Abstract. Let $L(x) = a_1x_1 + a_2x_2 + \ldots + a_nx_n$, $n \geq 2$ be a linear form with integer coefficients $a_1, a_2, \ldots, a_n$ which are not all zero. A basic problem is to determine nonzero integer vectors $x$ such that $L(x) = 0$, and the maximum norm $||x||$ is relatively small compared with the size of the coefficients $a_1, a_2, \ldots, a_n$. The main result of the paper asserts that there exist linearly independent vectors $x_1, \ldots, x_{n-1} \in \mathbb{Z}^n$ such that $L(x_i) = 0$, $i = 1, \ldots, n-1$ and

$$||x_1|| \cdot \ldots \cdot ||x_{n-1}|| < \frac{||a||}{\sigma_n},$$

where $a = (a_1, a_2, \ldots, a_n)$ and

$$\sigma_n = \frac{2}{\pi} \int_0^\infty \left( \frac{\sin t}{t} \right)^n dt.$$

This result also implies a new lower bound on the greatest element of a sum–distinct set of positive integers (Erdős–Moser problem). The main tools are the Minkowski theorem on successive minima and the Busemann theorem from convex geometry.

Keywords: sections of the cube, sinc integrals, Busemann’s theorem, intersection body, successive minima

1 Introduction

Let $a = (a_1, \ldots, a_n)$, $n \geq 2$ be a non-zero integral vector. Consider the linear form $L(x) = a_1 x_1 + a_2 x_2 + \ldots + a_n x_n$. Siegel’s Lemma w. r. t. the maximum norm $\| \cdot \|$ asks for an optimal constant $c_n > 0$ such that the equation

$$L(x) = 0$$

has an integral solution $x = (x_1, \ldots, x_n)$ with

$$0 < \|x\|^{n-1} \leq c_n \|a\|.$$

(1)

The only known exact values of $c_n$ are $c_2 = 1$, $c_3 = 4/3$ and $c_4 = 27/19$ (see [1], [14]). Note that for $n = 3, 4$ the equality in (1) is not attained. A. Schinzel [14] has shown that for $n \geq 3$

$$c_n = \sup \Delta(\mathcal{H}_{\alpha_1, \ldots, \alpha_{n-3}}^{n-1})^{-1} \geq 1,$$

where $\Delta(\cdot)$ denotes the critical determinant, $\mathcal{H}_{\alpha_1, \ldots, \alpha_{n-3}}^{n-1}$ is a generalized hexagon in $\mathbb{R}^{n-1}$ given by

$$|x_i| \leq 1, \quad i = 1, \ldots, n-1, \quad \left| \sum_{i=1}^{n-3} \alpha_i x_i + x_{n-2} + x_{n-1} \right| \leq 1$$

and $\alpha_i$ range over all rational numbers in the interval $(0, 1]$. The values of $c_n$ for $n \leq 4$ indicate that, most likely, $c_n = \Delta(\mathcal{H}_{1, \ldots, 1}^{n-1})^{-1}$. However, a proof of this conjecture does not seem within reach at present. The best known upper bound

$$c_n \leq \sqrt{n}$$

(2)

follows from the classical result of Bombieri and Vaaler ([3], Theorem 1).

In the present paper we estimate $c_n$ via values of the sinc integrals

$$\sigma_n = \frac{2}{\pi} \int_0^\infty \left( \frac{\sin t}{t} \right)^n dt.$$

The main result is as follows:

**Theorem.** For any non-zero vector $a \in \mathbb{Z}^n$, $n \geq 5$, there exist linearly independent vectors $x_1, \ldots, x_{n-1} \in \mathbb{Z}^n$ such that $L(x_i) = 0$, $i = 1, \ldots, n-1$ and

$$\|x_1\| \cdots \|x_{n-1}\| < \frac{\|a\|}{\sigma_n}.$$

(3)
From (3) we immediately get the bound
\[ c_n \leq \sigma_n^{-1}, \]  
and since
\[ \sigma_n^{-1} \sim \sqrt{\frac{\pi n}{6}}, \quad \text{as } n \to \infty \]  
(see Section 2), the theorem asymptotically improves the estimate (2). It is also known (see e. g. [13]) that
\[ \sigma_n = \frac{n}{2^{n-1}} \sum_{0 \leq r < n/2, r \in \mathbb{Z}} \frac{(-1)^r (n-2r)^{n-1}}{r!(n-r)!}. \]

The sequences of numerators and denominators of \( \sigma_n/2 \) can be found in [16].

