AN ASYMPTOTIC-PRESERVING DISCRETIZATION SCHEME
FOR GAS TRANSPORT IN PIPE NETWORKS

Abstract. We consider the simulation of barotropic flow of gas in long pipes and pipe networks.
Based on a Hamiltonian reformulation of the governing system, a fully discrete approximation
scheme is proposed using mixed finite elements in space and an implicit Euler method in time.
Assuming the existence of a smooth subsonic solution bounded away from vacuum, a full con-
vergence analysis is presented based on relative energy estimates. Particular attention is paid
to establishing error bounds that are uniform in the friction parameter. As a consequence, the
method and results also cover the parabolic problem arising in the asymptotic large friction
limit. The error estimates are derived in detail for a single pipe, but using appropriate coupling
conditions and the particular structure of the problem and its discretization, the main results
directly generalize to pipe networks. Numerical tests are presented for illustration.

Keywords: barotropic flow, port-Hamiltonian systems, mixed finite elements, relative
energy estimates, asymptotic preserving schemes

AMS-classification (2000): 35L65, 65M15, 65M60, 76M10

1. INTRODUCTION

We consider the systematic numerical approximation of gas transport in long pipes and
pipeline networks. The flow of gas on each pipe is described by the barotropic Euler equations
with a source term accounting for friction at the pipe walls. Under standard operating
conditions, the gas flows at moderate velocities and we therefore consider the following rescaled
equations [1] that account for the low Mach or high friction regime:

\[ a \partial_t \rho + \partial_x m = 0, \]
\[ \varepsilon^2 \partial_t m + \partial_x \left( \frac{\varepsilon^2 m^2}{a \rho} + ap(\rho) \right) = -\frac{\gamma}{a \rho} |m|m. \]

Here \( \rho \) is the density of the gas, \( m \) is the mass flux, \( a \) is the constant cross-sectional area of the
pipe, \( \gamma \) is a friction coefficient, \( p = p(\rho) \) is the pressure, and \( \varepsilon \) is a scaling parameter proportional
to the Mach number; see [1] or Appendix A for details.

Together with appropriate boundary conditions and, in the case of networks, with coup-
ling conditions that ensure conservation of mass and energy at pipe junctions [2, 3], the one-
dimensional Euler equations (1)–(2) define a port-Hamiltonian system. The particular problem

tkunkel@mathematik.tu-darmstadt.de, philippi@mathematik.tu-darmstadt.de.
structure becomes apparent by an appropriate reformulation of the equations and a variational characterization of its solutions, which immediately leads to an energy dissipation inequality; see [4, 5] and Section 2 for details. In the weak formulation, the coupling and boundary conditions are incorporated variationally, which allows for a structure-preserving discretization by Galerkin projection. In this paper, we consider the discretization by a mixed finite element scheme in space, using piecewise constant approximations \( \rho_h \) for \( \rho \) and continuous and piecewise linear approximations \( m_h \) for \( m \), combined with an implicit Euler time discretization. This amounts to a standard approximation for related linear wave propagation problems [7, 8]. A closely related scheme has been considered in [2, 6] for isentropic flow in pipe networks; let us also refer to [9, 10] for similar approaches.

The main contribution of the current work is a rigorous convergence analysis for the discretization scheme outlined above. We will establish order optimal error estimates

\[
\| \rho(\tau^n) - \rho_h^n \|_{L^2}^2 + \varepsilon^2 \| m(\tau^n) - m_h^n \|_{L^2}^2 + \sum_{k=1}^n \Delta \tau \| m(\tau^k) - m_h^k \|_{L^2}^2 \leq C(\Delta \tau^2 + h^2)
\]

in the temporal and spatial mesh size, which hold uniformly for all \( 0 \leq \varepsilon \leq \bar{\varepsilon} \). In particular, the proposed method yields a viable discretization scheme with order optimal convergence also for the parabolic limit problem, which results from formally setting \( \varepsilon = 0 \) in the equations. This parabolic model is widely used in the gas network community [1, 11], and studied intensively in the literature, see e.g. [12] or [13] for a full analysis on networks. The parameter-robust error estimate above is proven under the assumptions that the flow is subsonic and bounded away from vacuum and that certain derivatives of the solution are bounded uniformly in \( \varepsilon \). These assumptions are reasonable for gas flows in pipe networks under standard operating conditions. The consideration of shocks or discontinuities, as in [14], is beyond the scope of this work.

Our analysis is based on discrete stability of the proposed scheme, which is established via relative energy estimates and uses similar arguments as in [4], where the asymptotic limit \( \varepsilon \downarrow 0 \) of (1)–(2) was investigated on the continuous level. Relative energy or entropy estimates are a well known tool for the analysis of quasi-linear partial differential equations; see [15] for an overview on its use in parabolic equations and [16] for applications in hyperbolic balance laws. They have also been employed successfully for the numerical analysis of the compressible Navier-Stokes equations [17, 18, 19] and of the Euler equations in the large friction limit [20].

The remainder of this manuscript is organized as follows: In Section 2, we state our basic assumptions and introduce the Hamiltonian reformulation of the barotropic Euler equations as well as its variational formulation. Moreover, we briefly discuss the underlying port-Hamiltonian structure and the corresponding energy dissipation law. The discretization method, some basic properties, and a complete statement of the above error estimates are presented in Section 3 and their detailed proof is given in Section 4. Particular emphasis is payed on explicitly tracking the dependence of all estimates on the parameter \( \varepsilon \). In Section 5, we show that the proposed method and its analysis seamlessly generalize to gas networks, if appropriate coupling conditions are required at pipe junctions. For illustration of our results, some numerical tests are presented in Section 6. Some auxiliary results are summarized in a small appendix.

2. Formulation on a single pipe

In this section, we briefly state our basic assumptions, introduce a weak formulation of the problem, and collect some auxiliary results concerning the energy of the system.
2.1. Problem statement. We start with rewriting the momentum equation into an evolution equation for the rescaled flow velocity $w$. Then, (1)–(2) can be stated as

$$a \partial_\tau \rho + \partial_x m = 0$$
$$\varepsilon^2 \partial_\tau w + \partial_x h = -\gamma |w| w$$

for $0 < x < \ell$, $\tau > 0$, with mass flux $m$ and total specific enthalpy $h$ given by

$$m = a \rho w, \quad h = \frac{1}{2} \varepsilon^2 w^2 + P'(\rho).$$

The potential $P$ here is connected to the pressure $p$ by $p'(\rho) = \rho P''(\rho)$; see Appendix A for a detailed derivation of the equations. Any pair of functions $\rho, w \in C^1([0, \tau_{\text{max}}]; L^2(0, \ell)) \cap C^0([0, \tau_{\text{max}}]; H^1(0, \ell))$ with $\rho > 0$, that satisfies (3)–(5) in a pointwise sense, will be called a classical solution. For such smooth solutions away from vacuum, the two systems (1)–(2) and (3)–(5) are equivalent. We further complement the system (3)–(5) by boundary conditions

$$h(v, \tau) = h_0^v(\tau)$$

at the end points $v \in \{0, \ell\}$ of the pipe and $\tau > 0$, which make sense for classical solutions.

2.2. Main assumptions. For our analysis later on, we assume that

(A1) the pressure potential $P : \mathbb{R}_+ \to \mathbb{R}$ is smooth and strongly convex;
(A2) the constants $\varepsilon, \gamma, a$ satisfy $0 \leq \varepsilon \leq \bar{\varepsilon}$, $0 < \bar{\gamma} \leq \gamma \leq \bar{\gamma}$, and $0 < \bar{a} \leq a \leq \bar{a}$, as well as

$$\rho P''(\rho) \geq 4 \varepsilon^2 |\bar{w}|^2 \quad \forall 2\rho/3 \leq \rho \leq 3\bar{\rho}/2$$

with appropriate positive constants designated by bar symbols;
(A3) there exists a classical solution $(\rho, w)$ such that

$$0 < \rho \leq \rho(t, x) \leq \bar{\rho} \quad \text{and} \quad -\bar{w} \leq w(t, x) \leq \bar{w}$$

for all $0 \leq \tau \leq \tau_{\text{max}}$ and a.a. $0 \leq x \leq \ell$; this is called a subsonic bounded state solution.

In order to obtain quantitative error estimates, we additionally require that

(A4) the solution provided by (A3) is sufficiently smooth, i.e., $\rho$ and $w$ are uniformly bounded in $W^{2,\infty}(0, \tau_{\text{max}}; L^2(0, \ell))$ and $W^{1,\infty}(0, \tau_{\text{max}}; H^1(0, \ell))$ by a constant $\bar{C}$.

Bounds for derivatives of $m$ and $h$ follow from equation (5) and the previous assumptions.

Remark 1. Condition (A2) implies strict convexity of the pressure potential $P(\rho)$, or equivalently, strict monotonicity of $p(\rho)$, which is a natural thermodynamic requirement ensuring hyperbolicity of the barotropic Euler equations. Let us further note that $c(\rho) = \sqrt{p'(\rho)} = \sqrt{\rho P''(\rho)}$ is the speed of sound, and hence assumption (A3) characterizes solutions bounded away from the sonic point and from vacuum. In that case, one can require exactly one boundary condition at every end of the pipe; see e.g. [21].
2.3. Weak form of the problem. The following variational characterization of classical solutions is the starting point for our discretization strategy and the further investigations.

Lemma 2. Let \((\rho, w)\) denote a classical solution of (3)–(6). Then
\[
\langle a\partial_\tau \rho(\tau), q \rangle + \langle \partial_\tau m(\tau), q \rangle = 0 \quad \forall q \in L^2(0, \ell),
\]
\[
\langle \varepsilon^2 \partial_\tau w(\tau), r \rangle - \langle h(\tau), \partial_\tau r \rangle = -h_\theta(\tau)r^{(0)} - \langle \gamma |w(\tau)|w(\tau), r \rangle \quad \forall r \in H^1(0, \ell),
\]
and all \(0 \leq \tau \leq \tau_{\text{max}}\). Here and below, we use \(\langle u, v \rangle := \int_0^\ell a b \, dx\) to denote the standard scalar product of \(L^2(0, \ell)\) and \(h_\theta r^{(0)} := h_\theta^r(\ell) - h_\theta^r(0)\) to abbreviate the boundary terms.

Proof. The above identities follow immediately from (3)–(4) by multiplying with appropriate test functions and integration over the domain \((0, \ell)\). For the second equation, we utilize integration-by-parts for the spatial derivatives and the boundary conditions (6).

2.4. Energy dissipation and convexity. A particular feature of problem (3)–(4) is that the quantities arising in the equations can be understood, respectively, as state variables \((\rho, w)\) and co-state variables \((h, m)\), directly linked via the associated energy functional
\[
\mathcal{H}(\rho, w) := \int_0^\ell a \left( \frac{1}{2} \varepsilon^2 \rho^2 + P(\rho) \right) \, dx.
\]
(11)

More precisely
\[
\delta_\rho \mathcal{H}(\rho, w) = ah, \quad \delta_w \mathcal{H}(\rho, w) = \varepsilon^2 m
\]
(12)
are the variational derivatives of \(\mathcal{H}\), i.e., the partial derivatives of the integrand in (11). We will write \(\mathcal{H}' = (\delta_\rho \mathcal{H}, \delta_w \mathcal{H})\) for the variational derivative of \(\mathcal{H}\) in the sequel. As a direct consequence of these relations, we obtain the following structural property.

Lemma 3. Let \((\rho, w)\) denote a classical solution of (3)–(6). Then
\[
\frac{d}{d\tau} \mathcal{H}(\rho, w) + \mathcal{D}(\rho, w) = -h_\theta m^{(0)}
\]
(13)
with dissipation functional \(\mathcal{D}(\rho, w) := \int_0^\ell a_\gamma \rho |w|^3 \, dx \geq 0\). The system energy thus only changes by dissipation and energy flow across the boundary.

Proof. By formal differentiation, the identities (12) and Lemma 2, we immediately get
\[
\frac{d}{d\tau} \mathcal{H}(\rho, w) = (\delta_\rho \mathcal{H}, \partial_\tau \rho) + (\delta_w \mathcal{H}, \partial_\tau w) = \langle ah, \partial_\tau \rho \rangle + \langle \varepsilon^2 m, \partial_\tau w \rangle
\]
\[
= -\langle \partial_x m, h \rangle + \langle h, \partial_x m \rangle - h_\theta m^{(0)} - \langle \gamma |w|w, m \rangle = -h_\theta m^{(0)} - \int_0^\ell a_\gamma \rho |w|^3 \, dx,
\]
which already proves the required identity.

Remark 4. Let us emphasize that the energy-identity (13) follows immediately from the variational identities (9)–(10) and the constitutive relations (12) connecting the state and co-state variables. The particular form of the weak formulation also reveals the underlying port-Hamiltonian structure, which can be preserved under Galerkin projection; see e.g. [6] for details. This will be the rationale behind our structure-preserving discretization strategy.
For later reference, let us state a further important property of the energy functional. For ease of notation, we abbreviate \( u = (\rho, w) \) and introduce the \( \varepsilon \)-weighted norms
\[
\| u \|_\varepsilon^2 := \| \rho \|^2_{L^2(0, \ell)} + \varepsilon^2 \| w \|^2_{L^2(0, \ell)}, \quad \| u \|_{\varepsilon, \infty} := \| \rho \|_{L^\infty(0, \ell)} + \varepsilon \| w \|_{L^\infty(0, \ell)},
\]
which are well defined for all bounded measurable functions.

