoted by $\{\mathbb{E}\}.$ We obtain a basis for $T_{(\hat{R}, \hat{p})}SE(3)$ using the right translation of $\{\mathbb{E}\}$. Denote this basis by $\{T_{(\hat{R}, \hat{p})}\mathbb{E}\}$ and its corresponding dual basis of $T^*_{(\hat{R}, \hat{p})}SE(3)$ by $\{\mathbb{E}^\perp\}.$

In order to use Proposition 6.1 we start by designing suitable
cost functions $f_i$ : $M_i \to \mathbb{R}$. A simple cost function is constructed by $f_i^0(\hat{y}_i) := \frac{1}{2}||\hat{y}_i||^2; k_i > 0$ where $||.||$ denotes the Eu-
clidean distance. It is straightforward to verify that $f_i^0$ satisfies
the requirements imposed by part [C] of Proposition 6.1, i.e.
$Df^0_i(\hat{y}_i) = 0$ and $Hess f^0_i(\hat{y}_i)$ is symmetric positive definite.
The cost functions $f_i^\Gamma : \Gamma \times M_i \to \mathbb{R}^+; i = 1, \ldots, n$ are obtained as $f_i^\Gamma (\hat{y_i}, (\hat{R}_i, \hat{p}_i), \hat{y}^a_i) = \frac{1}{2}||\hat{y}_i^a||^2 = \frac{1}{2}||\hat{y}_i - \hat{p}_i||^2$.
Denoting an arbitrary element of $\mathbb{S}(3)$ by $\hat{\Omega}, \hat{\hat{V}}$, we have $T_{(\hat{R}, \hat{p})}R_{(\hat{R}, \hat{p})}^\perp(\hat{\Omega}, \hat{\hat{V}}) = (\hat{\Omega}R, \hat{\hat{V}} + \hat{\hat{V}} \hat{R}) \in \mathbb{T}_{(\hat{R}, \hat{p})}SE(3)$. One can obtain $D_{(\hat{R}, \hat{p})}f_i^\Gamma (\hat{y}_i, (\hat{R}_i, \hat{p}_i), \mathbb{E}^\perp) : \mathbb{T}_{(\hat{R}, \hat{p})}SE(3) \to \mathbb{R}$ as

$$D_{(\hat{R}, \hat{p})}f_i^\Gamma (\hat{y}_i, (\hat{R}_i, \hat{p}_i), \mathbb{E}^\perp) \mathbb{E} = \sum_{i=1}^{n} k_i [\hat{y}_i^a (\hat{R} + \hat{p})_x, \alpha_i^a]^T.$$ Let $\alpha_i := (\hat{R}_i, \hat{p}_i - \hat{y}_i, \hat{y}^a_i) \in \mathbb{R}^3$. The $\mathbb{R}^6$ representation of $D_{(\hat{R}, \hat{p})}f_i^\Gamma (\hat{y}_i, (\hat{R}_i, \hat{p}_i), \mathbb{E}^\perp) : \mathbb{T}_{(\hat{R}, \hat{p})}SE(3) \to \mathbb{R}$, i.e. $[D_{(\hat{R}, \hat{p})}f_i^\Gamma (\hat{y}_i, (\hat{R}_i, \hat{p}_i), \mathbb{E}^\perp)]_{\mathbb{E}^\perp} = [D_{(\hat{R}, \hat{p})}f_i^\Gamma (\hat{y}_i, (\hat{R}_i, \hat{p}_i), \mathbb{E}^\perp)]_{\mathbb{E}^\perp}$ be $\{[\hat{y}_i^a (\hat{R} + \hat{p})_x, \alpha_i^a]^T\}$

$$D_{(\hat{R}, \hat{p})}f_i^\Gamma (\hat{y}_i, (\hat{R}_i, \hat{p}_i), \mathbb{E}^\perp) \mathbb{E}^\perp = \sum_{i=1}^{n} k_i [\hat{y}_i^a (\hat{R} + \hat{p})_x, \alpha_i^a]^T.$$ We choose $K_{(\hat{R}, \hat{p})} = \mathbb{E}$ (35)

$$K_{(\hat{R}, \hat{p})} = \mathbb{E} \mathbb{E}^\perp[\hat{y}_i^a (\hat{R} + \hat{p})_x, \alpha_i^a]^T$$