**Remark 1**

1. Calculation shows that for all \( 5 \leq n \leq 1000 \) the bound (4) is slightly better than (2).

2. For \( n \leq 4 \) the constant \( \sigma_n^{-1} \) in (3) can be replaced by \( c_n \). This follows from the observation that any origin–symmetric convex body in \( \mathbb{R}^n, n \leq 3 \) has anomaly 1 (see [17]).

As it was observed by A. Schinzel (personal communication), Siegel’s Lemma w. r. t. maximum norm can be applied to the following well known problem from additive number theory. A finite set \( \{a_1, \ldots, a_n\} \) of integers is called sum–distinct set if any two of its \( 2^n \) subsums differ by at least 1. We shall assume w. l. o. g. that \( 0 < a_1 < a_2 < \ldots < a_n \). In 1955, P. Erdős and L. Moser ([8], Problem 6) asked for an estimate on the least possible \( a_n \) of such a set. They proved that
\[ a_n > \max \left\{ \frac{2^n}{n}, \frac{2^n}{4\sqrt{n}} \right\} \]  
and Erdős conjectured that \( a_n > C_0 2^n \), \( C_0 > 0 \). In 1986, N. D. Elkies [7] showed that
\[ a_n > 2^{-n} \binom{2n}{n} \]  
and this result is still cited by Guy ([11], Problem C8) as the best known lower bound for large \( n \). Following [7], note that references [8, 11] state the problem equivalently in terms of “inverse function”. They ask to maximize the size \( m \) of a sum–distinct subset of \( \{1, 2, \ldots, x\} \), given \( x \). Clearly, the bound \( a_n > C_1 n^{-s} 2^n \) corresponds to
\[ m < \log_2 x + s \log_2 \log_2 x + \log_2 \frac{1}{C_1} - o(1). \]
Corollary 1. For any sum–distinct set \( \{a_1, \ldots, a_n\} \) with \( 0 < a_1 < \ldots < a_n \), the inequality
\[
a_n > \sigma_n 2^{n-1}
\] (8)
holds.

Since
\[
2^{-n} \left( \frac{2n}{n} \right) \sim \frac{2^n}{\sqrt{\pi n}} \quad \text{and} \quad \sigma_n 2^{n-1} \sim \frac{2^n}{\sqrt{\frac{2n}{3}}}, \quad \text{as} \ n \to \infty,
\]
Corollary 1 asymptotically improves the result of Elkies with factor \( \sqrt{3/2} \).

Remark 2

(1) Sum–distinct sets with minimal largest element are known up to \( n = 9 \) (see [5]). In the latter case the estimate (8) predicts \( a_9 \geq 116 \) and the optimal bound is \( a_9 \geq 161 \). Calculation shows that for all \( 10 \leq n \leq 1000 \) the bound (8) is slightly better than (7).

(2) Prof. Noam Elkies kindly informed the author about existing of an unpublished result by him and Andrew Gleason which asymptotically improves (7) with factor \( \sqrt{2} \).

2 Sections of the cube and sinc integrals

Let \( C = [-1, 1]^n \subset \mathbb{R}^n \) and let \( s = (s_1, \ldots, s_n) \in \mathbb{R}^n \) be a unit vector. It is a well known fact (see e. g. [2]) that
\[
\text{vol}_{n-1}(s^\perp \cap C) = \frac{2^n}{\pi} \int_0^\infty \prod_{i=1}^n \frac{\sin s_i t}{s_i t} dt,
\]
where \( s^\perp \) is the \((n-1)\)-dimensional subspace orthogonal to \( s \). In particular, the volume of the section orthogonal to the vertex \( v = (1, \ldots, 1) \) of \( C \) is given by
\[
\text{vol}_{n-1}(v^\perp \cap C) = \frac{2^n}{\pi} \int_0^\infty \left( \frac{\sin \frac{t}{\sqrt{n}}}{\frac{t}{\sqrt{n}}} \right)^n dt = 2^{n-1} \sqrt{n} \sigma_n.
\]
Laplace and Pólya (see [12], [15] and e. g. [6]) both gave proofs that
\[
\lim_{n \to \infty} \frac{\text{vol}_{n-1}(v^\perp \cap C)}{2^{n-1}} = \frac{\sqrt{6}}{\pi}.
\]
Thus, (5) is justified.
Lemma 1. For \( n \geq 2 \)

