Critical-point scaling function for the specific heat of a
Ginzburg-Landau superconductor

Dominic J. Lee* and Ian D. Lawrie

Abstract

If the zero-field transition in high temperature superconductors such as YBa$_2$Cu$_3$O$_{7-\delta}$ is a critical point in the universality class of the 3-dimensional XY model, then the general theory of critical phenomena predicts the existence of a critical region in which thermodynamic functions have a characteristic scaling form. We report the first attempt to calculate the universal scaling function associated with the specific heat, for which experimental data have become available in recent years. Scaling behaviour is extracted from a renormalization-group analysis, and the $1/N$ expansion is adopted as a means of approximation. The estimated scaling function is qualitatively similar to that observed experimentally, and also to the lowest-Landau-level scaling function used by some authors to provide an alternative interpretation of the same data. Unfortunately, the $1/N$ expansion is not sufficiently reliable at small values of $N$ for a quantitative fit to be feasible.

I. INTRODUCTION

In recent years, a considerable body of experimental evidence has accumulated to suggest that the zero-field transition in certain high-temperature superconductors, most notably YBa$_2$Cu$_3$O$_{7−δ}$ (YBCO), is a critical point in the universality class of the 3-dimensional XY model [1–7]. If this is the case, then, in the presence of a sufficiently small magnetic field $B$, the specific heat is expected to have a singular part which exhibits the scaling behaviour

$$C_{\text{sing}}(T, B) = B^{−\alpha/2\nu}C(x),$$

where $\alpha \approx −0.013$ and $\nu \approx 0.67$ are critical exponents and the scaling variable is $x = (T − T_c)B^{−1/2\nu}$. Similar scaling forms are expected for other thermodynamic quantities, such as the magnetization. In the limit $B → 0$, the scaling function must behave as $C(x) → C_±|x|^{−\alpha}$, so that $C_{\text{sing}}(T, 0) = C_±|T − T_c|^{−\alpha}$, where $+$ refers to $T > T_c$ and $−$ to $T < T_c$. For YBCO, zero-field measurements of the specific heat presented by several authors seem to agree well with this prediction [4,8] and to be consistent with the universal values of $\alpha$ and of the amplitude ratio $C_+/C_-$ as determined by precision measurements of the superfluid transition in $^4$He, which is also in the universality class of the 3-dimensional XY model [9,10]. A claim has recently been made that the zero field singularity is actually characterized by different exponents $\alpha_+$ and $\alpha_−$, above and below $T_c$, which would not be consistent with any ordinary type of critical point [11]. It has also been argued, though, that this conclusion rests on an inappropriate background subtraction [12].

In a nonzero applied field, one can test the scaling form (1) by the extent to which data for $B^{\alpha/2\nu}C_{\text{sing}}(T, B)$ collapse to a common curve when plotted as a function of $x$. Here, matters are complicated by the fact that a different kind of scaling behaviour

$$C(T, B) \approx C_{\text{LLL}}(x_{\text{LLL}})$$

is expected when only the lowest Landau level is significantly occupied [13,14]. Here, the scaling variable is $x_{\text{LLL}} = (T − T_{c2}(B))/(TB)^{2/3}$, where $T − T_{c2}(B)$ or, equivalently, $B = B_{c2}(T)$ is the upper critical field of the Ginzburg-Landau theory. Since $\alpha$ in (1) is very small, and $1/2\nu \approx 0.75$, the two predictions are rather hard to distinguish. Some authors claim that lowest-Landau-level scaling works just as well as, or indeed better than, critical point scaling [15–21]. For HgBa$_2$Ca$_2$Cu$_3$O$_{8+δ}$ [22], specific heat data appear to collapse to a common curve when plotted in the form of (1), but the scaling function $C(x)$, which ought to be universal, is apparently rather different from that found for YBCO. For LuBa$_2$Cu$_3$O$_7$, the authors of Ref. [23] find that a two-dimensional lowest-Landau-level scaling form best fits the data, though they claim that it is also consistent with 3-dimensional XY scaling for fields below 1T. Most recently, Junod et al [24] have concluded that optimally-doped YBCO is the only material to show convincing evidence of critical-point scaling.

