QUANTUM TOROIDAL $\mathfrak{gl}_1$ ALGEBRA : PLANE PARTITIONS

B. FEIGIN, M. JIMBO, T. MIWA AND E. MUKHIN

Abstract. In third paper of the series we construct a large family of representations of the quantum toroidal $\mathfrak{gl}_1$ algebra whose bases are parameterized by plane partitions with various boundary conditions and restrictions. We study the corresponding formal characters. As an application we obtain a Gelfand-Zetlin type basis for a class of irreducible lowest weight $\mathfrak{gl}_\infty$-modules.

1. Introduction

In this paper we continue our study of representations of an algebra $\mathcal{E} = \mathcal{E}_{q_1,q_2,q_3}$, depending on three complex parameters $q_1,q_2,q_3$ with $q_1q_2q_3 = 1$. It was originally introduced by Miki [Mi] as a two parameter analog of the $W_{1+\infty}$ algebra. The basic structure theory of $\mathcal{E}$ and its representations have been established in [Mi]. Its connection with the Macdonald operator and the deformed Virasoro/W-algebras was also revealed there. Some of his results will be recalled in Section 2. Essentially the same algebra has been rediscovered later on and was given various other names: the Ding-Iohara algebra in [FT],[FHHSY], or the elliptic Hall algebra in [SV1], [SV2]. Having been unaware of the work of Miki, we have called $\mathcal{E}$ “quantum continuous $\mathfrak{gl}_\infty$” in [FFJMM1],[FFJMM2]. We are sorry about this oversight.

We have decided to call $\mathcal{E}$ the quantum toroidal $\mathfrak{gl}_1$ algebra for the following reason. Let $\mathfrak{d}_q$ be the algebra generated by the symbols $Z^{\pm 1}, D^{\pm 1}$ satisfying $DZ = qZD$, where $q \in \mathbb{C}^\times$, and regard it as a Lie algebra endowed with the Lie bracket $[a,b] = ab - ba$. The Lie algebra $\mathfrak{d}_q$ has a two-dimensional central extension $\mathfrak{d}_{q,c_1,c_2}$. As mentioned in [Mi], the algebra $\mathcal{E}_{q_1,q_2,q_3}$ is a quantization of the universal enveloping algebra $U(\mathfrak{d}_{q,c_1,c_2})$, where one of the parameters, say $q_1$, is the quantization parameter and $q_2 = q$. The situation is similar to that of the quantum toroidal algebra $U_q(\mathfrak{sl}_N,\text{tor})$, whose classical limit is a central extension of the Lie algebra of $N \times N$ matrices $x$ with entries in $\mathfrak{d}_q$, such that $\text{res tr}(x) = 0$. (Here $\text{res}(a) = a_{0,0}$ for $a = \sum a_{i,j}Z^iD^j \in \mathfrak{d}_q$.)

Throughout this paper we shall restrict our considerations to representations of a quotient of $\mathcal{E}$ by one-dimensional center. The classical limit of the quotient algebra is $\mathfrak{d}_{q,\kappa,0}$, see Section 2.

The algebra $\mathfrak{d}_q$ is isomorphic to the algebra of $q$-difference operators. Namely $\mathfrak{d}_q$ has a faithful representation in the space $V = \mathbb{C}[Z, Z^{-1}]$, such that $Z$ acts as the multiplication operator $f(Z) \mapsto Zf(Z)$, and $D$ as the $q$-difference operator $f(Z) \mapsto f(qZ)$. This gives rise to a Lie algebra homomorphism $\mathfrak{d}_{q,\kappa,0} \to \mathfrak{gl}_\infty,\kappa$, where $\mathfrak{gl}_\infty,\kappa$
is the central extension of the Lie algebra of linear transformations $T : V \to V$, $T(Z^j) = \sum_j T_{ij} Z_i$, such that there exists $N \in \mathbb{Z}$ for which $T_{ij} = 0$ whenever $|i-j| > N$.

The Lie algebra $\mathfrak{gl}_{\infty, \kappa}$ has a rich representation theory. Let $\mathfrak{gl}_\infty \subset \mathfrak{gl}_{\infty, \kappa}$ be the Lie subalgebra of linear operators $T$ with finitely many non-zero matrix elements $T_{ij}$. Let $W_\theta$ be the irreducible representation of $\mathfrak{gl}_\infty$ with the lowest weight

$$\theta = (\ldots, \theta_{-2}, \theta_{-1}, 0, \theta_1, \theta_2, \ldots), \quad E_{i,j} v_\theta = \theta_i v_\theta,$$

where $v_\theta$ is a lowest weight vector in $W_\theta$:

$$E_{i,j} v_\theta = 0 \text{ if } i > j.$$

If the sequence $\{\theta_i\}$ stabilizes as $i \to \pm \infty$, then $W_\theta$ can be extended to the representation of $\mathfrak{gl}_{\infty, \kappa}$. Suppose that $\theta_i = \theta_-$ for $i < 0$, and $\theta_i = \theta_+$ for $i > 0$. Then the central element $\kappa$ acts in $W_\theta$ by the scalar $\theta_- - \theta_+$.

Conjecturally all such $W_\theta$ can be deformed to the representations of $\mathcal{E}$. In this paper we confirm it in several special cases.

If $\theta = (\ldots, 0, 0, 0, 1, 1, 1, \ldots)$, then $W_\theta$ is the well-known Fock representation given by semi-infinite wedges. In [FFJMM1] the construction of the semi-infinite wedges was performed as a result we get the Fock representation of $\mathcal{E}$. If the weight $\theta$ is anti-dominant, i.e., $\theta_i \in \mathbb{Z}$ and $\theta_i - \theta_{i+1} \leq 0$ for all $i \in \mathbb{Z}$, $E_i$-modules corresponding to $W_\theta$ were also constructed in [FFJMM1], see also Section 5.

Note that all these representations of $\mathcal{E}$ are described explicitly. We have a natural basis and an explicit formula for the action on this basis.

In the present paper we continue with the case $\theta(r) = (\ldots, 0, 0, 0, r, r, r, \ldots)$, where $r \in \mathbb{C}$ is generic. The character of $W_{\theta(r)}$ in the principal grading is given by the infinite product $\prod_{i=1}^{\infty} (1 - q^i)^{-i}$. Incidentally, it coincides with the well-known Macmahon formula for the generating series of the plane partitions. Recall that a plane partition is a collection of non-negative integers $\{\mu_i^{(k)}\}_{i,k=1}^{\infty}$ satisfying $\mu_i^{(k)} \geq \mu_i^{(k+1)}$, $\mu_i^{(k)} \geq \mu_{i+1}^{(k)}$ for all $i$, $k$ and $\mu_i^{(k)} = 0$ for $i + k$ large enough.

We construct a representation of $\mathcal{E}$ which is a deformation of $W_{(r)}$. It depends on a complex parameter $K \neq 0$, which is the value of a central element of $\mathcal{E}$ and is called the level of the representation. It has an additional complex parameter $u \neq 0$, which is related to an automorphism of $\mathcal{E}$. Most importantly, it has a distinguished basis labeled by the plane partitions and the action of $\mathcal{E}$ is explicit in this basis. We call this $\mathcal{E}$-module the Macmahon representation, and denote it by $M(u, K)$.

Next, we observe that our construction has the following natural generalization. Given three partitions $\alpha, \beta, \gamma$, we call a collection of numbers $\{\mu_j^{(k)}\}_{i,k=1}^{\infty}$, $\mu_j^{(k)} \in \mathbb{Z}_{\geq 0} \cup \{\infty\}$, a plane partition with the boundary condition $\alpha, \beta, \gamma$, if the following conditions are satisfied

(i) $\mu_i^{(k)} \geq \mu_i^{(k+1)}$, $\mu_i^{(k)} \geq \mu_{i+1}^{(k)}$ for all $i$, $k$,

(ii) $\mu_i^{(k)} = \alpha_k$ for $i \gg 0$,

(iii) $\mu_i^{(k)} = \gamma_i$ for $k \gg 0$,
(iv) $\mu^{(k)}_i = \infty$ if and only if $i \leq \beta_k$.

Let $\mathcal{P}[\alpha, \beta, \gamma]$ be the set of plane partitions with the boundary condition $\alpha, \beta, \gamma$.

The set $\mathcal{P}[\alpha, \beta, \gamma]$ appears in topological field theory as a fixed point set on Hilbert schemes on toric 3-dimensional Calabi-Yau manifolds [ORV].

We show that for generic values of $q_1, q_2, K$ the algebra $\mathcal{E}_{q_1, q_2, q_3}$ has an irreducible representation $\mathcal{M}_{\alpha, \beta, \gamma}(u, K)$ depending on an additional arbitrary complex parameter $u$ with a basis labeled by the set $\mathcal{P}[\alpha, \beta, \gamma]$ and give an explicit formula for the action.

Here the genericity assumption for $q_1, q_2$ means $q_1^{i_1} q_2^{i_2} q_3^{i_3} \neq 1$ unless $i_1 = i_2 = i_3$ and for $K$ means $K \neq q_1^{i_1} q_2^{i_2} q_3^{i_3}$ for all integers $i_1, i_2, i_3$. If $\alpha = \beta = \gamma = \emptyset$ we have $\mathcal{M}_{\alpha, \beta, \gamma}(u, K) = \mathcal{M}(u, K)$.

In the resonance case $K = q_1^{i_1} q_2^{i_2} q_3^{i_3}$ we show that the module $\mathcal{M}_{\alpha, \beta, \gamma}(u, K)$ is still well-defined, but becomes reducible. We describe singular vectors of $\mathcal{M}_{\alpha, \beta, \gamma}(u, K)$ and the irreducible quotient generated by the vector corresponding to the minimal partition in $\mathcal{P}[\alpha, \beta, \gamma]$. In the simplest case where $\alpha = \beta = \gamma = \emptyset$ and $K = q_1^{i_1} q_2^{i_2} q_3^{i_3}$ ($i_2, i_3 \geq 1$), the irreducible quotient has a basis labeled by plane partitions $\mu^{(k)}_i \in P(0, 0, 0)$ such that $\mu^{(i_3)}_i = 0$.

For the case of general $\alpha, \beta, \gamma$ the representation $\mathcal{M}_{\alpha, \beta, \gamma}(u, K)$ does not have the limit $q_1 \rightarrow 1$. But we show that if $\beta = \emptyset$, it does and therefore it is a deformation of a $\mathfrak{gl}_{\infty, \kappa}$-module. Suppose further that for $n, c \in \mathbb{Z}_{\geq 0}$

$$\gamma = \left( c, c, \ldots, c, 0, 0, \ldots \right), \ K = (q_2 q_3)^n,$$

then the irreducible quotient has the limit $q_1 \rightarrow 1$ and the limit is an irreducible $\mathfrak{gl}_{\infty, \kappa}$ module. The lowest weight $\theta$ of this module is given in (4.21).

The basis of this irreducible quotient is labeled by the set $P^n(\alpha, c)$ consisting of all $\left\{ \mu^{(k)}_i \right\}_{i, k=1}^{\infty} \in P(\alpha, 0, \gamma)$ such that $\mu^{(n+1)}_0 = 0$. This basis leads us to find a Gelfand-Tsetlin type basis for the $\mathfrak{gl}_{\infty, \kappa}$ module $W_{\theta}$, where $\theta$ is given by (4.21). The action is given explicitly by Gelfand-Zetlin type formulas, see (4.3), (4.4), (4.14), (4.19), (4.20). We expect that similar bases exist for all $\theta$, but we were unable to find them in the literature (except for the standard case of the dominant weights).

Following [KR2], we give an explicit bosonic construction of $W_{\theta}$. A version of the Schur-Weyl-Howe duality established in [KR2] allows us to write bosonic character formulas for $W_{\theta}$ in the principal grading. Equivalently, our formula computes the generating function for the set $P^n(\alpha, c)$.

We do not have a recipe for how to compute the characters of the $\mathcal{E}$-modules $\mathcal{M}_{\alpha, \beta, \gamma}(u, K)$ where $K = q_1^{i_1} q_2^{i_2} q_3^{i_3}$ in general, but this problem seems to have a very intriguing structure.

For example, if $K = q_3^N$, then $\mathcal{E}$ has a big two-sided ideal. After factorization we get a smaller algebra $\mathcal{E}^\text{red}_{q_1, q_2, q_3, K}$ which can be identified with the elliptic $W$-algebra. In particular, an appropriate limit of $\mathcal{E}^\text{red}_{q_1, q_2, q_3, K}$ gives us the $W$-algebra for $\widehat{\mathfrak{gl}}_N$. The
representation theory of the $W$-algebra for $\hat{\mathfrak{gl}}_N$ is a well-known subject. In particular, $W$-algebra has a class of representations appearing in the minimal models. In \cite{FFJM2} we showed that there exist $\mathcal{E}$-modules which have the same characters as the representations of minimal models of the $W$-algebra.

In the case $K = q_2^m q_3^n$ the algebra $\mathcal{E}$ also has a big two-sided ideal, and conjecturally the quotient in the appropriate limit gives us the $W$-algebra for the superalgebra $\hat{\mathfrak{gl}}(m, n)$. This conjecture allows us to predict some character formulas, which can be checked by a computer for small values of parameters. We give some of such formulas at the end of the paper.

The paper is organized as follows. In Section \ref{sec:preliminaries} we recall and discuss some known facts about algebra $\mathcal{E}$ and its representation. In Section \ref{sec:macmahon} we construct and study the Macmahon representations $M_{\alpha, \beta, \gamma}(u, K)$. In Section \ref{sec:limits} we study the $\mathfrak{gl}_\infty$ limits of the Macmahon representations. In particular, we describe the Gelfand-Zetlin type basis for some $\mathfrak{gl}_{\infty, r}$-modules. In Section \ref{sec:applications} we construct the $\mathfrak{gl}_\infty$-modules using Heisenberg algebra and compute their characters by the Schur-Weyl-Howe duality of $\mathfrak{gl}_N$. We finish with some conjectural character formulas.

2. Preliminaries

2.1. Algebra $\mathcal{E}$. Let $q_1, q_2, q_3 \in \mathbb{C}$ be complex parameters satisfying the relation $q_1 q_2 q_3 = 1$. We assume that $q_1, q_2, q_3$ are not a root of unity. Let

$$g(z, w) = (z - q_1 w)(z - q_2 w)(z - q_3 w).$$

The quantum toroidal $\mathfrak{gl}_1$ algebra is an associative algebra $\mathcal{E}$ with generators $e_i, f_i, i \in \mathbb{Z}, \psi_r^+, r \in \mathbb{Z}_{>0}$ and invertible elements $\psi_0^\pm, C$, satisfying the following defining relations:

$C$: central,

$$\psi^+(z)\psi^\pm(w) = \psi^\pm(w)\psi^+(z),$$

$$g(Cz, w)g(Cw, z)\psi^+(z)\psi^-(w) = g(z, Cw)g(w, Cz)\psi^-(w)\psi^+(z),$$

$$g(Cz, w)e(w) = -g(w, Cz)e(w),$$

$$g(z, w)e^-(z)e(w) = -g(w, z)e(w)e^-(z),$$

$$g(w, z)e^+(z)f(w) = -g(z, w)f(w)e^+(z),$$

$$g(w, Cz)e^-(z)f(w) = -g(Cz, w)f(w)e^-(z),$$

$$[e(z), f(w)] = \frac{1}{g(1, 1)}(\delta(Cw/z)\psi^+(w) - \delta(Cz/w)\psi^-(z)),$$

$$g(z, w)e(z)e(w) = -g(w, z)e(w)e(z),$$

$$g(w, z)f(z)f(w) = -g(z, w)f(w)f(z),$$

$$[e_0, [e_1, e_{-1}]] = [f_0, [f_1, f_{-1}]] = 0.$$
Here $\delta(z) = \sum_{n \in \mathbb{Z}} z^n$ denotes the formal delta function, and the generating series of the generators of $E$ are given by

$$e(z) = \sum_{i \in \mathbb{Z}} e_i z^{-i}, \quad f(z) = \sum_{i \in \mathbb{Z}} f_i z^{-i}, \quad \psi^\pm(z) = \sum_{i \geq 0} \psi_i^\pm z^{-i}.$$ 

Note that $E$ depends on the unordered set of parameters $\{q_1, q_2, q_3\}$, as all $q_i$ enter the relations symmetrically through the function $g(z, w)$.

