ITERATED RESIDUES AND MULTIPLE BERNOULLI POLYNOMIALS

ANDRÁS SZENES

1. Introduction

In this paper we consider the following problem: let $\mathfrak{A}$ be a central hyperplane arrangement over $\mathbb{Z}$; equivalently, let $V$ be an $n$-dimensional real vector space and $\Gamma \subset V$ a lattice of rank $n$. We will always assume that the $\cap \mathfrak{A} = \{0\}$ and that the lines dual to the hyperplanes in $\mathfrak{A}$ span $V^*$. Denote by $\Lambda$ the lattice in $V^*$ dual to $\Gamma$ over $\mathbb{Z}$. The integrality condition says that each hyperplane $H$ in the arrangement is the zero set of some linear form $x_H \in \Lambda$. We will call a real hyperplane arrangement (HPA) with this extra structure integral (IHPA). Of course, up to isomorphism we always have $\mathbb{Z}^n = \Lambda \subset V = \mathbb{R}^n$.

Some more notation: Let $U = V \setminus \cup \mathfrak{A}$ be the complement of the arrangement and $\Gamma \mathfrak{A} = U \cap \Gamma$. To avoid factors of $2\pi \sqrt{-1}$ in the formulas, introduce $j = j / (2\pi \sqrt{-1})$. We call a function on $V \mathfrak{A}$-rational if it is rational and its poles are contained in $\cup \mathfrak{A}$; similarly an $\mathfrak{A}$-meromorphic function is a meromorphic function defined in a neighborhood of $0 \in V$ with poles contained in $\cup \mathfrak{A}$. Denote these classes of functions by $R_{\mathfrak{A}}$ and $M_{\mathfrak{A}}$.

For any $\mathfrak{A}$-rational function $f$, we are interested in calculating the following sums:

\[ B_{f,\mathfrak{A}} = \sum_{j \in \Gamma \mathfrak{A}} f(j). \]

An example of such a sum is

\[ S(a,b,c) = \sum \frac{1}{m^a n^b (m+n)^c}, \quad m, n \in \mathbb{Z}; \quad m, n, m+n \neq 0, \]

where $a, b, c$ are positive integers.

More generally we will consider the Fourier series:

\[ B_{f,\mathfrak{A}}(t) = \sum_{j \in \Gamma \mathfrak{A}} \exp\langle t, j \rangle f(j), \]

where $t \in V^*$.

We will omit $\mathfrak{A}$ from the notation whenever it does not cause confusion. The infinite sum $B_{f,\mathfrak{A}}(t)$ makes sense as a distribution. For now, we assume

The research was supported by the Alfred Sloan Foundation and the Mittag-Leffler Institute.
that these sums converge absolutely, thus \( B_f(A)(t) \) is a continuous function of \( t \), although eventually we will consider all functions \( f \in R_A \).

A few basic properties: clearly, \( B_f(t) \) is \( A \)-periodic in \( t \) and \( B_f(0) = B_f \). We will show that that \( V^* \) has a chamber decomposition such that \( B_f(t) \) restricts to a polynomial inside each chamber. Because of the periodicity, this decomposition comes from one of \( T = V^*/A \). These polynomials are natural generalizations of the classical Bernoulli polynomials, which correspond to the one-dimensional case (see §2). When \( f \) has rational coefficients, these polynomials will have rational coefficients as well. Following Zagier [16] we named them \textit{multiple Bernoulli polynomials} (MBP).

Now we describe the shape of the result in general terms. The main goal is to give residue formulas, a certain type of generating series, for these MBPs. The singular locus of the MBPs are given by the \( A \)-translates of the dual arrangement \( A^* \) in \( V^* \) formed by the one-dimensional faces of \( A \). Thus for every \( f \in R_A \) and every chamber \( \Delta \) of \( \Lambda + A^* \) we have to find a polynomial \( B^{\Delta}_f(t) \) such that \( B^{\Delta}_f(t) = B_f(t) \), whenever \( t \in \Delta \).

The type of residues which appear naturally in our approach are the \textit{iterated residues} defined in §3. One of the features of our formula is that it is independent of \( f \), i.e. for any integral arrangement \( A \) and chamber \( \Delta \), we construct a local residue form \( \omega^\Delta(A) \) such that whenever \( t \in \Delta \) we have

\[
B^{\Delta}_f(t) = \langle \omega^\Delta(A), f \exp(t) \rangle.
\]

The precise definition of the pairing \( \langle \cdot, \cdot \rangle \) is given in §3.2. One can think of the collection \( \omega = \{ \omega^\Delta(A) \} \) as of a fundamental class of the IHPA \( A \).

The motivation for considering such sums came from the work of Witten on the intersection ring and volume of the moduli spaces of \( G \)-bundles on Riemann surfaces [15, 9], where \( G \) is a compact connected Lie group; the arrangement is given by the coroot hyperplanes in the dual of the Cartan subalgebra of \( G \); the lattice \( \Gamma \) is the weight lattice of the group. Some details are given in §5.

The existence of such \( \omega \) in the Lie group case mentioned above was conjectured in [13, Conjecture 4.2] in a weaker form. We will discuss the relevance of this statement to the topology of the moduli spaces in a separate paper. The sketch of the proof of this conjecture was given in [13] for \( G = SU(3) \), with the claim that the case of \( SU(n) \) is analogous. This result was later used and extended in the works of Jeffrey and Kirwan [7] (see also [11]). The Verlinde-type deformation of these formulas (cf. [13] for a detailed explanation) will be given in a future publication.

Naturally, besides the above, an explicit construction of \( \omega \) is also useful since it gives a simple, efficient calculus for the numbers \( B_f \). A different approach to the calculation of these numbers was given earlier by Zagier [16]. While the formulas in [16] are not as compact as ours, there the multiplicative structure of these numbers and even certain modular deformations of them are considered.
The contents of the paper: In §2 we describe the classical theory in terms of our general setup, in §3 we introduce our version of iterated residues – a very special case of the standard notions such as the Grothendieck residue and Parshin’s residue and show how it relates to the theory of hyperplane arrangements. We give a new interpretation of the broken circuit bases along the way. In §4 we prove the main theorem while in §5 we give some applications and calculations; we work out the most important example of the braid arrangements.

Acknowledgments. The first version of this paper (hep-th/9707114) was completed during my stay at the Mittag-Leffler Institute in the Spring of 1997. I am most grateful to Lev Rozansky and Kefeng Liu whose helpful comments and interest made this work possible. I would like to thank Victor Batyrev, Hiroaki Terao, Alexandr Varchenko, Michel Vergne and Andrei Zelevinski for their suggestions and encouragement. Eva Maria Feichtner provided me with some important references.

