Abstract The coronavirus disease (COVID-19) pandemic has a global effect on people’s daily lives, specifically on the ability to leave home, go to work, school, or access public services. Similar to the past epidemics (acquired immunodeficiency syndrome (AIDS), severe acute respiratory syndrome (SARS), swine flu, and Ebola), the most vulnerable groups, such as working mothers, are usually the ones that suffer the biggest brunt. The primary objective of this cross-sectional study is to investigate perceived stress, perceived social support, satisfaction with distance learning, and coping strategies among working mothers in Jordan during the COVID-19 pandemic. In this study, a total of 204 women participated in an online survey using the Perceived Stressors Scale (PSS), Multidimensional Scale of Social Support (MSPSS), the Brief Coping Orientation to Problems Experienced (B-COPE) Inventory, and Distance Learning Satisfaction Scale (DLSAT). These instruments were employed to analyze the study variables. The results revealed that working mothers reported a high level of perceived stress (M = 44.15, SD = 7.25), a low level of perceived social support (M = 29.78, SD = 9.41), a low level of satisfaction with distance learning (M = 17.50, SD = 6.60), and a moderate level of effectively coping with their life circumstances (M = 60.56, SD = 11.07). Furthermore, the mothers’ perceived stressors, perceived social support, and satisfaction with children’s distance learning were all significantly associated with the score of coping strategies. The results in this study are significant in providing essential support and resources for working mothers to cope with stress in the future and identify effective coping strategies for working mothers’ well-being. Accordingly, implications and recommendations for future research were provided.

Keywords COVID-19, Perceived Stress, Perceived Social Support, Distance Learning Satisfaction, Coping Strategies, Working Mothers

1. Introduction

The COVID-19 pandemic has dramatically transformed the daily activities and behaviors of individuals. This phenomenon is inevitable with the imposed home quarantine and social distancing to limit the spread of the virus. Nevertheless, these restrictions have caused various psychological impacts on individuals, such as negative feelings of pressure or lack of control due to lifestyle changes. Additionally, the education system also changed into the distance learning mode, applying more pressure on students and their families. Specifically, the United Nations (UN) Social and Economic Commission for Western Asia [1] and UN Women discovered that the social and economic challenges faced by women in the Arab region have worsened due to the pandemic. Women particularly experience the negative multiplier effects on
social and economic levels due to their multiple social roles as mothers, workers, and wives. Moreover, women also generally have lower incomes and job security [2].

It has been indicated that working mothers are the most affected and vulnerable concerning conflict of interests. [3]. In particular, the Government of Jordan has created a partnership with the United States Agency International Development (USAID) [4] to help vulnerable groups, including women and youths, in education, health, and resilience programs. Although more than 70% of Jordanian women currently work outside their homes, their “traditional” duties such as household management, childcare, and other domestic responsibilities have not been reduced. Notably, working mothers often display an increased level of pressure. Thus, extra coping resources are needed to reduce the harmful effects of stress on women's physical and mental health.

Past studies have also discovered that work-family issues could significantly impact work effectiveness and life quality [5]. In most households, the distribution of family care and domestic work is unequal between men and women. Females, mainly working mothers, are responsible for securing their jobs, caring for the family, and managing the homes due to social traditions. Therefore, they tend to shoulder these increased responsibilities due to school closures, isolation of the elderly due to movement restriction, and the growing number of sick family members. Thus, the COVID-19 pandemic has impacted the world's health, social, economic, and education systems and an ultimate test for human beings.

Moreover, the spread of the COVID-19 has forced parents to stay home with their children [6], impacting their well-being and stress in handling their children and work-life [7]. In this study, the working mothers played multiple roles that create role conflict and role stress, contributing to stress [8]. Previous studies have addressed that an individual’s active participation in one role could distract them from another role simultaneously [9]. In other words, when an individual dedicates additional energy and time to work, the family role could be compromised and vice versa [10]. Thus, work quality and family life depend on the conflict between these multiple roles. Since women are expected to bear the primary responsibility of the home front for the family, they tend to face additional conflict when they assume multiple roles [9].