**Lemma 5.** Let assumptions (A1)–(A2) hold. Then the energy functional \( \mathcal{H} \) is well-defined, smooth, and uniformly convex on the set
\[
\mathcal{AS} := \{(\rho, w) \in L^\infty(0, \ell)^2 : 2\bar{\rho}/3 \leq \rho \leq 3\bar{\rho}/2, \ -3\bar{w}/2 \leq w \leq 3\bar{w}/2 \}
\]
of admissible states with respect to the weighted norm \( \| \cdot \|_{\varepsilon} \), i.e.,
\[
\mathcal{H}(u) - \mathcal{H}(\tilde{u}) - \langle \mathcal{H}'(\tilde{u}), u - \tilde{u} \rangle \geq \frac{\alpha}{2} \| u - \tilde{u} \|_{\varepsilon}^2
\]
for all \( u, \tilde{u} \in \mathcal{AS} \) and with some constant \( \alpha > 0 \) independent of the parameter \( \varepsilon \).

**Remark 6.** The bounds in the definition of the set \( \mathcal{AS} \) are slightly weaker than those in assumption (A3). Hence, sufficiently good approximations of a subsonic bounded state solution will therefore be admissible in the above sense, which will be used in the following.

**Proof.** We show that the Hessian of the integrand in (11), which is given by
\[
\mathcal{H}''(u) := \begin{pmatrix}
\delta_{\rho \rho} \mathcal{H} & \delta_{\rho w} \mathcal{H} \\
\delta_{w \rho} \mathcal{H} & \delta_{w w} \mathcal{H}
\end{pmatrix} = \begin{pmatrix}
ap''(\rho) & a \varepsilon^2 w \\
a \varepsilon^2 w & a \varepsilon^2 \rho
\end{pmatrix},
\]
is positive definite for any \( u = (\rho, w) \) satisfying the bounds in (15). To do so, we multiply \( \mathcal{H}''(u) \) from left and right by \( z = (x, y) \) and see that
\[
z^\top \mathcal{H}''(u) z = \alpha''(\rho) x^2 + 2a \varepsilon^2 w x y + a \varepsilon^2 \rho y^2
\geq a''(\rho) x^2 + \frac{4}{3} a \varepsilon^2 \frac{\bar{w}^2}{\bar{\rho}} x^2 - \frac{3}{4} a \varepsilon^2 y^2 + a \varepsilon^2 \rho y^2
\geq a(1 - \frac{2}{3}) \alpha''(\rho) x^2 + a(1 - \frac{2}{3}) \varepsilon^2 \rho y^2 \geq \frac{\alpha C_P}{\varepsilon^2} x^2 + \frac{\alpha C_P}{\varepsilon^2} \frac{\bar{w}^2}{\bar{\rho}} y^2,
\]
where we used Young’s inequality as well as (A1)–(A2), which yield \( P''(\rho) \geq C_P \) for some constant \( C_P > 0 \). The estimate (16) then follows with \( \alpha = \min\left\{\frac{2a}{\varepsilon}, \frac{\bar{w}}{\bar{\rho}}\right\} \) by Taylor expansion and integration over the spatial domain. \( \square \)

3. Structure-preserving discretization

For the numerical approximation of the system (3)–(6), we use a combination of a mixed finite-element method in space and the implicit Euler method in time. Let \( x_i = ih, \ 0 \leq i \leq M \) with \( h = \ell/M \) be the grid points and \( T_h = \{T_i : 1 \leq i \leq M\} \) denote the corresponding mesh consisting of elements \( T_i = [x_{i-1}, x_i] \). We denote by
\[
Q_h = P_0(T_h), \quad R_h = P_1(T_h) \cap H^1(0, \ell)
\]
the spaces of piecewise constant and continuous piecewise linear functions over the mesh \( T_h \). We further designate by \( \Pi_h : L^2(0, \ell) \to P_0(T_h) \) and \( I_h : H^1(0, \ell) \to P_1(T_h) \) the \( L^2 \)-orthogonal projection and the piecewise linear interpolation operator, respectively. We next define discrete time steps \( \tau^n = n \Delta \tau, \ n = 0, \ldots, N \), with \( \Delta \tau = \tau_{\text{max}}/N \) fixed for simplicity, and finally denote by \( \hat{d}_\tau u^n = \frac{1}{\Delta \tau} (u^n - u^{n-1}) \) the backwards difference quotient.
3.1. Definition of the discretization scheme. For the numerical approximation of the system (3)–(6) on a single pipe, we consider the following method.

**Problem 7** (Fully discrete scheme). Let \( \rho^0_h = \Pi_h \rho(0) \) and \( m^0_h = I_h m(0) \) be given. Then for all \( 1 \leq n \leq N, \) find \( \rho^n_h \in Q_h, \) \( m^n_h \in R_h \) such that

\[
\langle a \frac{d \rho^n_h}{d \tau}, q_h \rangle + \langle \partial_x m^n_h, q_h \rangle = 0 \quad \forall q_h \in Q_h, \tag{18}
\]

\[
\langle \varepsilon^2 \frac{d \rho^n_h}{d \tau}, w^n_h, r_h \rangle - \langle h^0_h, \partial_x r_h \rangle + h^0_g r_h |^0 + \langle \gamma |w^n_h| w^n_h, r_h \rangle = 0 \quad \forall r_h \in R_h, \tag{19}
\]

with \( h^0_g := h_\partial (\tau_n) \), \( w^n_h := \frac{m^n_h}{\rho^n_h} \), and \( h^n_h := \frac{\varepsilon^2 (m^n_h)^2}{2\omega^2 (\rho^n_h)} + P'(\rho^n_h) \) introduced for abbreviation.

3.2. Basic properties of the discretization scheme. The following result summarizes some of the basic properties of the numerical scheme introduced above.

**Lemma 8.** Let \( (\rho^{n-1}_h, m^{n-1}_h) \in Q_h \times R_h \) be given with \( 2\rho/3 < \rho^{n-1}_h < 3\rho/2 \) and \( |w^{n-1}_h| < 3\bar{w}/2 \). Then for any \( 0 < \Delta \tau \leq \Delta \tau_0 \) sufficiently small, the system (18)–(19) has a unique solution \( (\rho^n_h, m^n_h) \in Q_h \times R_h \) in a small neighborhood of \( (\rho^{n-1}_h, m^{n-1}_h) \) such that

\[
2\rho/3 < \rho^n_h < 3\rho/2 \quad \text{and} \quad |w^n_h| < 3\bar{w}/2.
\]

Moreover, any solution \( (\rho^n_h, m^n_h) \) of (18)–(19) with the above bounds further satisfies

\[
\frac{d}{d \tau} \mathcal{H}(\rho^n_h, w^n_h) + \mathcal{D}(\rho^n_h, w^n_h) \leq -h^n_h m^{n\ell}_h 0.
\]

**Proof.** The first claim follows by a homotopy argument: For \( \Delta \tau = 0 \) the existence of a unique solution \( \rho^n_h = \rho^{n-1}_h \) and \( m^n_h = m^{n-1}_h \) is trivial. Since the Jacobian of the nonlinear system is regular for \( \Delta \tau = 0 \) and depends continuously on the time-step, existence and local uniqueness of the solution follows by the implicit function theorem. To show the second claim, we note that \( f(u^n) - f(u^{n-1}) \leq f'(u^n)(u^n - u^{n-1}) \) for any smooth convex function \( f \). From this and Lemma 5, we conclude that

\[
\frac{d}{d \tau} \mathcal{H}(\rho^n_h, w^n_h) \leq \langle d_{\rho} \mathcal{H}(\rho^n_h, w^n_h), d_{\rho} \rho^n_h \rangle + \langle d_w \mathcal{H}(\rho^n_h, w^n_h), d_w w^n_h \rangle = \langle h^n_h, a \frac{d \rho^n_h}{d \tau} \rangle + \langle m^n_h, \varepsilon^2 \frac{d \rho^n_h}{d \tau} \rangle = \langle \Pi_h h^n_h, a \frac{d \rho^n_h}{d \tau} \rangle + \langle m^n_h, \varepsilon^2 \frac{d \rho^n_h}{d \tau} \rangle,
\]

where we used that \( \mathcal{H} \) is convex on the set \( \mathcal{A} \mathcal{S} \) of admissible states, the relations between the discrete state and co-state variables announced in the lemma, as well as the orthogonality of the \( L^2 \)-projection \( \Pi_h \). The second assertion then follows by employing the identities (18)–(19) with test functions \( q_h = \Pi_h h^n_h \) and \( r_h = m^n_h \), respectively. \( \square \)

**Remark 9.** By induction, one can see that for \( \Delta \tau \) sufficiently small, the numerical solution will stay in the set \( \mathcal{A} \mathcal{S} \) of admissible states at least for a couple of time steps, if the initial values satisfy the bounds of the lemma. We may therefore assume that

\[
(A3h) \quad 2\rho/3 < \rho^n_h < 3\rho/2 \quad \text{and} \quad |w^n_h| < 3\bar{w}/2 \quad \text{for all} \quad 0 \leq n \leq N^* \]

up to a certain index \( N^* \) which may be smaller than \( N = \tau_{max}/\Delta \tau \) in general. The index \( N^* \) will however increase when \( \Delta \tau \) and \( h \) decrease. We will later see that \( N^* = N \) if \( \Delta \tau \) and \( h \) are sufficiently small. The second assertion of the lemma shows that the proposed scheme inherits the energy-dissipation property of the continuous problem, i.e., it is a *structure-preserving discretization scheme*. 
3.3. Uniform convergence. We are now in the position to state and prove our main result, which is concerned with the convergence of the discretization scheme above.

Theorem 10. Let (A1)–(A2) hold and \((\rho, w)\) denote a classical solution of (3)–(6) satisfying assumptions (A3)–(A4). Then for any \(0 < \Delta \tau \leq \Delta \tau_0\) sufficiently small and \(h \approx \Delta \tau\), Problem 7 has a unique discrete admissible state solution \((\hat{\rho}_h^m, m_h^n)_{0 \leq n \leq N}\) which further satisfies

\[
\|\rho(\tau^n) - \hat{\rho}_h^n\|^2_{L^2(0,\ell)} + \varepsilon^2 \|m(\tau^n) - m_h^n\|^2_{L^2(0,\ell)} + \sum_{k=1}^n \Delta \tau \|m(\tau^k) - m_h^k\|^3_{L^1(0,\ell)} \leq C(\Delta \tau^2 + h^2).
\]

The constants \(C\) and \(\Delta \tau_0\) in this assertion can be chosen independent of \(\varepsilon\).

The proof of this theorem basically relies on stability of the discrete problem and projection error estimates. Since we face a nonlinear problem, the relative energy technique will be used for the former. A main subtlety here is to carefully track the dependence on the parameter \(\varepsilon\) in all estimates. Details will be discussed in the next section.

Remark 11. From the uniform error estimates, one can deduce that \((\rho_h^n, w_h^n) \in \mathcal{AS}\) for all \(0 \leq n \leq N\) if the meshing parameters are sufficiently small, which is why we call the discrete solution admissible. Further note that the theorem yields uniform convergence estimates for all \(\varepsilon \geq 0\), in particular for \(\varepsilon = 0\), which represents the parabolic limit problem. Hence, the proposed method and our estimates are asymptotic preserving, i.e., for \(\varepsilon = 0\) we obtain a viable discretization scheme for the parabolic limit problem with order optimal convergence rates. It will become clear later on, that the same convergence rates as for \(m\) also hold for the velocity \(w\), which plays an essential role in the stability analysis.

4. Proof of Theorem 10

Before going into the details, let us briefly discuss the main arguments of our analysis. We define projections \(\hat{\rho}_h(\tau) = \Pi_h \rho(\tau)\) and \(\hat{m}_h(\tau) = I_h m(\tau)\) and abbreviate

\[
\hat{\rho}_h^n = \hat{\rho}_h(\tau^n) = \Pi_h \rho(\tau^n) \quad \text{and} \quad \hat{m}_h^n = \hat{m}_h(\tau^n) = I_h m(\tau^n).
\]

By the triangle inequality, we can then decompose the error by

\[
\|\rho(\tau^n) - \hat{\rho}_h^n\|_{L^p(0,\ell)} \leq \|\rho(\tau^n) - \hat{\rho}_h^n\|_{L^p(0,\ell)} + \|\hat{\rho}_h^n - \rho_h^n\|_{L^p(0,\ell)},
\]

\[
\|m(\tau^n) - m_h^n\|_{L^p(0,\ell)} \leq \|m(\tau^n) - m_h^n\|_{L^p(0,\ell)} + \|m_h^n - m_h^n\|_{L^p(0,\ell)},
\]

into projection errors and discrete error components. The former can be estimated by standard arguments, and the main difficulty therefore is to show the respective bounds for the discrete error components. By inserting the projections into the weak formulation of the problem, we can define residuals \(\text{res}_1^n \in Q_h\), \(\text{res}_2^n \in R_h\), given by

\[
\langle a d \hat{\rho}_h^n, q_h \rangle + \langle \partial_x \hat{m}_h^n, q_h \rangle = : \langle \text{res}_1^n, q_h \rangle \quad \forall q_h \in Q_h,
\]

\[
\langle \varepsilon^2 d \tau \hat{w}_h^n, r_h \rangle - \langle \hat{h}_h^n, \partial_x r_h \rangle + \hat{h}_h^n r_h|_{\partial\Omega} + \langle \gamma |\hat{w}_h^n|\hat{w}_h^n, r_h \rangle = : \langle \text{res}_2^n, r_h \rangle \quad \forall r_h \in R_h.
\]

Like before, we use \(\hat{h}_h^n := h_\partial(\tau_h^n)\), \(\hat{w}_h^n := \hat{m}_h^n / \hat{\rho}_h^n\), and \(\hat{h}_h^n := \varepsilon^2 (\hat{m}_h^n)^2 / 2(\hat{\rho}_h^n)^2\) for abbreviation. The projections can thus be understood as solutions of a perturbed discrete problem. To estimate the difference between the discrete solution and the projections, we will utilize relative energy estimates, for which we require \((\hat{\rho}_h^n, w_h^n)\) and \((\hat{\rho}_h^n, \hat{w}_h^n)\) to be admissible in the sense of condition (A3b). Hence, our estimates will first only hold for the time steps \(1 \leq n \leq N^*\), which may
depend on the discretization parameters. As a consequence of the derived bounds, however, one can see that $N^* = N$ as soon as $\Delta \tau$ and $h$ are small enough.