2. Classical Bernoulli polynomials

The classical Bernoulli polynomials can be defined using the setup of the introduction as follows: let $V = \mathbb{R}$, $\Gamma = \mathbb{Z}$; there is one “hyperplane” – $\{0\}$, $\Gamma_\alpha = \mathbb{Z} \setminus \{0\}$.

By abuse of notation (we replace $x^{-k}$ by $k$ in the subscript of $B$) we have

$$B_k(t) = \sum_{n \in \Gamma_\alpha} \frac{\exp(nt)}{n^k}. \quad (2.1)$$

This function is defined by a Fourier series, therefore, it is periodic with period 1. Properties:

1. From the Fourier series it is clear that $B_k(t)$ is $k - 2$ times differentiable.
2. $\frac{d}{dt} B_k(t) = B_{k-1}(t)$.
3. $B_0(t) = \delta_Z(t) - 1$, where $\delta_Z(t)$ is the sum of delta-functions at all integers.
4. $\int_0^1 B_k(t) \, dt = 0$, by inspecting the Fourier series.
5. It follows from Properties 1–4 that $B_k$ restricts to a polynomial of degree exactly $k$ on each interval $(m, m + 1)$, which will be denoted by $B^m_k$. These polynomials are defined recursively and have rational coefficients.

The polynomials $B^m_k(t)$ are the Bernoulli polynomials up to a sign and a factor of $k!$.

2.1. Residue formulas. The main goal of this paper is to obtain residue formulas for $B_k(t)$ and its generalizations. The basic technical tool is

**Lemma 2.1.** Let $f$ be a rational function of degree $\leq -2$ on $\mathbb{C}$ and let $P$ be the set of its poles. Then for each $t$, $0 \leq t < 1$,

$$\sum_{n \in \mathbb{Z} \setminus P} \exp(nt)f(n) = \sum_{p \in P} \text{Res}_{x=p} \exp(tx)td(x)f(x), \quad (2.2)$$
where
\[ td(x) = \frac{dx}{1 - \exp(x)}. \]

Proof. Apply the Residue Theorem to a circle of radius \( \pi L \) for odd integer \( L \) and let \( L \to \infty \).

This immediately gives us a residue formula for the Bernoulli polynomials: denoting by \( \{ t \} \) the fractional part of \( t \)
\[ B_k^0(t) = \text{Res}_{x=0} \exp(\{ t \} x) \, td(x) \, x^{-k}, \]
at least for \( k \geq 2 \).

Note that for any \( k \) the series \( B_k(t) \) can be interpreted as a distribution. Then by differentiating \( B_k(t) \) considered as a distribution, we can extend (2.3):

**Lemma 2.2.** For arbitrary integer \( k \) the distribution \( B_k(t) \) is a polynomial function in each interval \(( m, m + 1) \), \( m \in \mathbb{Z} \). For a non-integral \( t \) we have
\[ B_k^m(t) = \text{Res}_{x=0} \omega^m x^{-k}, \]
where \( \omega^m = \exp(-mx) \, td(x) \).

Note that \( B_1(t) \) is a discontinuous function and \( B_0^0(t) = 1/2 - t \), while \( B_0(t) \) is a distribution and \( B_0^m(t) = -1 \) for all \( m \). For \( k < 0 \) always \( B_k^m = 0 \).

3. Iterated Residues and Hyperplane Arrangements

3.1. Residue Forms. In this section, let \( \mathfrak{A} \) be a complex HPA in an \( n \)-dimensional complex vector space \( V_\mathbb{C} \) with complement \( U_\mathbb{C} \). Consider a linearly independent ordered \( n \)-tuple \( S = (H_1, H_2, \ldots, H_n) \) of hyperplanes in \( \mathfrak{A} \). We define a linear operation on \( \mathfrak{A} \)-meromorphic functions \( \text{IRes}_S : M_\mathfrak{A} \to \mathbb{C} \) as follows. First note that there is a well defined notion of “the constant term at 0” of a meromorphic function \( f \) on a complex line (1-dimensional complex vector space), which we will denote by \( \text{Res}_{x=0} f \). This is simply the degree 0 coefficient in the Laurent expansion of \( f \). Take an element \( g \in R_\mathfrak{A} \) and consider the family of lines parallel to \( \cap_{i=2}^n H_i \). Each of these lines is a complex line with 0 on \( H_1 \) and the restriction of \( g \) onto them has a well-defined constant term. Thus we obtain a new function \( \text{Res}_{H_1} g \) on \( H_1 \). This procedure can be repeated with \( H_2 \), replacing \( V_\mathbb{C} \) by \( H_1 \), \( g \) by \( \text{Res}_{H_1} g \) and \( H_1 \) by \( H_1 \cap H_1 \). Iterating this \( n \) times, we arrive at a number
\[ \text{IRes}_S g = \text{Res}_{H_n} \cdots \text{Res}_{H_2} \text{Res}_{H_1} g. \]

We call this operation an iterated residue. A few important points:

**Remark 3.1.** 1. Usually taking a residue is applied to differential forms not instead of \( \text{Res} \) to mark the difference, but it may have been more proper to call this operation “constant term” rather than residue.
2. The operation $I\text{Res}_S$ is a degree 0 operation with respect to the $\mathbb{C}^*$ action on $V_C$.
3. A more practical method of computation of iterated residues is given in §5.
4. The operation $I\text{Res}_S g$ depends on the order of the hyperplanes!
5. The notation $\text{Res}_H g$ above is inconsistent since this operation actually depends on the other $H_i$-s as well. There is one case, however, when this is not so: when $g$ is regular along $H$, then $\text{Res}_H g = g|_{H_1}$, the restriction of $g$ onto $H_1$.

Now we explain how this operation is related to the standard calculus of homology and cohomology of the complement of HPAs [12, 14]. Let $\mathfrak{A}_k^{\text{ind}}$ be the set of ordered linearly independent $k$-tuples of elements of $\mathfrak{A}$ and let $\mathbb{Z}\mathfrak{A}_k^{\text{ind}}$ be the free $\mathbb{Z}$-module generated by $\mathfrak{A}_k^{\text{ind}}$. Any map $m : \mathfrak{A}_k^{\text{ind}} \to A$ to an Abelian group $A$ extends to a map $m : \mathbb{Z}\mathfrak{A}_k^{\text{ind}} \to A$ denoted by the same letter. Denote by $\Omega^*_\mathfrak{A}$ the graded algebra of local meromorphic differential forms on $V_C$ with poles along $\cup \mathfrak{A}$.