Despite its significance, studies on working-mother issues during the COVID-19 pandemic are still limited. Prior studies focused more on the benefits of family time [11] [12] and family support [13] [14]. Therefore, it is vital to explore the women’s perception of stress, social support, and coping strategies in order to identify their abilities in coping with additional burdens due to school closure and the need to undertake the responsibilities in educating their children remotely during the COVID-19 pandemic. Ultimately, the current study addresses four major variables, i.e., perceived stress, perceived social support, distance learning satisfaction, and coping strategies, accordingly.

Conceptualization of Terms

**Perceived Stress**: Perceived stress is the events that are perceived to be uncontrollable that often induce stress. For example, certain life events might put high demands on an individual. If the perceptions of controlling them are low, the events will likely create stress [15]. Past studies have reported a significant relationship between perceived stress and mental disorders [16] [17] [18]. It could be observed that the COVID-19 pandemic has placed unexpected extra demands on working mothers. Thus, it is crucial to analyze the mothers’ perception of stress in this time of difficulty. This study utilized the PSS to estimate the perceived stress among working mothers due to the COVID-19 epidemic [19] [20].

**Perceived Social Support**: Decreasing social interaction is the main preventive method to curb the spread of COVID-19. This situation produces an unwanted effect on social interaction and support between individuals. Generally, individual perception of social support is crucial for human well-being. During the COVID-19 crisis, social support could be considered a coping strategy [21]. Past literature has revealed the significance of the social support element during this crisis [16] [22]. Despite this fact, there is insufficient data on the perceived social support among working mothers. Thus, this study applied the MSPSS to measure the level of perceived support among working mothers during the COVID-19 pandemic [23].

**Distance Learning Satisfaction**: The impact of the COVID-19 outbreak is experienced by the educational system worldwide. In fact, as much as 80% of the total student population worldwide was affected by school closures in more than 138 countries. Due to this infectious disease, school closure is a necessary precautionary step to contain its spread. Nevertheless, the closures have created unprecedented challenges to governments, individuals, and societies to ensure the continuity of the learning process among students. The closure has also affected various sectors, including academic, economic, social, and family. Previous studies have identified the level of student satisfaction towards distance learning before and during the outbreak [24] [25] [26]. It should be noted that this study is the first to measure the working mothers’ satisfaction level towards the distance learning process for their children.

**Coping Strategies**: The COVID-19 epidemic has drastically changed people's lives. The rapid spread and contagious nature of the epidemic, coupled with no specific cure at this stage, have significantly threatened the human psyche and the health sector. The preventive measures imposed by governments in the economic, social, and educational sectors have affected individual mental health due to people experiencing different severity of psychological stress [27]. Interestingly, it was reported that
women were more concerned about COVID-19 than men [28]. Research also revealed that women were more likely to feel agonized from the outbreak [29]. Generally, people under stress tend to react negatively, while others remain resilient. Therefore, the outcome depends on how individuals cope with stressful situations. Previous research has identified two main coping strategies, namely emotion-focused and problem-focused. This study used the Problems Experienced utilizing (COPE) inventory to determine the working mothers’ coping orientation during the COVID-19 pandemic [30] [31].

2. Methodology

Research Design and Sampling Procedure

This study utilized an online survey design to analyze the working mothers’ perceived stress, perceived social support, satisfaction with children’s distance learning, and coping strategies during the COVID-19 outbreak. In addition, the target population included all working mothers. In this present study, a convenience sample of mothers’ group on social media, schools, hospitals, and other government institutions were identified before forwarding the survey link to them. In total, 204 working mothers participated in the survey.