Algebra $E$ has been introduced and studied by Miki [Mi] under the name "$(q, \gamma)$ analog of the $W_{1+\infty}$ algebra". (To be precise, in [Mi] an additional relation $\psi_0^+ \psi_0^- = 1$ is imposed, and $E$ is a one-dimensional split central extension of that of [Mi].)

Consider the associative $\mathbb{C}$ algebra with generators $Z^\pm 1, D^\pm 1$ with the relation $DZ = qZD$. Let $\mathfrak{d}_q$ be the same algebra viewed as a Lie algebra by $[a, b] = ab - ba$. Then $\mathfrak{d}_q$ has a two-dimensional central extension [KR] $\mathfrak{d}_{q,c_1,c_2} = \mathfrak{d}_q \oplus \mathbb{C}c_1 \oplus \mathbb{C}c_2$, where $c_1, c_2$ are central elements and the commutator is given by

$$[Z^{i_1}D^{j_1}, Z^{i_2}D^{j_2}] = (q^{i_1i_2} - q^{j_1j_2})Z^{i_1+i_2}D^{j_1+j_2} + \delta_{i_1+i_2,0}\delta_{j_1+j_2,0}q^{-i_1j_1}(i_1c_1 + j_1c_2).$$

The element $Z^0D^0 = 1$ is (split) central in $\mathfrak{d}_{q,c_1,c_2}$. The quantum toroidal $\mathfrak{gl}_1$ algebra $E$ is a quantization of the universal enveloping algebra $U\mathfrak{d}_{q,c_1,c_2}$ where $q_1$ is a parameter of the quantization and $q_2 = q^2$. Algebra $E$ has three central elements, $C$ and $\psi_0^\pm$. Among the latter only the ratio $(\psi_0^+)^-\psi_0^-$ is essential. We say that an $E$-module $V$ has level $(x, y) \in \mathbb{C}^2$ if $C^2$ acts by $x$ and $(\psi_0^+)^-\psi_0^-$ acts by $y$.

In what follows, we shall always consider representations of $E$ on which $C$ acts as identity. In other words we study representations of the quotient algebra $E/(C - 1)$, where the defining relations simplify as follows.

\begin{align*}
(2.1) \quad & \psi^\epsilon(z)\psi^{\epsilon'}(w) = \psi^{\epsilon'}(w)\psi^\epsilon(z) \quad (\epsilon, \epsilon' \in \{+, -\}), \\
(2.2) \quad & g(z, w)\psi^\pm(z)e(w) = -g(w, z)e(w)\psi^\pm(z), \\
(2.3) \quad & g(w, z)\psi^\pm(z)f(w) = -g(z, w)f(w)\psi^\pm(z), \\
(2.4) \quad & [e(z), f(w)] = \frac{\delta(z/w)}{g(1, 1)}(\psi^+(w) - \psi^-(z)), \\
(2.5) \quad & g(z, w)e(z)e(w) = -g(w, z)e(w)e(z), \\
(2.6) \quad & g(w, z)f(z)f(w) = -g(z, w)f(w)f(z), \\
(2.7) \quad & [e_0, [e_1, e_{-1}]] = [f_0, [f_1, f_{-1}]] = 0.
\end{align*}

In the quotient algebra, the subalgebra generated by $\psi^\pm_{i, i}, i \in \mathbb{Z}_{\geq 0}$, is commutative. We call an $E$-module $V$ tame if $\psi^\pm_{i, i}, i \in \mathbb{Z}_{\geq 0}$, act by diagonalizable operators with simple joint spectrum.

Algebra $E$ is $\mathbb{Z}^2$-graded with the assignment

$$\deg e_i = (1, i), \quad \deg f_i = (-1, i), \quad \deg \psi^\pm_i = (0, i), \quad \deg C = (0, 0).$$

Let $E_{(j, k)}$ denote the homogeneous component of $E$ of degree $(j, k) \in \mathbb{Z}^2$. We say that an $E$ module $V = \oplus_{n \in \mathbb{Z}} V_n$ is $\mathbb{Z}$-graded if $E_{j}V_n \subset V_{n+j}$ where $E_j = \sum_{k \in \mathbb{Z}} E_{(j, k)}$. We call
it *quasifinite* if \( \dim V_n < \infty \) for all \( n \in \mathbb{Z} \). Let \( \phi^\pm(z) \in \mathbb{C}[[z^{\pm 1}]] \) be formal power series in \( z^{\pm 1} \) with non-vanishing constant term. We say that a \( \mathbb{Z} \)-graded \( \mathcal{E} \) module \( V \) is a *lowest weight module* with *lowest weight* \((\phi^+(z), \phi^-(z))\) if it is generated by a non-zero vector \( v \) such that

\[
f(z)v = 0, \quad \psi^\pm(z)v = \phi^\pm(z)v, \quad Cv = v.\]

The following result due to Miki is an analog of the classification theorem for finite dimensional modules of quantum affine algebras.

**Theorem 2.1** ([Mi]). Up to isomorphisms, an irreducible lowest weight module \( V \) is uniquely determined by its lowest weight. It is quasifinite if and only if there exists a rational function \( R(z) \), which is regular and non-zero at \( z = 0, \infty \), such that \( \phi^\pm(z) \) is the expansion of \( R(z) \) at \( z^{\pm 1} = \infty \).

**Remark.** In [Mi], highest weight modules are considered. Though this is purely a matter of convention, in this paper we shall deal with lowest weight modules for historical reasons. We note that we have called the same object ‘highest weight modules’ in [FFJMM1], [FFJMM2].

Algebra \( \mathcal{E} \) has the formal comultiplication

\[
\Delta e(z) = e(z) \otimes 1 + \psi^-(z) \otimes e(z),
\]

\[
\Delta f(z) = f(z) \otimes \psi^+(z) + 1 \otimes f(z),
\]

\[
\Delta \psi^\pm(z) = \psi^\pm(z) \otimes \psi^\mp(z).
\]

These formulas do not define a comultiplication in the usual sense since the right hand sides contain infinite sums. In [Mi], it is shown that the twisted coproduct by a certain automorphism is well defined on tensor products of a class of modules (called restricted modules). In this paper, we shall take a slightly different approach and use the original coproduct given by \((2.8), (2.9), (2.10)\) when it makes sense. The arguments for justification can be found e.g. in the proof of Proposition 3.1 in [FFJMM1].

### 2.2. Fock modules

Let \( u \in \mathbb{C} \). Let \( V(u) = V_1(u) \) be a complex vector space spanned by basis \( [u]_i, \ i \in \mathbb{Z} \). Then the formulas

\[
(1 - q_1) e(z)[u]_i = \delta(q_1 z)[u]_{i+1},
\]

\[-(1 - q_1^{-1}) f(z)[u]_i = \delta(q_1^{-1} z)[u]_{i-1},
\]

\[
\psi^+(z)[u]_i = \frac{(1 - q_1^i q_3 u/z) (1 - q_1^i z/u) }{(1 - q_1^i z/u)(1 - q_1^{-1} z/u)} [u]_i,
\]

\[
\psi^-(z)[u]_i = \frac{(1 - q_1^{-i} z/u)(1 - q_1^{-i} z/u) }{(1 - q_1^{-i} z/u)(1 - q_1^{i+1} z/u)} [u]_i,
\]

define a structure of an irreducible tame quasifinite \( \mathcal{E} \)-module on \( V(u) \) of level \((1,1)\). We call the \( \mathcal{E} \)-module \( V(u) \) the *vector representation*. The vector representation is not a lowest weight representation, it is the counterpart of the \( \mathfrak{d}_q \) module \( \mathbb{C}[Z, Z^{-1}] \).
Note that \( q_1 \) plays a special role in the definition of \( V(u) \) while \( q_2 \) and \( q_3 \) participate symmetrically. Therefore there are two other vector representations obtained from \( V(u) \) by switching roles of \( q_1 \).

We set

\[
\psi_i(z) = \psi(q_i^i z), \quad \psi(z) = \frac{(1 - q_3 z)(1 - q_2 z)}{(1 - z)(1 - q_2 q_3 z)}.
\]

By (2.11), (2.12), we have \( \psi^\pm(z)[u]_i = \psi_i(u/z)[u]_i \).

The Fock representation \( \mathcal{F}(u) = \mathcal{F}_2(u) = \oplus \mathbb{C}[\lambda] \) is constructed in the infinite tensor product of the vector representations (see [FFJMM1]):

\[
\mathcal{F}(u) \subset V(u) \otimes V(u q_2^{-1}) \otimes V(u q_2^{-2}) \otimes \cdots
\]

(2.13)

\[
|\lambda\rangle = [u]_{\lambda_1} \otimes [u q_2^{-1}]_{\lambda_2 - 1} \otimes [u q_2^{-2}]_{\lambda_3 - 2} \otimes \cdots.
\]

Here \( \lambda = (\lambda_1, \lambda_2, \ldots) \) is a partition: \( \lambda_1 \geq \lambda_2 \geq \cdots \geq 0, \lambda_j \in \mathbb{Z}_{\geq 0}; \lambda_N = 0 \) for a large \( N \). We denote the corresponding Young diagram by \( Y_\lambda \).

In this tensor product we have two problems. First, we should avoid poles in the substitution. Let us examine the factor in the action of \( e(z) \).

We prepare some notations. Let \( \lambda \pm 1_i \) denote the partition \( \mu \) such that \( \mu_j = \lambda_j \) if \( j \neq i \) and \( \mu_i = \lambda_i \pm 1 \). We say \( (i, j) \) is a concave (resp., convex) corner of \( \lambda \) if and only if

\[
\lambda_i = j - 1 < \lambda_{i-1} \quad (\text{resp., } \lambda_i = j > \lambda_{i+1}).
\]

Denote by \( CC(Y_\lambda) \) (resp., \( CV(Y_\lambda) \)) the set of concave (resp., convex) corners of \( \lambda \).

From the comultiplication rule we have

\[
e(z)|\lambda\rangle = \sum_{i=1}^{\infty} \frac{\psi_{\lambda,i}}{1 - q_1} \delta(q_1^i q_3^{i-1} u/z)|\lambda + 1_i\rangle,
\]

(2.14)

\[
\psi_{\lambda,i} = \prod_{k=1}^{i-1} \frac{(1 - q_1^{\lambda_k - \lambda} q_3^{k-i+1})(1 - q_1^{\lambda_k - \lambda - 1} q_3^{k-i})}{(1 - q_1^{\lambda_k - \lambda} q_3^{k-i})(1 - q_1^{\lambda_k - \lambda - 1} q_3^{k-i})}.
\]

Note that \( \psi_{\lambda,i} \) has no pole. It has a zero when \( \lambda_{i-1} = \lambda_i \). This zero prohibits a term \( |\mu\rangle \) with \( \mu = \lambda + 1_i \) which breaks the condition \( \mu_{i-1} \geq \mu_i \) from appearing in the right hand side. Thus the above sum reduces to a finite sum:

\[
e(z)|\lambda\rangle = \sum_{(i, j) \in CC(\lambda)} \frac{\psi_{\lambda,i}}{1 - q_1} \delta(q_1^{j-1} q_3^{j-1} u/z)|\lambda + 1_i\rangle.
\]

Second, when we deal with the semi-infinite tensor product we have to give a meaning to the infinite product which appears in the action of \( \psi^\pm(z) \) and \( f(z) \). Let us give a meaning to the infinite product which appears in the action of \( \psi^\pm(z) \):

\[
\psi^\pm(z)|\lambda\rangle = \psi_\lambda(u/z)|\lambda\rangle, \quad \psi_\lambda(u/z) = \prod_{i=1}^{\infty} \psi_{\lambda, -i+1}(u q_2^{-i+1} / z).
\]
The product can be written as

\begin{equation}
(2.15) \quad \psi_{\lambda}(u/z) = \frac{1 - q_{1}^{\lambda-1} q_{3}^{-1} u/z}{1 - q_{1}^{\lambda} u/z} \prod_{j=1}^{\infty} \left(1 - q_{1}^{\lambda} q_{3}^{j} u/z \right) \left(1 - q_{1}^{\lambda+1} q_{3}^{j-1} u/z \right),
\end{equation}

which is convergent because of the boundary condition \( \lambda_N = 0 \) for large \( N \). We remark that the convergence is valid, in general, if \( \lim_{i \to \infty} \lambda_i \) exists. We will use (2.15) under that condition later. This formula implies that the level of \( \mathcal{F}(u) \) is \( (1, q_{2}) \). For the vacuum |\( \emptyset \rangle \), i.e., the empty Young diagram, we have

\begin{equation}
(2.16) \quad \psi_{\emptyset}(u/z) = \frac{1 - q_{2} u/z}{1 - u/z}.
\end{equation}

This is the lowest weight of \( \mathcal{F}(u) \). The general formula (2.15) for \( |\lambda\rangle \) can be understood as starting from the lowest weight (2.16) for the vacuum, and multiplying the contribution from each box of \( \Lambda \). Namely, set

\[ \psi_{i,j}(u/z) = \frac{\psi_{j-i+1}(u q_{2}^{-i+1}/z)}{\psi_{j-i}(u q_{2}^{i+1}/z)} = \frac{(1 - q_{1}^{j+1} q_{3}^{i} u/z)(1 - q_{1}^{i-1} q_{3}^{j} u/z)(1 - q_{1}^{j-1} q_{3}^{i-1} u/z)}{(1 - q_{1}^{i-1} q_{3}^{j} u/z)(1 - q_{1}^{i-1} q_{3}^{j-1} u/z)(1 - q_{1}^{j-1} q_{3}^{i-1} u/z)}.
\]

The rational function \( \psi_{\lambda}(u/z) \) can be determined recursively by

\begin{equation}
(2.17) \quad \psi_{\lambda}(u/z) = \psi_{i,\lambda_{i}}(u/z) \psi_{\lambda-1}(u/z).
\end{equation}

This formula immediately follows from (2.11), (2.12) and the comultiplication rule. It says that the contribution from the box \((i, j)\) is \( \psi_{i,j}(u/z) \). Using (2.17), it is easy to see that

\begin{equation}
(2.18) \quad \psi_{\lambda}(u/z) = \prod_{(i,j) \in CC(\lambda)} \frac{1 - q_{1}^{i-2} q_{3}^{i-2} u/z}{1 - q_{1}^{i-1} q_{3}^{i-1} u/z} \prod_{(i,j) \in CV(\lambda)} \frac{1 - q_{1}^{j} q_{3}^{j} u/z}{1 - q_{1}^{j-1} q_{3}^{j-1} u/z}.
\end{equation}

From this, one can see that the representation is tame.

The formula for the action of \( f(z) \) is obtained similarly:

\[ f(z)|\lambda\rangle = \sum_{i=1}^{\infty} \frac{q_{1} \psi_{\lambda_{i}}^{'} \delta(q_{1}^{\lambda_{i}-1} q_{3}^{i-1} u/z)|\lambda - 1_{i}\rangle}{1 - q_{1}} \]

\begin{equation}
(2.19) \quad \psi_{\lambda_{i}}^{'} = \frac{1 - q_{1}^{\lambda_{i+1} - \lambda_{i}}}{1 - q_{1}^{\lambda_{i+1} - \lambda_{i}} q_{3}^{k_{i+1} - 1} q_{3}^{k_{i}} q_{3}^{k_{i+1}}} \prod_{k_{i} \in i+1}^{\infty} \frac{1 - q_{1}^{\lambda_{i+1} - \lambda_{i}} q_{3}^{k_{i}-1} u/z}{1 - q_{1}^{\lambda_{i+1} - \lambda_{i}} q_{3}^{k_{i}-1} u/z} \frac{1 - q_{1}^{\lambda_{i+1} - \lambda_{i}} q_{3}^{k_{i}-1} u/z}{1 - q_{1}^{\lambda_{i+1} - \lambda_{i}} q_{3}^{k_{i}-1} u/z}.
\end{equation}

Again, \( \psi_{\lambda_{i}}^{'} \) has no pole, and the zero at \( \lambda_{i} = \lambda_{i+1} \) prohibits the appearance of terms \( |\mu\rangle \) which breaks the condition \( \mu_{i} \geq \mu_{i+1} \). Thus, the action of \( f(z) \) reads as

\begin{equation}
(2.20) \quad f(z)|\lambda\rangle = \sum_{(i,j) \in CV(\lambda)} \frac{q_{1} \psi_{\lambda_{i}}^{'} \delta(q_{1}^{\lambda_{i}-1} q_{3}^{i-1} u/z)|\lambda - 1_{i}\rangle}{1 - q_{1}}.
\end{equation}
If we exchange $q_1$ with $q_3$ the representation $\mathcal{F}(u)$ changes. Let us denote it by $\mathcal{F}'(u)$. This representation is realized inside the semi-infinite tensor product $V_3(u) \otimes V_3(uq_2^{-1}) \otimes V_3(uq_2^{-2}) \otimes \cdots$. Since $\mathcal{F}'(u)$ has the same lowest weight $\lambda'$ as that of $\mathcal{F}(u)$, these two modules are isomorphic by Theorem [2.1]. We can construct the isomorphism explicitly. Look at the action of $\psi^\pm(z)$ [2.18]. If we exchange $(i,j) \leftrightarrow (j,i)$ and $q_1 \leftrightarrow q_3$ simultaneously, the factors are invariant. Therefore, as $\psi^\pm(z)$ modules, for arbitrary nonzero constants $c_\lambda$ the mapping $|\lambda\rangle \mapsto c_\lambda|\lambda'\rangle$, with $\lambda'$ being the transpose of $\lambda$, is an intertwiner. Since the representations are tame, this is the only way of intertwining these two $\mathcal{E}$-modules. Theorem [2.1] shows the existence of the set of constants $c_\lambda$.