Consider an ordered $k$-tuple of hyperplanes $S = (H_1, \ldots, H_k) \in \mathfrak{A}_k^{\text{ind}}$, and assume that $H_i$ is represented by a form $x_i$ and let $\alpha_i = d\log x_i$, $i = 1, \ldots, k$. Denote by $\mu(S)$ the differential form $\alpha_1 \wedge \cdots \wedge \alpha_k$. Then $\mu$ is a map from a $\mathbb{Z}\mathfrak{A}_k^{\text{ind}}$ to $\Omega^*_\mathfrak{A}$, and it clearly induces a map $\mu^\wedge$ from the $k$th exterior product of $\mathbb{Z}\mathfrak{A}$ to differential $k$-forms. All these forms are integral and closed and the fundamental statement in the theory is that $\mu$ factors through a surjective map $b$ to $H^k(U_C, \mathbb{Z})$.

The story is summarized in the commutative diagram below. The maps $b^\wedge, \mu^\wedge$ and $q$ are algebra homomorphisms.

![Diagram](image)

To simplify the notation we will not put an index on the maps marking the degree.

**Remark 3.2.** The subalgebra of differential forms generated by logarithmic forms $O\mathfrak{S}^* = \mu(\mathbb{Z}\mathfrak{A}_k^{\text{ind}})$ is naturally isomorphic to $H^*(U_C, \mathbb{Z})$. This algebra is called the Orlik-Solomon algebra of $\mathfrak{A}$ and it can be defined combinatorially in a more general framework. We cannot do justice to the subject here and
refer the reader to the monograph [12] and the original works of Arnold [1], Brieskorn [3], Orlik and Solomon [11] and Björner [2].

There is an interesting picture related to the homology of the complement as well. Denote by $\mathcal{F}_k^A$ the set of partial $k$-flags (sequences of subspaces of codimensions $1, \ldots, k$) of $A$ and again consider an element $S \in \mathcal{A}_{\text{ind}}$ as above. Then we can associate to $S$ an element $\text{fl}(S) = (H_1, H_1 \cap H_2, \ldots, \cap_{i=1}^k H_i)$.

One can also associate to $S$ a $k$-cycle represented by a $k$-torus as follows (cf. p. 159 in [14]): fix a set of positive $\varepsilon_i$, $i = 1, \ldots, n$ such that $0 < \varepsilon_1 \ll \varepsilon_2 \ll \cdots \ll \varepsilon_n$ and let $(H_1, \ldots, H_k, H_{k+1}, \ldots, H_n)$ be a completion of $S$ to an independent $n$-tuple. Then the homotopy class of the torus
\[
\{ |x_i| = \varepsilon_i, \; i = 1, \ldots, k, \; x_i = \varepsilon_i, \; i = k+1, \ldots, n \}
\]
in $U_C$ is well-defined, and its orientation is fixed by the complex structure. The homology of this torus, $Z(S)$, only depends on $\text{fl}(S)$.

\[
\begin{array}{ccc}
\mathbb{Z}\mathcal{A}_k^A & \xrightarrow{\text{fl}} & \mathcal{F}_k^A \\
Z & \xrightarrow{\text{fl}} & Z^\text{fl} \\
\mathbb{Z}\mathcal{A}_k^A_{\text{ind}} & \xrightarrow{b \otimes Z} & H^k(U_C, \mathbb{Z}) \otimes H_k(U_C, \mathbb{Z})
\end{array}
\]

One can give explicit generators for the kernels of the maps $b^\wedge$ and $Z^\text{fl}$ (cf. Proposition 3.4 and [14]).

By tensoring the maps in the above diagrams we obtain

\[
\Omega_k^A \otimes H_k(U_C, \mathbb{Z})
\]

\[
\text{IR} = \mu \otimes Z
\]

\[
\mathbb{Z}\mathcal{A}_k^A_{\text{ind}} \xrightarrow{b \otimes Z} H^k(U_C, \mathbb{Z}) \otimes H_k(U_C, \mathbb{Z})
\]

We introduce the notation IR for the iterated residue map $\mu \otimes Z$, and use the same symbol $q$ for the map $q \otimes \text{id}$.

The connection of IR with iterated residues can be seen as follows: let $k = n$ and define a pairing between $H_n(U_C, \mathbb{Z}) \otimes \Omega_n^A$ and $\text{Mer}_A$ by

\[
\langle C \otimes \eta, g \rangle = \int_C g \eta,
\]

where $C \in H_n(U_C, \mathbb{Z})$ and $\eta \in \Omega_n^A$. Note that it is essential that we restrict to $k = n$ here, because only in this case is $g \eta$ necessarily a closed form.

Then we have

**Proposition 3.1.** Let $S \in \mathcal{A}_{\text{ind}}$ and $g \in \text{Mer}_A$. Then

\[
\text{IR}_S g = \langle \text{IR}(S), g \rangle.
\]
Proof: The proof easily follows from Cauchy’s theorem. The residue integrals which appear in calculating the pairing give exactly the same result as the procedure in the definition of the iterated residues.

Remark 3.3. The last diagram suggests an interesting application of this formalism. Since $H^k(U_C, \mathbb{Z})$ and $H_k(U_C, \mathbb{Z})$ are naturally dual to each other, there is a canonical diagonal element $\text{diag}^k \in H^k(U_C, \mathbb{Z}) \otimes H_k(U_C, \mathbb{Z})$. Thus there is an invariantly defined notion of the “constant term” of any $f \in \text{Mer}_\mathfrak{A}$ defined by the formula

$$\langle q(\text{diag}^n), f \rangle.$$  

This will be more exciting if we show that this is an iterated residue, i.e. that $\text{diag}^n \in \text{im}(b \otimes \mathbb{Z})$. This is indeed the case as we will prove in the next paragraph (cf. Proposition 3.6).

We make a much stronger conjecture:

Conjecture 3.2. The map $b \otimes \mathbb{Z} : \mathfrak{A}^n_{\text{ind}} \rightarrow H^n(U_C, \mathbb{Z}) \otimes H_n(U_C, \mathbb{Z})$ is surjective.

3.2. Broken circuit bases. Here we recall some of the basics of the theory of HPAs and broken circuit bases of Orlik-Solomon algebras (cf. [12]). We show how “non-commutative” broken circuit bases fit naturally into the picture of the previous paragraph.

A circuit $C$ is a minimally dependent subset of $\mathfrak{A}$, i.e. $C$ is dependent but $C \setminus \{H\}$ is independent for any $H \in C$. The kernel of the map $\mu^\wedge : \bigwedge \mathfrak{A}^* \rightarrow \Omega^*_\mathfrak{A}$ can be described using circuits as follows: Assume that the elements of a circuit $C$ are linearly ordered and denote by $C \setminus \{i\} \in \mathfrak{A}^{|C|-1}$ the ordered set obtained by omitting the $i$th element of $C$.