where the argument $(\hat{X}, \hat{y}, \hat{\hat{V}}, \mathbb{E}^\perp)$ to $K_{(\hat{R}, \hat{p})}$ has been omitted for brevity. We use (45) of Lemma 5.1 given in the Appendix to obtain

$$K_{(\hat{R}, \hat{p})} = \mathbb{E} \mathbb{E}^\perp \mathbb{E}^\perp = \sum_{i=1}^{n} k_i [\hat{y}_i^a (\hat{R} + \hat{p})_x, \alpha_i^a]^T.$$
Choosing the gain $\| \Gamma_{\text{pe}} \|_F = \text{diag}(\gamma_1 I_{3 \times 3}, \gamma_2 I_{3 \times 3})$, we have

$$\| \Gamma_{\text{fe}} \|_F\| D_l [\phi(y) x] \|_F \leq \| \Gamma_{\text{pe}} \|_F \| (D_l [\phi(y) x])^\top \|_F \leq \| \Gamma_{\text{pe}} \|_F \gamma_y \left( \sum_{i=1}^{\gamma_2} \rho_i \right) \left( \sum_{i=1}^{\gamma_2} k_i \phi_i \right)$$

where the term $\| T_l L_k [\phi(\hat{x}, y)] \|_F$ has been computed in the Appendix. One can employ (43) of Lemma 8.1 given in the Appendix to obtain

$$\| \Gamma_{\text{fe}} \|_F \| D_l [\phi(y) x] \|_F = \| \sum_{i=1}^{\gamma_2} k_i \phi_i \|_{\| T_l L_k [\phi(\hat{x}, y)] \|_F} \leq \| \sum_{i=1}^{\gamma_2} k_i \phi_i \|_{\| T_l L_k [\phi(\hat{x}, y)] \|_F}$$

Using (37) and (39), the observer is summarized as

$$\hat{R} = \hat{R}(\Omega_x - \hat{b}_\omega) + k_\omega \sum_{i=1}^{\gamma_2} k_i (\hat{R} y_i + \hat{\rho} y_i) x R \hat{\rho} \hat{\rho}$$

$$\hat{\rho} = \hat{\rho}(R y_i - \hat{\rho} y_i) x$$

$$\hat{b}_\omega = \gamma_\omega \gamma_\omega \sum_{i=1}^{\gamma_2} k_i (R y_i - \hat{\rho} y_i) x$$

$$\hat{b}_\omega = \gamma_\omega \gamma_\omega \sum_{i=1}^{\gamma_2} k_i (R y_i - \hat{\rho} y_i) x$$

Notice that the resulting observer formulas (40a)-(40d) do not depend on the chosen basis. Omitting the bias estimator, the group estimator (40a) has a similar form as the gradient-like observer proposed in (21) equation (35) since the chosen gain mapping $K_2$ is symmetric positive definite and yields a gradient innovation term.

The pose estimator of (20) has a different form from (40). Here, we derive the observer of (20) by choosing different gain mappings and output maps. Similar to (20) equation (8)), consider the new set of outputs $z_j$, $j = 1, \ldots, n$ given by

$$z_j := \sum_{i=1}^{n-1} a_{ij} (y_{i+1} - y_i), \quad j = 1, \ldots, n - 1$$

$$z_n := -\frac{1}{n} \sum_{i=1}^{n} y_i$$

We assume that $a_{ij} \in \mathbb{R}$ are such that the matrix $A := [a_{ij}] \in \mathbb{R}^{(n-1) \times (n-1)}$ is full rank. This requirement guarantees that no information is lost by applying the linear transformation (41) to the measurements. Substituting $y_i$ from (6) into (41) and defining new reference outputs $\tilde{z}_j := \sum_{i=1}^{n-1} a_{ij} (y_{i+1} - y_i)$, $j = 1, \ldots, n - 1$, $\tilde{z}_n = -\frac{1}{n} \sum_{i=1}^{n} y_i$ yields

$$z_j = g_j(R, \rho, \tilde{z}_j) := R^\top j z_j, \quad j = 1, \ldots, n - 1$$

$$z_n = g_n(R, \rho, \tilde{z}_n) := R^\top n 0 + R^\top p$$

where $g_j, j = 1, \ldots, n$ are right output actions of $G$. Consider the new combined output $z := (z_1, \ldots, z_n)$ and the combined reference output $\tilde{z} := (\tilde{z}_1, \ldots, \tilde{z}_n)$. One can show that the necessary and sufficient condition for $\gamma_1 j \text{stab}_G (z_j) = |I|$ is the existence of at least two non-collinear reference outputs $\tilde{z}_j, \tilde{z}_k$. Assuming that $A = [a_{ij}]$ is invertible, it is straightforward to show that the above mentioned condition on $\tilde{z}$ is equivalent to the condition on $\tilde{z}$ we derived before.