Now let us discuss the relation (2.4). On the subspace of $V(u) \otimes V(uq_2^{-1}) \otimes \cdots \otimes V(uq_2^{-N+1})$ that is spanned by the vector
\[
|\lambda\rangle^{(N)} = [u]_{\lambda_1} \otimes [uq_2^{-1}]_{\lambda_2-1} \otimes \cdots \otimes [uq_2^{-N+1}]_{\lambda_N-N+1},
\]
where $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_N$, the relation (2.25) is valid. The left hand side is a sum of products of delta functions of the form $c(q_1, q_3)\delta(z/w)\delta(q_1^{a_1}q_3^{b_1}u/z)$. The right hand side is a difference of two series $\psi^\pm(z)$: one is obtained from the rational function with simple poles,
\[
\psi^\lambda_{\lambda}^{(N)}(u/z) = \prod_{j=1}^{N} \psi_{\lambda_j-j+1}(q_2^{-j+1}u/z),
\]
by expanding it in $z^{-1}$, and the other from the same rational function by expanding it in $z$. The difference is a sum of delta functions. They can be computed from the position of the poles of $\psi^\lambda_{\lambda}^{(N)}(u/z)$ and their residues.

Now, consider the semi-infinite action on (2.13), and compare it with the action on (2.21). If $N$ is large enough so that $\lambda_N = 0$, we identify (2.13) with (2.21). Then the action of $e(z)$ is the same. The actions of $\psi^\pm(z)$ are slightly different:
\[
\psi^\lambda_{\lambda}^{(N)}(u/z) = \psi_\lambda(u/z) \frac{1 - q_3^N u/z}{1 - q_1^{-1}q_3^{N-1}u/z},
\]
The factor $\frac{1 - q_1^N u/z}{1 - q_1^{-1} q_3^{N-1} u/z}$ is dropped in the action of $\psi^\pm(z)$ on $\mathcal{F}(u)$. We also drop the same factor from the action of $f(z)$. This explains the factor $\psi'_{\lambda,i}$ in (2.20): for large $N$, we have

$$\psi'_{\lambda,i} = \prod_{k=1}^{N} \psi_{\lambda_k - k+1}(q_2^{-k+1} u/z) \times \frac{1 - q_3^N q_2 u/z}{1 - q_3^N u/z} \bigg|_{u/z \to q_1^{-\lambda_1-1} q_3^{-i+1}}. \quad (2.23)$$

Since the tensor product (2.13) does not have the $(N+1)$st component, the equality (2.5) for (2.21) contains an extra term with the delta function $\delta(q_1^{-1} q_3^{N-1} u/z)$. On the other hand, in the action on $\mathcal{F}(u)$, this term is killed by the zero of $\psi'_{\lambda,N}$ as discussed before; going to (2.13) this term is dropped in both sides of (2.5). The effect of the modification (2.22) is the same on each delta function term because it is the multiplication by the same factor. Thus the equality (2.5) is valid on $\mathcal{F}(u)$.

The value of $\psi_0^-$ has been changed by the multiplication because the value of this factor at $z = 0$ is $q_2$. The modification produces the non-trivial level $(1, q_2)$ for the representation $\mathcal{F}(u)$.

### 3. Macmahon modules

#### 3.1. Vacuum Macmahon modules.

Let us construct a level $(1, K)$ representation

$$(3.1) \quad \mathcal{M}(u, K) \subset \mathcal{F}(u) \otimes \mathcal{F}(u q_2) \otimes \mathcal{F}(u q_2^2) \otimes \cdots$$

with basis

$$\mathcal{M}(u, K) = \bigoplus_{\lambda} \mathbb{C} |\lambda\rangle, \quad \lambda = (\lambda^{(1)}, \lambda^{(2)}, \lambda^{(3)}, \cdots),$$

where $\lambda$ is a plane partition, i.e., each $\lambda^{(k)} = (\lambda^{(k)}_1, \lambda^{(k)}_2, \cdots, 0, 0, \cdots)$ is a partition and

$$\lambda^{(k)}_i \geq \lambda^{(k+1)}_i \quad (3.2)$$

is satisfied. We require $\lambda^{(N)} = \emptyset$ for large $N$. In particular, we set

$$\emptyset = (\emptyset, \emptyset, \emptyset, \cdots).$$

With each $\lambda$ we associate a subset $Y_\lambda$ of $(\mathbb{Z}_{\geq 1})^3$ such that $(i, j, k) \in Y_\lambda$ if and only if $j \leq \lambda^{(k)}_i$. This is a finite set.

We call the representation $\mathcal{M}(u, K)$ the vacuum Macmahon representation.

In [FFJMM2], Theorem 3.4, the action of $E$ was defined on the subspace $\mathcal{M}^{(n)}_{a,b}$ ($a = (a_1, \ldots, a_{n-1})$, $b = (b_1, \ldots, b_{n-1})$) of $\mathcal{F}(u_1) \otimes \mathcal{F}(u_2) \otimes \cdots \otimes \mathcal{F}(u_n)$ where

$$u_{i+1} = u_i q_1^{-a_i} q_2 q_3^{-b_i} \quad (3.3)$$

spanned by the vectors

$$|\lambda^{(n)}\rangle = |\lambda^{(1)}\rangle \otimes \cdots \otimes |\lambda^{(n)}\rangle$$
satisfying

\begin{equation}
\lambda_i^{(k)} + a_k \geq \lambda_i^{(k+1)}.
\end{equation}

The tensor product \([3.1]\) with the restriction \([3.2]\) is the limit \(n \to \infty\) of this construction in the case \(a = b = 0\). From the discussion in the previous subsection, the method for constructing the action on the infinite tensor product based on the results in \([FFJM2]\) is clear. However, we must be careful on the definition of \(\psi^\pm(z)\) since the level of the representation \(N^{(n)}_{a,b}\) is not defined. In fact, this is not a defect but here is a room for introducing an arbitrary parameter for the level.

We define the action of \(\psi^\pm(z)\) by

\begin{equation}
\psi^\pm(z)|\lambda\rangle = \psi_\lambda(u/z)|\lambda\rangle,
\end{equation}

\begin{equation}
\psi_\lambda(u/z) = \psi_\emptyset(u/z) \prod_{(i,j,k) \in Y_\lambda} \psi_{i,j,k}(u/z),
\end{equation}

\begin{equation}
\psi_\emptyset(u/z) = \frac{1 - K u/z}{1 - u/z},
\end{equation}

\begin{equation}
\psi_{i,j,k}(u/z) = \frac{(1 - q_1^{i_2}q_2^{i_3}u/z)(1 - q_1^j q_2^k q_3^{i_1} u/z)(1 - q_1^j q_2^k q_3^{i_1} u/z)}{(1 - q_1^j q_2^k q_3^{i_1} u/z)(1 - q_1^j q_2^k q_3^{i_1} u/z)(1 - q_1^j q_2^k q_3^{i_1} u/z)}.
\end{equation}

Here \(K\) is an arbitrary nonzero parameter. The level of representation is \((1, K)\). It is easy to see that the action of \(\psi^\pm(z)\) is tame. In fact, the partition \(\lambda^{(1)}\) can be read from \(\psi_\lambda(u/z)\) by identifying its concave and convex corners recursively: the rightmost concave corner \(\lambda^{(1)}\) can be identified by the pole coming from the factor \(1 - q_1^{i_2} u/z = 1 - q_1^{i_1} q_3^{i_3} u/z\). Among the factors of the form \((1 - q_1^j u/z)\) in the denominator of \(\psi_\lambda(u/z)\), the one with \(x = \lambda_1^{(1)}\) is the largest in \(x\). Next, the rightmost convex corner \(\lambda^{(1)}\) can be identified by the zero at \((1 - q_1^{i_2} q_3^{i_3} u/z)\). Among the factors of the form \((1 - q_1^{i_2} q_3^{i_3} u/z)\) in the numerator of \(\psi_\lambda(u/z)\), the one with \(x = i_2\) is the largest in \(x\). Similarly, one can identify the concave corner \((i_2 + 1, j_2)\), then the convex corner \((i_3, j_2 - 1)\), etc., from the factors in \(\psi_\lambda(u/z)\). After identifying \(\lambda^{(1)}\), we divide \(\psi^{(1)}(u/z) = \psi_\lambda(u/z)\) by the factors corresponding to \(\lambda^{(1)}\), and obtain new \(\psi^{(2)}(u/z)\). Then, one can determine \(\lambda^{(2)}\) by the same procedure using this \(\psi^{(2)}(u/z)\). Continuing in this way, we can completely determine \(\lambda\) from \(\psi_\lambda(u/z)\).

The rational function \(\psi_\lambda(u/z)\) can be determined recursively. Denote \(\mu\) such that \(\mu^{(m)} = \lambda^{(m)}\) if \(m \neq k\), and \(\mu^{(k)} = \lambda^{(k)} \pm 1_i\) by \(\lambda \pm 1^{(k)}_i\). Then we have

\begin{equation}
\psi_\lambda(u/z) = \psi_{i_1^{(k)}, k}(u/z) \psi_{\lambda - 1^{(k)}_i}(u/z).
\end{equation}

Let us compare \(\psi_\lambda(u/z)\) with

\begin{equation}
\psi^{(k)}_\lambda(u/z) = \prod_{m=1}^k \psi_{\lambda^{(m)}}(u_m/z), \quad u_m = u_{d_2^{m-1}}.
\end{equation}
For $N \gg 1$, we have

$$
(3.8) \quad \psi_\lambda(u/z) = \psi_\lambda^{(N)}(u/z) \frac{1 - Ku/z}{1 - q_2^N u/z}.
$$

This is because for large $N$ we have the same recursion

$$
\psi_\lambda^{(N)}(u/z) = \psi_{i_1,\lambda_1^{(k)}, k}(u/z)\psi_{\lambda_1^{-1}}^{(N)}(u/z).
$$

Note that the structure of poles is the same for $\psi_\lambda^{(N)}(u/z)$ and $\psi_\lambda(u/z)$ because the former (for large $N$) has a zero at $1 - q_2^N u/z = 0$ and the latter at $1 - Ku/z = 0$. This is important in the derivation of (2.5). Namely, the position of delta functions appearing in the right hand side of the equality does not change by changing the rational function from $\psi_\lambda^{(N)}(u/z)$ to $\psi_\lambda(u/z)$. It is also invariant in the left hand side because for large $N$ we have $\lambda^{(N)} = \emptyset$ and $|\lambda^{(N)}| = |\emptyset|$ is the lowest weight vector, which is killed by the action of $f(z)$. Thus, we can establish the existence of the representation on $\mathcal{M}(u, K)$ with the level $(1, K)$ and the lowest weight $\frac{1-Ku/z}{1-u/z}$.

For completeness we give the action of $e(z), f(z)$ on $\mathcal{M}(u, K)$.

The action of $e(z)$ on $|\lambda\rangle$ is defined by

$$
(3.9) \quad e(z)|\lambda\rangle = \sum_{k=1}^{\infty} \psi_\lambda^{(k-1)}(u/z) \sum_{i=1}^{\infty} \psi_{\lambda(k), i} \frac{1}{1 - q_1} \delta(q_1^{\lambda,i} q_2^{k-1} q_3^{i-1} u/z) |\lambda + 1^{(k)}\rangle.
$$

From [FFJMM2] follows that for the finite tensor product the delta function does not pick up poles of $\psi_\lambda^{(k-1)}(u/z)$, and does pick up a zero if and only if $\mu = \lambda + 1^{(k)}$ breaks the condition $\mu_i^{(k-1)} \geq \mu_i^{(k)}$. Here we give a simple proof of these statements using (2.1N).

Set $j = \lambda_i^{(k)} + 1$. Suppose that

$$(i, j) \in CC(\lambda^{(k)}).$$

From (2.18) we see that the function $\psi_\lambda^{(k-1)}(u/z)$ has a pole at $q_1^{i-1} q_2^{k-1} q_3^{i-1} u/z = 1$ only if for some $m \leq k - 1$, there exists a box $(\tilde{i}, \tilde{j})$ such that

$$(\tilde{i}, \tilde{j}) \in CC(\lambda^{(m)}) \cup CV(\lambda^{(m)})$$

and

$$q_1^{\tilde{i}-1} q_2^{k-1} q_3^{i-1} = q_1^{\tilde{j}-1} q_2^{m-1} q_3^{\tilde{j}-1}.$$}

The latter implies

$$\tilde{i} = i + m - k < i, \quad \tilde{j} = j + m - k < j.$$}

This is a contradiction with $\lambda_i^{(m)} \geq \lambda_i^{(k)}$. We have shown the statement about the poles.

Let us show the statement about the zeros. A zero occurs only if either

$$(\tilde{i}, \tilde{j}) \in CC(\lambda^{(m)})$$

and

$$q_1^{\tilde{i}-1} q_2^{k-1} q_3^{i-1} = q_1^{\tilde{j}-2} q_2^{m-1} q_3^{\tilde{j}-2}.$$
or
\[(i, j) \in CV(\lambda^{(m)}) \quad \text{and} \quad q_1^{j-1} q_2^{k-1} q_3^{i-1} = q_1^{j} q_2^{m-1} q_3^{i}.
\]
The former case really occurs when the condition \(\mu_i^{(k-1)} \geq \mu_i^{(k)}\) is broken, while the latter leads to a contradiction.

A box \((i, j, k)\) is called a concave (resp., convex) corner of \(Y_\lambda\) if
\[(i, j, k) \notin Y_\lambda \quad \text{(resp., } (i, j, k) \in Y_\lambda)\]
and
\[(i - 1, j, k), (i, j - 1, k), (i, j, k - 1) \in Y_\lambda\]
\[(\text{resp., } (i + 1, j, k), (i, j + 1, k), (i, j, k + 1) \notin Y_\lambda)\].

We denote by \(CC(Y_\lambda)\) (resp., \(CV(Y_\lambda)\)) the set of concave (resp., convex) corners of \(\lambda\). They are finite sets. The action of \(e(z)\) adds a box at each concave corner (see (2.14), (3.7)):
\[
e(z)|\lambda) = \sum_{(i, j, k) \in CC(Y_\lambda)} \psi_{\lambda,i,j,k} |\psi_{\lambda(i)}i,1/q_1^{j} q_2^{k} q_3^{i} - 1)\delta(q_1^{j} q_2^{k} q_3^{i} u/z)|\lambda + 1^{(k)},\]
(3.10)
\[
\psi_{\lambda,i,j,k} = \psi_{\lambda(i)}^{(k-1)}(q_1^{j} q_2^{k} q_3^{i}).
\]
(3.11)

Similarly, we have the formula for the action of \(f(z)\) (see (2.23)).
\[
f(z)|\lambda) = \sum_{(i, j, k) \in CV(Y_\lambda)} \psi'_{\lambda,i,j,k} |\psi'_{\lambda(i)}i,1/q_1^{j} q_2^{k} q_3^{i} - 1)\delta(q_1^{j} q_2^{k} q_3^{i} u/z)|\lambda - 1^{(k)},\]
\[
\psi'_{\lambda,i,j,k} = \psi'_{\lambda(i+1)}^{(k-1)}(q_1^{j} q_2^{k} q_3^{i}),
\]
\[
\psi'_{\lambda(i)}^{(k)}(u/z) = \lim_{N \to \infty} \prod_{m=k}^{N} \psi^{'(m)}_{\lambda} |(q_2^{m-1} u/z)| 1/q_1^{j} q_2^{k} q_3^{i} - 1).
\]

As we discussed \(\psi'_{\lambda(i),i}\) (see (2.19)) has no pole, and it has a zero if and only if \(\mu = \lambda - 1^{(k)}\) breaks the condition for the plane partitions. The discussion for poles and zeros of \(\psi_{\lambda(i),i}\) is exactly the same as \(\psi_{\lambda(i),i}\) for \(e(z)\).