Proposition 3.3 ([12]). Every ordered circuit $C$ gives rise to an element $\text{rel}(C) \in \ker b$ given by

$$\text{rel}(C) = \sum_{i=1}^{|C|} (-1)^i C[i].$$  

(3.3)

Proof. We give a proof of this statement here, as it will be needed later.

Recall that $b$ takes the $k$-tuple $(H_1, \ldots, H_k)$ to the form $\alpha_1 \wedge \cdots \wedge \alpha_k$. Since $\alpha_i = d \log(x_i)$ depends on $x_i$ only up to a scalar multiple, and using that $C$ is a circuit, we can assume that the relation among the elements of $C$ is given by $\sum x_i = 0$. Then for $1 \leq s, t \leq k$ we have $\wedge_{i \notin s} dx_i = (-1)^{s-t} \wedge_{i \notin t} dx_i$, and thus $\mu(\text{rel}(C))$ reduces to

$$\left( \sum_{i=1}^k \prod_{j \neq i} x_j^{-1} \right)^{k-1} \wedge_{i=1} dx_i.$$  

This clearly vanishes since the coefficient reduces to $\sum x_i$ after multiplication by $\prod x_i$.  

\hfill $\Box$
Proposition 3.4 ([12]). The kernel of $\mu^*\cup$ is given by the ideal in $\bigwedge \mathbb{Z} A^*$ generated by the elements $\{\wedge (\text{rel}(C)) | C \text{ is a circuit}\}$.

See [12] for the proof.

There is a way to construct a basis of the Orlik-Solomon algebra by "breaking" the relations given by the circuits. Denote by $|A|$ the number of elements in $A$, and by $\mathbb{N}$ the set of integers from 1 to $|A|$. Then one can represent an ordering $\sigma$ of the elements of $A$ by a bijection $\sigma : A \rightarrow \mathbb{N}$. Below, we define special subsets $\text{BCB}_k^\sigma \subset A_k^{\text{ind}}$ for every ordering $\sigma$ and every $k$. To simplify the notation, we will regard elements $S \in A_k^{\text{ind}}$ as functions $S : \{1, \ldots, k\} \rightarrow A$, but, when it does not cause confusion, we will use the notation $H \in S$ to say that $H$ is one of the hyperplanes in $S$.

Definition 3.1. $\text{BCB}_k^\sigma$ consists of those elements of $A_k^{\text{ind}}$ ordered according to $\sigma$ which do not contain "broken circuits":

(3.4) $\text{BCB}_k^\sigma = \{S \in A_k^{\text{ind}} | \sigma(S(i)) < \sigma((S(i)+1)), \ 1 \leq i < k \text{ and for any } H \notin S \{H\} \cup \{G \in S | \sigma(G) > \sigma(H)\} \text{ is independent}\}$

Note that our definition is somewhat different from the standard one in that we retain the ordering among the elements of the BCB.

Using BCBs one can construct bases of the Orlik-Solomon algebra:

Proposition 3.5 ([12] Theorem 3.43). For any ordering $\sigma$, the set $\mu(\text{BCB}_k^\sigma)$ is a $\mathbb{Z}$-basis of $\text{OS}^k$ and, equivalently, $b(\text{BCB}_k^\sigma)$ is a basis of $H^k(U_C, \mathbb{Z})$.

Our "non-commutative" version of broken circuit bases has a stronger property. This is the statement mentioned in Remark 3.3.

Proposition 3.6. For every ordering $\sigma$ introduce the element

$$D_k^\sigma = \sum_{S \in \text{BCB}_k^\sigma} S \in A_k^{\text{ind}}, \ (1 \leq k \leq n).$$

Then

$$(b \otimes Z)(D_k^\sigma) = \text{diag}^k.$$

Proof. Let $S, Q \in A_k^{\text{ind}}$, and for a permutation $\tau \in S_k$ denote by $S^\tau$ the $n$-tuple in $A_k^{\text{ind}}$ with the same elements as $S$, but permuted by $\tau$. Then [14, §4]

$$\langle b(S), Z(Q) \rangle = \begin{cases} 0, & \text{if } \text{fl}(S^\tau) \neq \text{fl}(Q) \text{ for any } \tau \in S_k \\ (-1)^{\text{parity}(\tau)}, & \text{if } \text{fl}(S^\tau) = \text{fl}(Q), \end{cases}$$

where $\langle , \rangle$ is the pairing between cohomology and homology. In particular, clearly $\langle b(S), Z(S) \rangle = 1$ for all $S \in A_k^{\text{ind}}$.

Combining this observation with the previous proposition, the statement reduces to showing that there are no $S, Q \in \text{BCB}_\sigma$ and $\tau \in S_k$ such that

(3.5) $\text{fl}(S^\tau) = \text{fl}(Q)$.
Indeed, assume that such \( S, Q, \tau \) exist. First, by the assumption we have \( S^\tau(k) = Q(k) \); denote this element by \( H \). Next, again because of (3.3) the triple \( S^\tau(k - 1), Q(k - 1), H \) must be linearly dependent. Now if \( \sigma(S^\tau(k - 1)) < \sigma(Q(k - 1)) \), then this contradicts \( Q \in \text{BCB}_{\sigma} \), while \( \sigma(S^\tau(k - 1)) > \sigma(Q(k - 1)) \) contradicts \( S \in \text{BCB}_{\sigma} \). Thus the only possibility is \( S^\tau(k - 1) = Q(k - 1) \). Continuing inductively we can show that \( S^\tau(j) = Q(j) \) for \( j = 1, \ldots, k \), which implies \( S = Q \). \( \square \)

**Corollary 3.7.** The set \( Z(\text{BCB}_k^k) \) is a basis of \( H_k(U_C, Z) \).

**Remark 3.4.** Compare this result with Lemmas 2.10-11 in [4].

Let us give a name to the property introduced in Proposition 3.6:

**Definition 3.2.** A set \( DB^k \subset \mathfrak{A}_{\text{ind}}^k \) is a diagonal basis in degree \( k \) if

\[
\sum_{S \in DB^k} (b \otimes Z)(S) = \text{diag}^k.
\]

Proposition 3.6 shows that any ordering \( \sigma \) gives rise to a diagonal basis \( \text{BCB}^k_\sigma \) for \( k = 1, \ldots, n \). In [4] we will see an example of a diagonal basis which does not come from a BCB.

Note that Proposition 3.6 also shows, that \( D_{\sigma'}^k = D_{\sigma}^k \mod \ker(b \otimes Z) \) for any two orderings \( \sigma \) and \( \sigma' \). This formally gives us \(|\mathfrak{A}|! - 1 \) relations in \( \ker(\text{IR}) \subset \mathbb{Z}\mathfrak{A}_{\text{ind}}^k \) for each \( k \).

