**KEYWORDS**
Soft coral; *Sarcophyton*; *Sarcophyton mililatensis*; Cembrane-type diterpenoids; Modified Mosher's method; ECD calculation; Cytotoxicity; NF-κB inhibitory activity

**Abstract**
Eight cembrane-type diterpenoids, namely, (+)-(6R)-6-hydroxyisosarcophytoxide (1), (+)-(6R)-6-acetoxyisosarcophytoxide (2), (+)-17-hydroxyisosarcophytoxide (3), sarcomililatins A–D (4–7), and sarcomililatol (8), were isolated from the soft coral *Sarcophyton mililatensis* collected from Weizhou Island, Guangxi Autonomous Region, together with 2 known related analogues, (+)-isosarco-saphytoxide (9) and (+)-isosarcophine (10). The structures of these compounds were elucidated by a combination of detailed spectroscopic analyses, chemical methods, and comparison with reported data. The absolute configuration of compound 1 was established by the modified Mosher's method, while the absolute configurations of compounds 4 and 5 were assigned by electronic circular dichroism (ECD) spectroscopy and that of compound 8 was established by time-dependent density functional theory electronic circular dichroism (TD-DFT ECD) calculation. In *in vitro* bioassays, compound 9 displayed significant cytotoxicity against the human cancer cell lines human promyelocytic leukemia cells (HL-60) and human lung adenocarcinoma cells (A-549) with IC\(_{50}\) values of 0.78 ± 0.21 and 1.26 ± 0.80 μmol/L, respectively. Compounds 4 and 9 also showed moderate inhibitory effects on the TNFα-induced Nuclear factor kappa B (NF-κB, a therapeutic target in cancer) activation, showing IC\(_{50}\) values of 35.23 ± 12.42 and 22.52 ± 4.44 μmol/L, respectively.

1. Introduction

Literature reports concerning the natural products chemistry of soft corals of the cosmopolitan genus *Sarcophyton* (Alcyonacea, Alcyoniidae) indicate that they are well-known to be a rich source of specialised metabolites, particularly diterpenoids of the cembrane-type\(^1\)\(^-\)\(^2\). To date, more than 220 cembranes have been discovered, besides undefined species, from approximately 18 species of this genus. Moreover, some of them have been reported to be responsible for a diverse range of significant bioactivities, especially cytotoxic and anti-inflammatory effects\(^3\)\(^-\)\(^4\). Their excellent bioactivities have for a long time attracted great interest from synthetic organic chemists as challenging targets for total synthesis\(^5\)\(^,\)^\(^6\).

*Sarcophyton* species are prolific in the South China Sea. In the course of our ongoing search for bioactive secondary metabolites from the South China Sea marine invertebrates\(^7\)\(^-\)\(^9\), we collected the soft coral *S. mililatensis* from Weizhou Island, Guangxi Autonomous Region, China. Notably, only 2 prior phytochemical studies have been performed on this species collected from Baycanh Island, Vietnam, resulting in the isolation of one 9,11-secosteroid and 6 cembranes\(^10\)\(^,\)^\(^11\). The present investigation of the EtO\(_2\) soluble fraction from the acetone extract of *S. mililatensis* has now led to the discovery of eight previously undescribed cembrane-type diterpenoids, namely, (+)-(6\(R\))\(-6\)-hydroxyisosarcophytoxide (**1**), (+)-(6\(R\))\(-6\)-acetoxyisosarcophytoxide (**2**), (+)-(17\(R\))-hydroxyisosarcophytoxide (**3**), sarcomililatins A–D (4–7), and sarcomililatol (8), along with 2 known structural analogues, (+)-isosarcophytoxide (**9**) and (+)-isosarcophine (**10**) as shown in Fig. 1. The absolute configuration of compound **1** was established by the modified Mosher’s method. The absolute configurations of compounds **4** and **5** were assigned by ECD spectroscopy, while for compound **8** TD-DFT ECD calculation was used.

Cancer is a group of diseases characterized by uncontrolled cell growth, which has become the major public health concern over the last several decades\(^12\)\(^-\)\(^15\). NF-\(\kappa\)B, as a family of inducible transcription factors in all cells discovered by Sen and Baltimore\(^16\) in 1986, has become one of the major targets for drug development\(^17\). In particular, the aberrant activation of NF-\(\kappa\)B has been frequently observed in various types of human cancers, and suppression of NF-\(\kappa\)B can limit the proliferation of cancer cells\(^18\). Hence, we focus on testing cytotoxic activity and the NF-\(\kappa\)B inhibitory effects. According to the results, compound **9** exhibited moderate cytotoxic activity, both compounds **4** and **9** showed moderate NF-\(\kappa\)B inhibitory effects on the TNF\(\alpha\)-induced NF-\(\kappa\)B. Reported herein are the isolation and structural elucidation of these compounds as well as their biological properties.