\[
0 < \sigma_{n+1} < \sigma_n \leq 1.
\]

Proof. This result is implicit in [4]. Indeed, Theorem 1 (ii) of [4] applied with \( a_0 = a_1 = \ldots = a_n = 1 \) gives the inequalities

\[
0 < \sigma_{n+1} \leq \sigma_n \leq 1.
\]

The strict inequality \( \sigma_{n+1} < \sigma_n \) follows easily from the observation that in this case the inequality in equation (3) of [4] is strict with \( a_{n+1} = a_0 = y = 1 \).

\[\Box\]

3 An application of the Busemann theorem

Let \(| \cdot |\) denote the euclidean norm. Recall that we can associate with each star body \( L \) the distance function \( f_L(x) = \inf \{ \lambda > 0 : x \in \lambda L \} \). The intersection body \( IL \) of a star body \( L \subset \mathbb{R}^n, n \geq 2 \) is defined as the \( o \)-symmetric star body whose distance function \( f_{IL} \) is given by

\[
f_{IL}(x) = \frac{|x|}{\text{vol}_{n-1}(x^\perp \cap L)}.
\]

Intersection bodies played an important role in the solution to the famous Busemann–Petty problem. The Busemann theorem (see e. g. [9], Chapter 8) states that if \( L \) is \( o \)-symmetric and convex, then \( IL \) is the convex set. This result allows us to prove the following useful inequality. Let \( f = f_{IC} \) denote the distance function of \( IC \).

Lemma 2. For any non–zero \( x \in \mathbb{R}^n \)

\[
f\left(\frac{x}{||x||}\right) \leq f(v) = \frac{1}{\sigma_n 2^{n-1}}, \quad (10)
\]

with equality only if \( n = 2 \) or \( \frac{x}{||x||} \) is a vertex of the cube \( C \).

Proof. We proceed by induction on \( n \). When \( n = 2 \) the result is obvious. Suppose now (10) is true for \( n-1 \geq 2 \). Since, if some \( x_i = 0 \), the problem reduced to that in \( \mathbb{R}^{n-1} \), we may assume inductively that \( x_i > 0 \) for all \( i \). Clearly, we may also assume that \( w = \frac{x}{||x||} \) is not a vertex of \( C \), in particular, \( w \neq v \).

Let \( Q = [0, 1]^n \subset \mathbb{R}^n \) and let \( L \) be the 2-dimensional subspace spanned by vectors \( v \) and \( x \). Then \( P = L \cap Q \) is a parallelogram on the plane \( L \). To see this, observe that the cube \( Q \) is the intersection of two cones \( \{ y \in \mathbb{R}^n : y_i \geq 0 \} \) and \( \{ y \in \mathbb{R}^n : y_i \leq 1 \} \) with apexes at the points \( o \) and \( v \) respectively.
Suppose that $P$ has vertices $o, u, v, v - u$. Then the edges $ou, o v - u$ of $P$ belong to coordinate hyperplanes and the edges $uv, v v - u$ lie on the boundary of $C$. W. l. o. g., we may assume that the point $w$ lies on the edge $uv$. Let

$$v' = \sigma_n v = \frac{\text{vol}_{n-1}(v^\perp \cap C) \cdot v}{|v|} \in \frac{1}{2^{n-1}} IC,$$

$$u' = \sigma_{n-1} u.$$

Since the point $u$ lies in one of the coordinate hyperplanes, by the induction hypothesis