We make the following

**Conjecture 3.8.** The kernel of IR is generated by the relations \( D_{\sigma}^k \sim D_{\sigma'}^k \) for all \( k \).

Now, we check how BCBs behave under the standard deletion-contraction in \( \mathfrak{A} \). What follows is parallel to the arguments in [12].

We take advantage of the usual technique of a triple, basic in the theory of HPAs [12, Chapter 3]. For \( H \in \mathfrak{A} \), the corresponding triple consists of \( \mathfrak{A} \), \( \mathfrak{A} \setminus H \) and \( \mathfrak{A} | H \), the arrangement induced on \( H \) by intersections with other elements of \( \mathfrak{A} \). Thus there is a natural surjection \( \pi : \mathfrak{A} \setminus H \to \mathfrak{A} | H \).

Pick an element \( H \in \mathfrak{A} \) and fix an ordering \( \sigma : \mathfrak{A} \to |\mathfrak{A}| \), compatible with \( H \) in the following sense:

1. \( H \) is last, i.e. \( \sigma(H) = |\mathfrak{A}| \) and
2. if \( H_1 \cap H = H_3 \cap H \) and \( \sigma(H_1) < \sigma(H_2) < \sigma(H_3) \), then \( H_1 \cap H = H_2 \cap H \).

The ordering \( \sigma \) induces an obvious ordering \( \sigma \setminus H \) on \( \mathfrak{A} \setminus H \), and in view of the second property also an ordering \( \sigma | H \) on \( |\mathfrak{A}| \). via the lift Denote by \( l_\sigma \) the lift \( \mathfrak{A} | H \to \mathfrak{A} \setminus H \) which takes an element \( H' \in \mathfrak{A} | H \) to the element \( H'' \in \mathfrak{A} \setminus H \) which satisfies \( \pi(H'') = H' \) and has the least \( \sigma \)-value.

**Proposition 3.9.**

\[
\text{BCB}^k_{\sigma}(\mathfrak{A}) = \text{BCB}^k_{\sigma \setminus H}(\mathfrak{A} \setminus H) \cup l_\sigma(\text{BCB}^k_{\sigma | H(|\mathfrak{A}|)}) \ast H;
\]
In words: the BCB of $A$ is the BCB of $A \setminus H$ plus the set of elements of $A^{k}_{\text{ind}}$ obtained by appending $H$ to the end of the lifts of the BCB of $A|H$.

**Proof.** The proof is a straightforward check of the definitions based on the following fact from linear algebra: a set of hyperplanes $H_1, \ldots, H_k, H \in A$ is linearly independent if and only if the hyperplanes $H_1 \cap H, \ldots, H_k \cap H$ in $H$ are linearly independent. \(\square\)

4. Integral arrangements and the main result

Let $A$ be an integral arrangement. In this section, we describe a deformation of the constructions of the previous section, which uses the extra structure of integrality. Note that most constructions will work for $k = n$ only.

We retain the notation of §1 and introduce some more: $A^* \subset V^*$ is the dual arrangement in $V^*$, consisting of the hyperplanes dual to the one-dimensional faces of $A$; $\Delta$ will stand for an open chamber in the decomposition of $V^*$ generated by all lattice translates of these dual hyperplanes, i.e. by $\Lambda + \cup A^*$. We will call a point $t \in V^*$ in the complement of $\Lambda + \cup A^*$ regular, and denote by $\Delta(t)$ the chamber which contains $t$.

Our goal is to find a residue form $\omega_\Delta \in \Omega^m_\Lambda \otimes H_n(U_C, \mathbb{Z})$ such that for every regular $t \in \Delta$ and $f \in R_\Lambda$ we have

$$B_f(t) = \langle \omega_\Delta, \exp(t)f \rangle.$$  

Here we think of $t \in V^*$ as linear function on $V$.

As a first step, we construct a new map $\hat{\mu}_\Delta : \mathfrak{A}^n_{\text{ind}} \to \Omega^m_\Lambda$ as follows. Let $S \in \mathfrak{A}^n_{\text{ind}}$, and choose an ordered set of forms $\vec{x} = (x_1, \ldots, x_n)$, so that $x_i \in \Lambda$ and $x_i$ defines $S(i)$. Let $\square(\vec{x})$ be the unit cube

$$ \{ z \in V^* | z = \sum \lambda_i x_i, \ 0 \leq \lambda_i < 1 \},$$

and denote by vol$(\vec{x})$ the volume of this cube with respect to $\Lambda$. Then define

$$\hat{\mu}_\Delta(S) = \frac{1}{\text{vol}(\vec{x})} \Lambda_{i=1}^n \text{td}(x_i) \sum_{y \in \Lambda \cap (\square(\vec{x}) - t)} \exp(y),$$

where $t$ is a point in $\Delta$; the form $\text{td}(x)$ was defined in Lemma 2.1. Note that the sum in the definition contains vol$(\vec{x})$ terms. The definition is justified by the following

**Proposition 4.1.** The form $\hat{\mu}_\Delta(S)$ is independent of the representative forms $x_i$ and only depends on $S$ and $\Delta$.

**Example:** Consider the one-dimensional case and let $t \in (0, 1)$. Then we have

$$ \frac{dx}{1 - \exp(x)} = \frac{1 + \exp(x)}{2} \frac{d2x}{1 - \exp(2x)} = \frac{\exp(-x) d(\exp(-x))}{1 - \exp(-x)}.$$

To place this statement in the correct framework, it is convenient to introduce the analogs of the spaces of rational functions and logarithmic differentials in the integral case.
Definition 4.1. Let $E(\Lambda)$ be the ring over $\mathbb{C}$ generated by $\{\exp(x) | x \in \Lambda\}$, the coordinate ring of the torus $V/\Gamma$. Let $\hat{\mathcal{OS}}(\mathfrak{H})$, the graded $E(\Lambda)$-subalgebra of $\Omega^*_\mathfrak{H}$ generated by the forms $td(x)$, for $x \in \Lambda$, defining some hyperplane in $\mathfrak{H}$. A related object is the $E(\Lambda)$-algebra $\hat{\mathcal{R}}_A$ generated by the functions $(1 - \exp(x))^{-1}$ for the same set of $x \in \Lambda$. There is an extension of graded algebras $\hat{h} : \hat{\mathcal{OS}}(\mathfrak{H}) \rightarrow \mathcal{OS}(\mathfrak{H})$ taking $td(x)$ to $d\log(x)$ and $\exp(x) \in E(\Lambda)$ to $1 \in \mathbb{C}$.