2. Results and discussion

Compound **1** was isolated as a colorless oil, and had a molecular formula of \(C_{20}H_{30}O_3\) as established by (+)-HR-ESI-MS ion peak at \(m/z\) 341.2096 [\(M + Na^+\)] (Calcd. for \(C_{20}H_{30}O_3Na\, 341.2087\)) and \(^{13}\)C NMR data (Table 1), implying 6 degrees of unsaturation. Its IR spectrum showed the presence of a hydroxyl group (3363 cm\(^{-1}\)). The \(^1\)H NMR spectrum (Table 1) displayed signals due to 3 vinyl proton signals were also observed for one oxymethylene at 2.39 (1 H, dd, \(\delta \quad J = 9.2, 2.8\) Hz, H-7) and 5.09 (1 H, d, \(J = 10.0, 3.2\) Hz, H-3), which were attributed to 2 trisubstituted double bonds. In addition, proton signals were also observed for one oxymethylene at \(\delta \quad J = 12.0, 4.0\) Hz, H-16a) and 4.47 (1 H, d, \(J = 12.0, 3.2\) Hz, H-16b) and 2 oxymethines at \(\delta \quad J = 10.0, 4.0\) Hz, H-2) and 2.39 (1 H, dd, \(J = 11.2, 2.8\) Hz, H-11) in the \(^1\)H NMR spectrum. The \(^{13}\)C NMR spectrum indicated the presence of 20 signals which were attributed by DEPT and HSQC experiments to 4 methyls, 6 methylenes, 5 methines, and 5 quaternary carbons. Of these carbons, 5 were bonded to oxygen and 6 were olefinic (2 were trisubstituted). These data suggested that **1** was a cembrane-type diterpenoid.

A comparison of the NMR data of **1** with those of the co-occurring known cembrane diterpenoid, (+)-isosarcophytoxide (**9**)\(^19\)\(^-\)\(^20\), revealed that they were structural analogues, with the only difference being the presence of an additional hydroxyl group at C-6 in **1**, in agreement with the mass data. The hydroxyl group

Cembrane-type diterpenoids from the South China Sea soft coral Sarcophyton mililatensis

The absolute configuration at C-6 of 1 was assigned via a modified Mosher's method. Esterification of 1 with (R)- and (S)-MTPA chloride occurred at the C-6 hydroxyl group to give the (S)- and (R)-MTPA ester derivatives, 1S and 1R, respectively. The observed $\Delta \delta(C_6(R,S))$ value distribution pattern (Fig. 4) established the 6R-configuration for 1. Therefore, the structure of 1 was elucidated as $\alpha$-((+)(6R))-6-hydroxyisosarcophytoxide.

Compound 2, which was obtained as a colorless oil, gave the molecular formula $C_{22}H_{32}O_4$ on the basis of its (+)-HR-ESI-MS ion peak at $m/z$ 383.2193 [M + Na]$^+$ (Calcd. for $C_{22}H_{32}O_4Na$, 383.2193), requiring 7 degrees of unsaturation. The IR spectrum displayed a strong absorption at 1732 cm$^{-1}$, consistent with the presence of a saturated ester carbonyl group. The $^1$H and $^{13}$C NMR spectra (Table 1) of 2 were virtually identical to those of 1, with the exception of an acetoxy moiety in 2 instead of the C-6 hydroxyl group in 1. This replacement caused the $^{13}$C NMR resonance of C-6 to be shifted downfield (from $\delta_C$ 65.4 to $\delta_C$ 67.9). The position of the acetoxy group at C-6 was further secured by the HMBC correlation (Fig. 2) from H-6 ($\delta_H$ 5.78) and the ester carbonyl carbon ($\delta_C$ 170.2). The similar NOESY correlation (Fig. 3) of 2 and 1 indicated that they have the same relative configuration. Finally, the absolute configuration of 2 was assigned as 25,6R,11R,12R, the same as those of 1. This is because acetylation of 1 yielded 2, which gave optical rotations $\{[\alpha]_D^{25} +51$ (c 0.09, CH$_3$OH); $[\alpha]_D^{25} +65$ (c 0.09, CHCl$_3$)$\}$, compared to those $\{[\alpha]_D^{25} +53$ (c 0.5, CH$_3$OH); $[\alpha]_D^{25} +63$ (c 0.24, CHCl$_3$)$\}$ observed for the natural sample of 2. The structure of 2 was thereby proposed as (+)-(6R)-6-acetoxyisosarcophytoxide.

A literature search revealed that the assigned structure of 2 was the same as that of sarcophytonoxide A, a known cembrane diterpenoid isolated previously from the soft coral Sarcophyton ehrenbergii$^{22}$. Furthermore, the $^1$H and $^{13}$C NMR data of 2 were also the same as those of sarcophytonoxide A. However, when the optical rotation of 2 (dextrorotatory, $[\alpha]_D^{25} +3$ (c 0.5, CH$_3$OH)), recorded in the same conditions, was compared with that reported for sarcophytonoxide A (levo-rotatory, $[\alpha]_D^{25} -36.8$ (c 0.5, CH$_3$OH))$^{12}$, it appeared quite equal in value but opposite in sign. This result indicated that the 2 compounds are enantiomers and that the absolute configuration of sarcophytonoxide A should be 2R,6S,11S,12S.

Compound 3 was isolated as a colorless oil. Its molecular formula of $C_{22}H_{34}O_5$, the same as that of 1, was deduced from the (+)-HR-ESI-MS ion peak at $m/z$ 341.2087 [M + Na]$^+$ (Calcd. for $C_{22}H_{34}O_5Na$, 341.2087). A comparison of the $^1$H and $^{13}$C NMR data (Table 1) of 3 and 1 indicated similarities between them. In fact, the structure of 3 differed from that of 1 only by the location of the hydroxyl group from C-6 to C-17 in 3. This deduction was based on the chemical shift observed for C-6 ($\delta_C$ 22.8) and C-17 ($\delta_C$ 57.0), which was further confirmed by the $^1$H-1H COSY cross-peaks (Fig. 2) of H$_7$-17 ($\delta_H$ 2.31 and 2.18)/H$_6$-16 ($\delta_H$ 2.42 and 1.09)/H$_7$-16 ($\delta_H$ 5.00) and the HMBC correlations (Fig. 2) from H$_7$-17 to C-1 ($\delta_C$ 136.8), C-15 ($\delta_C$ 132.0), and C-16 ($\delta_C$ 75.9). The relative configurations of all the asymmetric centers were determined to be the same as those of 1 on the basis of the NOESY experiment (Fig. 3). According to the previous findings$^{22,23}$, the absolute configuration at C-2 of 3 was proposed as S from the large dextrorotatory optical rotation $\{[\alpha]_D^{25} +98$ (c 0.1, CHCl$_3$)$\}$. The absolute configuration of 3 was tentatively assigned as 25,11R,12R. Hence, the structure of 3 was shown to be (+)-17-hydroxyisosarcophytoxide.