The remainder of this section is organized as follows: In Section 4.1, we state estimates for the projection errors and show that $(\hat{\rho}_n^h, \hat{\bar{w}}_n^h)$ is admissible for all $1 \leq n \leq N$ if $h$ is sufficiently small. In Section 4.2, we introduce and derive some properties of the relative energy. Section 4.3 then contains a technical results concerning time differences of the relative energy and Section 4.4 presents the relative energy estimates for the discrete error components. The proof of Theorem 10 is finally completed in Section 4.5.

4.1. Projection errors. Let us start with summarizing some elementary properties of the projection operators $I_h : C([0, \ell]) \to P_1(\mathcal{T}_h) \cap H^1(0, \ell)$ and $\Pi_h : L^2(0, \ell) \to P_0(\mathcal{T}_h)$. Also recall that $\mathcal{T}_h$ is a uniform mesh with elements $[x_{i-1}, x_i]$ of size $h$ by assumption.

**Lemma 12.** For any $z \in W^{1,p}(0, \ell)$, $1 \leq p \leq \infty$, there holds
\[
\partial_x(I_hz) = \Pi_h(\partial_xz).
\]
Moreover, $\|\Pi_hz\|_{L^\infty(0, \ell)} \leq \|z\|_{L^\infty(0, \ell)}$ and $\|I_hz\|_{L^\infty(0, \ell)} \leq \|z\|_{L^\infty(0, \ell)}$, as well as
\[
\|z - \Pi_hz\|_{L^p(0, \ell)} \leq ch\|\partial_xz\|_{L^p(0, \ell)}
\]
and
\[
\|z - I_hz\|_{L^p(0, \ell)} \leq ch\|\partial_xz\|_{L^p(0, \ell)}
\]
hold with generic constant $c$ independent of $z$, $p$, and $h$. By the local definition of the operators, all assertions also hold locally on every element $[x_{i-1}, x_i]$.

**Proof.** The first assertion is known as commuting diagram property and follows immediately from the fundamental theorem of calculus. The boundedness of the projection $\Pi_h$ follows by noting that $\Pi_hz(\xi_i) = z(\xi_i)$ for some $\xi_i \in [x_{i-1}, x_i]$, and noting that $\Pi_hz$ is constant on every element $[x_{i-1}, x_i]$. That for the interpolation follows with a similar argument. The error estimates can for instance be found in [22, Ch. 4].

As a direct consequence of the above estimates, we obtain the following assertions.

**Lemma 13.** Let (A1)–(A4) hold and $\hat{\rho}_n^h = \Pi_h\rho(\tau^n)$ and $\hat{m}_n^h = I_hm(\tau^n)$. Then
\[
\|\rho(\tau^n) - \hat{\rho}_n^h\|_{L^2(0, \ell)}^2 + \varepsilon^2\|m(\tau^n) - \hat{m}_n^h\|_{L^2(0, \ell)}^2 + \sum_{k=1}^n \Delta \tau\|m(\tau^k) - \hat{m}_n^h\|_{L^2(0, \ell)}^2 \leq Ch^2
\]
with constant $C$ only depending on the bounds in the assumptions. Moreover, $\hat{\rho} \leq \bar{\rho}_n^h \leq \bar{\rho}$ and for any $0 < h \leq h_0$ sufficiently small, we have $-3\bar{\omega}/2 \leq \bar{\omega}_n^h \leq 3\bar{\omega}/2$ where $\bar{\omega}_n^h = \frac{\bar{m}_n^h}{\bar{\rho}_n^h}$.

**Proof.** The error estimate is a direct consequence of the bounds stated in the previous lemma and the regularity of the solution provided by condition (A4). From the properties of the projection operators $\Pi_h$ and $I_h$ and assumption (A3), one can see that $\bar{\rho} \leq \bar{\rho}_n^h \leq \bar{\rho}$, which implies the pointwise bounds for the density, as well as $|m| \leq \bar{\rho}\bar{\omega}$ and $|\hat{m}_n^h| \leq \bar{\rho}\bar{\omega}$. For the velocity $w = \frac{m}{\bar{\rho}}$ and its discrete counterpart $\hat{w}_n = \frac{\bar{m}_n^h}{\bar{\rho}_n^h}$, we may expand
\[
w - \hat{w}_n = \frac{1}{\bar{\rho}}(m - \hat{m}_n^h) + \frac{\bar{m}_n^h}{\bar{\rho}_n^h}(\hat{\rho}_n^h - \rho).
\]
By the uniform bounds for density and mass flux and the approximation error estimates of the previous lemma, we hence conclude that
\[
\|w(\tau^n) - \hat{w}_n^h\|_{L^\infty(0, \ell)} \leq \frac{1}{\bar{\rho}}\|m(\tau^n) - \hat{m}_n^h\|_{L^\infty(0, \ell)} + \frac{\bar{m}_n^h}{\bar{\rho}}\|\rho(\tau^n) - \hat{\rho}_n^h\|_{L^\infty(0, \ell)} \leq Ch,
\]
with some constant $C$ depending only on the bounds in the assumptions. For $h$ small enough, we have $Ch \leq \tilde{w}/3$, which yields the pointwise bounds for $\tilde{w}^n_h$. \hfill \Box

The projections of smooth bounded subsonic state solutions therefore always lie in the set $\mathcal{AS}$ of admissible states, as soon as the mesh size $h$ is sufficiently small. It is further clear from the proof, that one could simply replace $m$ by $w$ in the error estimate to obtain corresponding approximation error bounds for the velocity.

4.2. Relative energy. In order to measure the distance between two (approximate) solutions, we will utilize the concept of relative energy; see [16]. For ease of notation, we abbreviate $u = (\rho, w)$, $\tilde{u} = (\tilde{\rho}, \tilde{w})$ in the following, and recall the definition

\begin{equation}
\mathcal{H}(u \mid \tilde{u}) := \mathcal{H}(u) - \mathcal{H}(\tilde{u}) - \langle \mathcal{H}'(\tilde{u}), u - \tilde{u} \rangle
\end{equation}

of the relative energy. Since $\mathcal{H}$ is strictly convex on the set of admissible states, see Lemma 5, the relative energy $\mathcal{H}(u \mid \tilde{u})$ is positive on the set $\mathcal{AS}$ and defines a distance measure there, which is equivalent to the $\varepsilon$-weighted $L^2$-norm defined in (14).

**Lemma 14.** Let assumptions (A1)–(A2) hold and $u, \tilde{u} \in \mathcal{AS}$ be admissible. Then

\begin{equation}
c_0 \| u - \tilde{u} \|_\varepsilon^2 \leq \mathcal{H}(u \mid \tilde{u}) \leq C_0 \| u - \tilde{u} \|_\varepsilon^2,
\end{equation}

and for all $x \in L^\infty(0, \ell)^2$, $y \in L^2(0, \ell)^2$, one has

\begin{equation}
\langle (\mathcal{H}''(u) - \mathcal{H}''(\tilde{u})) x, y \rangle \leq C \| u - \tilde{u} \|_\varepsilon \| x \|_{\varepsilon, \infty} \| y \|_\varepsilon.
\end{equation}

The constants $c_0, C_0, C$ in these estimates only depend on the bounds in (A1)–(A2).

**Proof.** Define $F(s) := \mathcal{H}(su + (1 - s)\tilde{u})$. Then by Taylor’s theorem and the chain rule

\[ \mathcal{H}(u \mid \tilde{u}) = \mathcal{H}(u) - \mathcal{H}(\tilde{u}) - \langle \mathcal{H}'(\tilde{u}), u - \tilde{u} \rangle = F(1) - F(0) - F'(0) \]

for some $0 < s^* < 1$ and $u^* := s^*u + (1 - s^*)\tilde{u}$ satisfying the bounds of the lemma, since the set $\mathcal{AS}$ is convex. The lower bound then is a direct consequence of $\mathcal{H}$ being strictly convex for bounded subsonic states w.r.t. $\| \cdot \|_\varepsilon$, see Lemma 5. From the formula for the Hessian in (17), one can further see that

\[ \langle \mathcal{H}''(u)(u - \tilde{u}) \rangle \leq C_0 \| u - \tilde{u} \|_\varepsilon^2, \]

where we used that $P$ is smooth, with some upper bound $C_P$ for $P''(\rho)$, as well as Young’s inequality and the bounds in the definition of the set $\mathcal{AS}$; this proves the first assertion. For functions $u, \tilde{u} \in \mathcal{AS}$ and $x \in L^\infty(0, \ell)^2$, $y \in L^2(0, \ell)^2$, one can further see that

\[ \langle (\mathcal{H}''(u) - \mathcal{H}''(\tilde{u})) x, y \rangle = (a(P''(\rho) - P''(\tilde{\rho}))x_1, y_1) + (a\varepsilon^2(w - \tilde{w})x_1, y_1) \\
+ (a\varepsilon^2(w - \tilde{w})x_2, y_1) + (a\varepsilon^2(\rho - \tilde{\rho})x_2, y_2) \]

\[ \leq C\| \rho - \tilde{\rho} \|_{L^2} \| x_1 \|_{L^\infty} \| y_1 \|_{L^2} + a\varepsilon \| x_2 \|_{L^\infty} \| y_1 \|_{L^2} + a\| \rho - \tilde{\rho} \|_{L^2} \| x_2 \|_{L^\infty} \varepsilon \| y_2 \|_{L^2}, \]

where we used that the third derivative of $P$ is bounded on the set $\mathcal{AS}$. The terms in the estimate can further be bounded by $C' \| u - \tilde{u} \|_\varepsilon \| x \|_{\varepsilon, \infty} \| y \|_\varepsilon$ by definition of the norms. \hfill \Box
4.3. Time differences of the relative energy. In order to measure the distance between two discrete functions recursively, we will utilize the following technical result.

Lemma 15. Let (A1)–(A2) hold and assume that \( u^k, \dot{u}^k \in \mathcal{AS} \) for \( k \in \{n-1, n\} \). Then

\[
\dot{d}_r \mathcal{H}(u^n | \dot{u}^n) \leq \langle \mathcal{H}'(u^n) - \mathcal{H}'(\dot{u}^n) - \mathcal{H}''(\dot{u}^n)(u^n - \dot{u}^n), \dot{d}_r \dot{u}^n \rangle
\]

\[
+ \langle \mathcal{H}'(u^n) - \mathcal{H}'(\dot{u}^n), \dot{d}_r u^n - \dot{d}_r \dot{u}^n \rangle
\]

\[
+ C\|\dot{d}_r \dot{u}^n\|_{\varepsilon, \infty}(\mathcal{H}(u^n | \dot{u}^n) + \mathcal{H}(u^{n-1} | \dot{u}^{n-1})) + C'\|\dot{d}_r \dot{u}^n\|_{\varepsilon, \infty}\|\dot{u}^n - \dot{u}^{n-1}\|_\varepsilon^2
\]

with constants \( C, C' \) independent of \( \varepsilon \) and \( \Delta \tau \) as well as the functions \( u^k \) and \( \dot{u}^k \).