Proof of Proposition 4.1. For any subset $U \subset V^*$ define the function $\chi(U) = \sum_{y \in U \cap \Lambda} \exp(y)$ which will be called the character of $U$. Also, denote by $d\Lambda_x$ the volume form on $V^*$ induced by $\Lambda$ and oriented according to $x$. The proof is based on the following geometric interpretation of (4.1):

$$\hat{\mu}_\Delta(S) = \chi(-t + \text{Cone}(x)) \, d\Lambda_x,$$

(4.2)

where $\text{Cone}(x)$ is the closed cone generated by the $x_i$-s and the equality means that in the LHS the denominators are expanded according to

$$(1 - u)^{-1} = \sum u^i.$$

The following is a central technical statement. It shows that the relations in the algebra $\hat{\mathcal{R}}_A$ reflect the geometry of the cones in the lattice $\Lambda$.

Lemma 4.2. Define $P(x) \in \hat{\mathcal{R}}_\Lambda$ by

$$P(x) = \prod_{x \in \Lambda} \frac{1}{1 - \exp(x)}$$

for a linearly independent subset $x \subset \Lambda$. Let $x_\beta, \beta \in a$ be a finite collection of linearly independent subsets of $\Lambda$ and $x_\beta \in \Lambda, \beta \in a$ such that the disjoint union $\bigcup(x_\beta + \text{Cone}(x_\beta))$ is invariant with respect to some translation $y \in \Lambda$. Then the following relation holds in $\hat{\mathcal{R}}_\Lambda$:

$$\sum_{\beta \in a} \exp(x_\beta) P(x_\beta) = 0.$$

(4.3)

Proof. The character $\chi(\bigcup(x_\beta + \text{Cone}(x_\beta)))$ is exactly the LHS of (L3). Thus the lemma follows from the fact that the character of a translation invariant set is a distribution with support in codimension 1. \qed

Now we can complete the proof of the Proposition. The ambiguity in the definition (L1) of $\hat{\mu}_\Delta(S)$ arises because one can multiply an $x_i$ by an integer. The definition given in (L2) is more invariant, since it does not change if we multiply some $x_i$ by a positive integer. It does change if some $x_i$ changes sign, however the difference between the two formulas will be a volume form with a coefficient which is the character of an $x_i$-invariant set. Thus by the Lemma the two definitions coincide. \qed

The Lemma can be also used to prove the following deformation of the circuit relations. Recall the notation of Proposition 3.3.
Proposition 4.3. For any ordered circuit \( C \), one has

\[
\sum_{i=1}^{|C|} (-1)^i \hat{\mu}_\Delta (C[i]) = 0
\]

\[ (4.4) \]

Proof. The proof is modeled on the corresponding proof of the circuit relation (Proposition 3.3) described in the previous paragraph. Indeed, using Proposition 4.1 we can again assume that the linear dependence among the \( x_i \)-s is of the form \( \sum_{i=1}^{n+1} x_i = 0 \) by taking if necessary, suitable integer multiples of the defining forms. Then the expression in (4.4) simply reduces to the sum of characters of the \( n + 1 \) cones generated by the the \( x_i \)-s with vertex at \(-t\). The union of these cones is the the whole of \( V^* \). Now the proposition follows from Lemma 4.2. \( \square \)

This Proposition is of key importance for us. Combined with Proposition 3.4 it shows that \( \hat{\mu}_\Delta \), just as \( \mu \), factors through \( b \), thus there is a map \( \hat{q}_\Delta : H^n(\mathcal{U}_C, \mathbb{Z}) \to \Omega^n_\Delta \) such that \( \hat{\mu}_\Delta = \hat{q}_\Delta \circ b \). The following diagram summarizes the situation. The map \( s_\Delta \) is a splitting of the extension \( \hat{h} \).

\[
\[
\text{Remark 4.1.} \quad \text{Our deformed embedding of the top piece of the Orlik-Solomon algebra into differential forms seems to be a trigonometric deformation of the constructions in \S 5 of [5].}
\]

Now we can extend the constructions of the previous section as follows. Again, tensor this diagram with diagram (3.1), use the symbol \( \hat{q}_\Delta \) for \( \hat{q}_\Delta \otimes \text{id} \), and introduce the notation \( \hat{\text{IR}}_{\Delta} = \hat{\mu}_\Delta \otimes \mathbb{Z} \). For every chamber \( \Delta \), we obtain special elements

\[
\hat{q}_\Delta(\text{diag}^n) \in \Omega^n_\Delta \otimes H_n(\mathcal{U}_C, \mathbb{Z}),
\]

which can be represented by an “iterated residue”

\[
\hat{q}_\Delta(\text{diag}^n) = \sum_{S \in DB^n} \hat{\text{IR}}_{\Delta}(S),
\]

(4.5)

where \( DB^n \) is any diagonal basis.

Theorem 4.4. Let \( f \in R_\mathcal{A} \) and \( t \in V^* \) regular element.
1. For \( f \in \mathbb{R}^\Lambda \) the distribution \( B_f \) defined by the Fourier series (1.2) is a polynomial function inside every chamber \( \Delta \in V^* \) of \( \Lambda + \cup \mathfrak{A}^* \).

2. For \( t \in \Delta \) we have the following three formulas for the multiple Bernoulli polynomials:

\[
\begin{align*}
\text{(A)} & \quad B_f(t) = \langle \hat{q}_\Delta(\text{diag}^n), \exp(t)f \rangle, \\
\text{(B)} & \quad B_f(t) = \sum_{S \in DB^n} \langle \text{IR}_\Delta(S), \exp(t)f \rangle, \\
\text{(C)} & \quad B_f(t) = \sum_{S \in DB^n} \text{Res}_S \frac{1}{\text{vol}(\bar{x})} \prod_{i=1}^n \text{Todd}(x_i) \left( \sum_{y \in \Lambda \cap (\bar{x} - t)} \exp(y) \right) \exp(t)f,
\end{align*}
\]

where \( \bar{x} = (x_1, \ldots, x_n) \) is a sequence of forms representing \( S \), \( DB^n \) is any diagonal basis in degree \( n \) and

\[
\text{Todd}(x) = \frac{x}{1 - \exp(x)}.
\]

**Proof.** First note that the formulas (A) and (B) are equivalent in view of (4.5) and formula (C) follows from formula (B) by Proposition 3.1 and the definition of \( \mu_\Delta \) in (4.1).

We will prove the first part of the theorem and formula (B) by induction on the number of hyperplanes \( |\mathfrak{A}| \).