Compound 4 was obtained as a colorless oil with the molecular formula of $C_{20}H_{30}O_3$ on the basis of (+)-HR-ESI-MS ion peak at $m/z$ 371.1829 [M + Na]$^+$ (Calcd. for $C_{20}H_{30}O_3Na$, 371.1829) and $^{13}$C NMR data (Table 1), suggesting that 4 possessed 7 degrees of
unsaturation. Its IR spectrum exhibited a broad absorption at 3356 cm\(^{-1}\) (OH) and strong absorptions at 1751 and 1678 cm\(^{-1}\), consistent with the presence of an \(\alpha,\beta\)-unsaturated \(\gamma\)-lactone moiety. This was supported by the \(^{13}\)C NMR signals at \(\delta_{c} 174.7\) (C-16), 161.3 (C-1), 123.8 (C-15), and 79.1 (C-2) and UV absorption maxima at 246 and 275 nm\(^{12}\). The third oxygen atom was determined to be part of a trisubstituted epoxy ring, which was confirmed by the appearance of signals at \(\delta_{H} 2.69\) (1 H, dd, \(J = 7.8, 4.8\) Hz, H-11) and \(\delta_{H} 7.35\) (1 H, s, 8-OOH), respectively, strongly implying that the remaining 2 oxygen atoms were involved in a hydroperoxy group. This conclusion was also supported by the significant downfield shift of the resonance for C-8 in 4 with respect to that of the corresponding carbon (\(\delta_{c} 72.6\)) for mayolide B, a known cambranoid with the same 14-membered ring substituted with a hydroxy group at C-8 previously isolated the soft coral \textit{Simularia maya} \(^{14}\). Further analysis of the \(^{13}\)C NMR and DEPT spectra of 4 displayed 20 signals for 4 methyls, 5 methylenes, 5 methines (3 olefinic and 2 oxygenated), 5 quaternary carbons (3 olefinic and 2 oxygenated), and one conjugated ester carbonyl carbon (C-16). The planar structure of 4 was extensively elucidated by \(\text{H}^1\)-H COSY and HMBC spectra (Fig. 2). The \(\text{H}^1\)-H COSY cross-peaks readily determined the presence of 4 spin systems from H-2 to H-3; H-2 to H-7; H-2 to H-11; and H-2 to H-14. The significant HMBC correlations from Me-17 to C-1, C-15, and C-16; Me-18 to C-3, C-4, and C-5; Me-19 to C-7, C-8, and C-9; Me-20 to C-11, C-12; and C-13; H-2 to C-1, C-15, and C-16; and H-2 to C-1 and C-15 constructed the cambran skeleton as depicted in Fig. 1. The hydroperoxy group and the epoxy ring in 4 were placed at C-8 and C-11/C-12, respectively, based on the strong HMBC correlations from Me-19 to C-8 and from Me-20 to C-11 and C-12.

The relative configuration of 4 was deduced from interpretation of the coupling constants and a NOEYX experiment (Fig. 3). The large coupling constants (\(J_{\text{HH}} = 15.6\) Hz) and the chemical shift of the C-18 methyl group (\(\delta_{c} 17.1\)) established the E geometries of the \(\Delta^1\) and \(\Delta^8\) double bonds, and this was further supported by the strong NOEYX cross-peaks of H-6 (\(\delta_{H} 5.97\))/Me-18 (\(\delta_{H} 1.83\)) and Me-19 (\(\delta_{H} 1.47\)) and of H-5a (\(\delta_{H} 2.86\))/H-3 (\(\delta_{H} 4.91\)) and H-7 (\(\delta_{H} 5.62\)). The observed correlations in the NOEY spectrum as shown in Fig. 3 assigned H-11, Me-19, and Me-20 as \(\beta\)-oriented, while H-2 was the \(\alpha\)-orientation. Furthermore, the absolute configuration at C-2 in 4 was defined by an ECD experiment. The ECD spectrum of 4 (Fig. 5) showed a negative Cotton effect at 249 nm (\(\Delta\varepsilon = -3.1\)) and a positive Cotton effect at 221 nm (\(\Delta\varepsilon = +33.4\)), indicative of a 2S-configuration. Accordingly, the structure of 4 was characterized as shown, and the compound was designated with the trivial name sarcomililatin A.

