Twisted Cohomotopy implies twisted String structure on M5-branes

Domenico Fiorenza, Hisham Sati, Urs Schreiber

February 27, 2020

Abstract

We show that charge-quantization of the M-theory C-field in J-twisted Cohomotopy implies emergence of a higher Sp(1)-gauge field on single heterotic M5-branes, which exhibits worldvolume String\textsuperscript{C2} structure.

Towards an understanding of the elusive mathematical formulation of M-theory\cite{Du99, BBS06} the following assumption has been proposed\cite{Sa13, FSS19b}:

**Hypothesis H:** The M-Theory C-field is charge-quantized in J-twisted Cohomotopy theory, hence the C-field flux densities \(G_4, G_7\) are in the image of the cohomotopical twisted Chern character.

Assuming this, fields of the M5-brane sigma-model\cite{FSS19d} are found to be encoded by classifying maps shown in green in the following homotopy-commutative diagram of topological spaces\cite{FSS19c} (based on\cite{FSS19b}):

\[
\begin{align*}
\text{Sp}(1)_R & \simeq S^3 \\
\mathbb{R}^{2,1} \times X^8 & \to S^3/\text{Sp}(2)_{\mathbb{C}} \\
& \to B\text{String}^{C2}(4) \quad \text{universal integral 4-flux} \quad \text{universal integral shifted C-field 4-flux} \\
& \to B^3 U(1) \quad \text{charge-quantization of C-field} \quad \text{Page charge, Hopf WZ term}
\end{align*}
\]

This diagram is best read from bottom-left to top right. Detailed explanation follows, recalling the green maps from\cite{FSS19c}, and showing how the magenta maps come about, and what this means for the M5 sigma-model.
Open problem M5. It is a widely acknowledged open problem (e.g., [Mo12, p. 77]|La12, p. 49]|Hu13, p. 1]|La19, 6.3) to find a formulation of the non-abelian higher degree gauge field theory which is expected to arise on coincident M5-branes in M-theory (“non-abelian gerbe theory” [Wi02, p. 6, 15]). There are two aspects to this:

Q. 1 – Non-abelian gauge structure on M5-branes. How does a non-abelian gauge group arise on coincident M5-branes? (Given that the traditional argument for non-abelian gauge fields on D-branes via perturbative open string scattering does not apply.)

Q. 2 – Higher gauge structure on M5-branes. How does this get promoted to a higher gauge group for a non-abelian gerbe gauge theory? (Given that the gauge potential on the M5-brane is, locally, not a 1-form as in Yang-Mills theory, but a 2-form.)

Open problem M. These are, of course, just aspects of the broader problem of providing a formulation of M-theory itself. This, too, has remained widely open (e.g., [Du96, 6]|HLW98, p. 2]|Du98, p. 6]|NH98, p. 2]|Du99, p. 330]|Mo14, 12]|CP18, p. 2]|Wi19, Du19). Hence it is a rather plausible possibility that properly understanding M5-branes in M-theory is impossible without first understanding fundamental principles of M-theory itself.

Hypothesis H. A candidate for a fundamental mathematical principle of M-theory has been proposed [Sa13, 2.5] under the name Hypothesis H [FSS19b]. This hypothesis is motivated from hidden structures found in the “brane scan” or rather “brane bouquet” [FSS13b]|HSS18, 2.1] which were revealed by a re-analysis of the \(\kappa\)-symmetric super \(p\)-brane sigma-models through the lens of super homotopy theory [FSS15]|FSS16] (reviewed in [FSS19a, 7]). This hypothesis has since been checked to rigorously imply a fair number of phenomena expected to be characteristic of M-theory [FSS19a]|FSS19c]|BSS19]|SS19a]|SS19b]|SS20] (with exposition in [Sc20]).

The single heterotic M5-brane... In particular, we proved in [FSS19d] that the \(\kappa\)-symmetric Perry-Schwarz action functional [PS97]|Sc97]|APPs97] for the single M5-brane in heterotic M-theory (Hofava-Witten theory [HW95]|Wi96]|LLO97]|LOW99]|DOP99]|DOPW09]|Ov02]|Ov18] emerges from Hypothesis H (following an analogous but much simpler derivation of the action functional for the single M2-brane in [HSS18, 6.2]).