The starting step of the induction will be the case when \( \mathfrak{A} \) is elementary, i.e. \( |\mathfrak{A}| = n \). In this case \( \mathfrak{A}_{\text{ind}}^n \) consists of one element and there is a single iterated residue. For \( n = 1 \) formula (B) reduces to Lemma 2.2. For \( n > 1 \), pick some representative forms \( \bar{x} = (x_1, \ldots, x_n) \) and denote by \( \Lambda_{\bar{x}} \) the sublattice of \( \Lambda \) they generate. Without loss of generality we can assume that \( f = \prod_{k=1}^n x_i^{-\lambda_i} \). If \( \Lambda_{\bar{x}} = \Lambda \) then the infinite sum defining \( B_f \) is simply a product of the one-dimensional sums, thus \( B_f(t) = \prod_{k=1}^n B_{\lambda_k}(t_i) \), where the function \( B_k \) was defined in (2.1) and \( t_i \) are the components of \( t \) in the basis \( \bar{x} \). The iterated residues also split into a product of one-dimensional residues: for example, for the basic chamber \( \Delta = \{x | 0 < x_i < 1 \} \)

\[
\langle \text{IR}_\Delta(H_1, \ldots, H_n), \exp(t) \prod_{k=1}^n x_i^{-\lambda_i} \rangle = \prod_{k=1}^n \text{Res}_{H_i} \frac{x_i}{1 - \exp(x_i)} \exp(0)x_i^{-\lambda_i}.
\]

Clearly, both formula (B) and part 1 hold.

For the general case \( \Lambda_{\bar{x}} \neq \Lambda \), note that if we ignore the correction factor

\[
\frac{1}{\text{vol}(\bar{x})} \sum_{y \in \Lambda \cap (\bar{x} - t)} \exp(y)
\]
in (4.1) for the moment, we obtain the formula for the product Bernoulli polynomial \( B_{f,\vec{x}}(t) \), corresponding to the lattice \( \Gamma_{\vec{x}} \), which is dual to \( \Lambda_{\vec{x}} \), and, naturally, contains \( \Gamma \). A simple computation shows that

\[
B_f(t) = \frac{1}{\text{vol}(\vec{x})} \sum_{y \in \Lambda/\Lambda_{\vec{x}}} B_f(t + y).
\]

This uses the fact that the sum of the characters of a finite group \( G \) (in our case \( \Gamma_{\vec{x}}/\Gamma \)) is the function on the group with support at the identity and value \(|G|\). It is easy to see then that (4.7) exactly gives rise to the above correction factor in the iterated residue formulas.

Now consider an arbitrary \( n \) dimensional arrangement \( A \) such that \(|A| > n\). According to our inductive hypothesis, we can assume that the theorem holds for all arrangements with fewer hyperplanes than \(|A|\).

To proceed, we recall an important fact: the partial fraction decomposition in several dimensions. A weak version of the decomposition theorem is sufficient for us (cf. [6, Theorem 5.2]).

**Lemma 4.5.** The subset of those elements of \( R_A \) which are singular along at most \( n \) hyperplanes, span \( R_A \).

According to this Lemma, we can always assume for the purpose of proving the Theorem that \( f \in R_A \) is singular along at most \( n \) hyperplanes. Since \( A \) is not elementary, we can pick a hyperplane \( H \in A \), along which \( f \) is regular. Let \( r_H \) be the restriction map from \( V^* \) to \( H^* \). Then for \( f \in R_A \) regular along \( H \) by the definition of \( B_f \) we have the key equality:

\[
B_{f, A}(t) = B_{f, A \setminus H} - B_{f|_H, A \setminus H}(r_H(t)),
\]

where \( f|_H \) is the restriction of \( f \) onto \( H \). Note that that the theorem is assumed to hold for \( A|_H \) and \( A \setminus H \) via our inductive hypothesis. Note that we Then (4.8) immediately implies Part 1 of the theorem since, according to the inductive assumption, all the walls which can appear as singularities of \( B_{f, A \setminus H} \) and \( B_{f|_H, A \setminus H}(r(t)) \), have the form \( \lambda + H \) for some \( H \in A^* \). To prove formula (B), we compare (4.8) with Proposition 3.9. Choose an ordering \( \sigma \) compatible with \( H \) (see the definition before Proposition 3.9). Then

\[
\sum_{S \in \text{BCB}^n_{\sigma}(A)} \langle \widehat{\text{IR}}_\Delta(S), \exp(t)f \rangle = \sum_{S \in \text{BCB}^n_{\sigma\setminus H}(A \setminus H)} \langle \widehat{\text{IR}}_\Delta(S), \exp(t)f \rangle + \sum_{S \in \text{BCB}^{n-1}_{\sigma|_H}(A|_H)*H} \langle \widehat{\text{IR}}_\Delta(S), \exp(t)f \rangle.
\]

Since the chamber structure of \( A \setminus H \) is coarser than that of \( A \), every chamber \( \Delta \) of \( A \) defines a chamber \( \Delta \setminus H \) of \( A \setminus H \). Similarly, a chamber \( r(\Delta) \) of the arrangement \( A|_H \) is defined. Then the first term on the RHS of (4.9) is equal to

\[
B_{f, A \setminus H} = \sum_{S \in \text{BCB}^n_{\sigma\setminus H}(A \setminus H)} \langle \widehat{\text{IR}}_{\Delta \setminus H}(S), \exp(t)f \rangle,
\]
by the inductive hypothesis. For the second term note that by the last point of Remark 3.1 we have
\[
\text{Res}_H \text{Todd}(x_H) \exp(t) f = - \exp(r_H(t)) f | H
\]
Similarly, taking the correction factor into consideration one obtains that the second term on the RHS of (4.9) is equal to
\[
- \sum_{S \in \text{BCB}_n^\pi \setminus (\emptyset \setminus H)} \langle \hat{\text{IR}}_{r_H(\Delta)}(S), \exp(r_H(t)) f | H \rangle.
\]
This expression is exactly \( B_{f|H,H}(r(t)) \) by the inductive hypothesis. Thus we have shown that formula (B) is compatible with (4.8) and this completes the proof.

5. Calculations, Applications

5.1. A more practical formula. Formula (C) in Theorem 4.4 is easy to implement in actual computations. The best way to do this is to perform a change of variables, so that each element of the diagonal basis \( DB^n \) is transformed into the standard coordinate planes in \( \mathbb{C}^n \).