Proof. Using Taylor’s theorem and rearranging the terms, we observe that

\[
\dot{d}_r \mathcal{H}(u^n | \dot{u}^n) = \frac{1}{\Delta \tau}(\mathcal{H}(u^n) - \mathcal{H}(u^{n-1}) - \mathcal{H}(\dot{u}^n) + \mathcal{H}(\dot{u}^{n-1}))
\]

\[
= \langle \mathcal{H}'(u^n), \dot{d}_r u^n \rangle - \frac{1}{\Delta \tau} \langle \mathcal{H}''(u^n) \dot{d}_r u^n, \dot{d}_r u^n \rangle - \langle \mathcal{H}'(\dot{u}^n), \dot{d}_r \dot{u}^n \rangle + \frac{1}{\Delta \tau} \langle \mathcal{H}''(\dot{u}^n) \dot{d}_r \dot{u}^n, \dot{d}_r \dot{u}^n \rangle
\]

\[
- \langle \mathcal{H}'(\dot{u}^n), \dot{d}_r u^n - \dot{d}_r \dot{u}^n \rangle - \frac{1}{\Delta \tau} \langle \mathcal{H}'(\dot{u}^n) - \mathcal{H}'(\dot{u}^{n-1}), u^n - \dot{u}^{n-1} \rangle
\]

with intermediate values \( u^*, \dot{u}^* \) lying on the lines between \( u^n \) and \( u^{n-1} \) and \( \dot{u}^*_h \) and \( \dot{u}^{n-1}_h \), respectively; in particular, \( u^*, \dot{u}^* \in \mathcal{AS} \). By suitably adding and subtracting terms of the form \( \langle \mathcal{H}'(u^n), \dot{d}_r \dot{u}^n \rangle, \langle \dot{d}_r \mathcal{H}(\dot{u}^n), u^n - \dot{u}^n \rangle \) and \( \langle \mathcal{H}''(\dot{u}^n)(u^n - \dot{u}^n), \dot{d}_r \dot{u}^n \rangle \), one can further see that

\[
\dot{d}_r \mathcal{H}(u^n | \dot{u}^n) = \langle \mathcal{H}'(u^n) - \mathcal{H}'(\dot{u}^n), \dot{d}_r u^n - \dot{d}_r \dot{u}^n \rangle
\]

\[
+ \langle \mathcal{H}'(u^n) - \mathcal{H}'(\dot{u}^n) - \mathcal{H}''(\dot{u}^n)(u^n - \dot{u}^n), \dot{d}_r \dot{u}^n \rangle
\]

\[
- \langle \mathcal{H}'(u^n), \dot{d}_r u^n \rangle - \frac{1}{\Delta \tau} \langle \mathcal{H}''(\dot{u}^n) \dot{d}_r u^n, \dot{d}_r \dot{u}^n \rangle + \Delta \tau \langle \dot{d}_r \mathcal{H}(\dot{u}^n), u^n - \dot{u}^n \rangle + \Delta \tau \langle \mathcal{H}'(\dot{u}^n), \dot{d}_r u^n - \dot{d}_r \dot{u}^n \rangle.
\]

The terms in the first two lines already appear in the final estimate, and by Taylor’s theorem, the last two lines can be transformed into

\[
(* ) = -\frac{\Delta \tau}{2} \langle \mathcal{H}'(u^n) \dot{d}_r u^n, \dot{d}_r u^n \rangle + \frac{\Delta \tau}{2} \langle \mathcal{H}'(\dot{u}^n) \dot{d}_r \dot{u}^n, \dot{d}_r \dot{u}^n \rangle
\]

\[
- \langle \mathcal{H}'(\dot{u}^n) - \mathcal{H}'(\dot{u}^{n-1}), \dot{d}_r u^n \rangle + \Delta \tau \langle \dot{d}_r \mathcal{H}(\dot{u}^n), u^n - \dot{u}^n \rangle + \Delta \tau \langle \mathcal{H}'(\dot{u}^n), \dot{d}_r u^n - \dot{d}_r \dot{u}^n \rangle
\]

with intermediate values \( \dot{u}^{**}, \dot{u}^* \in \mathcal{AS} \). After rearranging the terms and expanding by \( \Delta \tau \langle \mathcal{H}'(u^n) \dot{d}_r u^n, \dot{d}_r u^n \rangle \) and \( \frac{\Delta \tau}{2} \langle \mathcal{H}'(u^n) \dot{d}_r u^n, \dot{d}_r u^n \rangle \), we obtain

\[
(* ) = -\frac{\Delta \tau}{2} \langle \mathcal{H}'(u^n) \dot{d}_r u^n, \dot{d}_r u^n \rangle + \Delta \tau \langle \mathcal{H}'(u^n) \dot{d}_r u^n, \dot{d}_r u^n \rangle - \frac{\Delta \tau}{2} \langle \mathcal{H}'(u^n) \dot{d}_r u^n, \dot{d}_r u^n \rangle
\]

\[
+ \Delta \tau \langle \mathcal{H}'(\dot{u}^n) - \mathcal{H}'(\dot{u}^{n-1}), \dot{d}_r u^n \rangle + \frac{\Delta \tau}{2} \langle \mathcal{H}'(\dot{u}^n) - \mathcal{H}'(\dot{u}^{n-1}), \dot{d}_r u^n \rangle
\]

\[
+ \frac{\Delta \tau}{2} \langle \mathcal{H}'(\dot{u}^n) - \mathcal{H}'(\dot{u}^{n-1}), \dot{d}_r u^n \rangle - \langle \mathcal{H}'(\dot{u}^n) - \mathcal{H}'(\dot{u}^{n-1}), \dot{d}_r u^n \rangle,
\]

Since \( \mathcal{H} \) is convex on the set \( \mathcal{AS} \), the first line is non-positive, i.e.,

\[
-\frac{\Delta \tau}{2} \langle \mathcal{H}'(u^n) \dot{d}_r u^n, \dot{d}_r u^n \rangle \leq 0.
\]

Inequality (26) then further allows us to estimate the remaining four terms such that

\[
(* ) \leq C(\|\dot{d}_r \dot{u}^n\|_{\varepsilon, \infty} \|u^n - \dot{u}^{**}\|_{\varepsilon} \|u^n - u^{n-1}\|_{\varepsilon} + \|\dot{d}_r \dot{u}^n\|_{\varepsilon, \infty} \|u^n - \dot{u}^{**}\|_{\varepsilon} \|\dot{u}^n - \dot{u}^{n-1}\|_{\varepsilon})
\]

\[
+ \|\dot{d}_r \dot{u}^n\|_{\varepsilon, \infty} \|u^n - \dot{u}^{**}\|_{\varepsilon} \|u^n - \dot{u}^{n-1}\|_{\varepsilon} + \|\dot{d}_r \dot{u}^n\|_{\varepsilon, \infty} \|u^n - \dot{u}^{**}\|_{\varepsilon} \|u^n - \dot{u}^{n-1}\|_{\varepsilon})
\]
By elementary manipulations, one can see that

\[
\|u^n - u^{n-1}\| \leq \|u^n - \tilde{u}\| + \|u^n - \tilde{u} - u^{n-1}\| + \|u^{n-1} - \tilde{u}\|,
\]

\[
\|u^* - \tilde{u}^*\| \leq \|u^n - \tilde{u}\| + \|\tilde{u} - u^{n-1}\| + \|u^{n-1} - \tilde{u}\|,
\]

\[
\|\tilde{u}^* - \tilde{u}^*\| \leq \|\tilde{u} - u^{n-1}\|, \quad \|\tilde{u} - u^{n-1}\| \leq \|u^n - \tilde{u} - u^{n-1}\|,
\]

which together with Lemma 14 and the previous calculations yields the assertion.

Remark 16. On the continuous level, the time derivative of the relative energy is given by

\[
\frac{d}{d\tau}\mathcal{H}(u, \tilde{u}) = \langle \mathcal{H}'(u) - \mathcal{H}'(\tilde{u}) - \mathcal{H}''(\tilde{u})(u - \tilde{u}), \partial_{\tau} u \rangle.
\]

The terms in the last line of the estimate in Lemma 15 hence are perturbations that are caused by the time discretization. Further note that the result is only based on smoothness and convexity of the energy functional and thus independent of the particular problem.

4.4. Relative energy estimates. We now turn our attention to the discrete error. By carefully estimating the terms in the right hand side of (27), we show the following result.

Lemma 17. Let (A1)–(A4) hold and \(0 < h \leq h_0\), \(0 < \Delta \tau \leq \Delta \tau_0\) be sufficiently small, such that assumption (A3b) is valid for all \(n \leq N^*\). Then

\[
\tilde{d}_\tau\mathcal{H}(u^n_h | \tilde{u}^n_h) \leq C\mathcal{H}(u^n_h | \tilde{u}^n_h) + C'\mathcal{H}(a_{n-1}^h | \tilde{u}^n_h) + \frac{1}{C} (h - \tilde{h}_n) (\rho - \tilde{\rho}_n)^2\tau_n\tau_{n-1}
\]

\[
+ C'' (\Delta \tau^2 + h^2) - \frac{1}{2} D(u^n_h | \tilde{u}^n_h)
\]

holds for all \(n \leq N^*\) with relative dissipation functional defined by

\[
D(u^n_h | \tilde{u}^n_h) := \int_0^1 \frac{1}{2} a\tilde{\rho}_k^2 w^n_h - \tilde{w}^n_h || |w^n_h| + |\tilde{w}^n_h| || dx \geq \frac{1}{2} a\tilde{\rho}^2 \|w^n_h - \tilde{w}^n_h\|^2_{L^2(0, \ell)} \geq 0.
\]

The constants \(h_0, \Delta \tau_0, C, C'\) and \(C''\) depend only on the bounds in the assumptions.

A discrete Gronwall estimate and Lemma 14 then already yield the following estimate for the discrete error components for time steps \(n \leq N^*\), i.e,

\[
\|\tilde{\rho}_k^2 - \rho_k^2\|^2_{L^2(0, \ell)} + \epsilon^2 \|w^n_h - \tilde{w}^n_h\|^2_{L^2(0, \ell)} + \sum_{k=1}^n \Delta \tau \|\tilde{w}_k^n - w_k^n\|^2_{L^2(0, \ell)} \leq C(\Delta \tau^2 + h^2).
\]

Using that \(\tilde{m}_k^n = a\tilde{\rho}_k^2 \tilde{w}_k^n\) and \(m_k^n = a\rho_k^2 w_k^n\) by definition, one can show the same bounds with \(w\) replaced by \(m\), which already leads to the estimate of Theorem 10.

Proof of Lemma 17. Inequality (29) follows directly from (27) by appropriately estimating the terms in the three lines of the right hand side of the latter. For the remainder of this section, we assume (A1)–(A4) to be true.

Step 1. By the properties of the projections and assumption (A4), we can bound

\[
\|\tilde{d}_\tau \tilde{u}^n_h\|_{L^\infty(\tau_{n-1}, \tau_n; \|\cdot\|_{L^\infty})} \leq \tilde{C},
\]

and by Taylor estimates and similar arguments, we further see that

\[
\|\tilde{u}^n_h - \tilde{u}^n_{h-1}\|_{L^\infty(\tau_{n-1}, \tau_n; \|\cdot\|_{L^\infty})} \leq C\Delta \tau^2 \|\tilde{d}_\tau \tilde{u}^n_h\|_{L^\infty(\tau_{n-1}, \tau_n; \|\cdot\|_{L^\infty})} \leq C' \Delta \tau^2 \|\tilde{d}_\tau \tilde{u}^n_h\|_{L^\infty(\tau_{n-1}, \tau_n; \|\cdot\|_{L^\infty})} \leq C''\Delta \tau^2.
\]

This already allows to estimate the two terms in the third line of (27) accordingly.
Step 2. From the formulas for the derivatives of the energy functional, we see that
\[
\mathcal{H}'(u^n_h) - \mathcal{H}'(\hat{u}^n_h) - \mathcal{H}''(\hat{u}^n_h)(u^n_h - \hat{u}^n_h) = \left( aP'(\rho^n_h|\rho^n_h) + \frac{a^2}{2}(\rho^n_h - \hat{\rho}^n_h)(w^n_h - \hat{w}^n_h)^2 \right).
\]
By Taylor expansion and assumption (A1), we can further estimate
\[
|P'(\rho^n_h|\rho^n_h)| = |P''(\rho^n_h)|(|\rho^n_h - \hat{\rho}^n_h|^2 \leq C |\rho^n_h - \hat{\rho}^n_h|^2
\]
with intermediate value \(\rho^n_h \in [\rho, \hat{\rho}]\). Using assumptions (A1)–(A3) as well as Hölder and Young inequalities, we further deduce that
\[
\langle \mathcal{H}'(u^n_h) - \mathcal{H}'(\hat{u}^n_h) - \mathcal{H}''(\hat{u}^n_h)(u^n_h - \hat{u}^n_h), \bar{\tau} \rangle_{\epsilon, \infty} \leq C' \|\bar{\tau}\|_{\epsilon, \infty} \|u^n_h - \hat{u}^n_h\|^2 \leq C'' \mathcal{H}(u^n_h | \hat{u}^n_h).
\]
Here we employed that \(\|\bar{\tau}\|_{\epsilon, \infty}\) is bounded, see Step 1, as well as Lemma 14. This already yields the bound for the second term in the right hand side of (27).