Compound 5 was isolated as a colorless oil, possessing the same molecular formula of C\(_{20}\)H\(_{28}\)O\(_{5}\) as 4 by \(+\)-HR-ESI-MS ion peak at \(m/z\) 371.1830 [M + Na\(^+\)] (Calcd. for C\(_{20}\)H\(_{28}\)O\(_{5}\)Na, 371.1829). The IR, UV, and 1D NMR data (Table 2) of 5 were similar to those of 4, except for the migration of the \(\Delta^\beta\) double bonds in 4 to \(\Delta^\beta\) in 5 (\(\delta_{H} 5.24\) (1 H, br s, H-19a) and 5.18 (1 H, br s, H-19b); \(\delta_{c} 148.4\) (s, C-8) and 113.8 (t, C-19)) and the position of the hydroperoxy group at C-8 in 4 to C-7 (\(\delta_{H} 7.71\) (1 H, s, 7-OOH) and 4.22 (1 H, dd, \(J = 7.6, 5.6\) Hz, H-7); \(\delta_{c} 83.3\) (d, C-7)). However, a literature survey revealed that 5 showed exactly the same \(\text{H}^1\) and \(^{13}\)C NMR data as trocheliolide A, a known cambrane diterpenoid isolated previously from the soft coral \textit{Sarcophyton trocheliophorum} \(^{15}\). This observation readily prompted us to assign the structure of 5 as trocheliolide A. Nevertheless, the optical rotations (\text{dextorotatory}, \([\alpha]_{D}^{25} +34\) (c 0.1, CHCl\(_3\)) and \([\alpha]_{D}^{25} +23\) (c 0.1, CH\(_3\)OH)) sign of 5 as opposite to that of trocheliolide A (\text{levorotatory}, \([\alpha]_{D}^{25} -76\) (c 0.3, CH\(_3\)OH)) \(^{16}\). These results suggested that 5 is the enantiomer of trocheliolide A. Moreover, the absolute configuration at C-2 in 5 was deduced to the same (S) as in 4 on the basis of an ECD spectrum with \(\epsilon\) values (\(-1.5\) at 249 nm and +11.3 at 223 nm). Thus, the structure of 5 (the trivial name sarcomililatin B) was assigned as depicted.

Compound 6 was obtained as a colorless oil. The molecular formula of 6 was established as C\(_{20}\)H\(_{29}\)O\(_{5}\), based on the [M – H\(^-\)]\(^+\) ion peak at \(m/z\) 363.1813 (Calcd. for C\(_{20}\)H\(_{29}\)O\(_{5}\), 363.1813) in its \((-\)-HR-ESI-MS, which was 16 mass units more than that of 4, appropriate for 7 degrees of unsaturation. The IR spectrum of 6 closely resembled that of 4, showing similar functionalities in the molecule. Analysis of the \(\text{H}^1\) and \(^{13}\)C NMR spectra (Table 5) of 6 also revealed similarities to 4, except for the location of one of the double bond from the \(\Delta^1\) to \(\Delta^8\) accompanied by hydroxylation occurring at C-3 in 6. These observations were supported by the HMBC correlations (Fig. 2) from the olefinic proton H-3 resonating at \(\delta_{H} 5.31\) to C-1 (\(\delta_{c} 151.0\)), C-2 (\(\delta_{c} 147.8\)), C-4, C-5, C-7 (\(\delta_{c} 47.0\)), and C-18 (\(\delta_{c} 29.6\)) and from the methyl proton singlet H-18 (\(\delta_{H} 1.55\)) to C-3 (\(\delta_{c} 115.6\)), C-4, and C-5. Its relative configurations at C-8, C-11, and C-12 were proven the same as those of 4 on the basis of a NOEYX experiment (Fig. 3). The diagnostic NOEYX cross-peaks of H-19/1/H-7 and of H-7/one of the H-5 protons (\(\delta_{H} 2.53\)) and H-6 (\(\delta_{H} 5.81\)) suggested that Me-18 was \(\alpha\)-oriented. Finally, from a biogenetic point of view, the

Figure 4  \(\Delta\delta\) values [\(\Delta\delta \) (in ppm) = \(\delta_{c} - \delta_{H}\)] obtained for (S)- and (R)-MTPA esters of compound 1 in pyridine-\(d_5\).

*aδ in ppm, assignments made by DEPT, COSY, HSQC, HMBC, and NOESY experiments.

*bAt 600 MHz for ¹H and 150 MHz for ¹³C NMR experiments.

*cAt 400 MHz for ¹H and 100 MHz for ¹³C NMR experiments.
absolute configurations at C-8, C-11, and C-12 of 6 were suggested to be the same as those of 4. The absolute configuration of 6 was tentatively defined as 4S,8R,11R,12R. Accordingly, the structure of 6 (the trivial name sarcomililatin C) was characterized as depicted.

Compound 7 was isolated as a colorless oil. The HR-ESI-MS of 7 showed a fragment ion peak at m/z 315.1957 [M – H2O + H]+ (Calcd. for C20H32O2, 315.1955) corresponding to the loss of water from 7, suggesting a molecular formula of C20H32O2 with 7 degrees of unsaturation. The 1H and 13C NMR spectra (Table 2) of 7 showed similarities to those of 6. However, the signal resonating at δH 7.40 (1 H, s) for the hydroperoxy group at C-8 in 6 was absent. Also, the 2 mutually coupled olefinic proton signals at δH 5.81 (1 H, dt, J = 15.6, 7.2 Hz, H-6) and 5.63 (1 H, d, J = 15.6 Hz, H-7) in 6 were replaced by an olefinic proton triplet at δH 5.26 (1 h, t, J = 6.8 Hz, H-7) in 7. The above observations, combined with the 1H–1H COSY cross-peaks (Fig. 2) of H-2/H(15, 20) and H-2/H(5, 6) and the HMBC correlations from H-19 to H-7 (δC 127.4) and C-8 (δC 134.0), indicated the loss of the hydroperoxy group in 6 accomplished by the isomerization of the olefin from the Δ2 to Δ2. The E geometry of the Δ2 double bond in 7 was suggested by the chemical shift of the signal for the C-19 methyl group (δC 15.5), which was further confirmed by the NOESY cross-peaks (Fig. 3) of H-19/H-2/6 and of H-7/H-9 (δH 2.26 and 2.07). The relative configurations of all the asymmetric centers in 7 remained intact, with respect to those of 6, which was supported by a NOESY experiment. Analogously, the absolute configurations at C-11 and C-12 of 7 were suggested to be the same as those of 4. The absolute configuration of 7 was tentatively defined as 4S,11R,12R. Therefore, the structure of 7 (the trivial name sarcomililatin D) was proposed as depicted.