Theoretically, it seems that the scaling form (1) is an unambiguous prediction of the theory of critical phenomena [25] and ought to be observed sufficiently close to the zero-field critical point. Lowest-Landau-level scaling, on the other hand, is to be expected in large fields, in the neighbourhood of the upper critical field. There is in principle no region where both scaling forms could be simultaneously valid [26]. There is, however, no reliable means of estimating the largest field in which critical-point scaling ought to be observable or the
smallest field consistent with lowest-Landau-level scaling. Calculations are somewhat sim-
plified by the lowest-Landau-level approximation, and scaling functions have been obtained
by both perturbative \[27,29,28\] and nonperturbative \[30\] methods. In particular, Tešanović
and Andreev \[30\] have obtained scaling functions which agree quite well with experimental
data for the specific heat and magnetization of YBCO, though the fit is rather better in the
case of the magnetization than the specific heat \[18\].

For the critical-point scaling function, no theoretical estimate has been obtained (al-
though some general consequences of scaling have been discussed in \[31\]), and the calcu-
lation of this scaling function is the object of the work reported here. The calculation is
based on the Ginzburg-Landau-Wilson model of an isotropic superconductor. Although the
superconductors of interest are anisotropic, layered materials, this seems to be a reasonable
approximation in the case of YBCO. More generally, in fact, it is the divergence of the
coherence length near a critical point which gives rise to characteristic critical phenomena.
To the extent that the critical behaviour is that of a 3-dimensional system, therefore, one
might expect the universal scaling function for an isotropic system to be that observed in
the asymptotic critical region. We assume that the magnetic coupling is weak enough for
fluctuations in the vector potential \( \mathbf{A}(\mathbf{r}) \) to be neglected. In fact, it is only in this approxi-
mation that critical behaviour is to be expected \[32\]. One barrier to this calculation is that,
in the low-field regime, all the the Landau levels must be included, and the eigenfunctions
are extremely inconvenient to deal with. Here, we exploit an integral representation of the
order-parameter propagator \[25\] in which the sum over Landau levels is carried out once
and for all.

Our initial attempts to estimate the scaling function \( C(x) \) made use of perturbation
theory, which yields accurate results for the critical exponents. Unfortunately, perturbation
theory does not yield a well-controlled approximation to the function \( C(x) \), because it gives
a spurious singularity in the neighbourhood of \( T_{c2}(B) \) and we have been unable to cure
this problem satisfactorily by \textit{ad hoc} methods. The alternative we adopt here is to study
a generalized Ginzburg-Landau-Wilson superconductor having an order parameter with \( N 

complex components and to make use of the expansion in powers of \( 1/N \). The scaling
function must be extracted by means of a renormalization-group analysis. Curiously, we
have not found in the literature a formulation of the renormalization group that is well
adapted to the use of the \( 1/N \) expansion as a means of approximation. We have therefore
developed a suitable formulation, which is presented in detail for the zero-field case in \[33\].
The extension of the \( 1/N \) formalism and the renormalization-group analysis to the case
of a nonzero magnetic field are summarized in sections II - IV below. The calculation of
the scaling function requires a numerical means of estimating several cumbersome integrals,
and the techniques we have devised for doing this are described in section V. As has long
been known in connection with the estimation of, the convergence of the \( 1/N \) expansion
is very poor. The next-to-leading order calculations reported here do not yield meaningful
results for small values of \( N \) (in particular for the physically relevant value \( N = 1 \)), but
for larger values we obtain scaling functions which are qualitatively similar to that observed
experimentally. These results are presented and discussed in section VI.
II. THE 1/N EXPANSION

We consider the Ginzburg-Landau-Wilson theory for an isotropic superconductor with $N$ complex order-parameter components $\phi_i(r)$ in a fixed, uniform magnetic field of strength $B_0$. It is defined by the effective reduced Hamiltonian density

$$\mathcal{H} = \sum_{i=1}^{N} \left\{ |(\nabla - iA(r)) \phi_i(r)|^2 + t_0 |\phi_i(r)|^2 \right\} + \frac{\lambda_0}{4N} \left( \sum_{i=1}^{N} |\phi_i(r)|^2 \right)^2,$$

(3)

where $t_0$ is taken to be linear in temperature ($t_0 \propto T - T_0$), and the coupling strength $\lambda_0$ to be temperature-independent. A convenient choice of gauge for the magnetic vector potential is $A(r) = B_0(0, x, 0)$, corresponding to a uniform field in the $z$ direction, and we have absorbed the charge of a Cooper pair into the magnitudes of $A$ and $B_0$. As explained in [33], a standard integral transformation of the Hubbard-Stratonovich type allows us to express the partition function as a functional integral over an auxiliary field $\Psi$,

$$Z = N \int \prod_{i=1}^{N} \mathcal{D}\phi_i \mathcal{D}\phi_i^* \exp \left[ - \int d^3r \mathcal{H} \right]$$