3.2. Macmahon modules with non-trivial boundary conditions. In this subsection we generalize the Macmahon representation to the case where the plane partitions have non-trivial boundary conditions. We repeat the semi-infinite tensor product construction. We remove the restriction \(\alpha = \beta = \gamma = 0\) in (3.4), and also remove the condition \(\lambda^{(N)} = \emptyset\) for large \(N\).

It is convenient to use another notation. Consider a set of three partitions \(\alpha = (\alpha_1, \alpha_2, \ldots, 0, \ldots)\), \(\beta = (\beta_1, \beta_2, \ldots, 0, \ldots)\), \(\gamma = (\gamma_1, \gamma_2, \ldots, 0, \ldots)\). We call a sequence \(\mu = (\mu_1, \mu_2, \mu_3, \ldots)\) where \(\mu_i \in \mathbb{Z}_{\geq 0} \cup \{\infty\}\) a generalized partition if and only if \(\mu_i \geq \mu_{i+1}\) holds for all \(i \geq 1\). A sequence of generalized partitions \(\mu = \{\mu^{(k)}\}_{k \geq 1}\) is called a plane
partition with the boundary conditions \( (\alpha, \beta, \gamma) \) if and only if the following conditions hold.

\[
\mu^{(k)}_i \geq \mu^{(k+1)}_i, \\
\lim_{i \to \infty} \mu^{(k)}_i = \alpha_k, \\
\mu^{(k)}_i = \infty \text{ if } 1 \leq i \leq \beta_k, \\
\lim_{k \to \infty} \mu^{(k)}_i = \gamma_i.
\] (3.12)

We denote by \( \mathcal{P}[\alpha, \beta, \gamma] \) the set of \( \mu \) satisfying these conditions. For each \( \mu \) we define a subset \( Y_{\mu} \subset (\mathbb{Z}_{\geq 1})^3 \) by

\[
(i, j, k) \in Y_{\mu} \leftrightarrow j \leq \mu^{(k)}_i.
\] (3.13)

This definition is a generalization of \( Y_{\lambda} \) when \( \alpha = \beta = \gamma = \emptyset \). A new feature is that \( Y_{\mu} \) can be an infinite set. If \( \alpha \) is non-zero for \( \mu \), then \( Y_{\mu} \) has an elevation in the \( i \)-axis. Similarly, if \( \beta \) (resp., \( \gamma \)) is non-zero, an elevation in the \( j \)-axis (resp., \( k \)-axis) (see Figure 3.2).

Plane partitions \( \mu \) with the boundary conditions \( (\alpha, \beta, \gamma) \) are in one-to-one correspondence with sets of partitions \( \lambda = (\lambda^{(1)}, \lambda^{(2)}, \lambda^{(3)}, \ldots) \).

Set

\[
a_k = \alpha_k - \alpha_{k+1}, \quad b_k = \beta_k - \beta_{k+1}, \quad c_k = \gamma_k,
\]

\[
\lambda^{(k)}_i = \mu^{(k)}_{i+\beta_k} - \alpha_k.
\] (3.14) (3.15)

The condition (3.12) for \( \mu \) and the condition (3.4) for \( \lambda \) are equivalent through (3.14) and (3.15).

We fix the parameter \( u_i \) as

\[
u = u q_1^{a_i} q_2^{j-1} q_3^{b_i},
\]

which implies (3.3). When we discuss the tensor product we use

\[
|\lambda\rangle = |\lambda^{(1)}\rangle \otimes |\lambda^{(2)}\rangle \otimes |\lambda^{(3)}\rangle \otimes \cdots \subset \mathcal{F}(u_1) \otimes \mathcal{F}(u_2) \otimes \mathcal{F}(u_3) \otimes \cdots,
\]

and when we discuss the plane partition we use \( Y_{\mu} \). We show this correspondence by denoting \( \lambda = \lambda_{\mu} \) when it is necessary.

Consider a linear subspace of the semi-infinite tensor product

\[
\mathcal{M}_{\alpha, \beta, \gamma} \subset \mathcal{F}(u_1) \otimes \mathcal{F}(u_2) \otimes \cdots.
\] (3.16)

By definition the space \( \mathcal{M}_{\alpha, \beta, \gamma} \) is spanned by \( |\lambda\rangle \) where \( \lambda = (\lambda^{(1)}, \lambda^{(2)}, \lambda^{(3)}, \ldots) \) is a sequence of partitions satisfying (3.4) and the boundary condition.

\[
\lim_{k \to \infty} \lambda^{(k)}_i = \gamma_i.
\] (3.17)

The construction of representation with basis \( |\lambda\rangle \) can be done by using the result on the finite tensor product, [FFJMM2], Theorem 3.4.
We consider $|\lambda^{(i)}\rangle$ as an element of $\mathcal{F}(u_i)$, and identify $|\lambda\rangle$ with

$$|\lambda^{(1)}\rangle \otimes |\lambda^{(2)}\rangle \otimes \cdots \otimes |\lambda^{(N)}\rangle \in \mathcal{F}(u_1) \otimes \mathcal{F}(u_2) \otimes \cdots \otimes \mathcal{F}(u_N)$$

for large enough $N$. Then, the action of $e(z)$ on $M_{\alpha,\beta,\gamma}$ is the same as in the finite tensor product. In the below let us describe the action of $\psi^\pm(z)$ and $f(z)$.

We describe the action of $e(z)$. The action of $e(z)$ adds a box at each concave corner as before (see (3.10), (3.11)):

$$e(z)|\lambda\rangle = \sum_{(i,j,k) \in CC(Y_\mu)} \psi_{\lambda,i,j,k} \psi_{\lambda^{(k)},i-\beta_k} \frac{1}{1-q_1^i q_2^j q_3^k u/z} |\lambda + 1^{(k)}_{i-\beta_k}\rangle.$$

Let us discuss the well-definedness of this action. This point was discussed in the previous subsection in the case of $\alpha = \beta = \gamma = \emptyset$. The argument is the same in the general case, but $\mu$ must be used instead of $\lambda$ because the structure of plane partitions is respected by $\mu$, not by $\lambda$ (see (3.13)).
Recall \((2.15)\), and change \((3.7)\) to
\[
\psi^{(k)}(u/z) = \prod_{m=1}^{\lambda} \psi^{(m)}(u_m/z), \quad u_m = q_1^{\alpha_m} q_2^{m-1} q_3 u.
\]
Then using \((3.15)\) we obtain
\[(3.18)\]
\[
\psi^{(m)}(u_m/z) = \psi^{(m)}(q_2^{m-1} u/z),
\]
where we understand \(q_1^\infty = 0\). Thus, the action of \(e(z)\) takes the same form as in the vacuum case wherein \(\lambda\) is replaced by \(\mu\).

Define the action of \(\psi^{\pm}(z)\) on \(M_{\alpha, \beta, \gamma} = M_{\alpha, \beta, \gamma}(u, K)\) by setting
\[(3.19)\]
\[
\psi^{\lambda}(u/z) = \frac{1 - Ku/z}{1 - \lambda^{(1)}} \prod_{i=1}^{\infty} \frac{1 - \lambda^{(i)} u_i/z}{1 - \lambda^{(i+1)} u_{i+1}/z}
\]
\[
\times \prod_{j=1}^{\infty} \frac{1 - \lambda^{(j)} q_j u_j/z}{1 - \lambda^{(j+1)} q_j u_{j+1}/z}
\]
in the formula \((3.5)\). This is a finite product. This expression follows from the formal infinite product
\[
\psi^{\lambda}(u) = \prod_{i=1}^{\infty} \psi^{(i)}(u_i/z)
\]
by substituting \((2.15)\), and modifying it as we did in \((2.15)\) and \((3.8)\).

The function \(\psi^{\lambda}(u/z)\), in general, can be better understood in terms of \(Y_{\mu}\). Let \((i, j, k) \in CC(Y_{\mu})\) be a concave corner. Then, adding one box at \((i, j, k)\) to \(Y_{\mu}\) corresponds to changing \(\lambda\) to \(\lambda + 1_{i-\beta_k}\), where \(\lambda^{(i)} = \lambda_{i-\beta_k} + \alpha_k + 1 = j\). From \((3.15)\), this relation can be rewritten as
\[
\mu^{(i)} + 1 = j.
\]
Using \((3.6)\), \((3.19)\) we obtain
\[
\psi^{\lambda+1_{i-\beta_k}}(u/z) = \psi_{i,j,k}(u/z) \psi^{\lambda}(u/z).
\]
Using \((3.18)\), for \(\lambda = \lambda_{\mu}\), we have
\[(3.20)\]
\[
\psi^{\lambda}(u/z) = \frac{1 - Ku/z}{1 - u/z} \prod_{(i,j,k) \in Y_{\mu}} \psi_{i,j,k}(u/z).
\]
Here the infinite product is defined as follows. Set
\[
Y^{(N)}_{\mu} = \{(i, j, k) \in Y_{\mu} \mid i, j, k \leq N\},
\]
define \(\psi^{(N)}_{\lambda}(u/z)\) by \((3.20)\) with \(Y_{\mu}\) replaced by \(Y^{(N)}_{\mu}\). For large \(N\) the difference between \(\psi^{(N)}_{\lambda}(u/z)\) and \(\psi^{(N+1)}_{\lambda}(u/z)\) consists only of \(N\) dependent factors which come from the \(\psi_{i,j,k}(u/z)\) such that \(i \sim N\) or \(j \sim N\) or \(k \sim N\). We define the infinite product by
removing these factors from $\psi_\lambda^{(N)}(u/z)$. By the definition it is independent of $N$. Once we define the infinite product in this way, the equality (3.20) is clear from (3.18) for $\gamma = \emptyset$. We discuss the case $\gamma \neq \emptyset$ at the end of this subsection.

In fact, it is possible to rewrite the infinite product as a finite product. We will do it later in Section 3.3. Here we remark that each cube in $Y_\mu$ contributes to poles and zeros through eight corners of the cube: poles from $(i,j,k)$, $(i-1,j-1,k)$, $(i,j-1,k-1)$, $(i,j,k-1)$, and zeros from $(i-1,j-1,k-1), (i-1,j,k), (i,j-1,k), (i,j,k-1)$; two of them, $(i,j,k)$ and $(i-1,j-1,k-1)$, cancel each other because of the restriction $q_1q_2q_3 = 1$. From this follows that the $\psi^\pm(z)$ action enjoys the $S_3$ symmetry

\begin{align}
(i,j,k) &\leftrightarrow (j,i,k) \leftrightarrow (q_1,q_2,q_3) \leftrightarrow (q_3,q_2,q_1), \\
(i,j,k) &\leftrightarrow (k,j,i) \leftrightarrow (q_1,q_2,q_3) \leftrightarrow (q_1,q_3,q_2).
\end{align}

(3.21) (3.22)

The first line means the following. If we transform $Y_\mu$ where $\mu \in \mathcal{P}[\alpha, \beta, \gamma]$, by the involution $(i,j,k) \leftrightarrow (j,i,k)$, we obtain $Y_{\tilde{\mu}}$ where $\tilde{\mu} \in \mathcal{P}[\beta, \alpha, \gamma']$. Set $\lambda = \lambda_{\mu}$, and $\tilde{\lambda} = \lambda_{\tilde{\mu}}$. Then, we have the equality

$$\psi_\lambda(u/z) |_{(q_1,q_2,q_3) \rightarrow (q_3,q_2,q_1)} = \psi_{\tilde{\lambda}}(u/z).$$

Similarly, from the involution $(i,j,k) \leftrightarrow (j,i,k)$, we have

$$\psi_\lambda(u/z) |_{(q_1,q_2,q_3) \rightarrow (q_1,q_3,q_2)} = \psi_{\tilde{\lambda}}(u/z),$$

where $\tilde{\lambda} = \lambda_{\tilde{\mu}}$ and $\tilde{\mu} \in \mathcal{P}[\gamma, \beta', \alpha]$.

Define a plane partition $\omega = \{\omega^{(k)}\}_{k \geq 1}$ with the boundary condition $(\alpha, \beta, \gamma)$ by

\begin{align}
\omega^{(k)}_i &= \begin{cases} 
\infty & \text{if } i \leq \beta_k; \\
\max(\gamma_i, \alpha_k) & \text{otherwise}.
\end{cases} \\
\omega^{(k)}_i &= \begin{cases} 
\omega^{(k)}_{i+1} & \text{if } \omega^{(k)}_i = \alpha_k; \\
\omega^{(k+1)}_i & \text{if } \omega^{(k)}_i = \gamma_i.
\end{cases}
\end{align}

(3.23)

Then we have

$$\omega^{(k)}_i = \begin{cases} 
\omega^{(k)}_{i+1} & \text{if } \omega^{(k)}_i = \alpha_k; \\
\omega^{(k+1)}_i & \text{if } \omega^{(k)}_i = \gamma_i.
\end{cases}$$

Among all $\mu \in \mathcal{P}[\alpha, \beta, \gamma]$, $Y_\omega \subset Y_\mu$ is the minimum. There is no convex corner in $Y_\omega$. See Figure 3.2. The set of partitions $\lambda = \lambda_\omega$ associated with $\omega$ is given by

$$\lambda^{(k)}_i = \max(\gamma_{i+\beta_k}, \alpha_k) - \alpha_k.$$
Let us compute a few examples of the eigenvalues \((3.19)\) for \(\lambda = \lambda_\omega\).

\[
\begin{array}{ccc}
\alpha & \beta & \gamma \\
0 & 0 & 0 \\
\{1\} & 0 & 0 \\
\{2\} & 0 & 0 \\
\{1\} \{1\} & 0 & 0 \\
\{1\} \{1\} \{1\} & (1-Ku/z)(1-q_1q_2u/z) & (1-Ku/z)(1-q_1q_2u/z) \\
& (1-Ku/z)(1-q_1q_2u/z) & (1-Ku/z)(1-q_1q_2u/z) \\
& (1-Ku/z)(1-q_1q_2u/z)(1-q_1q_3u/z) & (1-Ku/z)(1-q_1q_2u/z)(1-q_2q_3u/z) \\
& (1-Ku/z)(1-q_1q_2q_3u/z)^2 & (1-Ku/z)(1-q_1q_2q_3u/z)
\end{array}
\]

Finally, we give the action of \(f(z)\) on \(M_{\alpha,\beta,\gamma}(u,K)\):

\[
f(z)|\lambda\rangle = \sum_{(i,j,k) \in CV(Y_\mu)} \psi_{\lambda',i,j,k}(u/z) \frac{q_1}{1-q_1} \delta(q_1^{i}q_2^{j}q_3^{k}u/z)|\lambda - 1^{(k)}_{i-j-k}\rangle,
\]

\[
\psi_{\lambda',i,j,k} = \psi^{(k+1)}_{\lambda}(q_1^{-i}q_2^{-j}q_3^{-k}),
\]

\[
(3.24) \quad \psi^{(k)}_{\lambda}(u/z) = \lim_{N \to \infty} \prod_{m=k}^{N_N} \psi_{\lambda(m)}(q_2^{m-1}u/z) \cdot \frac{1 - Ku/z}{1-q_1^{i}q_2^{j}q_3^{k}u/z} \cdot \frac{1 - q_1^{i}q_2^{j}q_3^{k}u/z}{1-q_1^{i+1}q_2^{j}q_3^{k}u/z}.
\]

We do not repeat the argument which assures the well-definedness of this action. However, we note that the multiplication of the last infinite product is in fact a finite product corresponding to the convex corners of \(\gamma\) and it removes the extra poles and zeros in the finite tensor product which do not occur in the semi-infinite product. It is also important to notice that

\[
(3.25) \quad \psi_{\lambda}(u/z) = \psi^{(1)}_{\lambda}(u/z),
\]

where the left hand side is given by \((3.19)\) and the right hand side by \((3.24)\). From this the equality \((3.20)\) for non-trivial \(\gamma\) follows.