Instrumentation

The cross-sectional survey consisted of the following instruments:

Perceived Stress Scale (PSS)

This scale is a self-reported psychological tool that measures the individual’s perception of the degree of stress experienced [20]. It consists of 14 items on a five-point Likert scale ranging from zero = never to four = always. The total score ranges from zero to 56, whereby higher scores indicate a greater stress perception level. It is noteworthy to mention that several studies have reported PSS as psychometrically sound. The coefficient alpha reliability, $\alpha$, was high at 0.85, and the test-retest correlation was 0.85. Thus, the PSS showed an adequate degree of concurrent validity [20]. This study utilized the Arabic version of the PSS that is proven to have good psychometric properties. Besides, the internal consistency reliability of the PSS-Arabic in a previous study was high ($\alpha = 0.80$) [19]. In this study, the internal consistency was calculated, and the Cronbach’s alpha coefficient value of 0.933 also indicated an excellent internal consistency for the study sample of working mothers.

Multidimensional Scale of Perceived Social Support (MSPSS)

The MSPSS is a widely applied tool to estimate the perception of individuals’ social support from three primary sources: family, friends, and significant others across various cultures. It consists of a 12-item questionnaire on a seven-point Likert scale ranging from one = very strongly disagree to seven = very strongly agree. Past studies have revealed that the MSPSS displayed adequate psychometric properties. The alpha value for the total score and its subscales was good. Meanwhile, the divergent validity of MSPSS was supported through its negative correlation with the General Health Questionnaire.

Furthermore, the coefficient alphas of the entire instrument and its three subscales ranging from 0.85 to 0.91 indicated good internal consistency, and the test-retest scores between 0.72 and 0.85 indicated good stability. The concurrent validity is also confirmed through a positive correlation between the Lubben Social Network Scale and MSPSS [23] [32]. In this current study, the researcher used the MSPSS to measure the perceived social support level among working mothers. The Arabic version of MSPSS was reported to be psychometrically sound, thus making it a reliable and culturally valid scale to assess the perceived social support in the Arabic population.

Brief Coping Orientation to Problems Experienced (B-COPE) Inventory

This inventory is a self-reported measure used to determine an individual’s coping strategies to manage stressful situations in their lives. This scale consists of 14 domains with 28 items. All items are scored on a four-point Likert scale ranging from “one = I have not been doing this at all” to “four = I have been doing this a lot.” The original scale showed good internal inconsistency ($\alpha = 0.83$) [30]. Furthermore, the Arabic version of the B-COPE Inventory demonstrated good psychometric properties. Furthermore, the confirmatory factor analysis showed an acceptable domain structure, and the test-retest reliability was significant at 0.8. The current study presented a Cronbach’s alpha of 0.85, indicating acceptable internal reliability [31] [33].

Distance Learning Satisfaction Scale (DLSAT)

This scale is a self-reported scale consisting of ten items scored on a five-point Likert scale (one = strongly disagree to five = strongly agree) [34] used to rate students' satisfaction towards their online learning experience. In this study, the researcher adopted Cobb’s version [35] that comprises nine items. The minimum and maximum possible scores for the items are nine and 45, respectively. A higher score signifies a higher satisfaction level. Additionally, no adjustments to the scale were made. In this particular study, the working mothers were asked to rate their satisfaction with their children’s distance learning. The original scale presented an acceptable reliability alpha value of 0.78 for the entire scale. In the current study, the DLSAT showed a high-reliability coefficient with $\alpha = 0.92$. 
Data Analysis

In this particular study, the Statistical Package for the Social Sciences (SPSS) version 21.0 was used in the data analysis. Additionally, the mean, standard deviation, and Cronbach’s alpha values of all variables were described using descriptive statistics. Subsequently, Pearson’s correlation coefficients were computed using the bivariate correlations to determine the correlation degree between PSS, MSPSS, DLSAT, and B-COPE. Lastly, the internal consistency for the entire scale was evaluated by calculating the Cronbach’s alpha coefficient.

3. Results and Discussion

Demographic Profile of Participants

A total of 204 mothers participated in the cross-sectional online survey, ranging from 27 to 49 years old (\(M = 35.38, SD = 5.18\)) (Figure 1).