(4)

$$= \int \mathcal{D}\Psi \exp \left[ -NH_{\text{eff}}(\Psi) \right],$$

(5)

where the effective Hamiltonian is

$$H_{\text{eff}}(\Psi) = \int d^3r \lambda_0^{-1}\Psi^2(r) - \text{Tr}_{r,r'} \ln \Delta(r,r';\Psi)$$

(6)

and $N$ is an irrelevant normalization constant. The propagator $\Delta(r,r';\Psi)$ is the solution of

$$\left[ -\nabla^2 + 2iB_0x\partial_y + B_0^2x^2 + t_0 + i\Psi(r) \right] \Delta(r,r';\Psi) = \delta(r-r').$$

(7)

As in [33], it is helpful to formulate the $1/N$ expansion in terms of a self-energy $\tilde{t}_0$, which can be defined as follows. The full 2-point function

$$G^{(2)}(r,r') = \langle \phi_i^*(r)\phi_i(r') \rangle = Z^{-1} \int \mathcal{D}\Psi \Delta(r,r';\Psi)e^{-NH_{\text{eff}}(\Psi)}$$

(8)

can be expressed as

$$G^{(2)}(r,r') = \int \frac{dk_z d\sigma}{(2\pi)^2} B_0 \sum_n \frac{\chi_{k_z,\sigma,n}(r)\chi^*_{k_z,\sigma,n}(r')}{\Gamma^{(2)}(n, k_z)},$$

(9)

where the $\chi_{k_z,\sigma,n}(r)$ are eigenfunctions of the differential operator in (7), whose eigenvalues are the Landau levels $E(n,k_z) = k_z^2 + (2n+1)B_0 + t_0$, and we define

$$\tilde{t}_0 = \Gamma^{(2)}(0,0).$$

(10)

In the limit $B_0 \to 0$, this agrees with the definition adopted in [33]. Because the Landau eigenfunctions are extremely inconvenient to deal with, we shall exploit the fact that $e^{-i(x-x')(y-y')B_0/2}G^{(2)}(r,r')$ is a translationally invariant function to write

4
\[ G^{(2)}(\mathbf{r}, \mathbf{r}') = e^{i(x+x')(y-y')B_0/2} \int \frac{d^3k}{(2\pi)^3} e^{i\mathbf{k} \cdot (\mathbf{r}-\mathbf{r}')} G^{(2)}(\mathbf{k}). \]  

(11)

Using the eigenfunctions given in [25], we find

\[ \left[ \Gamma^{(2)}(0, k_z) \right]^{-1} = (\pi B_0)^{-1} \int dk_xdk_y e^{-(k_x^2+k_y^2)/B_0} G^{(2)}(\mathbf{k}). \]  

(12)

Owing to the factors of \( N \) multiplying \( H_{\text{eff}}(\Psi) \) in [9] and [8], the \( 1/N \) expansion is generated by the method of steepest descent. We expand \( \Psi \) about the the position-independent saddle point by writing

\[ \Psi(\mathbf{r}) = i(t_0 + B_0 - \tilde{t}_0 + N^{-1}\delta) + (2N)^{-1/2} \psi(\mathbf{r}), \]

(13)

where \( \delta \) is defined by the condition \( \langle \psi(\mathbf{r}) \rangle = 0 \). The propagator \( \Delta(\mathbf{r}, \mathbf{r}'; \Psi) \) can be expanded as \( \Delta(\mathbf{r}, \mathbf{r}'; \Psi) = \Delta(\mathbf{r}, \mathbf{r}') + O(N^{-1/2}) \), where the leading term is the solution of

\[ [-\nabla^2 + 2iB_0\mathbf{x} \partial_y + B^2 + \tilde{t}_0 - B_0] \Delta(\mathbf{r}, \mathbf{r}') = \delta(\mathbf{r} - \mathbf{r}'). \]

(14)

In real space, the diagrammatic expansion is identical to that explained in [33], to which we refer the reader for details, except that the propagators are modified by the presence of the magnetic field. The \( \phi \) propagator \( \Delta(\mathbf{r}, \mathbf{r}') \) is given by

\[ \Delta(\mathbf{r}, \mathbf{r}') = e^{i(x+x')(y-y')B_0/2} \int \frac{d^3k}{(2\pi)^3} e^{i\mathbf{k} \cdot (\mathbf{r}-\mathbf{r}')} \Delta(\mathbf{k}) \]