...is already non-abelian. But the heterotic M5-brane is special in that even a single such brane is expected to carry a non-abelian (higher) gauge field, namely for gauge group the quaternionic unitary group \(\text{Sp}(1) \simeq \text{SU}(2)\). This has been argued by identifying heterotic NS5-branes with “small instantons” in the \(so(32)\)-heterotic gauge field [Wi95]|AG96]|AM97], and it has dually [Se99] been argued as an effect of gauge enhancement for coincident 5-branes on orientifolds [Mu97]: D5-branes in type I string theory [GP96], M5-branes in heterotic M-theory [GH96].

This second perspective says that a single heterotic M5-brane may be understood as consisting of two coincident M5-branes that are bound as mirror images of the orientifold group action, thus revealing the non-abelian Sp(1) gauge field on the brane as an instance of the general phenomenon expected on coincident M5-branes. Thus it makes sense to investigate Q. 1 and Q. 2 already in the case of single heterotic M5-branes.

| Coincident M5s \(\rightarrow\) and their worldvolume fields: | \(N = 1\) M5 | \(N_{\text{HET}} = 1\) M5\(^{_{\text{HET}}}\) \(\simeq\) \(N = 2/\mathbb{Z}_2\) M5 | \(N > 2\) M5 |
|---|---|---|---|
| Gauge field | none | \(\text{Sp}(1)\)-bundle | unclear |
| Higher gauge field | \(U(1)\)-gerbe | \(\text{nonabelian gerbe: String}^{2}(4)\)-2-bundle | unclear |

Results. We prove here that Hypothesis H implies, for the topological sector of single heterotic M5-branes:

1. the emergence of a non-abelian \(\text{Sp}(1)\)-gauge field structure on the brane worldvolume;
2. the emergence of a lift to a higher non-abelian gauge field (non-abelian gerbe field), specifically to a String\(^2\)-structure on the M5-brane worldvolume (as in [Sa11, 2.1]), generalizing the notion of \(\text{CHZ11}\);
3. the worldvolume 3-flux \(H_3\) being the corresponding non-abelian Chern-Simons 2-gerbe [FSS13a]|NSS12] (cf. [CJMSW05]|Wa13) reflecting a Green-Schwarz-type mechanism on the worldvolume [SSS12]|FSS12a].

All these results follow from inspection of the single encapsulating homotopy-commutative diagram (1) in Theorem I using just basic homotopy theory (see pointers in [NSS12]), the results of [FSS19a]|FSS19c] and, for interpreting the factorization as String\(^2\)-structure, the concepts developed in [FSS12a]. We explain all this on the following pages.
First we explain the existence of the outer part of diagram (1). All statements, proofs and references that we appeal to here are given in [FSS196].

**The classifying space of J-twisted 4-cohomotopy** is the homotopy quotient $S^4//O(5)$ of the 4-sphere by its canonical action of the orthogonal group. Up to homotopy equivalence this may be taken to be the Borel construction $S^4 \times EO(5)/O(5)$, where $EO(5)$ is the total space of the universal $O(5)$-principal bundle. This is manifestly equipped with a map to ("fibered over") the classifying space $BO(5) = (EO(5))/O(5)$. Pulling this back along $BS\mathrm{Pin}(5) \to BO(5)$ and then pushing forward along $BS\mathrm{Pin}(5) \to BS\mathrm{Pin}(8)$ yields the vertical map shown on the right.

A **cocycle in J-twisted Cohomotopy** on a spin-manifold $X^8$ is a continuous function $c_3$ to this classifying space, such that composition with this vertical map classifies (the frame bundle of) the tangent bundle $TX^8$.