We summarize the result in this and the previous subsections as

**Theorem 3.1.** There is an action of the algebra \(E\) on \(M_{\alpha,\beta,\gamma}(u,K)\) induced from the infinite tensor product \((3.16)\). This is an irreducible, quasifinite and tame representation. The level is \((1,K)\) with a generic parameter \(K\). The lowest weight is given by \((3.19)\), (see also \((3.27)\) below) with \(\mu = \omega\) given by \((3.23)\). The representations thus obtained admit the \(S_3\) symmetry \((3.21), (3.22)\).

### 3.3. Shell formula for the action of \(\psi^{\pm}(z)\).

For the Fock representation the rational function \(\psi_{\lambda}(u/z)\) is factorized into the contribution from the concave and convex corners. Let us derive the three dimensional version of this statement for the Macmahon representations. It follows from \((3.20)\).

Define an auxiliary object

\[
\Psi_{\lambda}(u/z) = \prod_{(i,j,k) \in Y_\mu} \psi_{i,j,k}(u/z),
\]
where we consider $q_1, q_2, q_3$ as free, i.e., we do not require $q_1 q_2 q_3 = 1$. Once we obtain $\Psi_\lambda(u/z)$ as a finite product we get $\psi_\lambda(u/z)$ by

$$\psi_\lambda(u/z) = \frac{1 - Ku/z}{1 - u/z} \Psi_\lambda(u/z),$$

where $q_1 q_2 q_3 = 1$ is imposed. Let us define the shell of $Y_\mu$ by

$$S_\mu = \{(i, j, k) \in \mathbb{Z}^3 | i, j, k \geq 0,\}
\{(i + 1, j + 1, k + 1) \notin Y_\mu,\}
\{(i, j, k), (i + 1, j, k), (i, j + 1, k), (i, j, k + 1),\}
\{(i + 1, j + 1, k), (i + 1, j, k + 1), (i, j + 1, k + 1)\} \cap Y_\mu \neq \emptyset}.\}

For example

$$Y_\mu \quad S_\mu
\{\} \quad \{\}
\{(1, 2, 1)\} \quad \{(0, 0, 1), (0, 1, 0), (1, 0, 0), (0, 1, 1), (1, 0, 1), (1, 1, 0), (1, 1, 1)\}.$$

The rational function $\Psi_\lambda(u/z)$ has neither a pole nor a zero at $1 - q_1^j q_2^k q_3^i u/z = 0$ unless $(i, j, k) \in S_\mu$. It is also worth noting that for a fixed $(i, j, k)$ the intersection of $\{(i + n, j + n, k + n) | n \in \mathbb{Z}\}$ with $S_\mu$ is at most one point.

We classify the points in the shell $S_\mu$ into $S_\mu^{(n)} (-1 \leq n \leq 2)$ where

$$S_\mu^{(n)} = \{(i, j, k) \in S_\mu | \Psi_\lambda(u/z) has a zero of order n at 1 - q_1^j q_2^k q_3^i u/z = 0\}.$$

For $(i, j, k) \in S_\mu$ and $\varepsilon_1, \varepsilon_2, \varepsilon_3 = 0, 1$, we define

$$A_{i,j,k}(\varepsilon_1, \varepsilon_2, \varepsilon_3) = \begin{cases} 1 & \text{if } (i + \varepsilon_1, j + \varepsilon_2, k + \varepsilon_3) \in Y_\mu; \\ 0 & \text{otherwise}. \end{cases}$$

According as the set of values given in the form of two matrices

$$T_{i,j,k} = \begin{pmatrix} A_{i,j,k}(0, 1, 0) & A_{i,j,k}(1, 1, 0) \\ A_{i,j,k}(0, 1, 1) & A_{i,j,k}(1, 1, 1) \end{pmatrix},$$

$$B_{i,j,k} = \begin{pmatrix} A_{i,j,k}(0, 0, 0) & A_{i,j,k}(1, 0, 0) \\ A_{i,j,k}(0, 0, 1) & A_{i,j,k}(1, 0, 1) \end{pmatrix},$$

the order of zero at $1 - q_1^j q_2^k q_3^i u/z = 0$ of the rational function $\Psi_\lambda(u/z)$ is determined:

$$T_{i,j,k} \quad \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$$

$$B_{i,j,k} \quad \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$$

order of zero $-1 \quad 1 \quad 1 \quad 1 \quad 2$
The cases not listed in this table are neither poles nor zeros.

For any $\alpha, \beta, \gamma$ and $\mu \in \mathcal{P}[\alpha, \beta, \gamma]$ the union of $S^{(a)}_{\mu}$ ($a = -1, 1, 2$) is finite. Thus, the formula (3.26) becomes a finite product

$$\psi_{\lambda}(u/z) = (1 - Ku/z) \prod_{a=-1,1,2} \prod_{(i,j,k) \in S^{(a)}_{\mu}} (1 - q_i^a q_j^b q_k^c u/z)^a.$$  

3.4. Resonance and submodules. Now we utilize the factor $1 - Ku/z$ (see (3.24)) in the action of $f(z)$. Consider the specialization of the level

$$K = q_1^a q_2^b q_3^c = q_2^m q_3^n.$$  

Note that

$$m = c - b, n = a - b.$$  

At this point, the $\mathcal{E}$-module $M_{\alpha,\beta,\gamma}(u, K)$ is reducible. We denote it by $M^{m,n}_{\alpha,\beta,\gamma}(u)$. In fact, the module $M^{m,n}_{\alpha,\beta,\gamma}(u)$ contains an infinite sequence of submodules. Let us describe these submodules.

Let $\omega$ be the minimum configuration in $\mathcal{P}[\alpha, \beta, \gamma]$ (see (3.23)). Recall $q_1 q_2 q_3 = 1$. For each triple $(\alpha, \beta, \gamma)$ and $K$ of the form (3.28), we determine a unique $(a, b, c)$ with $a, b, c \geq 1$, satisfying (3.28) and

$$(a, b, c) \not\in Y_{\omega}, \quad (a - 1, b - 1, c - 1) \in Y_{\omega}.$$  

The action of $f(z)$ on $M^{m,n}_{\alpha,\beta,\gamma}(u)$ is such that removing a box at

$$(i, j, k) = (a + t, b + t, c + t) \quad (t \in \mathbb{Z}_{\geq 0})$$

is prohibited. This is because the coefficient of $|\lambda - 1^{(k)}_{i}|$ in $f(z)|\lambda|$ where $(i, j, k) \in CV(Y_{\mu})$ ($\lambda = \lambda_{\mu}$ and $\lambda^{(k)}_{i} = j$, contains the factor $(1 - Ku/z)\delta(q_i^a q_j^b q_k^c u/z)$, but does not contain poles at $q_i^a q_j^b q_k^c u/z = 1$. The poles may appear only if for some $s \geq 0$, $(i + 1 + s, j + s, k + s) \in Y_{\mu}$ or $(i + s, j + 1 + s, k + s) \in Y_{\mu}$ or $(i + s, j + s, k + 1 + s) \in Y_{\mu}$. However, this is not possible if $(i, j, k) \in CV(Y_{\mu})$. Therefore if the position of the box is of the form (3.29) the coefficient vanishes when $K$ is specialized as (3.28).

The lowest weight vector $|\lambda_{\omega}|$ is still cyclic in $M^{m,n}_{\alpha,\beta,\gamma}(u)$. There is no $K$ in the action of $e(z)$. The above consideration tells us that once a box is added at $(i, j, k)$ of the
form (3.29), one cannot remove it by the action of \( f(z) \). In fact, we will show that the module \( M_{m,n}^{\alpha,\beta,\gamma}(u) \) contains an infinite series of singular vectors.

Define \( \omega_t = (\omega_t^{(1)}, \omega_t^{(2)}, ...) \in P[\alpha, \beta, \gamma] \) \((t \in \mathbb{Z}_{\geq 0})\) by

\[
\omega_t^{(k)}_{i,j} = \begin{cases} 
\max(b + t - 1, \omega_i^{(k)}) & \text{if } i \leq a + t - 1 \text{ and } k \leq c + t - 1; \\
\omega_i^{(k)} & \text{otherwise.}
\end{cases}
\]

This is the minimal configuration among \( \mu \in P[\alpha, \beta, \gamma] \) such that \((a + t - 1, b + t - 1, c + t - 1) \in Y_{\mu}\). Note that \( \omega_0 = \omega \) and 

\[
Y_{\omega_0} \subset Y_{\omega_1} \subset Y_{\omega_2} \subset \cdots
\]

For \( t \geq 1 \) we have

\[
CV(\omega_t) = \{(a + t - 1, b + t - 1, c + t - 1)\}.
\]

Set

\[
M_{m,n}^{\alpha,\beta,\gamma}(u) = \bigoplus_{Y_{\mu} \supset Y_{\omega_t}} \mathbb{C}|\lambda_{\mu}\rangle.
\]

This is a submodule of \( M_{m,n}^{\alpha,\beta,\gamma}(u) \) with the lowest vector \(|\lambda_{\omega_t}\rangle\) satisfying

\[
f(z)|\lambda_{\omega_t}\rangle = 0.
\]

We have the inclusions

\[
M_{m,n}^{\alpha,\beta,\gamma}(u) = M_{m,n,0}^{\alpha,\beta,\gamma}(u) \supset M_{m,n,1}^{\alpha,\beta,\gamma}(u) \supset M_{m,n,2}^{\alpha,\beta,\gamma}(u) \supset \cdots.
\]

In this subsection we study the quotient

\[
\mathcal{N}_{m,n}^{\alpha,\beta,\gamma}(u) = M_{m,n}^{\alpha,\beta,\gamma}(u)/M_{m,n,1}^{\alpha,\beta,\gamma}(u).
\]

As we explained \((a, b, c)\) is uniquely determined once \((a, b, c)\) and \(m, n\) are fixed.

**Proposition 3.2.** The module \( \mathcal{N}_{m,n}^{\alpha,\beta,\gamma}(u) \) is an irreducible, quasifinite, tame \( \mathcal{E} \)-module of level \( K = q_2^m q_3^n \). It has a basis parameterized by the set

\[
P_{\alpha,\beta,\gamma}^{m,n} = \{ \mu \in P_{\alpha,\beta,\gamma}, (a, b, c) \not\in Y_{\mu} \}.
\]

The lowest weight is given by (3.19), or (3.27), with \( \mu = \omega \) given by (3.23).

### 3.5. The case of tensor product of the Fock spaces.

Set

\[
\overline{Y}_{\omega} = \{(i, j, k) \in \mathbb{Z}^3 \mid i \leq 0 \text{ or } j \leq 0 \text{ or } k \leq 0\} \sqcup Y_{\omega}.
\]

In this subsection we consider the case where the following condition is satisfied for some \(a, b, c\):

\[
(a - 1, b - 1, s), (a - 1, s, c - 1), (s, b - 1, c - 1) \in \overline{Y}_{\omega}, \quad (s \in \mathbb{Z}_{>0}).
\]
Then, each of the Young diagrams $Y_\alpha, Y_\beta, Y_\gamma$ contains the following rectangle,

$$
Y_\alpha \supset C_\alpha = \{(k, j) \mid 1 \leq k \leq c - 1, 1 \leq j \leq b - 1\}, \\
Y_\beta \supset C_\beta = \{(k, i) \mid 1 \leq k \leq c - 1, 1 \leq i \leq a - 1\}, \\
Y_\gamma \supset C_\gamma = \{(i, j) \mid 1 \leq i \leq a - 1, 1 \leq j \leq b - 1\},
$$

and each of $\alpha, \beta, \gamma$ splits into three parts: core, arms and legs. We define partitions which determine arms and legs of $\alpha, \beta, \gamma$ as follows:

$$
\alpha_{\text{arms}} = (\alpha_1 - b + 1, \ldots, \alpha_{c-1} - b + 1), \\
\alpha_{\text{legs}} = (\alpha'_1 - c + 1, \ldots, \alpha'_{b-1} - c + 1), \\
\beta_{\text{arms}} = (\beta_1 - a + 1, \ldots, \beta_{c-1} - a + 1), \\
\beta_{\text{legs}} = (\beta'_1 - c + 1, \ldots, \beta'_{a-1} - c + 1), \\
\gamma_{\text{arms}} = (\gamma_1 - b + 1, \ldots, \gamma_{a-1} - b + 1), \\
\gamma_{\text{legs}} = (\gamma'_1 - a + 1, \ldots, \gamma'_{b-1} - a + 1).
$$
Let us consider a few examples. The simplest case is \((a, b, c) = (1, 1, 1)\) and \((\alpha, \beta, \gamma) = (\emptyset, \emptyset, \emptyset)\). In this case \(N^{0,0}_{\emptyset,\emptyset,\emptyset}(u)\) is the trivial 1 dimensional module, \(N^{0,0}_{\emptyset,\emptyset,\emptyset}(u) \simeq \mathbb{C}, \ K = 1, \ \psi_{\lambda_\omega}(u/z) = 1\).

We have other specializations for the same \((\alpha, \beta, \gamma) = (\emptyset, \emptyset, \emptyset)\):

\[N^{r,0}_{\emptyset,\emptyset,\emptyset}(u) \simeq M^{2,(r)}_{0,0}(u) \subset F_2(q_3u) \otimes F_2(q_2u) \otimes \cdots \otimes F_2(q_2^{-1}u),\]

\[K = q_2^r, \ \psi_{\lambda_\omega}(u/z) = \frac{1 - q_2^r u/z}{1 - u/z}, \ (a, b, c) = (1, 1, r + 1) \ (r \geq 1).\]

If \((\alpha, \beta, \gamma) = (\emptyset, (1), \emptyset)\) then we have the following cases; we consider the cases up to the symmetry.

\[N^{r,0}_{\emptyset,(1),\emptyset}(u) \simeq M^{2,(r)}_{0,(1,0,\ldots,0)}(u) \subset F_2(q_3u) \otimes F_2(q_2u) \otimes \cdots \otimes F_2(q_2^{-1}u),\]

\[K = q_2^r, \ \psi_{\lambda_\omega}(u/z) = \frac{1 - q_2^r u/z}{1 - q_2 u/z} \cdot \frac{1 - q_2 q_3 u/z}{1 - q_3 u/z}, \ (a, b, c) = (1, 1, r + 1) \ (r \geq 1);\]

\[N^{1,1}_{\emptyset,(1),\emptyset}(u) \simeq F_2(q_3u) \otimes F_3(q_2u),\]

\[K = q_2 q_3, \ \psi_{\lambda_\omega}(u/z) = \frac{(1 - q_2 q_3 u/z)^2}{(1 - q_2 u/z)(1 - q_3 u/z)}, \ (a, b, c) = (2, 1, 2).\]

If \((\alpha, \beta, \gamma) = ((1), (1), \emptyset)\) then we have the following cases up to the symmetry.

\[N^{r,0}_{(1),(1),\emptyset}(u) \simeq M^{(r)}_{(1,0,\ldots,0),(1,0,\ldots,0)}(u) \subset F_2(q_1 q_3 u) \otimes F_2(q_2 u) \otimes \cdots \otimes F_2(q_2^{-1}u),\]

\[K = q_2^r, \ \psi_{\lambda_\omega}(u/z) = \frac{1 - q_2^r u/z}{1 - q_2 u/z} \cdot \frac{1 - q_1 q_2 q_3 u/z}{1 - q_1 q_3 u/z}, \ (a, b, c) = (1, 1, r + 1) \ (r \geq 1);\]

\[N^{1,1}_{(1),(1),\emptyset}(u) \simeq F_2(q_1 q_3 u) \otimes F_3(q_2 u),\]

\[K = q_2 q_3, \ \psi_{\lambda_\omega}(u/z) = \frac{1 - q_2 q_3 u/z}{1 - q_2 u/z} \cdot \frac{1 - q_1 q_2 q_3 u/z}{1 - q_1 q_3 u/z}, \ (a, b, c) = (2, 1, 2).\]
Finally we give the general statement:

**Proposition 3.3.** Under condition [3.30], we have

\[ N_{\alpha, \beta, \gamma}^{-b, a, -b} (u) \simeq M_{\alpha_{\text{arms}}, \beta_{\text{arms}}}^{2,(c-1)} (q_1^{b-1}q_3^{-c}u) \otimes M_{\beta_{\text{legs}}, \gamma_{\text{arms}}}^{3,(a-1)} (q_1^{b-1}q_2^{-c}u) \otimes M_{\alpha_{\text{legs}}, \beta_{\text{legs}}}^{1,(b-1)} (q_2^{-c}q_3^{a-1}u). \]

4. **gl**\(_\infty\)-modules and Gelfand-Zetlin basis

4.1. **Algebra gl**\(_\infty\). In this section, we introduce a family of **gl**\(_\infty\)-modules which arises as a limit of **E**-modules considered in the previous section. We fix the notation as follows. By definition, **gl**\(_\infty\) is the complex Lie algebra with basis \{\(E_{i,j}\)\}_{i,j \in \mathbb{Z}} and the commutation relations [\(E_{i,j}, E_{k,l}\) = \(\delta_{j,k} E_{i,l} - \delta_{i,j} E_{k,l}\). We set

\[ E_i = E_{i,i+1}, \quad F_i = E_{i+1,i}, \quad H_i = E_{i,i} - E_{i+1,i+1}. \]

We shall consider also the following Lie subalgebras of **gl**\(_\infty\),

\[ \mathfrak{gl}_{\infty}/2^+ = \text{span} \{E_{i,j} \mid i, j \geq 1\}, \quad \mathfrak{gl}_{\infty}/2^- = \text{span} \{E_{i,j} \mid i, j \leq 0\}, \]

\[ \mathfrak{g}_{r,s} = \text{span} \{E_{i,j} \mid r \leq i, j \leq s\} \simeq \mathfrak{gl}_{s-r+1}; \]

where \(r, s \in \mathbb{Z}, r < s\).