Compound 8, assigned the trivial name sarcomililatol, was isolated as a colorless oil and exhibited the molecular formula C20H28O4 with 8 degrees of unsaturation, of which one was accounted for by a 14-membered epoxide ring. The intense IR absorption at 3362 cm⁻¹ in 8 suggested a molecular formula of C20H28O4 with 8 degrees of unsaturation. The 1H and 13C NMR spectra (Table 2) showed typical signals for a cembrane nucleus with 20 carbon signals which were classified as 20 carbon signals which were classified as 2 hybridized and 2 oxygenated), and 4 quaternary (2 sp³ hybridized and one oxygenated) carbons. The aforementioned data of 8 revealed that it should be a stereoisomer of (±)-isosarcophytol A, which was first isolated from the soft coral Lophophyta sp. When comparing their 13CNMR spectra, the signals of C-11 and C-12 were shown to be markedly different [δC 62.4 and 61.6 for 8; δC 58.4 and 59.8 for (±)-isosarcophytol A, respectively], indicating that the structural difference between them resided in the different configuration of the 11,12-ether linkage. Detailed analysis of its 1H–1H COSY, HSQC, and HMBC spectra (Fig. 2) allowed the assignment for all proton and carbon resonances of 8.

The relative configuration of 8 was deduced from interpretation of a NOEY experiment (Fig. 3). The NOEY cross-peaks of H-14 (δH 4.86)/H-11(δH 2.68) and Me-20 implied that these protons were cofacial and were assigned a β-orientation. The geometries of the Δ14(12), Δ3, and Δ3 double bonds were assigned as Z, E, and E, respectively, on the basis of the carbon chemical shifts of Me-18 (δC 17.6) and Me-19 (δC 15.3), and this was supported by the key NOEY cross-peaks of H-2 (δH 6.02)/H-16, H-17, and H-18; H-3 (δH 5.93)/H-5 (δH 2.20) and H-14; H-7 (δH 5.15)/H-9 (δH 2.24 and 1.09); and H-19/H-12 (δH 2.30 and 2.21). Thus, the relative configuration of 8 was determined as 1Z,3E,7E,11R*,12R*,14S*. However, the absolute configuration of the chiral center at C-14 in 8 was not determined by a modified Mosher’s method due to the limited quantity of sample.

In order to determine the absolute configuration of 8, the TD-DFT ECD calculation method was applied, which has proven to be a powerful and reliable method for the elucidation of the absolute configurations of natural products³⁸. As shown in Fig. 6, the ECD spectrum (CH3CN) of 8 displayed a positive π–π⁺ Cotton effect at 242 nm. The conformational searches of (11R,12R,14S)-8 were carried out using the torsional sampling (MCMC) method and OPLS_2005 force field. Conformers above 1% population were re-optimized at the B3LYP/6-311G(d,p) level with IEFCM (Polarizable Continuum Model) using the Integral Equation Formalism variant solvent model for acetonitrile (Supplementary Information Fig. S1 and Table S1). For the resulting geometries, ECD spectra were obtained by TD-DFT calculations performed with the same functional basis set and solvent model as the energy optimization. Finally, the Boltzmann-averaged ECD spectrum of (11R,12R,14S)-8 highly matched to the experimental ECD spectrum of 8, while the enantiomer showed completely opposite curve. Consequently, the absolute configuration of 8 was determined to be 11R,12R,14S.

The known diterpenoids were characterized as (±)-isosarcophytoide (9) and (±)-isosarcoiphytoide (10) by comparing their observed and reported spectroscopic data. Their HR-MS spectra are also supplied in the Supplementary Information Fig. S72 and Fig. S73, respectively.
Despite numerous cembrane-type diterpenoids isolated from soft corals of the genus *Sarcophyton*, the investigation of the Et<sub>2</sub>O-soluble portion of the acetone extract of the soft coral *S. mililatensis* led to the identification of eight new cembrane diterpenoids (1–8), of which sarcomililatins A–C (4–6) possess a rare hydroperoxy group at C-7 or C-8 in the family of cembrane diterpenoids. To explain the biogenetic origin of compounds 4–6, putative biosynthetic pathways are proposed as shown in Scheme 1. The 3 metabolites can be considered to derive from a common precursor, the co-occurring known cembrane (+)-isosarco phytoxide (9).

The growth inhibitory potential towards various cancer cell lines of numerous cembrane-type diterpenoids has been documented widely. Accordingly, the cytotoxicities of all the isolates were evaluated in vitro against HL-60 and A-549 by using the MTT and SRB methods, respectively. However, all of the tested compound, except for the known compound (+)-isosarco phytoxide (9), were inactive (IC<sub>50</sub> > 10 μmol/L). Compound 9 exhibited strong cytotoxic activities, with IC<sub>50</sub> values of 0.78 ± 0.21 and 1.26 ± 0.80 μmol/L against HL-60 and A-549 cells, respectively, comparable to the positive control (adriamycin, IC<sub>50</sub> 0.07 μmol/L for HL-60 and 0.01 μmol/L for A-549). In addition, all of the isolated compounds were also subjected to testing in vitro for their inhibitory activities against the tumor necrosis factor (TNF)-α-induced nuclear factor (NF)-κB, a transcription factor that plays a critically important role in regulation of cell cycle as well as influencing cell death pathways and has been used as a key target for the treatment of inflammatory diseases and cancer<sup>32,33</sup>. The results indicated that sarcomililatins A (4) and (+)-isosarco phytoxide (9) showed moderate inhibitory activities, showing IC<sub>50</sub> values of 35.23 ± 12.42 and 22.52 ± 4.44 μmol/L, respectively, compared with the positive control bortezomib (IC<sub>50</sub>, 0.03 μmol/L), whereas the other compounds were inactive (% inhibition < 50% at 20 μg/mL).