Working Mothers and Perceived Stress

The COVID-19 pandemic has disrupted various aspects of people’s lives. Hence, this study analyzed the relationship between perceived stress, perceived social support, satisfaction with children’s distance learning, and coping strategies among working mothers. The findings revealed that working mothers experienced a high level of stressors due to the outbreak. These outcomes are parallel with previous studies that investigated the impact of global health crises on people’s well-being [36] [37] [38].

An interesting finding is that mothers working in the education and health sectors had a greater stress level. Their PSS scores significantly correlated with their DLSAT. Similarly, mothers in these two sectors were reported with the lowest scores of coping strategies than mothers working in other fields such as engineering, government services, and private business (Table 1). Notably, a significant degree of perceived stress due to the COVID-19 pandemic is considered a risk factor of deteriorating mental health among mothers.

The means and standard deviations for the measures of perceived stress, perceived social support, satisfaction with distance learning, and coping strategies across working sectors (n = 204) are shown in Table 1.
Stress among working mothers is expected from their multiple and simultaneous roles. On the other hand, some of them could manage and balance between working and family life, resulting in lesser stress, whereas others cannot. The COVID-19 pandemic adds to their workload, specifically for those in the education and health sectors.

The perceived stress levels among working mothers are vital as they correlate with mental health. The findings in previous studies revealed that by enhancing their self-efficacy, the perceived capabilities of working mothers in coping with the stressors in their lives could be improved [36] [37] [38]. In this present pandemic, the state of working mothers’ mental health is worrying. They must cope with numerous issues and confront multiple stressors due to countless responsibilities. Moreover, working mothers are expected to be skilled workers in their jobs and childcare experts at home. These high expectations become significant stressors for working mothers, causing anxiety and stress. Due to this fact, they require help and support, specifically from their partners and families, to share the workload and responsibilities. Hence, future studies should highlight more on the strategies and improvement of self-efficacy to promote working mothers’ psychological well-being. This study should also be extended to explore other demographic variables in different populations and cultures.

### Table 1. Means and Standard Deviations Across Working Sectors

| Sector               | M    | SD   |
|----------------------|------|------|
| **Education**        |      |      |
| N = 109              |      |      |
| PSS                  | 47.53| 5.27 |
| MSPSS                | 28.33| 9.02 |
| DLSAT                | 16.43| 5.14 |
| B-COPE               | 59.46| 10.81|
| **Medical Field**    |      |      |
| N = 59               |      |      |
| PSS                  | 43.18| 4.67 |
| MSPSS                | 30.15| 8.32 |
| DLSAT                | 16.33| 4.75 |
| B-COPE               | 60.20| 9.39 |
| **Engineering**      |      |      |
| N = 16               |      |      |
| PSS                  | 35.25| 7.83 |
| MSPSS                | 31.18| 10.77|
| DLSAT                | 21.81| 8.447|
| B-COPE               | 62.31| 13.641|
| **Government directorate** | | |
| N = 4                |      |      |
| PSS                  | 38.25| 6.34 |
| MSPSS                | 37.50| 11.90|
| DLSAT                | 15.25| 3.09 |
| B-COPE               | 68.75| 6.50 |
| **Private Business** |      |      |
| N = 16               |      |      |
| PSS                  | 35.06| 9.46 |
| MSPSS                | 36.12| 11.08|
| DLSAT                | 25.3750| 11.78629 |
| B-COPE               | 65.5625| 14.98430 |

### Working Mothers and Perceived Social Support

Past literature has proven a significant relationship between individual mental health and social support. In this study, perceived social support has a significant impact on working mothers involved in this particular study. Thus, positive support could produce better psychological functioning besides being a buffer against emerging mental health problems [39] [40]. Moreover, it is suggested that a higher degree of social support could enhance an individual's resilience rate when handling stress [40]. This study discovered that perceived social support has a significant negative correlation with perceived stress. Furthermore, a positive correlation was also detected between MSPSS, coping strategies, and satisfaction with distance learning. Despite gaining family and social support, most working mothers still constantly experience perceived stress. Therefore, the social support perception is a crucial indicator of an individual’s psychological functioning during the COVID-19 pandemic. In particular, it is recommended to practice a flexible work environment and efficient social support to reduce working mothers' stress levels.