**The classifying space of J-twisted 7-Cohomotopy** is, similarly, the homotopy quotient $S^7//O(8) \simeq (S^7 \times EO(8))/O(8)$ of $S^7$ by the canonical action of the orthogonal group $O(8)$. We consider this action restricted to the quaternionic unitary group $\mathrm{Sp}(2)$ for the canonical action $\mathrm{Sp}(2) \to O(8)$ given by left multiplication of quaternion $2 \times 2$ matrices on the quaternion $2$-space $\mathbb{H}^2 \simeq \mathbb{R}^8$.

**The quaternionic Hopf fibration** $S^7 \xrightarrow{H\mathbb{H}} S^4$ is **equivariant** with respect to this group action, via the exceptional isomorphism $\mathrm{Sp}(2) \simeq \mathrm{Spin}(5)$. Via Borel-equivariance this induces the map, shown on the right, between the classifying spaces for J-twisted Cohomotopy in degrees 4 and 7, related by the fully Borel-equivariant quotient quaternion Hopf fibration:

Here we restrict attention to the subgroup $\mathrm{Sp}(2) \simeq \mathrm{Sp}(2) \cdot \mathbb{Z}_2 \subset \mathrm{Sp}(2) \cdot \mathrm{Sp}(1)$ only for sake of exposition.

**The homotopy equivalence** of classifying spaces $S^4//\mathrm{Spin}(5) \simeq \mathrm{BS}\mathrm{Pin}(4)$ is induced by the coset space realization of the 4-sphere $S^4 \simeq \mathrm{Spin}(5)/\mathrm{Spin}(4)$.

Under this equivalence, the **integral cohomology ring** $H^4(\mathrm{BS}\mathrm{Pin}(4); \mathbb{Z}) \simeq \mathbb{Z}[\frac{1}{2}p_1, \frac{1}{2}X_4 + \frac{1}{4}p_1]$ is identified as containing the **shifted Euler class** $\Gamma_4 := \frac{1}{2}X_4 + \frac{1}{4}p_1$; the plain Euler class $\frac{1}{2}X_4$ is the fiberwise volume element on $S^4$.

**Hypothesis H** identifies the C-field flux with the pullback of this class along the given cohomotopy cocycle $c_3$.

This way the **integral cohomology structure of $\mathrm{BS}\mathrm{Pin}(4)$** implies the shifted flux quantization of the C-field:

$$\frac{1}{2}X_4 + \frac{1}{4}p_1 \in H^4(\mathrm{BS}\mathrm{Pin}(4); \mathbb{Z}) \quad \Leftrightarrow \quad G_4 + \frac{1}{4}p_1 \in H^4(X^8; \mathbb{Z}).$$
The other homotopy equivalence of classifying spaces $S^7 // \text{Sp}(2) \simeq B\text{Sp}(1)$ is similarly induced by the coset space realization of the 7-sphere as $S^7 \simeq \text{Sp}(2)/\text{Sp}(1)$. This generalizes to the full equivariance group as the homotopy quotient $S^7 // (\text{Sp}(2) \cdot \text{Sp}(1)) \simeq B(\text{Sp}(1) \cdot \text{Sp}(1))$.

The homotopy-commutativity of the outer square is seen as follows:

With the exceptional isomorphisms

$$\text{Spin}(4) \simeq \text{Spin}(3) \times \text{Spin}(3) \simeq \text{Sp}(1) \times \text{Sp}(1)$$

(2)

and the induced cohomology identifications

$$H^*(B\text{Sp}(1); \mathbb{Z}) \simeq \mathbb{Z}[c_2]$$

$$H^*(B\text{Spin}(4); \mathbb{Z}) \simeq \mathbb{Z}[c_2, c_2^r]$$

(3)

the universal Pontrjagin class $\frac{1}{2} p_1$ on $B\text{Spin}(4)$ is identified with the sum of the second Chern classes of the two $\text{Sp}(1)$-factors (by [FSS19b Lemma 3.9]), and the Borel-equivariant quaternionic Hopf fibration is identified with the inclusion of the left $\text{Sp}(1)$-factors (by [FSS19b Prop. 2.22]), as shown here:

$$
\begin{align*}
S^7 // \text{Sp}(2) & \xrightarrow{\text{coset space realization}} B\text{Sp}(1) \xrightarrow{\text{inclusion of left factor}} B\text{Sp}(1)_L \times B\text{Sp}(1)_R \\
S^4 // \text{Spin}(5) & \xrightarrow{\text{coset space realization}} B\text{Spin}(4) \xrightarrow{\text{exceptional isomorphism}} B\text{Sp}(1)_L \times B\text{Sp}(1)_R \\
& \xrightarrow{\text{H^4(BSpin(4); Z) \simeq H^4(BSp(1); Z) \oplus H^4(BSp(1); Z)}}
\end{align*}
$$

(4)

$$
\begin{align*}
\text{first Pontrjagin class/ C-field background charge} & \quad \frac{1}{2} p_1 \\
\text{shifted fractional Euler class/ shifted integral C-field flux} & \quad \Gamma_4 = \frac{1}{2} \lambda_4 + \frac{1}{4} p_1 \\
\text{C-field flux relative to background charge} & \quad \Gamma_4 - \frac{1}{2} p_1
\end{align*}
$$

First Pontrjagin class/ C-field background charge

$$
\Gamma_4 = \frac{1}{2} \lambda_4 + \frac{1}{4} p_1
$$

(5)

This makes it manifest that the pullback of the Pontrjagin class along the Borel-equivariant quaternionic Hopf fibration kills the right Chern class summand and retains the left Chern class summand, which is again the plain Chern class on the single $\text{Sp}(1)$-factor that is the domain of the Borel-equivariant quaternionic Hopf fibration:

$$(h_H // \text{Sp}(2))^* \left( \frac{1}{2} p_1 \right) = c_2.$$

Since $B^3 U(1) \simeq K(\mathbb{Z}, 4)$, this equality of cohomology classes comes from a homotopy between their representative maps to classifying spaces, and this is the homotopy commutativity of the outer square above.
The pullback of the integral 4-flux class $\tilde{\Gamma}_4$ along the Borel-equivariant quaternionic Hopf fibration is also seen, from (4), to equal the Chern class. The meaning of this for the C-field flux becomes transparent when equivalently considering the pullback of the difference $\tilde{\Gamma}_4 - \frac{1}{2} p_1$: The last line of (4) shows that this difference vanishes after the pullback. Under the interpretation of vanishing of J-twisted 4-Cohomotopy as its factorization through $h_{\mathbb{H}} // Sp(2)$, this is the statement that $\frac{1}{2} p_1$ is the background charge of the C-field [FSS19b 3.5].

We now explain the factorization through twisted String structure in the inner part of the diagram (1). The terminology and conceptualization of twisted String structures and their relation to the Green-Schwarz mechanism [GS84] follows [Sa11] [SSS12] [ESS12] [ESS12a] [ESS12b].

The homotopy fiber product of the classifying maps for the Pontrjagin- and Chern-classes (hence the homotopy-pullback of one along the other, denoted “(pb)” in the diagram) is, by definition, the classifying space for $c_2^{Sp(1)}$-twisted String(4)-structure [Sa11]:

$$B\text{String}^c(4) := B\text{Spin}(4) \times_{B^2 U(1)} B\text{Sp}(1).$$

This being a homotopy-fiber product means that its defining square diagram is filled by a universal homotopy $H^3_{\text{min}}$, as shown above, that is a coboundary between cocycle representatives of these two characteristic classes after their pullback to the homotopy-fiber product space $B\text{String}^c(4)$. As such, $H^3_{\text{min}}$ is the homotopy-theoretic reflection of the Green-Schwarz mechanism [SSS12]: Upon enhancing all classifying spaces of topological structures in (5) to their corresponding moduli stacks of differential structures (according to [ESS10] [SSS12] [ESS12a] [ESS12b], see (11) below) this homotopy is given, locally, by a 3-form flux $H_3$ whose de Rham differential is the heterotic Bianchi identity:

$$d H_3 = \text{Tr}(R \wedge R) - \frac{1}{2} p_1(R) - \text{Tr}(F \wedge F).$$

Here $R$ and $F$ denote, as usual, the local curvature forms of connections on the given Spin(4)- and Sp(1)-bundle, respectively, and we take the traces to be integrally normalized.