We employ the cost functions $f_j(z_j) := \frac{1}{2} \| z_j - \hat{z}_j \|_2^2$, $k_j > 0$ and we choose the gain mappings $[K_i(\hat{x}, y, \hat{b}_\omega, t)]_{\| T_l L_k [\phi(\hat{x}, y)] \|_F} = \text{diag}(k_1 I_{3 \times 3}, k_1 I_{3 \times 3}) + \text{diag}(0_{3 \times 3}, (R(\hat{\Omega}_x - \hat{b}_\omega))_{\| T_l L_k [\phi(\hat{x}, y)] \|_F})$ and $[\| T_l L_k [\phi(\hat{x}, y)] \|_F] = \text{diag}(y_{I_2 I_3}, y_{I_2 I_3})$. It is easy to verify that this choice of cost functions and gain mappings satisfies the requirements of our method. Notice that $K_i$ is non-symmetric and depends also on $\Omega_x$ and $\hat{b}_\omega$, unlike the previous part. In particular, this implies that the observer innovation is not a gradient innovation. Nevertheless, the symmetric part of $K_i$ is $\text{diag}(k, I_{3 \times 3}, k, I_{3 \times 3})$ which implies that the resulting gain mapping $K_i$ is uniformly positive definite. Following the same procedure as was done to derive (40), we obtain the following observer.

$$\hat{R} = \hat{R}(\Omega_x - \hat{b}_\omega) - k_\omega k_n (R \tilde{z}_j x \tilde{z}_j) \hat{\rho} + k_\omega \sum_{j=1}^{n} k_j (R \tilde{z}_j x \tilde{z}_j)$$

$$\hat{\rho} = \hat{\rho}(R \tilde{z}_j x \tilde{z}_j + \hat{\rho} \tilde{z}_j) \hat{\rho} - k_\omega k_n (R \tilde{z}_j x \tilde{z}_j)$$

$$\hat{b}_\omega = \gamma_\omega k_n (R \tilde{z}_j x \tilde{z}_j + \hat{\rho} \tilde{z}_j) \hat{\rho} + k_\omega \sum_{j=1}^{n} k_j (R \tilde{z}_j x \tilde{z}_j)$$

$$\hat{b}_n = -\gamma_\omega k_n (R \tilde{z}_j x \tilde{z}_j + \hat{\rho} \tilde{z}_j) \hat{\rho}$$

In (20), it is assumed that the origin of inertial frame is located at the geometric center of the landmarks. In this case we have $\tilde{z}_n = 0$ which simplifies the observer (43) to the observer designed in (20). Compared to (20), the observer (43) has the advantage that it is well-defined even if only some of the measurements $y_i$ are unavailable at some period of time. In this case, the reference output $\tilde{z}_n$ can be recalculated using the reference outputs corresponding to the remaining available measurements. Also, we only require $A = [a_{ij}]$ to be full rank but (20) necessarily requires that $a_{ij}$ are chosen such that $[\tilde{z}_1, \ldots, \tilde{z}_n, \tilde{z}_{n+1}, \tilde{z}_{n+1}, \ldots, \tilde{z}_{n+1}] = I_{3 \times 3}$. For practical implementation purpose, discrete time representation of the observers could be obtained using standard structure preserving numerical integration methods (37).

8. Conclusion

We investigate the problem of observer design for invariant systems on finite-dimensional real connected Lie groups where the measurement of system input is corrupted by an unknown constant bias. We show that the corresponding standard error dynamics are non autonomous in general. We propose an observer design methodology that guarantees the uniform local asymptotic (or exponential) convergence of the observer trajectories to the system trajectories. We employ a gain mapping acting on the differential of a cost function to design the innovation term of the group estimator. The bias estimator is then designed using a Lyapunov method. The notion of homogeneous output spaces is generalized to multiple outputs, each of which is modeled via a right action of the Lie group on an output space.