3. Conclusions
A large amount of scientific research has been reported on the specialised metabolite chemistry of soft corals of the genus *Sarcophyton*, whereas related reports on *S. mililatensis* are relatively rare. In the present study, eight new cembrane-type diterpenoids, (+)-(6R)-6-hydroxyisosarco phytoxide (1), (+)-(6R)-6-acetoxyisosarco phytoxide (2), (+)-17-hydroxyisosarco phytoxide (3), sarcomililatins A–D (4–7), and sarcomililatol (8), were isolated and characterized from the soft coral *S. mililatensis*, along with 2 known ones (9 and 10). The absolute configurations of compounds 4 and 5 were elucidated by ECD spectroscopy, while the absolute configurations of compounds 1 and 8 were established by the modified Mosher’s method and TD-DFT ECD calculation, respectively. Among these isolates, compounds 4 and 9 showed inhibitory effects on the TNFα-induced NF-κB activation, while compound 9 also exhibited promising cytotoxicity.

4. Experimental
4.1. General experimental procedures
Optical rotations were measured on a Perkin-Elmer 241MC polarimeter (PerkinElmer, Fremont, CA, USA). UV spectroscopic spectra were recorded in chromatographic grade CH<sub>3</sub>OH on a Varian Cary 300 UV–Vis spectrophotometer (Varian, Palo Alto, CA, USA); peak wavelengths are reported in nm. ECD spectra were recorded on a Jasco J-810 spectropolarimeter (JASCO, Japan) at ambient temperature using chromatographic grade CH<sub>3</sub>OH and acetonitrile as solvents. IR spectra were recorded on a Nicolet 6700 spectrometer (Thermo Scientific, Waltham, MA, USA); peaks are reported in cm<sup>-1</sup>. The NMR spectra were measured at 300 K on Bruker DRX 400 and Avance 600 MHz NMR spectrometers (Bruker Biospin AG, Fallanden, Germany). Chemical shifts are
4.3. Extraction and isolation

The frozen animals (170 g, dry weight) were cut into pieces and immediately after collection. A voucher specimen is available for inspection at Shanghai Institute of Materia Medica, SIBS-CAS (No. WZ82).

4.4. Biological material

Specimens of *Sarcophyton miliatensis*, identified by Prof. Hui Huang from South China Sea Institute of Oceanology, Chinese Academy Sciences, were collected along the coast of Weizhou Island (21°05′N, 109°60′E), Beihai, Guangxi Autonomous Region, China, in May 2007, at a depth of ~20 m, and were frozen at inspection at Shanghai Institute of Materia Medica, SIBS-CAS (No. WZ82).

4.3. Extraction and isolation

The frozen animals (170 g, dry weight) were cut into pieces and ultrasonically extracted with acetone at room temperature (1 L x 3). The combined acetone extracts were filtered and concentrated in vacuo, affording a brown residue, which was suspended in H2O (4 L) and then partitioned with Et2O (3 times with 2 L each). The Et2O-soluble portion (5.0 g) was concentrated in vacuo, and then fractionated by silica gel CC (column: 40 cm × 2 cm) eluting with CHCl3 at 7.26 ppm; δC reported referred to CDCl3 at 77.16 ppm) and coupling constants (J) in Hz; assignments were supported by 1H–1H COSY, HSQC, HMBC, and NOESY experiments. EIMS and HREIMS spectra (70 eV) were recorded on a Finnigan-MAT-95 mass spectrometer (ThermoFisher Scientific, Waltham, USA). ESI-MS and HR-ESI-MS were carried out on a Bruker Daltonics Qspectro 3000 plus instrument (Bruker Daltonics K. K., Kanagawa, Japan) and a Waters Q-TOF Ultima mass spectrometer (Waters, MA, USA), respectively. Semi-preparative HPLC was performed on an Agilent-1260 system equipped with a DAD G1315D detector using ODS-HG-5 (250 mm × 9.4 mm, 5 μm) by eluting with CH2Cl2–H2O or CH3CN–H2O system at 3 mL/min. Commercial silica gel (200–300 and 400–500 mesh; Qingdao, China) was used for column chromatography (CC). Precoated SiO2 plates (HSGF-254; Yantai, China) were used for analytical TLC. Spots were detected on TLC under UV light or by heating after spraying (HSGF-254; Yantai, China) were used for analytical TLC. Spots were detected on TLC under UV light or by heating after spraying with anisaldehyde H2SO4 reagent. Sephadex LH-20 (Amersham Biosciences) was also used for CC. All solvents used for extraction and isolation were of analytical grade.

4.3.1. (+)-(6R)-6-Hydroxyisoarosorboxytoide (1)

Colorless oil; [α]20 D +100 (c 0.25, CHCl3); IR (KBr) νmax 3363, 2961, 2925, 2855, 1755, 1261, 1077, 1033 cm–1; For 1H and 13C NMR spectroscopic data, see Table 1; (+)-HR-ESI-MS m/z 341.2096 [M + Na]+ (Calcd. for C20H29O2Na, 341.2087).