During the COVID-19 pandemic, working mothers experience high distress while managing multiple roles. Thus, social support in any form they could obtain is required. In general, perceived social support can be acquired from a spouse, family, and friends. The three sources of perceived social support have specific relationships with psychological health aspects, such as depression, tension, fatigue, irritability, and well-being [39] [40]. In this current study, the findings revealed that perceived social support is strongly related to spouse and moderately related to family support. Surprisingly, it showed that friends' support is not related to the variables of working mothers' psychological well-being.

### Working Mothers and Distance Learning Satisfaction

In this study, the mothers had expressed their concerns about the whole experience of distance learning. Notably, they responded negatively concerning the children’s motivation, the value of online discussion, and the curriculum’s suitability to be taught remotely. The DLSAT results revealed that most mothers were dissatisfied with the level of effort and work assigned to their children. The working mothers’ scores also showed a significant inverse correlation with their perceived stress rate \( r = -.587^{**} \). The summary of intercorrelations, means, standard deviations, and Cronbach's alphas for all constructs, with the dependent variable \( n = 204 \) are shown in Table 2 below.
In the Arabic culture, mothers tend to be responsible for monitoring their children’s education. In these trying times, notably the COVID-19 pandemic, many working mothers face a growing challenge in balancing their responsibilities and their children’s motivation and self-efficacy towards online learning. The overall learning outcomes also depend highly on the accessibility of the distance learning system. All these demands add extra burden on the mothers, and other strategies are needed for them to cope with these types of stress. The results in this study also confirmed a recently published study’s finding that highlighted the parents’ struggles due to school closure during the COVID-19 pandemic [41].

Working mothers also experience difficulties in understanding interactive online learning. The findings of past studies described that one of the significant predictors of online learning satisfaction is the interaction and understanding of online learning [35] [41]. Most importantly, it was revealed that interaction is the main ingredient of a successful distance learning program. Unlike the traditional classroom, online interaction in distance learning must be more interactive using different media and pedagogical platforms. Hence, a mother’s understanding of using web-based media will determine their satisfaction in the distance learning experiences.

On the other hand, there is also a complex relationship between working mothers’ involvement in their children’s education in a low-income family. This dilemma between working and family involvement could cause a lack of understanding of how to engage effectively in an online learning environment. It is an interesting area to research further and provide recommendations for online collaborative skills among working professionals, especially working mothers.

Working Mothers and Coping Strategies

COVID-19 continues to spread and affect everybody’s daily lives, specifically women and mothers worldwide. Thus, cultivating effective coping methods (e.g., acceptance and seeking support) is inevitable as they are correlated with better psychological and mental health than other maladjustment methods such as self-blame and denial [42]. Regarding the participants’ coping skills in this study, the working mothers recorded a mean score of 60.65 ($SD = 10.21$) within the range of 28 to 90. This data indicates a moderate level of ability to handle stress from the COVID-19 pandemic effectively. There was also a statistically significant relationship between the working mothers’ coping strategies and all the study variables (PSS, MSPSS, and DLSAT).

Therefore, the effective usage of coping strategies could assist individuals in handling stressful life events. As shown in Table 1, mothers in the educational and medical fields displayed a significantly lower mean score of B-COPE than mothers from different fields. Nevertheless, the results in this study contradict recent studies on the coping patterns of women during COVID-19, whereby the majority of the working mothers used avoidance instead of problem-focused coping strategies [27] [29].