(15)

where, as obtained in [25], \( \Delta(\mathbf{k}) \) has the integral representation

\[ \Delta(\mathbf{k}) = \int_0^\infty du (\cosh B_0 u)^{-1} \exp \left[ -(k_x^2 + \tilde{t}_0 - B_0)u - (k_x^2 + k_y^2)\tau(u) \right] \]

(16)

with \( \tau(u) = B_0^{-1} \tanh B_0 u \). The \( \psi \) propagator \( D(\mathbf{r} - \mathbf{r}') \) is translationally invariant. Its inverse is

\[ D^{-1}(\mathbf{r} - \mathbf{r}') = \lambda_0^{-1} \delta(\mathbf{r} - \mathbf{r}') + \frac{1}{2} \Delta(\mathbf{r}, \mathbf{r}') \Delta(\mathbf{r}', \mathbf{r}) \]

(17)

and its Fourier transform is

\[ D(\mathbf{k}) = \left[ \lambda_0^{-1} + \Pi(\mathbf{k}) \right]^{-1} \]

(18)

where

\[ \Pi(\mathbf{k}) = \frac{1}{2} \int \frac{d^3k'}{(2\pi)^3} \Delta(\mathbf{k'}) \Delta(\mathbf{k'} + \mathbf{k}) \]

\[ = \left( \frac{1}{4\pi} \right)^{3/2} \frac{B_0}{2} \int_0^\infty du du' \left( u + u' \right)^{-1/2} \frac{\tau(u)\tau(u')}{\sinh B_0 (u + u')} \times \exp \left[ -\frac{uu'}{u + u'} k_z^2 - \frac{\tau(u)\tau(u')}{\tau(u) + \tau(u')} (k_x^2 + k_y^2) - (u + u')(\tilde{t}_0 - B_0) \right]. \]

(19)
To make use of this expansion, we need to determine the counterterm $\delta$ introduced in (13) and the relation between the self-energy $\tilde{t}_0$ and the variables $t_0$, $\lambda_0$ and $B_0$ with which we started. Consider first the expansion for the 2-point function $G^{(2)}(r, r')$ shown in figure 1(a). The first term is just $\Delta(r, r')$, which contains the exact self-energy $\tilde{t}_0$, and satisfies (10) by itself. Thus, the counterterm $\delta$ is required to cancel the one-loop contribution at $n = k_z = 0$ and we find

$$\delta = \frac{1}{2\pi B_0} \int dk_x dk_y e^{-(k_x^2 + k_y^2)/B_0} \int \frac{d^3k'}{(2\pi)^3} \Delta(k + k') D(k') \bigg|_{k_z=0} \int d^3k' \Delta(k) D(k), \quad (20)$$

where

$$\Delta(k) = \int_0^\infty du \exp \left[ -((k_z^2 + \tilde{t}_0)u - (2B_0)^{-1} (1 - e^{-2B_0 u}) (k_x^2 + k_y^2) \right]. \quad (21)$$

The requirement that $\langle \psi(r) \rangle = 0$ yields a constraint equation, which implicitly determines $\tilde{t}_0$. Figure 1(b) shows the expansion of $\langle \psi(r) \rangle$ to order $1/N$; the function $f$ is the coefficient of $\psi(r)$ in $H_{\text{eff}}$, as given in (13). From this we obtain

$$t_0 = \Phi_0(\tilde{t}_0, \lambda_0, B_0) \equiv \tilde{t}_0 - B_0 - \frac{\lambda_0}{2} \Delta + N^{-1} \left[ \frac{\lambda_0}{4} A - \delta [1 + \lambda_0 \Pi(0)] \right] \quad (22)$$

where

$$\Delta(\tilde{t}_0, \lambda_0, B_0) = \int \frac{d^3k}{(2\pi)^3} \Delta(k) = \left( \frac{1}{4\pi} \right)^{3/2} B_0 \int_0^\infty du \frac{\exp[-(\tilde{t}_0 - B_0)u]}{u^{1/2} \sinh B_0 u} \quad (23)$$

and

$$A(\tilde{t}_0, \lambda_0, B_0) = \int \frac{d^3k}{(2\pi)^3} A_3(k) D(k). \quad (24)$$

The function $A_3(k)$ corresponds to the loop of three $\phi$ propagators in figure 1(b), and is defined by

$$A_3(k) = \int d^3r' d^3r'' e^{ik\cdot(r'-r'')} \Delta(r, r') \Delta(r', r'') \Delta(r'', r). \quad (25)$$