The dashed factorization in the inner part of (1) through the homotopy fiber product (6), shown on the right equivalently with domain $S^7 // Sp(2)$, is now the immediate consequence of the commutativity of the outer square, as established above (5), due to the defining universal property of homotopy-fiber products.

In conclusion, this shows that Sp(1) gauge- and String$^c(4)$ higher gauge structure emerges whenever a cocycle in J-twisted 4-Cohomotopy factors through the classifying space $S^7 // Sp(2)$ of J-twisted 7-Cohomotopy via the Borel-equivariant quaternionic Hopf fibration.
Next we explain, with [FSS15][FSS19c][FSS19d], how this space \( S^7//\text{Sp}(2) \) is, under Hypothesis H, the classifying space for the higher gauge field in the M5-brane sigma-model with target space \( \mathbb{R}^{2,1} \times X^8 \).

The 3-sphere fibration over spacetime associated with the given cocycle \( c_3 \) in J-twisted Cohomotopy theory is the homotopy-pullback of the Borel-equivariant quaternionic Hopf fibration along \( c_3 \). This is the direct analog in fibered topological spaces of the construction in rational super-spaces (survey in [FSS19a]) which induces the super WZ term of the M5-brane sigma model [FSS15], exhibiting 3-spherical T-duality of the M5-brane sigma model [FSS18][SS18], and from that the full \( k \)-symmetric Lagrangian of the M5-brane sigma model [FSS19d].

In rational super-spaces

The 3-sphere fiber \( S^3 \) is identified with \( \text{Sp}(1)_R \) under the coset space realizations (4). This follows using basic facts of homotopy theory (the pasting law for homotopy pullbacks, the commutativity of homotopy fibers with homotopy pullbacks, and the looping/delooping equivalence, see [NSS12] for background): First, since homotopy-pullback preserves homotopy fibers, it is identified with the homotopy-fiber of the Borel-equivariant quaternionic Hopf fibration, which by (4) is obtained as follows:

\[
\text{fib} \left( h_{B//\text{Sp}(2)} \right) \simeq \text{fib} \left( B\text{Sp}(1)_{L} \xrightarrow{\text{id}} B\text{Sp}(1)_{L} \right) \simeq \text{Sp}(1)_R \tag{8}
\]

This implies that given any space \( \tilde{\Sigma} \) equipped with a map \( \phi \) to spacetime \( \mathbb{R}^{2,1} \times X^8 \), a lift \( b_3 \) up to specified homotopy (which is notationally suppressed in the diagram on the right), of \( \phi \) to the extended spacetime \( \mathbb{R}^{2,1} \times \hat{X}^8 \) is locally on \( \tilde{\Sigma} \) a map to \( S^3 \simeq \text{Sp}(1)_R \).

Such a map \( b_3 \) is a cocycle in twisted 3-Cohomotopy, with the twist being given by the pullback of the C-field cocycle \( c_3 \) in 4-Cohomotopy along the embedding field map \( \phi \). The pasting composition of the homotopy-commutative diagram shown on the right with the homotopy-commutative square shown above (4) identifies the pullback of the shifted integral C-field flux to \( \tilde{\Sigma} \) with that of the first fractional Pontrjagin class: Concretely, the image of this data in rational homotopy theory (see [FSS16][Al][BSS18][2.1]) is:

\[
\text{map to spacetime} \quad \left( \phi, \quad H_3 \right) \tag{9}
\]

such that

\[
dH_3 = \phi^* \left( \tilde{G}_4 - \frac{1}{2} p_1 \right) \tag{10}
\]