Step 3. Bounding the second term on the right hand side of (27) turns out to be the most difficult task. By definition of the co-state variables, we see that
\[
\langle \bar{d}_{r} u^n_h - \bar{d}_{r} \hat{u}^n_h, \mathcal{H}'(u^n_h) - \mathcal{H}'(\hat{u}^n_h) \rangle = \langle \bar{d}_{r} \rho^n_h - \bar{d}_{r} \hat{\rho}^n_h, a\ell_h^n \rangle + \langle \bar{d}_{r} w^n_h - \bar{d}_{r} \hat{w}^n_h, \varepsilon^2 m^n_h - \varepsilon^2 \hat{m}^n_h \rangle = (*).
\]
Since \((\rho^n_h, m^n_h)\) solves (18)–(19) and \((\hat{\rho}^n_h, \hat{m}^n_h)\) can be understood as solution of the perturbed system (22)–(23), the above expression equals
\[
(*) = -\langle \partial_x m^n_h - \partial_x \hat{m}^n_h, h^n_h - \hat{h}^n_h \rangle - \langle \text{res}_1^n, h^n_h - \hat{h}^n_h \rangle + \langle h^n_h - \hat{h}^n_h, \partial_x m^n_h - \partial_x \hat{m}^n_h \rangle
\]
\[
- \langle \gamma |w^n_h| w^n_h - \gamma |\hat{w}^n_h| \hat{w}^n_h, m^n_h - \hat{m}^n_h \rangle - \langle h^n_h - \hat{h}^n_h, (m^n_h - \hat{m}^n_h)(\delta_0 - \langle \text{res}_2^n, m^n_h - \hat{m}^n_h \rangle)
\]
\[
- \langle \gamma |w^n_h| w^n_h - \gamma |\hat{w}^n_h| \hat{w}^n_h, m^n_h - \hat{m}^n_h \rangle - \langle \text{res}_1^n, h^n_h - \hat{h}^n_h \rangle - \langle \text{res}_2^n, m^n_h - \hat{m}^n_h \rangle. \tag{32}
\]
By definition of \(\text{res}_1^n\) in (22) we have \(\text{res}_1^n = a\bar{d}_{r} \hat{\rho}^n_h + \partial_x \hat{m}^n_h\) which can be tested with any \(L^2\)-function. The following three lemmas provide the required estimates for the three terms in (32).

In the remainder of this section we require assumptions (A1)–(A4) as well as condition (A3h) to hold and \(n \leq N^*\).

Lemma 18. The first term in (32) can be estimated by
\[
-\langle \gamma |w^n_h| w^n_h - \gamma |\hat{w}^n_h| \hat{w}^n_h, m^n_h - \hat{m}^n_h \rangle \leq -D(u^n_h | \hat{u}^n_h) + C\mathcal{H}(u^n_h | \hat{u}^n_h).
\]
Proof. We refer to [4, Lemma 10] for a detailed proof of this technical result. \qed

Lemma 19. The second term in (32) can be estimated by
\[
-\langle \text{res}_1^n, h^n_h - \hat{h}^n_h \rangle \leq C\Delta^2 + C'\mathcal{H}(u^n_h | \hat{u}^n_h)
\]
with constants \(C, C'\) that only depend on the bounds in the assumptions.
Proof. Due to the definition of \(\text{res}_1^n\) in (22) it holds that \(\text{res}_1^n = a\bar{d}_{r} \hat{\rho}^n_h + \partial_x \hat{m}^n_h\). This identity can be tested with any \(L^2\)-function. We deduce
\[
-\langle \text{res}_1^n, h^n_h - \hat{h}^n_h \rangle = -\langle a\bar{d}_{r} \hat{\rho}^n_h, h^n_h - \hat{h}^n_h \rangle - \langle \partial_x \hat{m}^n_h, h^n_h - \hat{h}^n_h \rangle
\]
\[
= -\langle a\bar{d}_{r} \hat{\rho}^n_h - a\partial_x \hat{\rho}^n_h, h^n_h - \hat{h}^n_h \rangle - \langle a\partial_x \hat{\rho}^n_h, h^n_h - \hat{h}^n_h \rangle + \langle \partial_x \hat{m}^n_h, h^n_h - \hat{h}^n_h \rangle.
\]
The last two terms vanish due to the fact that \( \hat{\rho}_n \), \( \partial_r \hat{m}_n \) are piecewise constant in space, which implies together with the definition of the projection \( \Pi_h \) and \( J_h \) and (9) that
\[
\langle a \partial_r \hat{\rho}_n, q \rangle + \langle \partial_x \hat{m}_n, q \rangle = 0 \quad \forall q \in L^2(0, \ell).
\]
The first term can be estimated by Young’s inequality, i.e.,
\[
-(a \partial_r \hat{\rho}_n - a \partial_r \hat{\rho}_h, h_n - \hat{h}_n) \leq \frac{\Delta^2}{2} \| \partial_r \hat{\rho}_h \|_{L^\infty(r^{n-1}, r^n; L^2(0, \ell))}^2 + \frac{1}{2} \| h_n - \hat{h}_n \|_{L^2}^2.
\]
For the first term we deduce
\[
\| \partial_r \hat{\rho}_n - \partial_r \hat{\rho}_h \|_{L^2}^2 \leq \Delta^2 \| \partial_r \hat{\rho}_h \|_{L^\infty(r^{n-1}, r^n; L^2(0, \ell))}^2
\leq \Delta^2 \| \partial_r \rho \|_{L^\infty(r^{n-1}, r^n; L^2(0, \ell))}^2 \leq C \Delta^2,
\]
where the second estimate holds true due to the construction of the projection and the third due to (A4). In order to estimate the second term we use the bounds in (A2)–(A3) as well as the fact that the pressure potential \( P \) is smooth by (A1). It then holds that
\[
|h_n - \hat{h}_n| = |\frac{\Delta^2}{2}(|w_n^2| - |\hat{w}_n^2|)| + P'(\rho_n^h) - P'(\hat{\rho}_n^h) \leq \hat{\varepsilon} \varepsilon |w_n^2| - \hat{\varepsilon} \hat{w}_n^2| + C^n |\rho_n^h - \hat{\rho}_n^h|.
\]
By Lemma 14 we conclude that \( \| h_n - \hat{h}_n \|_{L^2}^2 \) can be estimated by \( \cal{C}'(u_h^+ | \hat{u}_n^h) \).

**Lemma 20.** The third term in (32) can be estimated by
\[
-\langle \text{res}_3, m_n^h - \hat{m}_n^h \rangle \leq C(\Delta^2 + \hat{h}^2) + C\cal{C}'(u_h^+ | \hat{u}_n^h) + C\cal{C}'(u_h^{-1} | \hat{u}_n^{-1})
\]
\[
+ \frac{1}{\Delta^2} (h - \hat{h}_n, \rho_n - \hat{\rho}_n)_{T_n^{-1}} + \frac{\hat{\varepsilon}}{2} \cal{D}(u_h^+ | \hat{u}_n^h)
\]
with constants \( C, \cal{C}' \) and \( C' \) only depending on the bounds in the assumptions.

**Proof.** By consistency of the discrete problem, the exact solution \((\rho, m)\) of (9)–(10) satisfies
\[
\langle \varepsilon^2 \partial_r w_n, r \rangle - \langle h_n, \partial_r r \rangle + h_n^2 r |_0^\ell + \langle \gamma |w_n|^2 |w_n^n, r \rangle = 0
\]
for all \( r \in H^1(0, \ell) \), where we abbreviate \( w^n = w(t^n), m^n = m(t^n), h^n = h(t^n) \). Adding this to \(-\langle \text{res}_3, m_n^h - \hat{m}_n^h \rangle\) with test function \( r = m_n^n - \hat{m}_n^n \) leads to
\[
-\langle \text{res}_3, m_n^h - \hat{m}_n^h \rangle = \langle \varepsilon^2 \partial_r w_n^h - \varepsilon^2 \partial_r \hat{w}_n^h, m_n^h - \hat{m}_n^h \rangle - \langle h_n - \hat{h}_n, \partial_r m_n^h - \partial_r \hat{m}_n^h \rangle
\]
\[
+ (\gamma |w_n^n|^2 |w_n^n, m_n^h - \hat{m}_n^h) = (i) + (ii) + (iii).
\]

Here we abbreviate \( u^n = u(t^n) \) for continuous functions of time. In the following we consider the terms \( (i) – (iii) \) separately, and use the projection error estimates from Lemma 12 in order to get convergence rates. Using Young’s inequality we can estimate
\[
(i) = \langle \varepsilon^2 \partial_r w_n^h - \varepsilon^2 \partial_r \hat{w}_n^h, m_n^h - \hat{m}_n^h \rangle \leq \frac{\varepsilon^2}{2} \langle \partial_r w_n^h - \partial_r \hat{w}_n^h \rangle_{L^2}^2 + \frac{\varepsilon^2}{2} \| m_n^h - \hat{m}_n^h \|_{L^2}^2.
\]
By Lemma 14 the second term can be estimated by the relative energy, more precisely
\[
\frac{\varepsilon^2}{2} \| m_n^h - \hat{m}_n^h \|_{L^2}^2 \leq \frac{\varepsilon^2}{2} \| \hat{\rho}_n^h \|_{L^\infty}^2 \| w_n^h - \hat{w}_n^h \|_{L^2}^2 + \varepsilon^2 \| w_n^h \|_{L^\infty}^2 \| \rho_n^h - \hat{\rho}_n^h \|_{L^2}^2 \leq \cal{C} \cal{H}(u_h^+ | \hat{u}_n^h),
\]
with constant \( C \) only depending on the bounds in the assumptions. The first term can be estimated by the triangle inequality, i.e.,
\[
\frac{\varepsilon^2}{2} \| \partial_r w_n^h - \partial_r \hat{w}_n^h \|_{L^2}^2 \leq \varepsilon^2 \| \partial_r w_n^h - \partial_r \hat{w}_n^h \|_{L^2}^2 + \varepsilon^2 \| \partial_r \hat{w}_n^h - \partial_r \hat{w}_n^h \|_{L^2}^2.
\]
We now consider both terms separately: For the first one we deduce
\[
\varepsilon \| \partial_t w^n - \partial_x \hat{w}_h^n \|_{L^2} \leq \varepsilon \| \partial_t \frac{m^n}{\alpha_p} - \partial_x \hat{m}_h^n \|_{L^2} + \varepsilon \| \partial_t \frac{m^n}{\alpha_p} - \partial_x \hat{m}_h^n \|_{L^2} \\
\leq \frac{\varepsilon}{\alpha_p} \| \partial_t m^n - \partial_x \hat{m}_h^n \|_{L^2} + \frac{\varepsilon}{\alpha_p} \| \partial_t m^n \|_{L^\infty} \| \rho^n - \hat{\rho}_h^n \|_{L^2} + \frac{\varepsilon \beta^2}{\alpha_p} \| \partial_t \rho^n - \partial_x \hat{\rho}_h^n \|_{L^2} \\
+ \| \partial_t \rho^n \|_{L^\infty} \left( \frac{\varepsilon}{\alpha_p} \right) m^n \| - \hat{m}_h^n \|_{L^2} + \frac{2 \varepsilon \beta^2}{\alpha_p} \| \rho^n - \hat{\rho}_h^n \|_{L^2} \leq C h
\]
where we used Lemma 12, the bounds of Lemma 13, and assumptions (A3)–(A4). The second term can be bounded by
\[
\varepsilon \| \partial_t \hat{w}_h^n - \hat{d}_x \hat{w}_h^n \|_{L^2} \leq C \Delta \tau \| \varepsilon \partial_{t\tau} \hat{w} \|_{L^\infty(0,\tau_{\max};L^2(0,\ell))},
\]
and \( \| \partial_{t\tau} \hat{w} \|_{L^\infty(0,\tau_{\max};L^2(0,\ell))} \) can further be estimated by bounds on \( \rho \) and \( m \) in (A3)–(A4). In summary, we thus obtain the following estimate
\[
(i) \leq C(h^2 + \Delta \tau^2) + C' \mathcal{H}(u_h^n | \hat{u}_h^n)
\]
with constants \( C, C' \) only depending on the bounds in the assumptions.