For a sequence of complex numbers \(\theta = (\theta_i)_{i \in \mathbb{Z}}\), we denote by \(W_\theta\) the unique irreducible **gl**\(_\infty\)-module generated by a vector \(v\) such that

\[ E_{i,j} v = 0 \quad (i > j), \quad E_{i,i} v = \theta_i v \quad (i \in \mathbb{Z}). \]

The \(\theta\) is called the lowest weight and the vector \(v\) is called the lowest weight vector.

4.2. **Gelfand-Zetlin basis.** Let \(N\) be a positive integer. We recall the Gelfand-Zetlin (GZ) basis for irreducible representations of \(\mathfrak{g}_{-N+1,0} \simeq \mathfrak{gl}_N\).

A Gelfand-Zetlin (GZ) pattern for **gl**\(_N\) is an array of integers

\[
\mu = \begin{pmatrix}
\mu_1^{(1)} \\
\mu_2^{(1)} & \mu_2^{(2)} \\
\vdots & \ddots & \ddots \\
\mu_1^{(N)} & \mu_2^{(N)} & \cdots & \mu_N^{(N)}
\end{pmatrix},
\]

such that

\[
\mu_j^{(i)} \geq \mu_j^{(i+1)}, \quad \mu_j^{(i)} \geq \mu_j^{(i+1)} \quad \text{for all } i, j.
\]
Quite generally, we shall denote by \( \mu \pm 1_j^{(i)} \) the GZ pattern obtained by changing \( \mu_j^{(i)} \) to \( \mu_j^{(i)} \pm 1 \) while keeping the rest of the entries unchanged.

Given a set of integers \( \eta = (\eta_1, \cdots, \eta_N), \eta_1 \geq \cdots \geq \eta_N, \) let \( L_\eta \) be the vector space with basis \( \{|\mu\rangle_{(N)}\}, \) where \( \mu \) runs over all GZ patterns for \( \mathfrak{gl}_N \) satisfying

\[
\mu_i^{(i)} = \eta_i \quad (i = 1, \cdots, N).
\]

We set \( |\mu\rangle_{(N)} = 0 \) if the condition \( \boxed{4.12} \) is violated.

Notation being as above, the following formulas define an action of \( \mathfrak{gl}_{-N+1,0} \) on \( L_0; \)

\[
E_{-i,i+1}|\mu\rangle_{(N)} = \sum_{j=1}^{N-i} |\mu + 1_j^{(i)}\rangle_{(N)} \prod_{k=1}^{N-i+1} (\ell_j^{(i,j)} - \ell_k^{(i+1,k)}) \prod_{1 \leq k(\neq j) \leq N-i} (\ell_j^{(i,j)} - \ell_k^{(i+k)}), 
\]

\[
(1 \leq i \leq N - 1),
\]

\[
E_{-i+1,-i}|\mu\rangle_{(N)} = -\sum_{j=1}^{N-i} |\mu - 1_j^{(i,j)}\rangle_{(N)} \prod_{k=1}^{N-i-1} (\ell_j^{(i,j)} - \ell_k^{(i+1,k)}) \prod_{1 \leq k(\neq j) \leq N-i} (\ell_j^{(i,j)} - \ell_k^{(i+k)}), 
\]

\[
(1 \leq i \leq N - 1),
\]

\[
E_{-i,i}|\mu\rangle_{(N)} = \left( \sum_{j=1}^{N-i} \mu_j^{(i,j)} - \sum_{j=1}^{N-i-1} \mu_j^{(i+1,j)} \right) |\mu\rangle_{(N)} \quad (0 \leq i \leq N - 1),
\]

where

\[
\ell_j^{(i,j)} = \mu_j^{(i,j)} - j + 1.
\]

The representation \( L_\eta \) is irreducible. The highest weight is \( (\theta_{-N+1}, \theta_{-N+2}, \cdots, \theta_0) = (\eta_1, \eta_2, \cdots, \eta_N) \) and the lowest weight is \( (\eta_N, \eta_{N-1}, \cdots, \eta_1) \), the corresponding highest (resp. lowest) weight vector being given by the GZ pattern with \( \mu_j^{(i)} = \eta_j \) (resp. \( \mu_j^{(i)} = \eta_i \)) for all \( i, j \).

Now we extend this construction to the case of \( \mathfrak{gl}_{\infty/2} \). In the following we fix a positive integer \( n \). Consider an infinite GZ pattern of width \( n \),

\[
\mu = \begin{pmatrix}
\mu_1^{(1)} & \cdots & \mu_1^{(n)} \\
\vdots & \ddots & \vdots \\
\mu_1^{(n+1)} & \cdots & \mu_1^{(n+2)} \\
\mu_1^{(n+2)} & \cdots & \mu_1^{(n+3)} \\
& \ddots & \vdots \\
& & \ddots & \vdots \\
& & & \ddots & \vdots \\
& & & & \ddots & \ddots & \ddots \\
& & & & & \ddots & \ddots & \ddots \\
& & & & & & \ddots & \ddots & \ddots \\
& & & & & & & \ddots & \ddots & \ddots \\
\end{pmatrix}
\]

that is, an array of integers \( \mu = (\mu_j^{(i)})_{i,j \geq 1} \) satisfying \( \boxed{4.12} \) and

\[
\mu_j^{(i)} = 0 \quad \text{if} \ j > n.
\]
Let \( \eta = (\eta_1, \ldots, \eta_n) \), \( \gamma = (\gamma_1, \ldots, \gamma_n) \) be partitions such that \( \eta_i \geq \gamma_i \), \( i = 1, \ldots, n \). Let \( Y^-_{\eta, \gamma} \) be the vector space with basis \( \{ |\mu\rangle \} \), where \( \mu = (\mu_j^{(i)})_{i \geq j \geq 1} \) runs over GZ patterns (4.7) of width \( n \) satisfying the conditions
\[
\begin{align*}
\mu_j^{(i)} &= \eta_i \quad (i = 1, \ldots, n), \\
\mu_j^{(i)} &= \gamma_j \quad (i \gg 1, \ j = 1, \ldots, n).
\end{align*}
\]

**Proposition 4.1.** The following formulas define a representation of \( \mathfrak{gl}^-_{\infty/2} \) on \( Y^-_{\eta, \gamma} \):
\[
\begin{align*}
E_{-i,-i+1}|\mu\rangle &= \sum_{j=1}^{n} |\mu + 1_j^{(i+j)}\rangle c_{i+j,j}^+ (\mu), \\
E_{-i+1,-i}|\mu\rangle &= \sum_{j=1}^{n} |\mu - 1_j^{(i+j)}\rangle c_{i+j,j}^- (\mu) \quad (i \geq 1),
\end{align*}
\]

(4.11) \( E_{-i,-i}|\mu\rangle = \sum_{j=1}^{n} (\mu_j^{(i+j)} - \mu_j^{(i+1+j)}) |\mu\rangle \quad (i \geq 0),
\]

(4.12)

where
\[
c_{i+j,j}^\pm (\mu) = \pm \prod_{k=1}^{n} (\ell_j^{(i+j)} - \ell_k^{(i+1+k)}) \prod_{1 \leq k \neq j \leq n} (\ell_j^{(i+j)} - \ell_k^{(i+k)}),
\]
and \( \ell_j^{(i+j)} \) is defined by (4.6).

**Proof.** Clearly the operators (4.11), (4.12) preserve the space \( Y^-_{\eta, \gamma} \). Given \( i \), take \( N \) so that \( N > n + i + 1 \). Then, under the condition (4.8), the formulas (4.11), (4.12) after making a base change of the form \( |\mu\rangle = f(\mu)|\mu\rangle_{(N)} \). Consider (4.3). The range of summation \( 1 \leq j \leq N - i \) reduces to that in (4.11) \( 1 \leq j \leq n \) because \( \mu_j^{(i+j)} = 0 \) is unchanged. We see also that the coefficient \( f(\mu) \) is to satisfy \( f(\mu + 1_j^{(i+j)}) = f(\mu)(\ell_j^{(i+j)} + N - i) \), which can be solved easily. Hence the commutation relations of the generators are obviously satisfied. \( \square \)

**Proposition 4.2.** If \( \gamma_1 = \cdots = \gamma_n \), then \( Y^-_{\eta, \gamma} \) is an irreducible \( \mathfrak{gl}^-_{\infty/2} \)-module.

**Proof.** For \( N > n \), consider the subspace of \( Y^-_{\eta, \gamma} \)
\[
W_N = \text{span}\{ |\mu\rangle \in Y^-_{\eta, \gamma} \mid \mu_j^{(i)} = \gamma_j \quad (i > N, \ j = 1, \ldots, n) \}.
\]
Because of the restriction \( \gamma_1 = \cdots = \gamma_n \), the subspace \( W_N \) is invariant under the action of \( \mathfrak{g}_{-N+1,0} \). The vector \( |\mu\rangle \in W_N \) defined by \( \mu_j^{(i)} = \eta_i \ (1 \leq i \leq n) \) and \( \mu_j^{(i)} = \gamma_1 \ (i > n) \) is a \( \mathfrak{g}_{-N+1,0} \)-singular vector with the lowest weight \( (\theta_{-N+1}, \ldots, \theta_0) = (0, \cdots, 0, \eta_n - \gamma_1, \ldots, \eta_1 - \gamma_1) \). Moreover \( W_N \) has the same dimension as that of the irreducible lowest weight module of the same lowest weight. To see this one can rearrange the table as the usual GT pattern:
Proposition 4.3. The following formulas define a representation of $\mathfrak{gl}_1$:

\[
\eta_1 \cdots \eta_n \quad \gamma_1 \cdots \gamma_1 \\
\mu_1^{(2)} \cdots \mu_n^{(n+1)} \cdots \\
\vdots \\
\mu_n^{(N)} \gamma_1 \\
\vdots \\
\mu_1^{(N)}
\]

Hence $W_N$ is $\mathfrak{g}_{-N+1,0}$-irreducible.

By the definition we have $\mathfrak{y}_{\eta,\gamma}^- = \cup_{N>n} W_N$. The irreducibility follows from this. \qed

By applying the involutive automorphism $\sigma(E_{i,j}) = -E_{1-j,1-i}$ of $\mathfrak{gl}_\infty$, we obtain representations of the subalgebra $\mathfrak{gl}_\infty^{\ast/2} = \sigma(\mathfrak{gl}_\infty^{\ast/2})$. For later reference let us write the relevant formulas for $\mathfrak{gl}_\infty^{\ast/2}$.

For $\mathfrak{gl}_\infty^{\ast/2}$, we use the transposed GZ patterns $\mu = (\mu_j^{(i)})_{1 \leq i \leq j}$ of depth $n$,

\[
\mu = \\
\mu_1^{(1)} \cdots \mu_n^{(1)} \mu_{n+1}^{(1)} \cdots \\
\vdots \\
\mu_n^{(n)} \mu_{n+1}^{(n)} \cdots \\
0 \quad 0 \cdots \\
0 \quad 0 \\
(4.13)
\]

Let $\eta = (\eta_1, \cdots, \eta_n)$, $\alpha = (\alpha_1, \cdots, \alpha_n)$ be partitions such that $\eta_i \geq \alpha_i$, $i = 1, \cdots, n$. We set $\alpha_i = 0$ for $i > n$. Let $\mathfrak{y}_{\eta,\alpha}^+$ be the vector space with basis $\{|\mu\rangle\}$ where the $\mu = (\mu_j^{(i)})_{1 \leq i \leq j}$ satisfy $\mu_j^{(i)} = 0$ if $i > n$ and

\[
\mu_i^{(i)} = \eta_i \quad (i = 1, \cdots, n), \\
\mu_j^{(i)} = \alpha_i \quad (i = 1, \cdots, n, j \gg 1).
\]

**Proposition 4.3.** The following formulas define a representation of $\mathfrak{gl}_\infty^{\ast/2}$ on $\mathfrak{y}_{\eta,\alpha}^+$:

\[
E_{i,i+1}|\mu\rangle = \sum_{j=1}^{n} |\mu + 1^{(j)}_{i+j}\rangle c^+_{j,i+j}(\mu), \quad E_{i+1,i}|\mu\rangle = \sum_{j=1}^{n} |\mu - 1^{(j)}_{i+j}\rangle c^-_{j,i+j}(\mu), \\
(4.14)
\]

\[
E_{i,i}|\mu\rangle = (\sum_{j=1}^{n} \mu_{i+j}^{(j)} - \sum_{j=1}^{n} \mu_{i+1+j}^{(j)} - n)|\mu\rangle, \\
(4.15)
\]

where $i \geq 1$, and

\[
c^+_{j,i+j}(\mu) = \frac{\prod_{k=1}^{n} (\gamma^{(j)}_{i+j} - \gamma^{(k)}_{i+1+k})}{\prod_{1 \leq k(\neq j) \leq n} (\gamma^{(j)}_{i+j} - \gamma^{(k)}_{i+k})}, \quad \gamma^{(j)}_{i+j} = \mu^{(j)}_{i+j} - j + 1.
\]
We note that it is always possible to twist a given representation by changing $E_{i,j}$ to $E_{i,j} + x\delta_{i,j} \cdot \text{id}$ for some $x \in \mathbb{C}$. Utilizing this freedom we have chosen $x = -n$ in (4.15), which will be convenient in the next subsection.

4.3. **Representations of $\mathfrak{gl}_\infty$.** In this subsection, we glue together the representations of $\mathfrak{gl}_{\infty/2}$ to define representations of the full algebra $\mathfrak{gl}_\infty$. Consider now a GZ pattern $\mu = (\mu_j^{(i)})_{i,j \geq 1}$ such that $\mu_j^{(i)} = 0$ if $i > n$ and $j > n$, that is

\[
\mu = \begin{pmatrix}
\mu_1^{(1)} & \cdots & \mu_n^{(1)} & \mu_{n+1}^{(1)} & \mu_{n+2}^{(1)} & \cdots \\
\vdots & \ddots & \vdots & \vdots & \vdots & \ddots \\
\mu_1^{(n)} & \cdots & \mu_n^{(n)} & \mu_{n+1}^{(n)} & \mu_{n+2}^{(n)} & \cdots \\
\mu_1^{(n+1)} & \cdots & \mu_n^{(n+1)} & 0 & 0 & \cdots \\
\mu_1^{(n+2)} & \cdots & \mu_n^{(n+2)} & 0 & 0 & \cdots \\
\vdots & \ddots & \vdots & \vdots & \vdots & \ddots 
\end{pmatrix}
\]

(4.16)

We say $\mu$ has a hook shape of width $n$. We assume further that

\[
\mu_j^{(i)} = \alpha_i \quad \text{for } i = 1, \ldots, n, j \gg 1,
\]

(4.17)

\[
\mu_j^{(i)} = \gamma_j \quad \text{for } j = 1, \ldots, n, i \gg 1.
\]

(4.18)

Let $\mathfrak{y}_{\alpha,\gamma}$ be the vector space with basis $\{|\mu\rangle\}$, where $\mu$ runs over hook-shape GZ patterns of width $n$, satisfying (4.17), (4.18).