Straightforward but tedious algebra suffices to show that it is independent of $r$ and is given by

$$\Delta_3(k) = \frac{\partial \Pi(k)}{\partial \tilde{t}_0}. \quad (26)$$

Our aim is to investigate the scaling properties of the specific heat. Within the Ginzburg-Landau-Wilson approximation, the specific heat per unit volume per order-parameter component is given by

$$C = \frac{1}{2NV} \frac{\partial^2 \ln Z}{\partial \tilde{t}_0^2} = (2N)^{-1} \int d^3r \sum_{i,j} \langle |\phi_i(0)|^2 |\phi_j(r)|^2 \rangle_c, \quad (27)$$
where \( V = \int d^3r \) is the volume and \( \langle \ldots \rangle_c \) denotes the connected correlation function. This correlation function can be obtained directly as

\[
\langle |\phi_i(0)|^2 |\phi_j(r)|^2 \rangle_c = \delta_{ij} Z^{-1} \int D\Psi \Delta(0, r; \Psi)\Delta(r, 0; \Psi)e^{-NH_{\text{eff}}},
\]

but it is not hard to obtain the convenient expression

\[
C = \lambda_0^{-1} \left[ 1 - \lambda_0^{-1} D(0) \right]
\]

where \( D(k) = D(k) + O(N^{-1}) \) is the Fourier transform of the 2-point function \( \langle \psi(r) \psi(r') \rangle \).

To order \( 1/N \), this 2-point function is given by the sum of diagrams shown in figure 2, and is conveniently expressed in terms of a self-energy \( \Pi(\psi)(k) \) as

\[
D(k) = D(k) + N^{-1} D(k) \Pi(\psi)(k) D(k).
\]

As explained in appendix A, the self-energy at \( k = 0 \) is given by

\[
\Pi(\psi)(0) = -\frac{1}{4} \frac{\partial A}{\partial t_0} + \delta \frac{\partial \Pi(0)}{\partial t_0} = -\frac{\partial}{\partial t_0} \left[ \frac{1}{4} A - \delta \Pi(0) \right] - \frac{\partial \delta}{\partial t_0} \Pi(0),
\]

the second expression being convenient for the purpose of renormalization.

### III. RENORMALIZATION

The scaling behaviour of thermodynamic functions emerges in the usual way from a renormalization-group analysis, but in the context of the \( 1/N \) expansion this requires a nonstandard renormalization scheme, which is developed in detail in [33] for the theory with \( B_0 = 0 \). According to this scheme, renormalized variables \( \tilde{t}, t, z \) and \( B \) are defined by

\[
\tilde{t}_0 = \mu^2 \tilde{t} \left[ 1 - N^{-1} \frac{S_3}{6b} \ln z + O(N^{-2}) \right]
\]

\[
t_0 = t_{0c} + \mu^2 \tilde{t} \frac{(z + 2a)}{z} \left[ 1 - N^{-1} \frac{2S_3}{3b} \ln z + O(N^{-2}) \right]
\]

\[
\lambda_0^{-1} = \mu^{-1} z \left[ 1 + N^{-1} \frac{4S_3}{3b} \ln z + O(N^{-2}) \right]
\]

\[
B_0 = \mu^2 B.
\]

In these expressions, \( t_{0c} \) is the value of \( t_0 \) at the zero-field critical point, \( S_3 = (2\pi)^{-2} \) is the usual factor arising from angular integrations, and the constants \( a = 1/16\pi \) and \( b = 1/16 \) arise from the large- and small-momentum limits of \( \Pi(k) \) when \( B = 0 \). As usual, \( \mu \) is an arbitrary renormalization scale, with the dimensions of inverse length. The magnetic field requires no renormalization; the definition [33] simply serves to make \( B \) dimensionless, as are \( \tilde{t}, t \) and \( z \). In this scheme, critical behaviour is governed by an infrared-stable renormalization-group fixed point at \( z = 0 \). The criterion for renormalization is that renormalized thermodynamic functions should have finite, non-zero limits as \( z \to 0 \), and we have implemented this requirement by a ‘minimal subtraction’ of the leading singularities proportional to \( \ln z \). It is crucial to our analysis that, as in the perturbative renormalization
of [25], the presence of a magnetic field introduces no additional divergences beyond those encountered at $B = 0$ and we shall return to this point shortly.