Using again that (18) and (22) can be tested with any \( L^2 \)-function, we can rewrite
\[
(ii) = -\langle h^n - \hat{h}_h^n, \partial_x m^n_h - \partial_x \hat{m}_h^n \rangle = a \langle h^n - \hat{h}_h^n, \hat{d}_x \hat{\rho}_h^n - \partial_x \hat{\rho}_h^n \rangle + \langle h^n - \hat{h}_h^n, \text{res}_h^n \rangle = (a) + (b).
\]
Similar to the proof of Lemma 19, we can further bound the second term by
\[
(b) = (h^n - \hat{h}_h^n, \text{res}_h^n) \leq \frac{1}{2} \| h^n - \hat{h}_h^n \|_{L^2}^2 + \frac{a^2}{2} \| \hat{d}_x \hat{\rho}_h^n - \partial_x \hat{\rho}_h^n \|_{L^2}^2 \leq C(\Delta \tau^2 + h^2),
\]
where we used that
\[
h^n - \hat{h}_h^n \leq \frac{3}{2} \hat{\rho} w^n - \hat{w}_h^n | + C \| \rho^n - \hat{\rho}_h^n \| \leq \frac{3 \hat{\rho} \hat{w}}{2 \alpha_p} \| m^n - \hat{m}_h^n \| + \left( \frac{3 \hat{\rho} \hat{w}}{2 \alpha_p} + C \right) | \rho^n - \hat{\rho}_h^n | \leq C' h^2
\]
together with the bounds in the assumptions and Lemma 13, as well as Lemma 12. For the first term, we use the following discrete integration-by-parts formula
\[
d_x u^n v^n = -u^{n-1} d_x v^n + \frac{1}{\Delta \tau} u^n v^n - \frac{1}{\Delta \tau} v^{n-1} v^n,
\]
which together with Young's inequality leads to
\[
(a) = \langle h^n - \hat{h}_h^n, \hat{d}_x \hat{\rho}_h^n - \partial_x \hat{\rho}_h^n \rangle = -\langle h^n - \hat{h}_h^n, \hat{d}_x \hat{\rho}_h^n - \partial_x \hat{\rho}_h^n \rangle + \frac{1}{\Delta \tau} \langle h - \hat{h}_h^n, \rho_h - \hat{\rho}_h^n \rangle_{\tau_{n-1}}^\tau_{n-1} \\
\leq \frac{1}{2} \| \hat{d}_x h^n - \hat{d}_x \hat{h}_h^n \|_{L^2}^2 + \frac{1}{4} \| \rho_h^{n-1} - \hat{\rho}_h^n \|_{L^2}^2 + \frac{1}{\Delta \tau} \langle h - \hat{h}_h^n, \rho_h - \hat{\rho}_h^n \rangle_{\tau_{n-1}}^\tau_{n-1}.
\]
The second term can be estimated by \( \mathcal{H}(u_h^n | \hat{u}_h^{n-1}, \hat{u}_h^{n-1}) \) and for the first term we use
\[
\| \hat{d}_x h^n - \hat{d}_x \hat{h}_h^n \|_{L^2} \leq \| \hat{d}_x h^n - \partial_x h^n \|_{L^2} + \| \partial_x h^n - \partial_x \hat{h}_h^n \|_{L^2} + \| \hat{\partial}_x h^n - \hat{d}_x \hat{h}_h^n \|_{L^2}.
\]
We can then further estimate the individual terms by
\[
\| \hat{d}_x h^n - \partial_x h^n \|_{L^2} \leq C \Delta \tau \| \partial_{t\tau} h \|_{L^\infty(\tau_{n-1}, \tau_n;L^2(0,\ell))} \leq C' \Delta \tau,
\]
\[
\| \partial_x h^n - \partial_x \hat{h}_h^n \|_{L^2} \leq C' h,
\]
\[
\| \hat{\partial}_x h^n - \hat{d}_x \hat{h}_h^n \|_{L^2} \leq C \Delta \tau \| \partial_{t\tau} \hat{h}_h^n \|_{L^\infty(\tau_{n-1}, \tau_n;L^2(0,\ell))} \leq C' \Delta \tau,
\]
with constants that only depend on the bounds in the assumptions. For the second inequality in the first and third line, we here used that \( | \partial_{t\tau} h | \) and \( \| \partial_{t\tau} \hat{h}_h^n \| \) can be estimated by the bounds for the time derivatives of \( \rho \) and \( m \) given in (A4). In summary, we thus arrive at
\[
(ii) \leq C(\Delta \tau^2 + h^2) + \frac{1}{\Delta \tau} \langle h - \hat{h}_h^n, \rho_h - \hat{\rho}_h^n \rangle_{\tau_{n-1}}^\tau_{n-1} + C' \mathcal{H}(u_h^{n-1} | \hat{u}_h^{n-1})
\]
with constants \( C, C' \) only depending on the bounds in the assumptions.
The remaining term in the estimate (33) can be split into

\[ \langle \gamma | w^n | w^n - \gamma | \hat{w}_h^n | \hat{w}_h^n, m_h^n - \hat{m}_h^n \rangle = \langle \langle \gamma | w^n | - \gamma | \hat{w}_h^n | \rangle (w^n - \hat{w}_h^n), m_h^n - \hat{m}_h^n \rangle + \langle \langle \gamma | \hat{w}_h^n | (w^n - \hat{w}_h^n), m_h^n - \hat{m}_h^n \rangle + \langle \gamma (| w^n | - | \hat{w}_h^n |) \rangle \hat{w}_h^n, m_h^n - \hat{m}_h^n \rangle = (A) + (B) + (C). \]

By Hölder and Young inequalities, the first term can further be estimated by

\[ (A) = \langle \langle \gamma (| w^n | - | \hat{w}_h^n |) \rangle (w^n - \hat{w}_h^n), m_h^n - \hat{m}_h^n \rangle \]

\[ \leq \gamma \alpha \psi (w^n - \hat{w}_h^n)^2 \| w^n - \hat{w}_h^n \|_{L^3/2} + \frac{3}{2} \gamma \alpha \hat{w} (w^n - \hat{w}_h^n)^2 \| \rho_h - \hat{\rho}_h \|_{L^2} \]

\[ \leq \frac{3}{2} \gamma (\alpha \rho)^{3/2} \delta^{-3/2} \| w^n - \hat{w}_h^n \|_{L^3} + \frac{1}{2} \delta \| w^n - \hat{w}_h^n \|_{L^3} + 2 + C^{*} \mathcal{H}(u^n | \hat{u}^n) \]

for arbitrary \( \delta > 0 \), where we used the projection error bounds of Lemma 12 as well as Lemma 14. Under assumption (A4) the first term in this estimate can be further bounded by \( C(\delta) h^3 \). Choosing \( \delta \) sufficiently small, we can bound the second term by \( \frac{1}{2} \mathcal{D}(u^n | \hat{u}^n) \). For estimation of the remaining terms we can again use the relative dissipation functional as well as the projection error estimate and Lemma 14, which yields

\[ (B) + (C) = \langle \gamma | \hat{w}_h^n | (w^n - \hat{w}_h^n), m_h^n - \hat{m}_h^n \rangle + \langle \gamma (| w^n | - | \hat{w}_h^n |) \rangle \hat{w}_h^n, m_h^n - \hat{m}_h^n \rangle \]

\[ \leq \frac{1}{2} \gamma (\alpha \rho)^{3/2} \delta^{-3/2} \| w^n - \hat{w}_h^n \|_{L^3} + \delta (m_h^n - \hat{m}_h^n) | \hat{w}_h^n |^{1/2} \| \rho_h - \hat{\rho}_h \|_{L^2} \]

\[ \leq C(\delta') h^2 + C(\delta') \int_{0}^{\tau} a \rho_h^n | w^n - \hat{w}_h^n | | \hat{w}_h^n | dx + \frac{1}{2} \delta ^2 \hat{w}^3 \| \rho_h - \hat{\rho}_h \|_{L^3}^2 \]

\[ \leq C h^2 + \frac{1}{2} \mathcal{D}(u^n | \hat{u}^n) + C' \mathcal{H}(u^n | \hat{u}^n) \]

for \( \delta' \) sufficiently small. In summary, the term (iii) in (33) can be bounded by

\[ (iii) = \langle \gamma | w^n | w^n - \gamma | \hat{w}_h^n | \hat{w}_h^n, m_h^n - \hat{m}_h^n \rangle \leq C h^2 + C' \mathcal{H}(u^n | \hat{u}^n) + \frac{1}{4} \mathcal{D}(u^n | \hat{u}^n). \]

Combination of the previous estimates finally yields the assertion of the lemma.

A combination of the bounds in Step 1–3 finally completes the proof of Lemma 17.

4.5. Proof of Theorem 10. We can now complete the proof of our main result. In view of the error splitting (29)–(31) and the bounds for the projection error stated in Lemma 13, it suffices to consider the discrete error in detail. By multiplying (29) with \( \Delta \tau \) and summing over the time steps, we obtain the inequality

\[ \mathcal{H}(u^n | \hat{u}^n) \leq \mathcal{H}(u^n | \hat{u}^n) + \Delta \tau \sum_{k=1}^{n} (C_1 \mathcal{H}(u^k | \hat{u}^k) + C_2 \mathcal{H}(u^{k-1} | \hat{u}^{k-1})) + (h - \hat{h}) (\rho_h - \hat{\rho}_h)^{\tau_n} \]

\[ + \Delta \tau \sum_{k=1}^{n} (C_3 (\Delta \tau^2 + h^3) + \frac{1}{2} \mathcal{D}(u^k | \hat{u}^k)). \]

(34)

Using the fact that \( \rho_h = \rho_h^0 \) together with Young’s inequality, we can estimate

\[ (h - \hat{h})(\rho_h - \hat{\rho}_h)^{\tau_n} \leq \frac{1}{2} \mathcal{C}_0 \| h^n - \hat{h}^n \|_{L^3} + \frac{1}{2} \mathcal{H}(u^n | \hat{u}^n) \leq C_4 h^2 + \frac{1}{2} \mathcal{H}(u^n | \hat{u}^n). \]

The last term is moved to the left hand side of (34), and we apply Lemma B26 with

\[ a^n = \mathcal{H}(u^n | \hat{u}^n), \quad c = 2 \max(C_1, C_2), \quad b^n = (2 \tau_n C_3 + 2 C_4) (\Delta \tau^2 + h^3), \quad d^n = \mathcal{D}(u^n | \hat{u}^n). \]

Noting that \( a^n = \mathcal{H}(u^n | \hat{u}^n) = 0, b^n \geq 0 \) and \( n \Delta \tau \leq \tau_{\max} \), we thus obtain

\[ \mathcal{H}(u^n | \hat{u}^n) + \Delta \tau \sum_{k=1}^{n} \mathcal{D}(u^k | \hat{u}^k) \leq C_5 (\tau_{\max}) (\Delta \tau^2 + h^3) \]
with constant $C_5$ that only depends on the bounds in (A1)–(A4) but not on $\varepsilon$. By the equivalence of the norm and the relative energy stated in Lemma 14, we finally arrive at

$$\|\hat{\rho}_h^n - \rho_h^n\|_{L^2(0, t)}^2 + \varepsilon^2\|w_h^n - \hat{w}_h^n\|_{L^2(0, t)}^2 + \sum_{k=1}^{n} \Delta t \|w_h^k - \hat{w}_h^k\|_{L^1(0, t)}^2 \leq C(\Delta t^2 + h^2). \tag{35}$$

This estimate initially holds for all $n \leq N^*$ given by assumption (A3h). Since the constant $C$ is independent of $h$, $\Delta t$, and $N^*$, we can now show that this assumption automatically holds for $N^* = N$, if $\Delta t_0$ and $h_0$ are chosen sufficiently small and $h \approx \Delta t$.

**Lemma 21.** Let (A1)–(A4) hold. Then one can choose $\Delta t_0$ and $h_0$ such that (A3h) holds for all $n \leq N^* = N$, $0 < h \leq h_0$, $0 < \Delta t \leq \Delta t_0$ with $h \approx \Delta t$ and for all $0 \leq \varepsilon \leq \bar{\varepsilon}$.

**Proof.** By an inverse inequality, we can estimate

$$\|\hat{\rho}_h^n - \rho_h^n\|_{L^\infty} \leq h^{-1}\|\hat{\rho}_h^n - \rho_h^n\|_{L^2} \leq C(h + \Delta t^2).$$

Assuming $\Delta t \approx h$ and adding the corresponding projection error, we thus obtain

$$\|\rho(\tau^n) - \rho_h^n\|_{L^\infty} \leq C\Delta t,$$

which can be made arbitrarily small. Next observe that for $h \approx \Delta t$, we get

$$\|\bar{\partial}_x(\hat{\rho}_h^n - \rho_h^n)\|_{L^2} \leq \frac{1}{\Delta t}((\|\hat{\rho}_h^n - \rho_h^n\|_{L^2} + \|\hat{\rho}_h^{n-1} - \rho_h^{n-1}\|_{L^2}) \leq C. \tag{36}$$

By the triangle inequality and Taylor estimates, we then conclude that

$$\|\partial_x\hat{\rho}_h^n - \hat{\rho}_h^n\|_{L^2} \leq \|\partial_x\hat{\rho}_h^n - \hat{\rho}_h^n\|_{L^2} \leq C',$$

where we used the contraction property for the $L^2$ projection, a Taylor estimate in time, and the previous bound. By the commuting diagram property of the projections, we get

$$\|\partial_x(\hat{m}_h^n - m_h^n)\|_{L^2} = \|\partial_x\hat{\rho}_h^n - \hat{\rho}_h^n\|_{L^2} \leq C'.$$

From the definition of $w_h^n$ and $\hat{w}_h^n$ and the uniform bounds for $\rho_h^n$ and $\hat{\rho}_h^n$, we see that

$$\|w_h^n - \hat{w}_h^n\|_{L^2} \leq C\|\hat{\rho}_h^n - \rho_h^n\|_{L^\infty} + C'|m_h^n - \hat{m}_h^n|_{L^\infty} = (i) + (ii).$$

Using an inverse inequality, we obtain

$$(i) \leq Ch^{-1}\|\hat{\rho}_h^n - \rho_h^n\|_{L^2} \leq C(\Delta t^2/h + h).$$

By the multiplicative interpolation inequality, the second term can be estimated by

$$(ii) \leq C\|\hat{m}_h^n - m_h^n\|_{L^2}^2 + C'|\hat{m}_h^n - m_h^n|_{L^\infty}\|\partial_x(\hat{m}_h^n - m_h^n)\|_{L^2}.$$