Let \( \vec{z} = (z_1, \ldots, z_n) \) be the sequence of standard coordinates on \( \mathbb{C}^n \), and let \( g \) be a meromorphic function. Then as in §3 define
\[
\text{IRes}_{\vec{z}} g = \text{Res}_{z_n=0} \ldots \text{Res}_{z_1=0} g.
\]
Introduce
\[
\text{Todd}(\vec{z}) = \prod_{i=1}^n \frac{z_i}{1 - \exp(z_i)}.
\]
If we perform the substitution \( \{x_i = z_i, \ i = 1, \ldots, n\} \) in each term of formula (C), then the function \( f \) transforms into some function \( f_{\vec{x}} \) on \( \mathbb{C}^n \), \( t \) becomes a vector \( t_{\vec{x}} \) and the set \( (\emptyset(\vec{x}) - t) \cap \Lambda \) transforms into a set \( \lambda_{\vec{x}} \) of \( \text{vol}(\vec{x}) \) vectors with rational coefficients. Then (C) can be rewritten as follows:

\[
B_f(t) = \sum_{S \in DB^n} \frac{1}{\text{vol}(\vec{x})} \text{IRes}_{\vec{z}} \text{Todd}(\vec{z}) \left[ f_{\vec{x}}(z) \exp(t_{\vec{x}} \cdot z) \sum_{y \in \lambda_{\vec{x}}} \exp(y \cdot z) \right],
\]
where the \( a \cdot b \) stands for scalar product in \( \mathbb{C}^n \). As \( S \) runs through \( DB^n \), the part \( \text{IRes}_{\vec{x}} \text{Todd}(\vec{z}) \) remains unchanged in this formula, while the part in square brackets changes according to a set of linear transformations.
5.2. Example: the Lie arrangements. We mentioned in the introduction, that our interest in this problem stems from an attempt to understand the formulas of Witten for the volumes of parabolic moduli spaces of principal $G$-bundles over Riemann surfaces. Denote the genus of the surface by $g$ and consider the case of one puncture. Then the relevant parameters of the problem are $g$, the genus, and a conjugacy class $\tilde{t} \in G/\text{Ad} G$.

The volume formulas can be described as follows. Fix a Cartan subalgebra of the Lie algebra of $G$, denote the set of roots by $\delta$, the set of positive roots by $\delta^+$ and let $(,)$ be the basic invariant bilinear form. Let $\mathfrak{A}_G$ be the integral arrangement with $V$ the dual of the Cartan subalgebra, $\Gamma$ the weight lattice; the arrangement is the set of hyperplanes perpendicular to the root vectors in $V$. Consider the $\mathfrak{A}_G$-rational function

$$W(\gamma) = \prod_{\alpha \in \Delta^+} (\alpha, \gamma)^{-1}.$$  

Up to a $\rho$-shift and a constant this function gives the dimension of the irreducible representation of $G$ of highest weight $\gamma$, when $\gamma$ is a dominant weight. Note that $W$ is Weyl-anti symmetric. According to [15, 9] the volume of the $[g, \tilde{t}]$-moduli space (up to some normalization) is given by

$$\text{Vol}(g, \tilde{t}) = B_{W^{-1}}(t),$$

where $t$ is a dominant representative of $\tilde{t}$. A detailed study of this formula will be given elsewhere.

5.3. The SU$(n)$ arrangement. Again let $\{z_i\}$ be the standard coordinates on $\mathbb{C}^{n+1}$. The arrangement $\mathfrak{D}_n$ is defined as follows: $V$ is the hyperplane $\sum z_i = 0$ in $\mathbb{C}^{n+1}$, $\Gamma = V \cap \mathbb{Z}^{n+1}$ and the hyperplanes $H_{ij}$ are given by the forms $x_{ij} = z_i - z_j$. This arrangement is the Lie arrangement corresponding to the group SU$(n)$; in particular, it has a Weyl-symmetry with respect to the symmetric group $S_{n+1}$.

There are several natural orderings on this arrangement, but there is a special diagonal basis $BB^n \subset \mathfrak{A}_{n}^{\text{ind}}$ with some beautiful properties which is not a BCB. To every $\tau \in S_n$ we can associate an element $B^\tau \in \mathfrak{A}_{n}^{\text{ind}}$ given by

$$B^\tau = (H_{\tau(1)\tau(2)}, \ldots, H_{\tau(n-1)\tau(n)}, H_{\tau(n)\tau(n+1)}).$$

Then $BB^n = \{B^\tau \mid \tau \in S_n\}$. It is easy to check that $BB^n$ is indeed a diagonal basis. It comes with a canonically associated set of representative forms

$$\mathbf{x}^\tau = (x_{\tau(1)\tau(2)}, \ldots, x_{\tau(n-1)\tau(n)}, x_{\tau(n)\tau(n+1)}),$$

The existence of such a basis was pointed out in [8] and goes back to a construction of Lidskii [8].

The most important property of $BB^n$ is that the group $S_n$, embedded into the Weyl group $S_{n+1}$, acts on it transitively. Since this action also preserves the lattice, it is easy to see that the substitutions in (5.1) are simply implemented by the natural action of $S_n$ on the expression in square brackets. Also, since $\text{vol}(\mathbf{x}^\tau) = 1$, the sum in the square brackets will consist
of only one term. If we assume that \( f \) is Weyl-symmetric and that the series (1.2) defining \( B_f(t) \) is absolutely convergent, then we obtain particularly simple formulas. For example, we have
\[
B_f(0) = n!(\hat{\text{IR}}_{\Delta}(B^e), f).
\]
where \( B^e \) is the element of \( \mathfrak{g}_{\text{ind}}^n \) corresponding to the trivial permutation, and \( \Delta \) is any chamber which has 0 as a vertex. With a natural choice of a chamber the formula expands into
\[
(5.2) \quad B_f(0) = n! \text{IR}_{\overline{x}} \text{Todd}(\overline{x}) f = \\
\quad n! \text{Res}_{x_n} \ldots \text{Res}_{x_1} \left( \prod_{k=1}^{n} \frac{x_k}{1 - \exp(x_k)} \right) f(x_1, \ldots, x_n).
\]
If we insert the \( t \)-dependence, the formula becomes more complicated:
\[
(5.3) \quad B_f(t) = (\hat{\text{IR}}_{\Delta}(B^e), f \sum_{\tau \in S_{n-1}} \exp(\{t^\tau\})),
\]
where \( \{t^\tau\} \) denotes the \( \Lambda \)-translate of \( t^\tau \) which lies in the unit cube, defined by the \( n \)-tuple \( \overline{x}^\tau \). For special values of \( t \) this formula simplifies. It reduces to
\[
(5.4) \quad B_f(c) = n!(\hat{\text{IR}}_{\Delta}(B^e), f \exp(c)),
\]
for \( c = \gamma(1, 1, \ldots, 1, -n) \), for \( 0 < \gamma < 1/n \), and for
\[
c = \left( \frac{k}{n+1}, \ldots, \frac{k}{n+1}, \frac{k-n-1}{n+1}, \ldots, \frac{k-n-1}{n+1} \right), \quad 1 \leq k \leq n.
\]
Formula (5.2) was first published in [13] in a slightly different form. It was later used and extended by other authors [7, 10], and we have incorporated some of their improvements.