4.3.2. (+)-(6R)-6-Acetoxyisisarosorboxytoide (2)

Colorless oil; [α]20 D +63 (c 0.24, CHCl3); [α]23 D +53 (c 0.5, MeOH); IR (KBr) νmax 2921, 2850, 1732, 1240, 1195, 1131, 1077 cm–1; For 1H and 13C NMR spectroscopic data, see Table 1; (+)-HR-ESI-MS m/z 383.2197 [M + Na]+ (Calcd. for C22H22O3Na, 383.2193).

4.3.3. (+)-17-Hydroxyisoarosorboxytoide (3)

Colorless oil; [α]20 D +98 (c 0.1, CHCl3); IR (KBr) νmax 3358, 2921, 2851, 1661, 1180, 1131, 1077 cm–1; For 1H and 13C NMR spectroscopic data, see Table 1; (+)-HR-ESI-MS m/z 341.2077 [M + Na]+ (Calcd. for C22H22O3Na, 341.2087).

4.3.4. Sarcomilitatin A (4)

Colorless oil; [α]23 D +43 (c 0.5, CHCl3); ECD [CH3CN, λ[Δmax] (Δε), c 0.0014 M]; 249 (~1.3), 221 (+3.34); UV (MeOH) λmax (logε) 246 (2.86), 275 (2.68) nm; IR (KBr) νmax 3356, 2924, 2853, 1751, 1678, 1450, 1180, 1132, 1077 cm–1; For 1H and 13C NMR spectroscopic data, see Table 1; (+)-HR-ESI-MS m/z 371.1822 [M + Na]+ (Calcd. for C23H23O3Na, 371.1829).

4.3.5. Sarcomilitatin B (5)

Colorless oil; [α]25 D +34 (c 0.1, CHCl3); [α]25 D +23 (c 0.1, MeOH); ECD [CH3CN, λ[Δmax] (Δε), c 0.0014 M]; 249 (~1.5), 223 (+11.3); UV (MeOH) λmax (logε) 247 (2.87), 275 (2.69) nm; IR (KBr) νmax 3358, 2921, 2851, 1659, 1468, 1180, 1132, 1077 cm–1; For 1H and 13C NMR spectroscopic data, see Table 2; (+)-HR-ESI-MS m/z 371.1830 [M + Na]+ (Calcd. for C23H23O3Na, 371.1829).
4.3.6. Sarcomilitatin C (6)
Colorless oil; [α]D20 +3 (c 0.2, CHCl3); UV (MeOH) λmax (logε) 247 (2.72), 288 (2.52), 295 (2.40) nm; IR (KBr) νmax 3357, 2920, 2850, 1762, 1662, 1463, 1180, 1132, 1077 cm⁻¹; For 1H and 13C NMR spectroscopic data, see Table 2; (-)-HR-ESI-MS m/z 363.1813 [M – H]+ (Calcd. for C26H32O2, 363.1813).

4.3.7. Sarcomilitmalol (7)
Colorless oil; [α]D20 +35 (c 0.1, CHCl3); UV (MeOH) λmax (logε) 247 (2.73), 286 (2.50), 297 (2.39) nm; IR (KBr) νmax 3359, 2921, 2851, 1763, 1659, 1632, 1468, 1180, 1132, 1077 cm⁻¹; For 1H and 13C NMR spectroscopic data, see Table 2; (+)-HR-ESI-MS m/z 315.1957 [M – H2O + H]+ (Calcd. for C23H29O5, 315.1955).

4.3.8. (+)-Isosarcophytoxide (9)
Colorless oil; [α]D20 +24 (c 0.1, CHCl3); ECD [CH2CN, λ(α) (nm) (Δε), c 0.0016 M]; 242 (+37); UV (MeOH) λmax (logε) 246 (3.87) nm; IR (KBr) νmax 3362, 2922, 2852, 1195, 1132, 1077 cm⁻¹; For 1H and 13C NMR spectroscopic data, see Table 2; EI-MS m/z 304 [M]+ (5), 289 (4), 261 (5), 243 (6), 151 (29), 137 (71), 135 (23), 133 (25), 123 (39), 121 (37), 109 (100), 107 (49); HR-ESI-MS m/z 304.2409 [M]+ (Calcd. for C29H32O2, 304.2402).

4.3.9. (+)-Isosarcophine (10)
Colorless oil; [α]D20 +111 (c 0.6, CHCl3); lit.: [α]D20 +160 (c 0.22, CHCl3); (+)-HR-ESI-MS m/z 302.2240 [M]+ (Calcd. for C29H32O2, 302.2246).

4.4. Preparation of the (S)- and (R)-MTPA ester derivatives of compound 1
To 0.92 mg of compound 1 was added 450 µL of pyridine-d5, and the solution was transferred into an NMR tube. To initiate the reaction, 15 µL of (S)-MTPA-Cl was added with careful shaking and then monitored immediately by 1H NMR at the following time points: 0, 5, 10, 15, and 20 min. The reaction was found to be complete in 20 min, yielding the mono (R)-MTPA ester derivative (1r) of 1.

In an analogous manner, 0.85 mg of compound 1 dissolved in 450 µL of pyridine-d5 was reacted in a second NMR tube with 15 µL of (R)-MTPA-Cl for 20 min, to afford the mono (S)-MTPA ester (1s).