For our immediate purposes, we need renormalized versions of the constraint equation (22) and the specific heat (29). The various integrals and subintegrals from which these are constructed must be re-expressed in terms of the renormalized variables. To this end, it is convenient to introduce the dimensionless quantities

$$\Pi_R(\mathbf{p}; \alpha) = (\mu^2 B)^{1/2} \Pi(k; \mu^2 \tilde{t}, \mu^2 B)$$

and

$$D_R(\mathbf{p}; \alpha, z, B) = [z + B^{-1/2} \Pi_R(\mathbf{p}; \alpha)]^{-1}$$

with rescaled variables $\mathbf{p}$ and $\alpha$ defined by

$$\mathbf{p} = (\mu^2 B)^{-1/2} k \quad \text{and} \quad \alpha = \tilde{t}/B.$$  

(43)

Subsequently, it will also be helpful to write

$$p_z^2 = p^2 \cos^2 \theta, \quad p_x^2 + p_y^2 = p^2 \sin^2 \theta.$$  

(44)

With this notation, the constraint equation becomes

$$t = (z + 2a)^{-1} \Phi(\tilde{t}, z, B)$$

$$\Phi(\tilde{t}, z, B) = z(\tilde{t} - B) - \frac{1}{2} B^{1/2} \Delta_R$$

$$+ N^{-1} \left[ \frac{1}{4} A_R + B^{1/2} \left( \Delta_R + \frac{\alpha}{4} \frac{\partial \Delta_R}{\partial \alpha} \right) \frac{S_3}{3b} \ln z ight.$$

$$\left. - z B^{1/2} \delta_R + \left( \frac{1}{2} \frac{\tilde{t}}{3b} - \frac{2}{3} B \right) \frac{S_3}{b} \ln z \right] + O(N^{-2}).$$  

(46)

The dimensionless, renormalized specific heat $C_R(\tilde{t}, z, B)$ is defined by

$$C(\tilde{t}_0, \lambda_0, B_0) = C(0, \lambda_0, 0) + C_1 \lambda_0^{-3} (t_0 - t_{0c}) + \bar{Z}_t^{-2} C_R(\tilde{t}, z, B),$$

(47)

where

$$\bar{Z}_t = \frac{(z + 2a)}{z} \left[ 1 - N^{-1} \frac{2 S_3}{3b} \ln z + O(N^{-2}) \right]$$

(48)

is the renormalization factor appearing in (33). The dimensionless constant $C_1$ multiplies a non-singular term, whose presence in three dimensions was first noted by Abe and Hikamai [34] and whose role in our renormalization scheme is discussed in [33]. Writing $C_R(\tilde{t}, z, B) = (z + 2a)^2 C_R(\tilde{t}, z, B)$, we find
\[ C_R(\tilde{t}, z, B) = -D_R(0; \alpha, z, B) - \frac{1}{2} C_1 \Phi(\tilde{t}, z, B) + N^{-1} \left[ E_1(\tilde{t}, z, B) + E_2(\tilde{t}, z, B) + E_3(\tilde{t}, z, B) \right] + O(N^{-2}), \]

where

\[
E_1 = \frac{1}{4} D_R^2 B^{-1} \frac{\partial A_R}{\partial \alpha} - D_R \frac{5 S_3}{6 b} \ln z - D_R^2 B^{-1/2} \frac{\partial \Pi_R}{\partial \alpha} \frac{S_3}{6 b} \ln z \]

\[
E_2 = D_R^2 B^{-1} \Pi_R \frac{\partial \delta_R}{\partial \alpha} - \frac{S_3}{b} z^{-1} - D_R \frac{S_3}{2 b} \ln z - C_1 \left( z(\tilde{t} - B) - \frac{1}{2} B^{1/2} \Delta_R \right) \frac{S_3}{b} \ln z \]

\[
E_3 = D_R^2 \frac{4 S_3}{3 b} z \ln z \]

and \( D_R \) and \( \Pi_R \) stand for \( D_R(0; \alpha, z, B) \) and \( \Pi_R(0; \alpha) \) respectively. The integrals \( A_R(\alpha, z, B) \) and \( \delta_R(\alpha, z, B) \) defined in (10) and (11) are both singular when \( z \to 0 \), but each of the quantities \( \Phi(\tilde{t}, z, B) \) and \( E_i(\tilde{t}, z, B) \) has a finite limit, provided that we choose \( C_1 = -2/b^2 \). To verify this assertion is not an entirely trivial matter. In particular, to verify that the expression (16) for \( \Phi(\tilde{t}, z, B) \) has a finite limit, it is necessary to show that

\[ A_R(\alpha, z, B) = -B^{1/2} \left( 4 \Delta_R(\alpha) + \alpha \frac{\partial \Delta_R(\alpha)}{\partial \alpha} \right) \frac{S_3}{3 b} \ln z + O(z \ln z). \]

Because the singularities arise from the large-\( p \) region of integration, the required cancellations can be verified by means of large-\( p \) expansions of the subintegrals \( \Pi_R(p; \alpha), \Delta_3 R(p; \alpha) \) and \( \Delta_R(p; \alpha) \), which are discussed in appendix B.