By the definition of $m_h^n$ and $\hat{m}_h^n$ and the uniform bounds for $\hat{\rho}_h^n$, $\rho_h^n$ and $\hat{w}_h^n$, $w_h^n$ for $n \leq N^*$, we can further estimate

$$\|\hat{m}_h^n - m_h^n\|_{L^2} \leq C\|\hat{w}_h^n - w_h^n\|_{L^2} + C'|\hat{\rho}_h^n - \rho_h^n|_{L^2} \leq C''\Delta t^{-1/3}(\Delta t^2 + h^2)^{1/3} + C''\Delta t(\Delta t^2 + h^2)^{1/2},$$

where we made use of the estimate (35). For $h \approx \Delta t$ and $\Delta t \leq \Delta t_0$ sufficiently small, both terms (i) and (ii) can be made as small as desired. As a consequence, $w_h^n$ satisfies the same uniform bounds as $\hat{w}_h^n$ up to some small perturbation that can be fully controlled by the choice of the mesh size. By the argument of Lemma 8, the next time step $n = N^* + 1$ will then also satisfy $w_h^n \in AS$, and we can continue applying the argument until $n = N$. \(\square\)
The above estimates provide the desired bounds for the discrete error in \( \rho \) and \( w \), which by Lemma 21 hold for all \( n \leq N^* = N \). Using the relations \( \hat{m}_h^n = a\hat{\rho}_h^n\hat{w}_h^n \) and \( m_h^n = a\rho_h^nw_h^n \) between the discrete mass fluxes and velocities, one can see that
\[
\varepsilon^2 \|\hat{m}_h^n - m_h^n\|_{L^2}^2 \leq 2\varepsilon^2 \|\hat{w}_h^n - w_h^n\|_{L^2}^2 + 9/4\varepsilon^2 \|\hat{\rho}_h^n - \rho_h^n\|_{L^2}^2 \leq C(\Delta\tau^2 + h^2).
\]
In a similar manner, we can bound
\[
\|\hat{w}_h^n - w_h^n\|_{L^3} \leq 3\bar{a}^3(\|\hat{w}_h^n - w_h^n\|_{L^3} + 27/8\bar{a}^3\|\hat{\rho}_h^n - \rho_h^n\|_{L^3}^2).
\]
By Hölder’s inequality and the uniform bounds for \( \hat{\rho}_h^n \) and \( \rho_h^n \), we further obtain
\[
\|\hat{\rho}_h^n - \rho_h^n\|_{L^2}^2 \leq 3/2\bar{a}\|\hat{\rho}_h^n - \rho_h^n\|_{L^2}^2.
\]
Together with the previous bounds, we see that \( \sum_{k=1}^n \Delta\tau \|\hat{m}_h^n - m_h^n\|_{L^2} \leq C(\Delta\tau^2 + h^2) \).
A combination of these estimates for the discrete error and Lemma 13 for the projection error finally yields the assertion of the theorem. \( \square \)

5. Extension to networks

We now extend our considerations to gas transport problems on pipe networks. The model equations (3)-(4) are then assumed to hold for each pipe, whereas additional coupling conditions are required at pipe junctions. A corresponding variational formulation will be derived and a mixed finite element approximation together with an implicit Euler time stepping is proposed for its numerical solution. Since the structure of the problem and its discretization is very similar to (9)-(10) and (18)-(19) on a single pipe, our error analysis almost verbatim carries over to networks.

5.1. Network topology and notation. The network is described by a directed, connected graph with vertices \( v \in \mathcal{V} \) and edges \( e \in \mathcal{E} \). Edges correspond to pipes and are identified by intervals \((0,\ell_e)\) for \( e \in \mathcal{E} \). Moreover, the edges incident to some vertex \( v \) are collected in the set \( \mathcal{E}(v) \). We distinguish between boundary vertices \( \mathcal{V}_0 = \{ v \in \mathcal{V} : |\mathcal{E}(v)| = 1 \} \) and inner vertices \( \mathcal{V}_0 = \mathcal{V} \setminus \mathcal{V}_b \), where \( |\mathcal{E}(v)| \) denotes the cardinality of the set \( \mathcal{E}(v) \). To each edge \( e = (0,\ell_e) = (v_1, v_2) \) we link two numbers \( n^e(v_1) = -1, n^e(v_2) = 1 \) to indicate start and end point, and set \( n^e(v) = 0 \) for all \( v \in \mathcal{V} \setminus \{v_1, v_2\} \).

We further denote by \( L^2(\mathcal{E}) = \{ u : u^e \in L^2(\ell_e) \forall e \in \mathcal{E} \} \) the space of square integrable functions on the network, where \( u^e = u|_e \) is the restriction onto the edge \( e \). The corresponding scalar product and norm are given by
\[
\langle u, v \rangle_{\mathcal{E}} := \sum_{e \in \mathcal{E}} \langle u^e, v^e \rangle_{L^2(e)}, \quad \|u\|^2_{\mathcal{E}} := (u, u)_{\mathcal{E}}.
\]
Similarly, we introduce the space \( H^1_{pw}(\mathcal{E}) = \{ u : u^e \in H^1(\ell_e) \} \) of edge-wise \( H^1 \)-functions that are continuous along edges but can be discontinuous at network junctions. We associate the following scalar product and norm
\[
\langle u, v \rangle_{H^1_{pw}(\mathcal{E})} := \sum_{e \in \mathcal{E}} \langle u^e, v^e \rangle_{H^1(\ell_e)}, \quad \|u\|^2_{H^1_{pw}(\mathcal{E})} := (u, u)_{H^1_{pw}(\mathcal{E})}.
\]
Other functions spaces can be defined in a similar manner.
5.2. **Gas transport in pipe networks.** We assume that the model equations (3)–(4) are satisfied on each pipe \( e \in \mathcal{E} \), i.e.,
\[
\begin{align*}
\alpha^e \partial_\tau \rho^e + \partial_x m^e &= 0, \\
\varepsilon^2 \partial_\tau w^e + \partial_x h^e &= -\gamma^e |w^e| w^e,
\end{align*}
\]
for \( 0 < x < \ell^e \), \( \tau > 0 \) and all \( e \in \mathcal{E} \) with
\[
m^e = \alpha^e \rho^e w^e, \quad h^e = \frac{1}{2} \varepsilon^2 (w^e)^2 + P'(\rho^e).
\]
To guarantee conservation principles at junctions \( v \in \mathcal{V}_0 \), we impose the coupling conditions
\[
\sum_{e \in \mathcal{E}(v)} m^e(v)n^e(v) = 0, \quad v \in \mathcal{V}_0, \quad (39)
\]
\[
h^e(v) = h^v, \quad v \in \mathcal{V}_0, \quad e \in \mathcal{E}(v). \quad (40)
\]
For a convenient formulation, the enthalpy \( h^v \) has been introduced as an additional degree of freedom for each \( v \in \mathcal{V}_0 \). As shown in [2, 3], these coupling conditions yield conservation of mass and energy and thus a thermodynamically consistent behavior at pipe junctions. At the boundary vertices of the network, we again prescribe
\[
h^e(v) = h^\partial, \quad v \in \mathcal{V}_\partial, \quad e \in \mathcal{E}(v). \quad (41)
\]
A classical solution of (37)–(41) then is a pair of functions
\[
\rho, w \in C^1([0, \tau_{\text{max}}]; L^2(\mathcal{E})) \cap C^0([0, \tau_{\text{max}}]; H^1_{\text{pw}}(\mathcal{E}))
\]
that satisfies the above equations in a pointwise sense. In particular, for every point in time, the co-state variable \( m = a \rho w \) lies in the space
\[
H(\text{div}; \mathcal{E}) := \{ u \in H^1_{\text{pw}}(\mathcal{E}) : \sum_{e \in \mathcal{E}} u^e(v)n^e(v) = 0 \ \forall v \in \mathcal{V}_0 \}
\]
of mass fluxes that are conservative across junctions. With a similar reasoning as on a single pipe and the use of the coupling conditions (39)–(40), one can see that any classical solution satisfies, for all \( 0 \leq \tau \leq \tau_{\text{max}} \) of interest, the variational identities
\[
\langle a \partial_\tau \rho, q \rangle_\mathcal{E} + \langle \partial_x m, q \rangle_\mathcal{E} = 0 \quad \forall q \in L^2(\mathcal{E}), \quad (42)
\]
\[
\langle \varepsilon^2 \partial_\tau w, r \rangle_\mathcal{E} - \langle h, \partial_x r \rangle_\mathcal{E} + \langle \gamma |w| w, r \rangle_\mathcal{E} = -\sum_{v \in \mathcal{V}_\partial} h^v r^e(v)n^e(v) \quad \forall r \in H(\text{div}; \mathcal{E}). \quad (43)
\]

**Remark 22.** Let us note that the coupling condition (39) on the mass flux is strongly enforced in the space \( H(\text{div}; \mathcal{E}) \), whereas the continuity condition (40) is included in the variational formulation. More precisely, when applying integration by parts on the second term in equation (38) the boundary contributions at inner vertices vanish, i.e.,
\[
\langle \partial_x h, r \rangle_\mathcal{E} = -\langle h, \partial_x r \rangle_\mathcal{E} + \sum_{v \in \mathcal{V}_\partial} \sum_{e \in \mathcal{E}(v)} h^e(v)r^e(v)n^e(v),
\]
and since \( h \) is assumed to be continuous along junctions and \( r \in H(\text{div}; \mathcal{E}) \) we see that
\[
\sum_{v \in \mathcal{V}_\partial} \sum_{e \in \mathcal{E}(v)} h^e(v)r^e(v)n^e(v) = \sum_{v \in \mathcal{V}_\partial} h^v \sum_{e \in \mathcal{E}(v)} r^e(v)n^e(v) = 0,
\]
and only the contributions at the boundary vertices remain.
The total energy contained in the network is now simply defined by accumulation of the contributions of the individual pipes, i.e.,

$$\mathcal{H}(\rho, w) = \sum_{e \in E} \int_0^\ell e a^E \left( \frac{1}{2} \varepsilon^2 \rho^e (w^e)^2 + P(\rho^e) \right) \, dx.$$  

Similar as on a single pipe, we can again deduce an energy-dissipation law

$$\partial_t \mathcal{H}(\rho, w) + \mathcal{D}(\rho, w) = - \sum_{v \in V_0} h_{v}^m m^v (v) n^v (v)$$

with dissipation functional $\mathcal{D}(\rho, w) = \sum_{e \in E} \int_0^{\ell_e} a^e \varepsilon^e \rho^e |w^e|^3 \geq 0$, which again follows directly from the particular form of the variational formulation. Based on relative energy estimates, the stability of solutions to (37)–(41) with respect to perturbations in the initial conditions and the problem parameters has been analysed in [4]. Here we use a similar reasoning to extend our discretization scheme and error estimates to gas networks.

### 5.3. A Galerkin scheme on networks

We approximate the density $\rho$ by piecewise constant functions over the grid $T_h = \{ [x_{i-1}, x_i] : x_0 = 0, x_{M+1} = \ell, x_i - x_{i-1} = h, e \in E \}$ and set $h = \max h_e$. The mass flux $m$ is approximated by piecewise linear functions over the mesh $T_h$, which are continuous on every pipe $e$ and satisfy the balance condition (39). The spatial approximation spaces are then given by

$$Q_h := P_0(T_h), \quad R_h := P_1(T_h) \cap H(\text{div}; E).$$

By $\Pi_h : L^2(E) \to Q_h$, $I_h : H(\text{div}; E) \to R_h$ we denote the canonical extensions of the locally defined projection and interpolation operators to the network setting. Based on the variational formulation (42)–(43) we then propose the following method.

**Problem 23** (Discretization scheme for gas networks).

Set $\rho_h^0 = \Pi_h \rho (0)$, $m_h^0 = I_h m (0)$, and for $1 \leq n \leq N$ find $\rho_h^n \in Q_h$, $m_h^n \in R_h$ such that

$$\langle ad \rho_h^n, q_h \rangle_E + \langle \partial_t m_h^n, q_h \rangle_E = 0 \quad (44)$$

$$\langle \varepsilon^2 d_t w_h^n, r_h \rangle_E - \langle h_{x_r}^m, \partial_t r_h \rangle_E + \langle \gamma |w_h^n|^2, r_h \rangle_E = - \sum_{v \in V_0} \sum_{e \in E(v)} h_{v}^m m^v (v) n^v (v) \quad (45)$$

for all $q_h \in Q_h$ and $r_h \in R_h$. We again use $w_h^n = \frac{m_h^n}{a \rho_h^n}$ and $h_h^n = \frac{\varepsilon^2 (m_h^n)^2}{2 a^2 (\rho_h^n)^2} + P'(\rho_h^n)$ to abbreviate the discrete velocity and enthalpy variables.

**Remark 24.** With the very same arguments as on a single pipe, one can show that solutions of Problem 23 satisfy the discrete energy inequality

$$\partial_t \mathcal{H}(\rho_h^n, w_h^n) + \mathcal{D}(\rho_h^n, w_h^n) \leq - \sum_{v \in V_0} \sum_{e \in E(v)} h_{v}^m m^v (v) n^v (v)$$

with dissipation functional $\mathcal{D}(\rho, w) = \sum_{e \in E} \int_0^\ell e a^e \varepsilon^e \rho^e |w^e|^3 \geq 0$.

### 5.4. Error analysis

Since the structure of the variational problem is exactly the same as for a single pipe, the analysis of the previous sections carries over verbatim by simply summing over all pipes. As an immediate consequence, we obtain the following result.