$$f(u') = f(\sigma_{n-1} u) \leq \frac{1}{2^{n-1}}.$$  

Thus, $u' \in \frac{1}{2^{n-1}} IC$. Consider the triangle with vertices $o, u, v$. Let $w'$ be the point of intersection of segments $ow$ and $u'v'$. Observing that by Lemma 1

$$|\sigma_n w| < |w'| < |\sigma_{n-1} w|,$$

we get

$$\frac{1}{\sigma_{n-1}} < \frac{|w|}{|w'|} < \frac{1}{\sigma_n}. \quad (11)$$

By the Busemann theorem $IC$ is convex. Therefore $w' \in \frac{1}{2^{n-1}} IC$ and thus

$$|w'| \leq \frac{\text{vol}_{n-1}(w^\perp \cap C)}{2^{n-1}}.$$  

By $(11)$ we obtain

$$f\left(\frac{x}{||x||}\right) = f(w) = \frac{|w|}{\text{vol}_{n-1}(w^\perp \cap C)} \leq \frac{|w|}{2^{n-1} |w'|} < \frac{1}{\sigma_n 2^{n-1}}. \quad \Box$$

Applying Lemma 2 to a unit vector $s$ and using $(9)$ we get the following inequality for sinc integrals.

**Corollary 2.** For any unit vector $s = (s_1, \ldots, s_n) \in \mathbb{R}^n$

$$||s|| \int_0^\infty \prod_{i=1}^n \sin s_i t \frac{dt}{s_i t} \geq \int_0^\infty \left(\frac{\sin t}{t}\right)^n dt,$$

with equality only if $n = 2$ or $s/||s||$ is a vertex of the cube $C$.

**Remark 3** Note that $IC$ is symmetric w. r. t. any coordinate hyperplane. This observation and Busemann’s theorem immediately imply $(10)$ with non–strict inequality in all cases.
4 Proof of the theorem

Clearly, we may assume that $||a|| > 1$ and, in particular, that the inequality in Lemma 2 is strict for $x = a$. We shall also assume w. l. o. g. that $\gcd(a_1, \ldots, a_n) = 1$.

Let $S = a^\perp \cap C$ and $\Lambda = a^\perp \cap \mathbb{Z}^n$. Then $S$ is a centrally symmetric convex set and $\Lambda$ is a $(n-1)$-dimensional sublattice of $\mathbb{Z}^n$ with determinant (colume) $\det \Lambda = |a|$. Let $\lambda_i = \lambda_i(S, \Lambda)$ be the $i$-th successive minimum of $S$ w. r. t. $\Lambda$, that is

$$\lambda_i = \inf \{ \lambda > 0 : \dim(\lambda S \cap \Lambda) \geq i \}.$$

By the definition of $S$ and $\Lambda$ it is enough to show that

$$\lambda_1 \cdot \lambda_{n-1} < \frac{||a||}{\sigma_n}.$$

The $(n-1)$-dimensional subspace $a^\perp \subset \mathbb{R}^n$ can be considered as a usual $(n-1)$-dimensional euclidean space. The Minkowski Theorem on Successive Minima (see e. g. [10], Chapter 2), applied to the $o$-symmetric convex set $S \subset a^\perp$ and the lattice $\Lambda \subset a^\perp$, implies that

$$\lambda_1 \cdots \lambda_{n-1} \leq \frac{2^{n-1} \det \Lambda}{\text{vol}_{n-1}(S)} = \frac{2^{n-1}|a|}{\text{vol}_{n-1}(a^\perp \cap C)} = 2^{n-1} f(a),$$

and by Lemma 2 we get

$$\lambda_1 \cdots \lambda_{n-1} \leq 2^{n-1} f(a) = 2^{n-1} f\left(\frac{a}{||a||}\right) ||a||$$

$$< 2^{n-1} f(v)||a|| = \frac{||a||}{\sigma_n}.$$

This proves the theorem.

5 Proof of Corollary 1

For a sum–distinct set $\{a_1, \ldots, a_n\}$ consider the vector $a = (a_1, \ldots, a_n)$. Observe that any non–zero integral vector $x$ with $L(x) = 0$ must have the maximum norm greater than 1. Therefore [3] implies the inequality

$$2^{n-1} < \frac{||a||}{\sigma_n}.$$