**IV. RENORMALIZATION GROUP AND SCALING**

The fact that the unrenormalized theory is independent of the renormalization scale \( \mu \) leads in the standard way to renormalization-group equations for the renormalized quantities \( t(\tilde{t}, z, B) \) and \( C_R(\tilde{t}, z, B) \), which take the form

\[
\left[ \beta(z) \frac{\partial}{\partial z} - (2 - \eta(z)) \frac{\partial}{\partial \tilde{t}} - 2 B \frac{\partial}{\partial B} + \frac{1}{\nu(z)} \right] t(\tilde{t}, z, B) = 0
\]

\[
\left[ \beta(z) \frac{\partial}{\partial z} - (2 - \eta(z)) \frac{\partial}{\partial \tilde{t}} - 2 B \frac{\partial}{\partial B} - \frac{\alpha(z)}{\nu(z)} \right] C_R(\tilde{t}, z, B) = 0,
\]

where \( \alpha(z) = 2 - 3 \nu(z) \) and the remaining functions are those derived in [B3]. In contrast to perturbative renormalization schemes, the additive renormalizations of the specific heat in (17) are independent of \( \mu \), so the associated renormalization group equation (55) is homogeneous. The asymptotic critical behaviour with which we are concerned here is governed by the infrared-stable fixed point at \( z = 0 \), where \( \beta(0) = 0 \) and the other function reduce to the critical exponents

\[
\nu = 1 - \frac{16}{3\pi^2 N} + O(N^{-2}), \quad \alpha = -1 + \frac{16}{\pi^2 N} + O(N^{-2}), \quad \eta = \frac{4}{3\pi^2 N} + O(N^{-2}).
\]

For \( z = 0 \), the renormalization-group equations are equivalent to the relations
where \( \ell \) is an arbitrary scaling factor. The functions \( t(\tilde{t}, 0, B) \) and \( C_R(\tilde{t}, 0, B) \) have infrared singularities when their first argument \( \tilde{t} \) vanishes. On the right-hand sides of (57) and (58), we exponentiate these singularities into the prefactors by choosing \( \ell \) to satisfy \( \ell^{-(2-\eta)}\tilde{t} = 1 \). Then, by setting \( \ell = B^{1/2}L \), we find that \( C_R \) has the scaling form

\[
C_R = B^{-\alpha/2\nu}C(tB^{-1/2\nu})
\]

where, with \( x = tB^{-1/2\nu} \), the scaling function is

\[
C(x) = L^{-\alpha/\nu}(x)C_R(1, 0, L^{-2}(x)),
\]

the function \( L(x) \) being determined by the constraint equation

\[
2ax = L^{1/\nu}(x)\Phi(1, 0, L^{-2}(x)).
\]

To obtain a numerical estimate of the scaling function \( C(x) \), we need an approximate means of evaluating the integrals in (14) and (19) which is discussed in the following section.

V. NUMERICAL ESTIMATION OF INTEGRALS

In order to determine the functions \( C_R(1, 0, L^{-2}) \) and \( \Phi(1, 0, L^{-2}) \), and hence the scaling function \( C(x) \), we need to estimate the renormalized counterparts of integrals such as (20) and (24). This requires analytic approximations to the functions \( \Pi_R(p; \alpha) \), \( \Delta_R(p; \alpha) \) and \( \Delta_{3R}(p; \alpha) \), which are themselves defined by rather intractable integrals. This section indicates the methods of approximation we have used, focussing on the example of \( \Delta_{3R}(p; \alpha) \), which we express in terms of the variables (14) as \( \Delta_{3R}(p, \theta; \alpha) \). Having used the renormalization group to replace \( \tilde{t} \) with 1 and \( B \) with \( L^{-2} \) in (60) and (61), we have \( \alpha = \tilde{t}/B = L^{2} \).

For large values of \( p \), we approximate all of the subintegrals by means of the large-momentum expansions developed in appendix B. Numerically, this turns out to be a good approximation for \( p \geq 6 \). In particular, this strategy allows us to cancel analytically the divergences that arise at the fixed point \( z = 0 \).