**Theorem 25.** Let the assumptions of Theorem 10 hold for the network setting. Then

$$\| \rho (\tau^n) - \rho_h^n \|_{L^2 (E)}^2 + \varepsilon^2 \| m (\tau^n) - m_h^n \|_{L^2 (E)}^2 + \sum_{k=1}^n \Delta \tau \| m (\tau^k) - m_h^k \|_{L^2 (E)}^2 \leq C (\Delta \tau^2 + h^2),$$

with $C$ depending only on the bounds in the assumptions, but independent of $\varepsilon$. 

6. Numerical experiments

For illustration of our theoretical results, we now report about some numerical tests. In the first example, we consider the \( \varepsilon \)-robustness of the convergence estimates for a single pipe, and in the second example, we briefly address the extension to pipe networks.

6.1. Parameter robust convergence. We consider the flow through pipes of different lengths \( L \approx \varepsilon^{-2} \) with the diameter and friction coefficient kept fixed. By the rescaling outlined in Appendix A, we can transform the equations into the system (3)–(4) for a rescaled pipe of length \( \ell = 1 \), with uniform cross section and friction coefficient, but with different scaling parameters \( \varepsilon \). For ease of presentation, we set \( a = 1 \) and \( \gamma = 1 \), and as a pressure law, we choose \( p(\rho) = c^2 \rho \), with speed of sound rescaled to \( c = 1 \). As boundary conditions, we choose \( h_0(\tau) = 0.2 \sin(\pi \tau)^3 + 1 \), \( h_\ell(\tau) = 0.1 \sin(\pi + \pi \tau)^3 + 1 \) over a time horizon of \( \tau_{\max} = 1 \). The initial conditions are determined by solving the stationary problem for the boundary conditions at time \( \tau = 0 \). Let us note that for \( \varepsilon \ll 1 \), we have \( h = \varepsilon^2 w^2 + P'(\rho) \approx P'(\rho) \); hence setting the enthalpy is more or less equivalent to prescribing the density or the pressure, respectively.

In Table 1 we display the errors and convergence rates in density and mass flux for different choices of the scaling parameter \( \varepsilon \). Since the exact solution is unknown, the numerical errors are computed as

\[
\text{err}_h(u) = \max_{n=1,...,N} \| u^n_{h/2} - u^n_h \|_{L^2(0,1)},
\]

where \( u = \rho \) or \( u = m \) and with \( u^n_{h/2} \) denoting the solution on a finer mesh with \( h = h/2 \) and \( \Delta \tau = \Delta \tau/2 \) at the same point \( \tau_n = n \Delta \tau \) in time. As predicted by our theoretical results, we observe linear convergence for both density and mass flux uniform for all parameters \( \varepsilon \) and, in particular, also in the parabolic limit \( \varepsilon = 0 \). Further note that the errors, and actually also the solutions, are very similar for all values of \( \varepsilon \leq 0.01 \), which clearly indicates the asymptotic convergence of solutions with \( \varepsilon \downarrow 0 \), which was proven in [4] for the continuous problem.

6.2. A simple gas network. As a second example, we consider the GasLib-11 example from the GasLib library [23]; see Figure 1 for a sketch of the network topology. This network consists of 8 pipes and 11 vertices, 4 of which are boundary vertices in the sense of the previous section.
The 2 compressor stations and the valve are treated here in by-pass mode, i.e., as additional pipes of length 0. The network thus degenerates to a reduced network, where the vertices $v_2$, $v'_2$, $v''_2$ as well as $v_6$, $v'_6$ are identified by single vertices $v_2$ and $v_6$ with ingoing edges $e_1$, $e_3$ and $e_5$, $e_6$ as well as outgoing edges $e_2$, $e_6$ and $e_7$, $e_8$, respectively. All pipes are assumed to have rescaled length $\ell = 1$ with cross-sectional area $a = 1$ and friction coefficient $\gamma = 1$. The pressure law is again given by $p(\rho) = c^2 \rho$ with rescaled speed of sound $c = 1$. The boundary conditions for the enthalpy are chosen as

$$h^u_\partial(\tau) = 0.2 \sin(\pi \tau)^3 + 1, \quad h^v_\partial(\tau) = 0.3 \sin(\pi \tau)^3 + 1, \quad h^w_\partial(\tau) = h^\gamma_\partial(\tau) = h^\delta_\partial(\tau) = 1$$

over a time horizon of $\tau_{\text{max}} = 1$, and the initial condition is again given by the stationary state corresponding to the boundary conditions at $\tau = 0$. In Table 2 errors in density and mass flux, computed as in (46), and convergence rates are presented. Again, we observe linear convergence uniform for all choices of the parameter $\varepsilon$. In the light of our theoretical results, the numerical results for the network are expected and also observed to be quasi identical to those for a single pipe; compare Table 1 and 2.

According to the specifications in [23], the real length of the pipes in the GasLib-11 network is about 55km and their diameter about 0.5m. Interesting time scales are in the range of hours and days, which corresponds to a scaling parameter of $\varepsilon \approx 0.01 - 0.001$ in the parabolic limit regime; see [1] for details. As observed in [24] and illustrated in our numerical tests, one can set $\varepsilon = 0$ in that case and directly use the parabolic limit problem for simulations with practically the same outcome. See [12, 11, 13] for alternative results for the parabolic limit problem obtained by a different discretization strategy.

| $\varepsilon$ | $\text{err}_h(\rho)$ rate | $\text{err}_h(m)$ rate |
|--------------|----------------|----------------|
| $\varepsilon = 1$ | 1.28e-2 | 1.17e-2 |
|               | 7.58e-3 | 7.19e-3 |
|               | 4.21e-3 | 4.06e-3 |
|               | 2.24e-3 | 2.19e-3 |
|               | 1.16e-3 | 1.15e-3 |
|               | 5.89e-4 | 5.92e-4 |

Table 1. Error and convergence rates for different values of $\varepsilon$. Space and time discretization with $h = \frac{1}{16} \cdot 2^{-r}$ and $\Delta \tau = \frac{1}{2} h$ in refinement $r = 0, \ldots, 5$. 

The 2 compressor stations and the valve are treated here in by-pass mode, i.e., as additional pipes of length 0. The network thus degenerates to a reduced network, where the vertices $v_2$, $v'_2$, $v''_2$ as well as $v_6$, $v'_6$ are identified by single vertices $v_2$ and $v_6$ with ingoing edges $e_1$, $e_3$ and $e_5$, $e_6$ as well as outgoing edges $e_2$, $e_6$ and $e_7$, $e_8$, respectively. All pipes are assumed to have rescaled length $\ell = 1$ with cross-sectional area $a = 1$ and friction coefficient $\gamma = 1$. Appendix A. Transformation and rescaling of model equations

Consider the one dimensional barotropic Euler equations with friction

\[ a \partial_t \rho + \partial_x m = 0, \]  
\[ \partial_t m + \partial_x \left( \frac{m^2}{a} + a p(\rho) \right) = -\frac{\lambda}{2d} \rho |m| a \rho v \]  

with gas density \( \rho \), mass flux \( m = a \rho v \), flow velocity \( v \), pipe diameter \( d \) and cross-sectional area \( a \), and friction coefficient \( \lambda \). Using the product rule of differentiation in (48) together with (47), one can see that

\[ \partial_t v = -\frac{1}{a \rho} \left( av \partial_t \rho + v \partial_x (a \rho v) + a \rho v \partial_x v + a \partial_x p(\rho) + \frac{1}{2} |v| a \rho v \right) \]
\[ = -\frac{1}{2} \partial_x v^2 - \frac{1}{\rho} \partial_x p(\rho) - \frac{\lambda}{2d} |v| v. \]

We further introduce the pressure potential \( P(\rho) = \rho \int_1^\rho \frac{p(r)}{r^2} dr \) and observe that

\[ \partial_x P'(\rho) = \partial_x \left( \frac{p(\rho)}{\rho} + \int_1^\rho \frac{p(r)}{r^2} dr \right) = -\frac{p(\rho)}{\rho^2} \partial_x \rho + \frac{\partial_x p(\rho)}{\rho} + \frac{p(\rho)}{\rho^2} \partial_x \rho = \frac{1}{\rho} \partial_x p(\rho), \]

which allows to rewrite the evolution equation for the velocity compactly as

\[ \partial_t v + \partial_x \left( \frac{v^2}{2} + P'(\rho) \right) = -\frac{\lambda}{2d} |v| v. \]  

(49)

We then employ two rescalings of the model equations: In a first step, we replace

\[ x \to x/\varepsilon^2, \quad t \to t/\varepsilon^2, \]  

(50)

which resembles the situation of long pipes and time scales. After division by \( \varepsilon^2 \), this leads to a friction term with parameter \( \lambda/\varepsilon^2 \to \lambda = O(1/\varepsilon^2) \), characterizing the large friction regime. In a second step, we rescale (47) and (48), now with parameter \( \lambda = O(1/\varepsilon^2) \), by

\[ t = \frac{1}{\varepsilon} \tau, \quad v = \varepsilon w, \quad \lambda = \frac{2d}{\varepsilon^2} \gamma, \]  

(51)

which corresponds to the long time, small velocity and low Mach setting of relevance in the large friction case \( \varepsilon \ll 1 \) typical for the gas transport in long pipelines.

A direct application of these rescalings to (47)–(48) leads to the system (1)–(2) considered in the introduction, and together with the above transformation of the momentum equation, one obtains the system (3)–(4) considered in Section 2.
Appendix B. Discrete Gronwall Lemma

For the proof of the discrete stability estimate, we employ the following technical result.

**Lemma B26** (Discrete Gronwall). Let \(a^n, b^n, d^n \geq 0\) for \(n = 0, \ldots, N\), and further \(N\Delta\tau = \tau_{\text{max}}\) and \(c > 0\) with \(c\Delta\tau < 1\) be given, such that
\[
a^n + \sum_{k=1}^{n} \Delta\tau d^k \leq a^0 + b^n + c \sum_{k=1}^{n} \Delta\tau (a^k + a^{k-1}). \tag{52}
\]

Then, it holds
\[
a^n + \sum_{k=1}^{n} \Delta\tau d^k \leq a^0 + b^n + c\Delta\tau e^{\frac{2nc\Delta\tau}{1-c\Delta\tau}} (a^0 + \sum_{k=1}^{n} e^{\frac{(1-2k)c\Delta\tau}{1-2c\Delta\tau}} (2a_0 + b^k + b^{k-1})).
\]

**Proof.** We set
\[
s^n := \sum_{k=1}^{n} (a^k + a^{k-1}), \quad s^0 = a^0 \quad \text{and} \quad w := \frac{1}{\frac{1}{1+c\Delta\tau}}.
\]

Then (52) can be written as
\[
a^n - c\Delta\tau s^n \leq a^0 + b^n \sum_{i=k}^{n} \Delta\tau d^i. \tag{53}
\]

Now, define \(\tilde{a}^n := w^n s^n\). Then
\[
\tilde{a}^n - a^{n-1} = w^n s^n - w^{n-1} s^{n-1} = w^{n-1}(w s^n - s^{n-1})
\]
\[
= w^{n-1}(1 + c\Delta\tau)^{-1} (s^n - c\Delta\tau s^n - s^{n-1} - c\Delta\tau s^{n-1})
\]
\[
= w^{n-1}(1 + c\Delta\tau)^{-1} ((a^n - c\Delta\tau s^n) + (a^{n-1} - c\Delta\tau s^{n-1}))
\]
\[
\leq w^{n-1}(1 + c\Delta\tau)^{-1} (a^0 + b^n - \sum_{k=1}^{n} \Delta\tau d^k + a^0 + b^{n-1} - \sum_{k=1}^{n-1} \Delta\tau d^k),
\]
where we used (53) in the last estimate. Summing up over \(n\) yields
\[
\tilde{a}^n \leq a^0 + \sum_{k=1}^{n} w^{k-1}(1 + c\Delta\tau)^{-1} (2a^0 + b^k + b^{k-1} - \sum_{j=1}^{k} \Delta\tau d^j - \sum_{j=1}^{k-1} \Delta\tau d^j).
\]

From the definitions \(\tilde{a}^0 = a^0\) and \(\tilde{a}^n = w^n s^n\) as well as \(d^j \geq 0\), we then deduce that
\[
s^n \leq w^{-n} a^0 + w^{-n} \sum_{k=1}^{n} w^{k-1}(1 + c\Delta\tau)^{-1} (2a^0 + b^k + b^{k-1}).
\]

For the terms on the right hand side, we further use
\[
w^{-n} w^{k-1}(1 + c\Delta\tau)^{-1} = \left(\frac{1-c\Delta\tau}{1+c\Delta\tau}\right)^{k-1} (1 + c\Delta\tau)^{-1} \leq e^{\frac{(2(n-k)+1)c\Delta\tau}{1-2c\Delta\tau}},
\]
which then leads to
\[
a^n + \Delta\tau \sum_{k=1}^{n} d^k \leq a^0 + b^n + c\Delta\tau e^{\frac{2nc\Delta\tau}{1-c\Delta\tau}} (a^0 + \sum_{k=1}^{n} e^{\frac{(1-2k)c\Delta\tau}{1-2c\Delta\tau}} (2a_0 + b^k + b^{k-1})).
\]

With \(n\Delta\tau \leq N\Delta\tau = \tau_{\text{max}}\), we finally obtain the claim of the lemma. \(\square\)