4.4.1. (R)-MTPA ester (1r) of 1
1H NMR data of 1r (400 MHz, pyridine-d5) δH 7.570 – 7.351 (5 H, m, Ar-H), 6.147 (1H, ddd, J = 10.8, 9.2, 5.6 Hz, H-6), 5.513 (1H, m, H-2), 5.256 (1H, d, J = 9.2 Hz, H-7), 5.157 (1H, d, J = 9.6 Hz, H-3), 4.581 (1H, dd, J = 12.0, 4.0 Hz, H-16a), 4.497 (1H, dd, J = 12.0, 3.2 Hz, H-16b), 3.627 (3H, s, OCH3-MTPA), 2.754 (1H, dd, J = 12.4, 5.2 Hz, H-5a), 2.441 (1H, dd, J = 11.2, 2.8 Hz, H-11), 2.316 (1H, dd, J = 12.4, 10.8 Hz, H-5b), 1.851 (3H, s, H3-19), 1.608 (3H, s, H3-17), 1.523 (3H, s, H3-18), 1.301 (3H, s, H3-20).

4.4.2. (S)-MTPA ester (1s) of 1
1H NMR data of 1s (400 MHz, pyridine-d5) δH 7.628 – 7.351 (5 H, m, Ar-H), 6.112 (1H, ddd, J = 10.8, 9.2, 5.6 Hz, H-6), 5.518 (1H, m, H-2), 5.193 (1H, d, J = 9.2 Hz, H-7), 5.120 (1H, d, J = 9.6 Hz, H-3), 4.586 (1H, dd, J = 12.0, 4.0 Hz, H-16a), 4.502 (1H, dd, J = 12.0, 3.2 Hz, H-16b), 3.632 (3H, s, OCH3-MTPA), 2.801 (1H, dd, J = 12.4, 5.2 Hz, H-5a), 2.431 (1H, dd, J = 11.2, 2.8 Hz, H-11), 2.444 (1H, dd, J = 12.4, 10.8 Hz, H-5b), 1.850 (3H, s, H3-19), 1.608 (3H, s, H3-17), 1.532 (3H, s, H3-18), 1.279 (3H, s, H3-20).

4.5. Acetylation of compound 1
Compound 1 (1.2 mg) was dissolved in pyridine (0.5 mL) and Ac2O (0.5 mL), and the reaction was left to stir at room temperature overnight. MeOH (5 mL) was added to the reaction mixture to remove excess pyridine and Ac2O in vacuo, yielding a brown oil (3.4 mg). The crude product was purified by silica gel CC eluting with PE (60–90°C)-Et2O (8:2–7:3) to afford a colorless oil (0.8 mg, [α]D20 +65 (c 0.09, CHCl3); [α]D20 +51 (c 0.09, MeOH)), which was identical to the natural sample of 2 in all respects.

4.6. ECD calculation of compound 8
Torsional sampling (MCMCM) conformational searches using OPLS_2005 force field were carried out by means of the conformational search module in the Macro model 9.9.223 software (Schrodinger; http://www.schrodinger.com/MacroModel) applying an energy window of 21 kJ/mol, which afforded 74 conformers for 8. The Boltzmann populations of the conformers were obtained based on the potential energy provided by the OPLS_2005 force field, which afforded 13 conformers for 8 above 1% population for re-optimization. The re-optimization and the following TDDFT calculations of the re-optimized geometries were all performed with Gaussian 0911 at the B3LYP/6-311G(d,p) level with IEFPCM solvent model for acetonitrile. Frequency analysis was performed as well to confirm that the re-optimized geometries were at the energy minima. Finally, the SpecDis1.62 software29 was used to obtain the Boltzmann-averaged ECD spectrum of the compound and visualize the results as shown (Fig. 6).

4.7. Cytotoxicity bioassays
The cytotoxicities of compounds 1–10 against human promyeloctyeic leukemia cells (HL-60) and human lung adenocarcinoma cells (A-549) was evaluated by using the MTT and SRB methods, respectively, according to the protocols described in previous literature. The half-maximal inhibition (IC50) was calculated with Graphpad Prism 5.0. IC50 > 10 µmol/L was considered inactive. Adriamycin was used as the positive control, with IC50 values of 0.07 µmol/L for the HL-60 cell line and 0.01 µmol/L for the A-549 cell line, respectively.

4.8. NF-κB signaling pathway inhibitory activity bioassays
NF-κB signaling pathway inhibitory activity was evaluated according to the previously reported protocol30. Stable HEK293/ NF-κB cells were plated into 96 well plates at a concentration of approximate 10,000 cells per well. After culturing overnight, compounds were added to the medium at a final concentration...
of 10 ng/mL. HEK293/NF-κB cells were seeded into 96 well cell culture plates (Corning, NY, USA) and allowed to grow for 24 h. The cells were then treated with compounds, followed by stimulation with TNF-α. Four hours later, cell title blue was added to each well. 2 hours later, the luciferase substrate was added to each well, and the released luciferin signal was detected using an EnVision microplate reader. The IC50 was calculated with Prism 4 software (Graphpad, CA, USA) from the nonlinear curve fitting of the percentage of inhibition (% inhibition) versus the inhibitor concentration [I] by using the Eq. (1): 

$$Inhibition\% = 100/(1 + [IC_{50}/I]^k)$$  \hspace{1cm} (1)$$

where $k$ is the Hill coefficient. Bortezomib was used as a positive control with an IC50 value of 0.03 μmol/L.

Acknowledgments

This work was financially supported by the Natural Science Foundation of China (Nos. 41506187, 8152010802, 21672230 and 81603022), NSFC-Shandong Joint Fund for Marine Science Research Centers (No. U1606403), SCTSM Project (No. 15431901000), the SKLDR/SIMM Projects (SIMM 1705ZZ-01). We thank Prof. Hui Huang from South China Sea Institute of Oceanology, Chinese Academy of Sciences, for the identification of the soft coral material.