This is the field content of the M5-brane sigma model with worldvolume \( \tilde{\Sigma} \) and target space \( \mathbb{R}^{2,1} \times X^8 \). Thus \( \mathbb{R}^{2,1} \times \hat{X}^8 \) is identified with the classifying space for M5-brane sigma-model fields, for given background C-field.
Now we are in position to state the main result of the present article:

If the worldvolume field $\phi$ is indeed an embedding of Spin manifolds, so that $\phi^* \frac{1}{2} p_1(TX^8) = \frac{1}{2} p_1(T\hat S)$, then the integral lift of the trivialization $\phi^* G_4$ is a twisted String structure on the M5-brane \cite{Sa11} 2.1 named a trivialization of $\frac{1}{2} p_1$ relative to a background 4-class $\phi^* G_4$ in integral cohomology.

Here with Hypothesis $H$ we see further further substructure in this phenomenon, in that the pullback of the shifted integral C-field flux to the M5 worldvolume is identified with the second Chern class of an Sp(1)-gauge field $\phi^* G_4 \simeq c_2$, whence we have specifically $c_2$-twisted String structure on the worldvolume. In direct analogy with Spin$^c$-structure, this is called String$^{c_2}$-structure \cite{Sa11}, with classifying space $B$String$^{c_2}$ \cite{Sa11}.

In conclusion, the above discussion shows:

(i) the homotopy-commutativity of the total outer part of the diagram \cite{Sa11};

(ii) the existence of the dashed factorization map \cite{Sa11} induced by the universal property of the homotopy fiber product $B$String$^{c_2}$, which identifies the field content \cite{Sa11} of the M5-brane sigma model with that of an embedding field together with a higher Sp(1)-gauge field with gauge 2-group String$^{c_2}$.

Hence we have proven the following, for the mathematical formulation of the M-theory C-field subject to Hypothesis $H$ according to \cite{FSS19b}, and the corresponding formulation of the B-field in the M5-brane sigma-model according to \cite{FSS19c}:

**Theorem 1.** Assuming C-field charge-quantization in J-twisted 4-Cohomotopy for M-theory on 8-manifolds, then the induced B-field charge quantization in twisted 3-Cohomotopy on the M5-brane worldvolume is equivalently charge-quantization in String$^{c_2}(4)$-cohomology, according to the homotopy-commutative diagram \cite{Sa11}.

**Outlook – Differential String structure on M5-branes.** We have focused here on discussion of the topological sector of all fields, for a non-abelian generalized but “topological” cohomology; while the full field content is in non-abelian generalized differential cohomology. For example, the classifying space $B$Spin$(8)$ in the above discussion is to be promoted to the smooth moduli stack $B$Spin$(8)_{conn}$ of principal Spin connections \cite{FSS10}. While we do not discuss such differential form data here, one impact of Theorem 1 is that it makes immediate how this discussion should proceed: namely directly by promoting \cite{Sa11} from a diagram in spaces to a diagram of the corresponding smooth $\infty$-stacks according to \cite{FSS10} \cite{FSS15} (reviewed in \cite{FSS13a}); hence, in particular, promoting the topological twisted String structure classified by the space $B$String$^{c_2}(4)$ \cite{Sa11} to twisted differential string structure classified by a smooth 2-stack $B$String$^{c_2}_{conn}$, according to \cite{SSS12} \cite{FSS12a} \cite{FSS12b}.

Following the method of \cite{SSS08} \cite{FSS10} for constructing such differential refinements, the idea of differential String structures on M5-branes has recently been explored in \cite{SaS17} in an attempt to find a higher gauge theoretic interpretation of the action functionals for non-abelian $D = 6$, $\mathcal{N} = (1,0)$ gauge theories proposed in \cite{SSW11}. But here the conceptual origin and precise flavor of the string gauge field on the M5 seems to have remained open.