\footnote{Here, the position vector $p$ is expressed in the inertial frame but in (21) the position vector is expressed in the body-fixed frame. One can transform the system of (20) to the form presented here using the change of variable $p \mapsto Rp$.}
A systematic method for constructing invariant cost functions on Lie groups is proposed, yielding implementable innovation terms for the observer. A verifiable condition on the stabilizer of the reference outputs associated with the output spaces ensures the stability of the observer. This condition is consistent with the observability criterion discussed in [11]. Our proposed method omits the limiting reductivity condition imposed in the authors’ previous work [12, 13]. As a case study, pose estimation on the Lie group $SE(3)$ was investigated where our observer design methodology unifies the state-of-the-art pose estimators of [20] and [21] into a single framework that applies to any invariant kinematic system on a Lie group. Extension of the proposed observer design methodology to the (co)tangent bundle of a Lie group could be considered by assigning a Lie group structure to the (co)tangent bundle that is trivial (see e.g. [18]).

APPENDIX

Proof of Lemma 5.2

The right-invariance property of $\phi_i$ implies $\phi_i(\hat{X}, y) = \phi_i \circ R_{\hat{X}}(\hat{Y}, y)$. Differentiating both sides in an arbitrary direction $v \in T_{\hat{X}}G$ and using the chain rule we obtain $D_{\hat{X}}\phi_i(X, y)[v] = D_1\phi_i(\hat{X}, y) \circ T_{\hat{X}}R^{-1} \circ T_{\hat{X}}R[1]$. Since $v$ is arbitrary and by using the duality we have $D_1\phi_i(\hat{X}, y) = T_{\hat{X}}R^{-1}[\phi_i(\hat{X}, y)]$ as shown in [13]. Applying $(T_{\hat{X}}R^{-1})^{-1} = T_{\hat{X}}R$ from the right to both sides of $D_{\hat{X}}\phi_i(X, y) = D_1\phi_i(\hat{X}, y) \circ T_{\hat{X}}R^{-1}$ yields $[19]$. ■

Proof of Proposition 6.7

Part [a]

For any arbitrary $Z \in G$ we have $\phi_1(\hat{X}Z, h(Z, y)) = \sum_{i=1}^{n} f_{i, y}(h(t(\hat{X}Z)^{-1}, h(Z, y))) = \sum_{i=1}^{n} f_{i, y}(h(t(\hat{X}Z)^{-1}, y)) = \phi_1(\hat{X}, y)$ which shows that $\phi_1$ is right-invariant.

Part [b]

Since $f_{i, y}(y)$ is positive definite around $y = \hat{y}$, there exists a neighborhood $N \subset M$ of $\hat{y}$ such that $f_{i, y}(y) \geq 0$ and $f_{i, y}(y) = 0 \Rightarrow y = \hat{y}$ for all $y \in N$. Corresponding to each $N$, define the set $\mathcal{N} := \{E \in G : h(E^{-1}, \hat{y}) \in N\}$ and consider the set $\mathcal{N} := \bigcap_{i=1}^{n} N_i$. It is easy to verify that $\mathcal{N} \subset G$ is a neighborhood of $I$ and we have $\phi_2(E, \hat{y}) = \sum_{i=1}^{n} f_{i, y}(h(E^{-1}, \hat{y})) \geq 0$ for all $E \in \mathcal{N}$. Moreover, for any $E \in \mathcal{N}$, $\phi_2(E, \hat{y}) = \sum_{i=1}^{n} f_{i, y}(h(E^{-1}, \hat{y})) = 0$ yields $f_{i, y}(h(E^{-1}, \hat{y})) = 0$ for all $i = 1, \ldots, n$. This in turn implies that $h(E^{-1}, \hat{y}) = \hat{y}$, $i = 1, \ldots, n$ and hence $E \in \bigcap_{i=1}^{n} \text{stab}_i(\hat{y})$. We assumed $\bigcap_{i=1}^{n} \text{stab}_i(\hat{y}) = \{I\}$ which ensures that $E = I$ and hence $\phi_2(E, \hat{y})$ is positive definite on $\mathcal{N}$.