**Proposition 4.4.** Define

\[
E_{0,1}|\mu\rangle = \sum_{j=1}^{n} |\mu + 1^{(j)}_j c_{j,j}^{+}(\mu)\rangle, \quad E_{1,0}|\mu\rangle = \sum_{j=1}^{n} |\mu - 1^{(j)}_j c_{j,j}^{-}(\mu)\rangle,
\]

(4.19)

\[
c_{j,j}^{+}(\mu) = \frac{1}{\prod_{k(\neq j)}(\ell_j^{(j)} - \ell_k^{(k)})}, \quad c_{j,j}^{-}(\mu) = -\frac{\prod_{k=1}^{n}(\ell_j^{(j)} - \ell_{k+1}^{(k+1)})(\ell_j^{(j)} - \ell_k^{(k)})}{\prod_{1 \leq k(\neq j) \leq n}(\ell_j^{(j)} - \ell_k^{(k)})},
\]

(4.20)

with

\[
\ell_k^{(k)} = \mu_k^{(k)} - k + 1.
\]

Then the above formulas along with (4.11), (4.12), (4.14), (4.15) give a representation of $\mathfrak{gl}_\infty$ on $\mathfrak{y}_{\alpha,\gamma}$.

**Proof.** The only non-trivial relations to check are $[E_i, F_j] = \delta_{i,j} H_i$ for $i = 0$ or $j = 0$, and the Serre relations involving them. First we check the former. For the relations...
\[ [E_0, F_i] = [E_i, F_0] = 0 \text{ to hold for } i \neq 0, \text{ we must have that} \]

\[
\frac{c_{j,j}^+(\mu + 1^{(k)})}{c_{j,j}^+(\mu)} = \frac{\ell_{k+1}^{(j)} - \ell_{j}^{(j)} + 1}{\ell_{k}^{(j)} - \ell_{j}^{(j)}} ,
\]

\[
\frac{c_{j,j}^+(\mu + 1^{(k+1)})}{c_{j,j}^+(\mu)} = \frac{\ell_{k+1}^{(j)} - \ell_{j}^{(j)} + 1}{\ell_{k}^{(j)} - \ell_{j}^{(j)}} ,
\]

and that \( c_{j,j}^+(\mu + 1^{(k)}) = c_{j,j}^+(\mu + 1^{(k+1)}) = c_{j,j}^+(\mu) \) in all other cases. These relations can be verified using (4.20).

A similar calculation shows that, in \([E_0, F_0]|\mu\), all terms cancel except

\[
\sum_{j=1}^{n} \left( c_{j,j}^-(\lambda)c_{j,j}^+(\mu + 1^{(j)}) - c_{j,j}^+(\mu)c_{j,j}^-(\mu - 1^{(j)}) \right)|\mu\).
\]

Substituting (4.20) we find that the coefficient in front of \(|\mu\rangle\) can be written as

\[
-\sum_{j=1}^{n} \left( \frac{\text{res}}{z=\ell_{j}^{(j)}} + \frac{\text{res}}{z=\ell_{j}^{(j)}-1} \right) \prod_{k=1}^{n} \frac{z - \ell_{k}^{(k+1)} + 1}{z - \ell_{k}^{(k)} + 1} - \ell_{k}^{(k)} - n .
\]

Comparing this with \( H_0 = E_{0,0} - E_{1,1} \) we obtain \([E_0, F_0]|\mu\rangle = H_0|\mu\rangle\).

Finally the Serre relations involving \( E_0 \) or \( F_0 \) can be checked by a tedious but straightforward calculation.  

\begin{proof}

Proposition 4.5. If \( \gamma_1 = \cdots = \gamma_n = c \), \( Y_{\alpha,\gamma} \) is an irreducible \( \mathfrak{gl}_\infty \)-module with the lowest weight vector \(|\mu^{(n)}(\alpha, c)\rangle\), where

\[
\mu^{(n)}(\alpha, c)_{j} = \begin{cases} 
\max(\alpha_i, c) & (1 \leq i, j \leq n); \\
\alpha_i & (1 \leq i \leq n, j > n); \\
c & (i > n, 1 \leq j \leq n).
\end{cases}
\]

If \( \alpha_1 \geq \cdots \geq \alpha_k \geq c \geq \alpha_{k+1} \geq \cdots \geq \alpha_n \), then \( Y_{\alpha,\gamma} \) is isomorphic to the irreducible lowest weight \( \mathfrak{gl}_\infty \)-module \( \mathcal{W}_{\theta^{(n)}(\alpha, c)} \), with the lowest weight

\begin{equation}
(4.21) \quad \theta^{(n)}(\alpha, c)_{i} = \begin{cases} 
0 & (i \leq -k); \\
\alpha_{-i+1} - c & (-k + 1 \leq i \leq 0); \\
\alpha_{n-i+1} - c - n & (1 \leq i \leq n - k); \\
-n & (i > n - k + 1).
\end{cases}
\end{equation}

\end{proof}

Proof. For \( N \geq 0 \), consider the Lie subalgebra \( \mathfrak{a}_N = \mathfrak{g}_{-\infty,N} \) spanned by \( E_{i,j} \) with \( i, j \leq N \). For each partition \( \eta = (\eta_1, \cdots, \eta_n) \) such that \( \eta_i \geq c \) if \( i + N \leq n \), we consider
the $\mathfrak{a}_N$-module $\mathfrak{X}_{N,\eta}$ given as follows. As a linear space, it is spanned by vectors $|\mu\rangle$ where $\mu = (\mu_j^{(i)})_{j\leq i+N}$ runs over GZ patterns of width $n$ such that

\[
\begin{align*}
\mu_{N+j}^{(i)} &= \eta_j \quad \text{for } j = 1, \ldots, n, \\
\mu_j^{(i)} &= c \quad \text{for } 1 \leq j \leq n, \ i \gg 1.
\end{align*}
\]

The action of the generators of $\mathfrak{a}_N$ is defined by the same formula as (1.3)–(1.15). We show that $\mathfrak{X}_{N,\eta}$ is an irreducible $\mathfrak{a}_N$-module for all $N$ and $\eta$. The irreducibility of $\mathfrak{Y}_{0,\gamma}$ is a simple consequence of this assertion.

For $N = 0$ we have $\mathfrak{a}_0 = \mathfrak{g}l^-_{\infty/2}$, and $\mathfrak{X}_{0,\eta} = \mathfrak{y}^-_{\eta,c}$ is an irreducible $\mathfrak{a}_0$-module by Proposition 4.2. Assume by induction that each $\mathfrak{X}_{N-1,\xi}$ is an $\mathfrak{a}_N$-irreducible for $N > 0$. By the definition, we have a direct sum decomposition into subspaces $\mathfrak{X}_{N,\eta} = \oplus \mathfrak{X}_{N-1,\xi}$, where $\xi_1 \geq \eta_1 \geq \xi_2 \geq \eta_2 \geq \cdots \geq \xi_n = \eta_n$. Each $\mathfrak{X}_{N-1,\xi}$ is an irreducible $\mathfrak{a}_N$-module, which are mutually inequivalent. Therefore, if $W \subset \mathfrak{X}_{N,\eta}$ is a non-zero $\mathfrak{a}_N$-submodule, then we have $W = \oplus \mathfrak{X}_{N-1,\xi}$ as $\mathfrak{a}_N$-module. If $W \cap \mathfrak{X}_{N-1,\xi} \neq 0$, then acting with $\mathfrak{E}_{N-1}, F_{N-1}$ we obtain that $W \cap \mathfrak{X}_{N-1,\xi} \neq 0$ for each $i$, as long as the condition $\eta_{i-1} \geq \xi_i \geq 1 \geq \eta_i$ is not violated. It is now easy to see that $W = \mathfrak{X}_{N,\eta}$. The proof is over.

Note that the lowest weight $\theta^{(n)}(\alpha, c)$ is increasing, i.e., “anti-dominant”, except

$$\theta^{(n)}(\alpha, c)_0 = \alpha_1 - c \geq 0 > -n \geq \theta^{(n)}(\alpha, c)_1 = \alpha_n - c - n.$$ 

4.4. Degeneration of the algebra $\mathfrak{E}$ and $\mathfrak{g}l_{\infty}$. In this subsection we examine the degeneration of the algebra $\mathfrak{E}$ and its modules when one of the parameters $q_i$ tends to 1.

In order to discuss the limit, it is convenient to introduce the elements $h_m \in \mathfrak{E}_{q_1,q_2,q_3}$ $(m \neq 0)$ via

$$\psi^\pm (z) = \psi^\pm_0 \exp \left( \mp \sum_{\pm m > 0} \frac{\gamma_m}{m} h_m z^{-m} \right), \quad \gamma_m = \prod_{i=1}^3 (1 - q_i^m).$$

We have $[h_m, e(z)] = z^m e(z), [h_m, f(z)] = -z^m f(z)$. Set further $\psi^+_0 = q_1^{\kappa^+}, \psi^-_0 = q_1^{\kappa^-}$. In the limit

$$q_1 \to 1, \quad q_2 \to q, \quad q_3 \to q^{-1} \quad (q \in \mathbb{C}^\times),$$

the algebra $\mathfrak{E}_{q_1,q_2,q_3}$ reduces to the Lie algebra $\mathfrak{g}l_{\infty}$ which has been mentioned already. The algebra $\mathfrak{g}l_{q,\kappa,0}$ is the associative algebra (viewed as a Lie algebra) generated by $Z^\pm, D^\pm$ with $DZ = qZD$, extended by a central element $\kappa$:

$$[Z^{i_1} D^{j_1}, Z^{i_2} D^{j_2}] = (q^{i_1 i_2} - q^{-i_1 i_2}) Z^{i_1 + i_2} D^{j_1 + j_2} + i_1 q^{-i_1 j_1} \delta_{i_1 + i_2, 0} \delta_{j_1 + j_2, 0} \cdot \kappa.$$ 

Writing the limit of the generators $e_m, f_m, h_m$ with bars, we have the identification

\[
\begin{align*}
(1 - q) \bar{e}_m &= D^m Z, \quad (1 - q^{-1}) \bar{f}_m = Z^{-1} D^m, \\
(1 - q^{-m}) \bar{h}_m &= D^m \quad (m \neq 0), \quad \kappa_+ - \kappa_- = \kappa.
\end{align*}
\]
Let $\mathfrak{gl}_{\infty,\kappa}$ be the Lie algebra defined by the symbols $E_{i,j}$ and a central element $\kappa$, with relations

$$\mathfrak{gl}_{\infty,\kappa} = \left\{ \sum_{i,j \in \mathbb{Z}} a_{i,j} : E_{i,j} \middle| \exists N > 0, \ a_{i,j} = 0 \text{ for } |i - j| > N \right\} \oplus \mathbb{C}\kappa,$$

$$\left[ \sum_{i,j} a_{i,j} : E_{i,j} ; \sum_{k,l} b_{k,l} : E_{k,l} \right] = \sum_k \left( \sum_{i,k} a_{i,k} b_{k,j} - \sum_{k} b_{i,k} a_{k,j} \right) : E_{i,j} : + \left( \sum_{i \leq 0 < j} a_{i,j} b_{j,i} - \sum_{i > 0 \geq j} a_{i,j} b_{j,i} \right) \kappa.$$

It is straightforward to verify that the map

$$D^m : E_{i,i} : u^m q^{-im}, \quad Z \mapsto E_{i+1,i} : u^m q^{-im},$$

$$D^m : E_{i,i} : u^m q^{-im} + \frac{u^m}{1 - q^m} \kappa \quad (m \neq 0), \quad \kappa \mapsto \kappa$$

gives an embedding of Lie algebras

$$\iota_u : \mathcal{Y}_{q,\kappa} \longrightarrow \mathfrak{gl}_{\infty,\kappa}.$$

Here $u$ is an arbitrary non-zero complex number.

We view $\mathfrak{gl}_{\infty}$ as a subalgebra of $\mathfrak{gl}_{\infty,\kappa}$ by $E_{i,j} \mapsto E_{i,j} : -\delta_{i,j} \theta(i > 0) \kappa$, where $\theta(i > 0) = 1$ if $i > 0$ and 0 otherwise. The action of $\mathfrak{gl}_{\infty}$ on $\mathcal{Y}_{\alpha,\gamma}$ can be extended to that of $\mathfrak{gl}_{\infty,\kappa}$, since acting with the latter on GZ patterns of hook shape only finitely many terms are produced.

Now let us turn to the Macmahon module $\mathcal{M}_{\alpha,\beta,\gamma}(u,K)$. In the limit (4.22), the eigenvalues (3.19) of $\psi^\pm(z)$ tend to

$$\frac{1 - K_1 u/z}{1 - q^1 u/z} \prod_{i=1}^{\infty} \frac{1 - q^{-\beta_i} u/z}{1 - q^{1-\beta_{i+1}} u/z},$$

where $K_1$ denotes the limiting value of $K$. In order that this limit be 1, we are forced to take $\beta_i = 0$ for all $i$ and $K_1 = 1$. Assuming this, consider the action of $e(z), f(z)$ which we write in the form

$$e(z) \mid \lambda = \sum_{k=1}^{\infty} C^+_i(k) \mid \lambda + 1^{(k)}_i, \quad f(z) \mid \lambda = \sum_{k=1}^{\infty} C^-_i(k) \mid \lambda - 1^{(k)}_i.$$

Let us compute the action of $e(z)$ in the limit $q_1 \to 1$. We use (3.9) in the form

$$e(z) \mid \lambda = \sum_{k=1}^{\infty} \frac{1}{1 - q_1} \psi_{\lambda(k)}(u/z) \delta(q_1^{1-s} u/z) \mid \lambda + 1^{(k)}_i,$$
where \( \lambda_i^{(k)} = \mu_i^{(k)} - \alpha_k \) and \( u_k = w_1^{\alpha_k} q_2^{k-1} \). We have for \( q_1 \to 1 \)

\[
\frac{1}{1 - q_1} \psi_{\lambda_i} = \begin{cases} O(1) & (i \neq 1); \\
O\left( \frac{1}{1 - q_1} \right) & (i = 1), 
\end{cases}
\]

\[
\frac{1}{1 - q_3^{k-1}} \psi_{\lambda_i} \psi_{(k-1)}(u/z) \delta(q_1^{\lambda_i} q_3^{i-1} u_k/z) = O(1),
\]

so that

\[
C_{i,k}^+(\lambda) = \begin{cases} O(1) & (i \neq k); \\
O\left( \frac{1}{1 - q_1} \right) & (i = k).
\end{cases}
\]

Similarly, using

\[
f(z)|\lambda\rangle = \sum_{i,k=1}^\infty \frac{q_1}{1 - q_1} \psi_{\lambda_i} \psi_{\lambda_i}^{(k+1)}(u/z) \delta(q_1^{\lambda_i} q_3^{i-1} u_k/z)|\lambda + 1^{(k)}\rangle,
\]

we find

\[
C_{i,k}^-\lambda(\lambda) = \begin{cases} O(1) & (i \neq k); \\
O(1 - q_1) & (i = k).
\end{cases}
\]

Hence, passing to the new basis \( |\lambda\rangle = (1 - q_1)^{p(\lambda)}|\lambda\rangle^{\text{new}} \) where \( p(\lambda) = \sum_{i=1}^\infty \lambda_i^{(i)} \), the matrix coefficients for \( e(z), f(z) \) have well defined limits. Clearly the same is true about the quotient module \( N_\alpha,\theta,\gamma(u) \).

Thus we have shown the first part of the following:

**Proposition 4.6.** (i) If \( \beta = \emptyset \), then the Macmahon module \( M_\alpha,\theta,\gamma(u, q_2^n q_3^n) \) and its irreducible quotient \( N_\alpha,\theta,\gamma(u) \) have well-defined limits.

(ii) Assume \( \gamma_1 = \cdots = \gamma_n = c, \kappa = n \). Then as \( \mathfrak{d}_{q,0} \)-modules, the limit of \( N_\alpha,\theta,\gamma(u) \) is isomorphic to the pullback \( \iota^*_u \left( \mathcal{W}_{\theta(\alpha,\kappa,0)} \right) \) of the \( \mathfrak{gl}_{\infty,\kappa} \)-module given in (4.21).