On another note, various media can be utilized to promote healthy behaviors. For instance, online counseling services can be provided to mothers, women, or other society members during the COVID-19 pandemic to protect an individual’s mental health during the crisis [43]. In summary, coping strategies represent personal efforts in managing stressful life situations, and thus, an individual’s circumstances are the pivotal factor in ensuring their adjustment.

4. Implications and Recommendations

Based on the above results and discussions, working mothers are among the most vulnerable groups in the COVID-19 pandemic. Their high-stress level could impact their physical and mental well-being. In light of this study, relevant health care practitioners such as counselors, social workers, and mental health professionals must prioritize working mothers’ needs besides helping them find alternative channels of care for support. Besides, helplines or online consultations can aid in emergency requests. Nevertheless, it is equally crucial to increase awareness about effective coping strategies and to educate people about common psychological consequences in such difficult situations.

Alternative care channels are crucial to support working mothers in managing multiple workloads and responsibilities. Most significantly, the findings of this study suggested focusing more on mothers who work in the education and health sectors since they experience a greater level of stress compared to working mothers in other fields.

| Variable                  | PSS  | MSPSS | DLSAT | B-COPE | M    | SD   | (α) |
|---------------------------|------|-------|-------|--------|------|------|-----|
| Perceived stress (PSS)    |      | -3.89** |       | -3.14** | 44.15 | 7.25 | .93 |
| Perceived Social Support (MSPSS) |      |       | -2.65** |       | .155** | 29.87 | 9.41 | .93 |
| Distance Learning Satisfaction (DLSAT) |      |       |       |       | .280** | 17.50 | 6.60 | .92 |
| Coping Strategies (B-COPE) |      |       |       |       | 60.56 | 11.07 | .85 |

**p < 0.01
of works. Hence, practitioners and professionals should develop a plan to arrange online programs related to stress management during the pandemic era.

Concurrently, stakeholders in the education field should establish an elaborate plan to organize the distance learning process as much as possible. Additionally, teachers and school counselors should intensify their efforts to identify and assist families struggling with distance learning. Supporting students to take responsibilities and triggering their motivation to learn via effective communication could reduce the stressors on their mothers.

5. Limitations

The limitations in this study include the working mothers who participated in the online survey via social media, which might not present a sample representative of the overall population. For instance, working mothers without access to the Internet or social media applications at the time of this study would not be able to participate. Secondly, although the sample size was statistically significant, it is still relatively small. In other words, the generalizability of this study's findings is only limited to working mothers with similar criteria from similar geographical areas in Jordan. Thirdly, since the current study's constructs were measured naturally without manipulation, the internal validity was low. Lastly, even though all the instruments used in this study were psychometrically valid, they were not tested on women or working mothers before.

6. Conclusions

The findings of this study support the idea that the current pandemic has a negative impact on all segments of society. This study selected working mothers due to their numerous social roles. Working mothers experience significant levels of psychological stress due to their workload. Since the end of this pandemic is still questionable, working mothers' mental health remains vulnerable to various negative impacts. This situation could prevent them from applying adaptive strategies that could temporarily help them perform their roles.

This study posits a critical question, “Who are the biggest losers in the COVID-19 pandemic?” The findings revealed sound judgment and interpretation that working mothers are in the most vulnerable groups facing the pandemic. Variables on perceived stress indicated that working mothers have high-stress levels, particularly those working in the education and health sectors. On the other hand, other variables of perceived social support, distance learning satisfaction, and coping strategies highlighted positive results on working mothers. This result indicates that working mothers cope well with the current situation as long as they receive the necessary support from their spouse, family, and friends and use coping strategies effectively.

Finally, the study shows that working mothers’ mental health is worrying and needs dedication to action. Governments and decision-makers should collaborate to establish an efficient financial and psychological system to support them. Therefore, the current study is crucial to identify the effects of COVID-19 on working mothers and propose effective coping strategies to help their well-being. Hence, distance (online) psychological counseling services are offered to decrease the stress level among working mothers. Further research should provide effective long-run coping strategies, which are required and significantly needed.