Theorem 1 solves this issue by pinpointing specifically String$^{c_2}(4)$-structure \cite{Sa11} and explaining how this connects to the broader structure of the M5-brane in M-theory, in particular by showing that this is the charge quantization on the M5-brane that relates to the web of anomaly cancellation conditions in M-theory \cite{FSS19b} \cite{SS20}. 

\begin{align*}
\text{Classifying spaces} & \quad \text{pass to shape (trad. “geometric realization")} & \text{Moduli stacks} \\
B\text{Spin}(n) & \Rightarrow B\text{Spin}(n)_{conn} & \text{for Spin connections} \\
B\text{Spin}^c(1)_{conn} & \Rightarrow B\text{Spin}(1)_{conn} & \text{for Spin connections} \\
B\text{String}(n)_{conn} & \Rightarrow B\text{String}(n)_{conn} & \text{for abelian gerbe connections} \\
B\Omega^2 S^0 & \Rightarrow B\Omega^2 S^0_{conn} & \text{for differential n-Cohomotopy} \\
B\Omega^2 S^0_{conn} & \Rightarrow B\Omega^2 S^0_{conn} & \text{for foreground connections} \\
\end{align*}
With the stringy field content on the M5-brane in hand, we close by discussing the Hopf WZ-term in the M5-brane action functional [In00] recast as a functional on a String^2 higher gauge field (noticing that the Hopf WZ term induces the full Lagrangian density, by the method of [FSS19d]).

The cocycle $c_6$ in twisted 7-Cohomotopy, on the classifying space $\hat{X}^8$ for M5-brane sigma-model fields, arises from the construction of the latter as a homotopy pullback of the Borel-equivariant quaternionic Hopf fibration. This $c_6$ is the dual of the C-field, with flux form $G_7$, in the situation that the C-field itself trivializes [FSS19b], as it does after pullback along $\phi$ to the M5, by (10).

The flux of the dual C-field on $X^8$ must measure the Page charge [DS91] (41) of solitonic M2-branes in the spacetime $\mathbb{R}^{2,1} \times X^8$, each stretched along the $\mathbb{R}^{2,1}$ factor. But this requires care:

By the Poincaré-Hopf theorem for 7-Cohomotopy [FSS19b] 2.6, 3.7], it follows that if the loci of these M2-branes are assumed to be removed from spacetime (as the locus of the magnetic monopole is in traditional Dirac charge-quantization [Fr11] 16.4e) then the Euler 8-class $\chi_8$ of $X^8$ vanishes. This is the situation of M-theory on 8-manifolds [SVW96] [FSS19b] 3.8 & Rmk. 3.1].

The vanishing of the Euler 8-class is homotopy-theoretically imposed by homotopy pullback of the whole diagram (1) to the homotopy fiber $\text{fib}(\chi_8)$ of the classifying map for $\chi_8$, which we denote by a subscript:

Thus in the case of vanishing Euler 8-class of $X^8$, the cocycle $c_6$ in J-twisted 7-Cohomotopy on the classifying space for M5-brane sigma model fields lifts to the dotted map shown above.

The universal Hopf WZ-term of the M5-brane is, assuming Hypothesis H, a class $\tilde{\Gamma}_7$ in integral 7-cohomology on this space (12), as shown in green below. This is the result of [FSS19c] Theorem 4.6:

Equivalently, this $\tilde{\Gamma}_7$ is the universal Page charge density sourced by M2-branes, and as such is the “dual” of the integral shifted 4-flux $\tilde{\Gamma}_4$. The integrality of $\tilde{\Gamma}_7$ is crucial both for the Hopf WZ term to be well defined as a Wess-Zumino term for the M5-brane, as well as its interpretation as M2-brane charge being consistent.

Now, the dashed factorization in (11) directly implies, under pullback to $\text{fib}(\chi_8)$ (12) that:

The Hopf WZ term descends to a class on String^2 higher gauge fields as shown in magenta in the above factorization. This means that as $H_3$ becomes the Chern-Simons term (7) of a higher $\text{Sp}(1)$-gauge field on the M5, after differential refinement (11), the integrality, and hence consistency, of the Hopf WZ term remains intact.
Acknowledgement. The current project was started at the January 2020 workshop *M-theory and Mathematics* supported by the NYUAD Research Institute. Domenico Fiorenza would like to thank New York University Abu Dhabi for hospitality during that time.