**Proof.** Let us show (ii). By construction, the limit of \( N_\alpha,\theta,\gamma(u) \) and \( \iota^*_u \left( \mathcal{W}_{\theta(\alpha,\kappa,0)} \right) \) both have bases labeled by the same combinatorial set, the GZ-pattern of hook type. It is easy to see that \( \iota^*_u \left( \mathcal{W}_{\theta(\alpha,\kappa,0)} \right) \) is an irreducible \( \mathfrak{d}_{q,0} \)-module. Hence it is sufficient to check that the lowest weights are the same.

The limit of \( \langle \psi^+(z) - \psi^-(z) \rangle/(1 - q_1) \) gives the eigenvalues of \( \bar{h}_m \), which in turn gives those of : \( E_{i,j} : v \) via (4.23), (4.26) and (4.23), (4.24). Denoting by \( \theta_i \) the eigenvalues of \( E_{i,j} \) we find

(4.27) \[
\theta_i = \begin{cases} d_{1,-i+1} - \sum_{j=1}^\infty (d_{j,j-i+1} - d_{j+1,j-i+1}) & (i \leq 0); \\
\kappa_- - \sum_{j=1}^\infty (d_{j+i-1,j} - d_{j+i,j}) & (i > 0), \end{cases}
\]

where \( d_{i,j} = \max(\gamma_i, \alpha_j) \) and \( K = q_1^{\kappa_-} \). In the case \( \kappa_- = -n, \alpha_j = \gamma_j = 0 \) \( (j > n) \), if \( \gamma_1 = \cdots = \gamma_n = c \) and \( \alpha_1 \geq \cdots \geq \alpha_k \geq c \geq \alpha_{k+1} \geq \cdots \geq \alpha_n \), this reduces to formula (4.21). \( \square \)
5. Characters

All \( \mathcal{E} \)-modules in this paper are graded by convention \( \deg e_i = -\deg f_i = 1, \deg \psi^\pm_i = 0 \). Computation of the characters of \( \mathcal{N}_{\alpha,\beta,\gamma}^{m,n} \) is a very interesting and challenging problem. It looks that in a lot of cases there are many seemingly unrelated highly non-trivial formulae.

In this section we compute the characters of \( \mathcal{N}_{\alpha,\beta,\gamma}^{m,n}(u) \). Note that \( \gamma = \emptyset \). In this case, by Proposition 4.6, our problem is equivalent to computing the characters of \( \mathfrak{gl}_\infty \) modules \( W_{\theta^{(1)}(\alpha,0)}(u) \) with the degree defined by \( \deg E_{ij} = j - i \). We also present several conjectures at the end.

5.1. Bosonic construction. In this subsection we follow [KR2]. The main tool is the bosonic construction of \( \mathfrak{gl}_\infty \) modules. We omit proofs when they are available in [KR2].

Let \( H \) be the algebra generated by generators \( d_i, d_i^* \), \( i \in \mathbb{Z} \) with defining relations
\[
[d_i, d_j] = [d_i^*, d_j^*] = [d_i^*, d_j] = 0, \quad [d_i^*, d_j] = \delta_{i,-j}.
\]

Let \( U \) be the cyclic representation of the algebra \( H \) with the cyclic vector \( v \) satisfying
\[
d_{i+1}v = d_i^*v = 0, \quad i \in \mathbb{Z}_{\geq 0}.
\]

The following lemma is clear.

**Lemma 5.1.** The module \( U \) is an irreducible \( H \) module. \( \square \)

Introduce the notation
\[
: d_i d_i^* : = \begin{cases} 
  d_i d_i^* & (i \leq 0); \\
  d_i^* d_i & (i > 0).
\end{cases}
\]

Define an action of \( \mathfrak{gl}_1 = \mathbb{C} \cdot e_{11} \) in \( U \) by
\[
e_{11} = \sum_{i \in \mathbb{Z}} : d_i d_i^* : .
\]

Define an action of \( \mathfrak{gl}_\infty \) in \( U \) by letting the generator \( E_{ij} \) act as
\[
E_{ij} = d_i d_i^* - j.
\]

**Proposition 5.2.** The actions of \( \mathfrak{gl}_1 \) and \( \mathfrak{gl}_\infty \) in \( U \) commute. We have the decomposition of \( \mathfrak{gl}_\infty \) modules
\[
U = \oplus_{k \in \mathbb{Z}} W_{\theta^{(1)}(k,0)}.
\]

Moreover, \( W_{\theta^{(1)}(k,0)} = \{ v \in U \mid e_{11} v = k v \} \). The module \( W_{\theta^{(1)}(k,0)} \) is the irreducible lowest weight \( \mathfrak{gl}_\infty \) module with the lowest weight \( \theta^{(1)}(k,0) \) given by (4.21) and with the lowest weight vector \( d_0^k v \) if \( k > 0 \) and \( (d_{-1}^*)^k v \) if \( k \leq 0 \).
Let \( H_n = H \otimes n \). We denote the generators of \( H_n \) by \( d_i^{(k)}, d_i^{(k)*}, i \in \mathbb{Z}, k \in \{1, \ldots, n\} \). We have
\[
\left[ d_i^{(k)}, d_j^{(l)} \right] = \left[ d_i^{(k)*}, d_j^{(l)*} \right] = 0, \quad \left[ d_i^{(k)}, d_j^{(l)*} \right] = \delta_{i,-j} \delta_{k,l}.
\]
Then \( U_n = U \otimes n \) is naturally an \( H_n \)-module. By Lemma 5.1, \( U_n \) is an irreducible \( H_n \)-module. We set \( v_n = v \otimes n \).

Define an action of \( \mathfrak{gl}_n \) in \( U_n \) by letting the matrix units \( e_{kl} \) act as
\[
e_{kl} = \sum_{i \in \mathbb{Z}} d_i^{(k)} d_i^{(l)*}, \quad k, l = 1, \ldots, n.
\]
Define an action of \( \mathfrak{gl}_\infty \) in \( U_n \) by letting the matrix units \( E_{ij} \) act as
\[
E_{ij} = \sum_{k=1}^{n} d_i^{(k)} d_{-j}^{(k)*}, \quad i, j \in \mathbb{Z}.
\]

Proposition 5.4 below generalizes Proposition 5.2 to the case where \( \mathfrak{gl}_1 \) is replaced with \( \mathfrak{gl}_n \). It was proved in [KR2], see also [W]. It is a \( \mathfrak{gl}_\infty \) version of the Schur-Weyl-Howe duality. The latter states

**Proposition 5.3.** Let \( N \) be an integer such that \( N \geq n \). In the above setting consider the subspace
\[
U_{n,N} = \mathbb{C}[d_i^{(k)}; 1 \leq k \leq n, -N + 1 \leq i \leq 0]v_n \subset U_n.
\]
We have mutually commutative actions of \( \mathfrak{gl}_n \) and \( \mathfrak{gl}_N \simeq \mathfrak{gl}^{-N+1,0} \) on \( U_{n,N} \), and with respect to these actions, we have the decomposition
\[
U_{n,N} = \bigoplus \alpha L_{\alpha} \otimes \tilde{L}_{\alpha},
\]
where \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n, 0, 0, \ldots) \), \( \alpha_i \in \mathbb{Z} \) such that \( \alpha_1 \geq \alpha_2 \geq \ldots \geq \alpha_n \geq 0 \), and \( L_\alpha \) (resp., \( \tilde{L}_\alpha \)) is the irreducible \( \mathfrak{gl}_n \) (resp., \( \mathfrak{gl}_N \)) module with the highest weight \((\alpha_1, \ldots, \alpha_n)\) (resp., the lowest weight \((0, \ldots, 0, \alpha_n, \ldots, \alpha_1)\)). The component \( L_\alpha \otimes \tilde{L}_\alpha \) is generated by the cyclic vector
\[
v_{\alpha,N} = \prod_{i=1}^{n-1} (D_i)^{\alpha_i-\alpha_{i+1}} (D_n)^{\alpha_n},
\]
where \( D_i \) are given by
\[
D_i = \det(d_i^{(l)})_{j=1,\ldots,i}.
\]
Similarly we define
\[
D_i^* = \det(d_{-j}^{(n+1-l)*})_{j=1,\ldots,i}.
\]
Now we give the duality statement for \( \mathfrak{gl}_n \) and \( \mathfrak{gl}_\infty \).
Proposition 5.4. We have the decomposition

\[ U_n = \bigoplus_{\alpha} \left( L_{\alpha} \otimes W_{\theta^{(n)}(\alpha,0)} \right), \]

where \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \) (\( \alpha_1 \geq \alpha_2 \geq \cdots \geq \alpha_n, \alpha_i \in \mathbb{Z} \)), and \( L_{\alpha} \) is the irreducible \( gl_n \) module with highest weight \( \alpha \) and \( W_{\theta^{(n)}(\alpha,0)} \) is the irreducible lowest weight \( gl_{\infty} \) module with lowest weight \( \theta^{(n)}(\alpha,0) \) given by [4.21]. Moreover, \( L_{\alpha} \otimes W_{\theta^{(n)}(\alpha,0)} \) is generated by

\[ v_{\alpha} = \prod_{i=1}^{k(\alpha)-1} (D_i)^{\alpha_i-\alpha_{i+1}}(D_{k(\alpha)})^{\alpha_{k(\alpha)}} \times \prod_{i=1}^{s(\alpha)-1} (D_i^{*})^{\alpha_{n-i}-\alpha_{n-i-1}}(D_{s(\alpha)})^{\alpha_{n-s(\alpha)+1}} v_n, \]

where \( k(\alpha), s(\alpha) \) are the numbers of positive and negative parts of \( \alpha \) respectively.

5.2. Characters of \( W_{\theta^{(n)}(\alpha,0)} \). Consider the set

\[ C_a = \{ (\lambda, \mu) | \lambda, \mu - \text{partitions}, \mu_1 + a \geq \lambda_1 \}. \]

Let

\[ \bar{\chi}_a = \sum_{(\lambda, \mu) \in C_a} q^{\lambda_1+\mu_1} \]

be the corresponding formal character.

Set

\[ (q)_{\infty} = \prod_{i=1}^{\infty} (1 - q^i). \]

Lemma 5.5. For \( k \in \mathbb{Z}_{\geq 0} \) we have the recursive relation

\[ \bar{\chi}_k(q) + q^{k+1} \bar{\chi}_{k+1}(q) = \frac{1}{(q)_{\infty}^2}. \]

Proof. We construct a map

\[ \iota_k : C_k \sqcup C_{k+1} \to C_{\infty} := \{ (\lambda, \mu) | \lambda, \mu - \text{partitions} \} \]

as follows. For \( (\lambda, \mu) \in C_k \) we set \( \iota_k(\lambda, \mu) = (\mu, \lambda) \). For \( (\lambda, \mu) \in C_{k+1} \) we set \( \iota_k(\lambda, \mu) = (\tilde{\mu}, \tilde{\lambda}) \), where

\[ \tilde{\lambda} = (\mu_1 + k + 1, \lambda_1, \lambda_2, \lambda_3 \ldots), \quad \tilde{\mu} = (\mu_2, \mu_3, \mu_4, \ldots). \]

Clearly, \( \iota_k \) is a bijection. The lemma follows. \( \square \)

Corollary 5.6. For \( k \in \mathbb{Z}_{\geq 0} \) we have

\[ \bar{\chi}_k = \frac{1}{(q)_{\infty}^2} \sum_{j=0}^{\infty} (-1)^j q^{j(j+1)/2+jk}. \]

Proof. Repeating using Lemma 5.5, we compute

\[ \bar{\chi}_k(q) = \frac{1}{(q)_{\infty}^2} - q^{k+1} \bar{\chi}_{k+1}(q) = \frac{1}{(q)_{\infty}^2} - q^{k+1} \left( \frac{1}{(q)_{\infty}^2} - q^{k+2} \bar{\chi}_{k+2}(q) \right) = \ldots. \]

Continuing, we obtain the corollary. \( \square \)
For \( k \in \mathbb{Z}_{\geq 0} \), set
\[
\chi_k = \bar{\chi}_k, \quad \chi_{-k} = q^k \bar{\chi}_k.
\]
We set \( \deg d_i = \deg d^*_i = -i \), \( \deg v = 0 \).

**Corollary 5.7.** For \( k \in \mathbb{Z} \), we have
\[
\chi(W_{\theta^{(1)}(k,0)}) = \chi_k.
\]

**Proof.** By Proposition 4.5, for \( k \in \mathbb{Z}_{\geq 0} \) the modules \( W_{\theta^{(1)}(k,0)} \) and \( W_{\theta^{(1)}(-k,0)} \) have bases parameterized by the set \( C_k \), therefore the corollary follows. \( \square \)

### 5.3. Characters of \( W_{\theta^{(\alpha)}(\alpha,0)} \)

Set \( \deg d_i^{(j)} = \deg d_i^{(j)*} = -i \), \( \deg v_n = 0 \). Proposition 5.4 allows us to compute the character of \( W_{\theta^{(\alpha)}(\alpha,0)} \) in terms of \( \chi_k \).

For \( \alpha = (\alpha_1, \ldots, \alpha_n) \) \( (\alpha_1 \geq \ldots \geq \alpha_n, \alpha_i \in \mathbb{Z}) \), let \( k(\alpha) \) be the number of positive parts of \( \alpha \). We set
\[
p(\alpha) = \sum_{i=1}^{k(\alpha)} (i-1)\alpha_i + \sum_{i=1}^{n-k(\alpha)} i\alpha_{n-i+1}.
\]
Then \( p(\alpha) \) is the degree of the singular vector \( v_\alpha \) given by (5.1).

Recall that the \( \mathfrak{gl}_n \) weight \( \rho \) is given by
\[
\rho = \left( \frac{n-1}{2}, \frac{n-3}{2}, \ldots, \frac{1-n}{2} \right),
\]
and that the symmetric group \( S_n \) acts on the \( \mathfrak{gl}_n \) weights by simply permuting the indexes.

**Theorem 5.8.** We have
\[
q^{p(\alpha)} \chi(W_{\theta^{(\alpha)}(\alpha,0)}) = \sum_{\sigma \in S_n} (-1)^\sigma \prod_{i=1}^{n} \chi(\sigma(\alpha+\rho)-\rho_i).
\]

**Proof.** The character of the subspace of vectors in \( U_n \) of the \( \mathfrak{gl}_n \) weight \( \mu = (\mu_1, \ldots, \mu_n) \) is obviously given by \( \prod_{i=1}^{n} \chi_{\mu_i} \). By Proposition 5.4, the space \( W_{\theta^{(\alpha)}(\alpha,0)} \) is identified with the space of \( \mathfrak{gl}_n \) singular vectors of weight \( \alpha \) in \( U_n \) with the shift of the degree given by \( p(\alpha) \). Moreover, Proposition 5.4 asserts that \( U_n \) is a direct sum of finite-dimensional \( \mathfrak{gl}_n \)-modules. Then the character of the space of \( \mathfrak{gl}_n \) singular vectors of weight \( \alpha \) is computed as the alternating sum of the characters of the weight subspaces. \( \square \)

### 5.4. Other character formulas

We finish with some conjectures which we checked for the small values of parameters.

**Conjecture 5.9.** The character of \( N_{0,0,0}^{(1,m)} \) is given by
\[
\chi(N_{0,0,0}^{(1,m)}) = \prod_{i=1}^{m-2} \frac{(1-q^i)^{m-i-1}}{(q)_{\infty}^2} \sum_{j=0}^{\infty} (-1)^j q^{\frac{1}{2}j(j+1)} \prod_{i=1}^{m-1} (1-q^{i+j}).
\]
Conjecture 5.10. The character of $N_{0,0,0}^{(n,m)}$, where $n \geq m$ is given by

$$
\chi(N_{0,0,0}^{(n,m)}) = \frac{1}{(q)_\infty^{m+n}} \sum_{\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_m \geq 0} (-1)^{\sum_{i=1}^{m} \lambda_i} q^{\frac{1}{2} \sum_{i=1}^{m} (\lambda_i^2 + (2i-1)\lambda_i)} \prod_{1 \leq i < j \leq m} (1 - q^{\lambda_i - \lambda_j + j - i}) \prod_{1 \leq i < j \leq n} (1 - q^{\lambda_i - \lambda_j + j - i}).
$$

Here we set $\lambda_j = 0$ if $j > m$.