Part [c]

Define the map $h_i : G \rightarrow M_i$ by $h_i(X, \hat{y}) = h_i(X, \hat{y})$. Differentiating both sides of $\phi_i(E, \hat{y}) = \sum_{i=1}^{n} f_{i, y}(h(E^{-1}, \hat{y}))$ in an arbitrary direction $v \in T_{E}G$ and using the chain rule we have $D_{\hat{X}}\phi_i(E, \hat{y})[v] = \sum_{i=1}^{n} (\frac{E}{T_{E}h_{i}}(h(E^{-1}, \hat{y}))) \circ T_{E}h_{i} \circ T_{I}E^{-1} \circ T_{E}h_{i} \circ T_{E}E^{-1} \circ v$.

Computing $\|D_{\hat{X}}\phi_1(\hat{X}, y)\|_{SE}$ employed in [55]

The standard basis for $\mathbb{R}^3$ is given by $[e] := \{e_1, e_2, e_3\}$. The standard basis for $\mathfrak{so}(3)$ is obtained as $[e_{\times}] := \{e_1 \times e_2, e_2 \times e_3, e_3 \times e_1\}$ and a basis for $\mathfrak{se}(3)$ is represented by $[\hat{e}] := \{(e_1 \times e_0, (e_1, e_0, 0)), (e_2 \times e_0, (e_2, e_0, 0)), (0, x_3, e_1), (0, x_3, e_2), (0, x_3, e_3)\}$. A basis for $T_{(\hat{X}, \hat{Y})}SE(3)$ is obtained by right-translating the basis of $\mathfrak{se}(3)$ as

$[\hat{e}] := \{(e_1 \times \hat{R}, e_1 \times \hat{p}), (e_2 \times \hat{R}, e_2 \times \hat{p}), (e_3 \times \hat{R}, e_3 \times \hat{p}), (0, x_3, e_1), (0, x_3, e_2), (0, x_3, e_3)\}$.

We employ the above basis to obtain

$\|D_{\hat{X}}\phi_1(\hat{X}, y)\|_{SE} = \sum_{i=1}^{n} k_i a_i^2 (e_1 \times \hat{R} a_i + e_2 \times \hat{R} a_i + e_3 \times \hat{R} a_i + e_1 \times \hat{p} a_i + e_2 \times \hat{p} a_i + e_3 \times \hat{p} a_i)$

$= \sum_{i=1}^{n} (\hat{R} a_i + \hat{p} a_i) \times \hat{R} a_i + \hat{p} a_i$.

Lemma 8.1. Suppose that the $R^6$ representation of $u \in \mathfrak{se}(3)$ and $w \in T_{(\hat{X}, \hat{Y})}SE(3)$ with respect to the basis $[\hat{e}]$ and $[\hat{e}]$ are respectively given by $[u]_{SE} = [u_{x_1}, u_{x_2}]$ and $[w]_{SE} = [w_{x_1}, w_{x_2}]$, where $u_{x_1}, u_{x_2}, w_{x_1}, w_{x_2} \in \mathbb{R}^3$. Then $u$ and $w$ can be written as in terms of their $R^6$ representation as follows.

$u = (u_{x_1}, u_{x_2}) \quad (44)$

$w = (w_{x_1}, w_{x_2}) \quad (45)$

Proof:

$w = w_{x_1} e_1 + w_{x_2} e_2 + w_{x_3} e_3 = w_{x_2} e_1 (0, x_3, e_1) + w_{x_3} e_2 (0, x_3, e_2) + w_{x_3} e_3 (0, x_3, e_3)$

$= (w_{x_1} e_1 + w_{x_2} e_2 + w_{x_3} e_3) \hat{R},

\sum_{i=1}^{n} (e_1 \times \hat{R} a_i + e_2 \times \hat{R} a_i + e_3 \times \hat{R} a_i + e_1 \times \hat{p} a_i + e_2 \times \hat{p} a_i + e_3 \times \hat{p} a_i)$

$= (w_{x_1} e_1 + w_{x_2} e_2 + w_{x_3} e_3) \hat{R},$
where we used the standard equation \( a = a^1 e^1 + a^2 e^2 + a^3 e^3 \) once for \( a = w_1 \) and once for \( a = w_2 \) to obtain the last line. This proves (45). Choosing \((\hat{R}, \hat{p}) = (I_{3 \times 3}, 0)\), it is easy to verify that (44) holds too.