For \( p < 6 \), an expansion in inverse powers of \( \alpha \) is possible when \( \alpha \) is large enough. More specifically, in the case of \( \Delta_{3R} \), we have an expansion of the form

\[
\Delta_{3R}(p, \theta; \alpha) = \alpha^{-3/2} \left[ f_0(q, \theta) + \alpha^{-1} f_1(q, \theta) + \alpha^{-2} f_2(q, \theta) + O(\alpha^{-3}) \right]
\]

where \( q = \alpha^{-1/2}p \). (This entails, of course, a rescaling of the integration variable in the final integral (24).) Using the representation (14), the change of variables \( v = w/\alpha, v^\prime = w^\prime/\alpha \) leads to a power series expansion in which each of the remaining integrals can be calculated analytically. We find that the functions \( f_i(q, \theta) \) are given by

\[
f_0 = (8\pi)^{-1}Q, \quad f_1 = (16\pi)^{-1}(Q + 8Q^2)
\]

\[
f_2 = (96\pi)^{-1}[3Q + 16Q^2 + (128 + 4q^2s^2)Q^3 + 96q^2s^2Q^4],
\]
where \( Q = (q^2 + 4)^{-1} \) and \( s = \sin \theta \). In practice, we have used this approximation for \( \alpha > 2.25 \), where it appears to yield results of satisfactory accuracy.

For \( p < 6 \) and \( \alpha < 2.25 \) no systematic expansion in any small parameter will serve our purpose. Instead, we have devised an approximation scheme which we again illustrate for the example of \( \Delta_{3R} \). The basic strategy is to evaluate the double integral \[(B2)\] numerically for selected values of \( \rho, \theta \) and \( \alpha \) and to construct an interpolating function from these numerical values. To interpolate simultaneously in all three variables is a difficult undertaking, however. To simplify it, we introduce a further approximation, which reduces the function of three variables to several functions, each depending on only two variables. In the expression \[(B2)\], we make the change of integration variables

\[
u = \rho \cos^2 \phi, \quad u' = \rho \sin^2 \phi.
\]

The integral becomes (again, with the notation \( s = \sin \theta \) and \( c = \cos \theta \))

\[
\Delta_{3R}(\rho, \theta; \alpha) = \frac{1}{2(4\pi)^{3/2}} \int_0^{\pi/2} d\phi \sin(2\phi) \int_0^{\infty} d\rho \frac{\rho^{3/2}}{\sinh \rho} \left[1 \right. \\
\left. \times \exp \left[-(\alpha - 1)\rho - (p^2c^2/4)\rho \sin^2(2\phi) - p^2s^2T(\rho, \phi)\right] \right]
\]

\[
T(\rho, \phi) = \frac{\tanh(\rho \cos^2 \phi) \tanh(\rho \sin^2 \phi)}{\tanh(\rho \cos^2 \phi) + \tanh(\rho \sin^2 \phi)}.
\]

Our approximation scheme is based on the observation that \( T(\rho, \phi) \approx (\rho/4) \sin^2(2\phi) \) for \( \rho \to 0 \) while \( T(\rho, \phi) \approx \frac{1}{2} \) for \( \rho \to \infty \), except at the endpoints \( \phi = 0 \) and \( \phi = \pi/2 \). We divide the region of integration into two parts: region I, where \( 0 < \rho < S(\phi) \), and region II, where \( S(\phi) < \rho < \infty \). The boundary \( \rho = S(\phi) \) is determined in a manner to be explained shortly. We have \( \Delta_{3R} = \Delta_{3R}^I + \Delta_{3R}^II \), where

\[
\Delta_{3R}^I = \frac{1}{2(4\pi)^{3/2}} \int_0^{\pi/2} d\phi \sin(2\phi) \int_0^{S(\phi)} d\rho \frac{\rho^{3/2}}{\sinh \rho} \left[1 \right. \\
\left. \times \exp \left[-(\alpha - 1)\rho - (p^2/4)\rho \sin^2(2\phi) + p^2s^2X^I\right] \right]
\]

\[
\Delta_{3R}^II = \frac{e^{-p^2/2}}{2(4\pi)^{3/2}} \int_0^{\pi/2} d\phi \sin(2\phi) \int_{S(\phi)}^{\infty} d\rho \frac{\rho^{3/2}}{\sinh \rho} \left[1 \right. \\
\left. \times \exp \left[-(\alpha - 1)\rho - (p^2c^2/4)(\rho \sin^2(2\phi) - 2) + p^2s^2X^{II}\right] \right]
\]

with

\[
X^I(\rho, \phi) = \left[(\rho/4) \sin^2(2\phi) - T(\rho, \phi)\right]
\]

\[
X^{II}(\rho, \phi) = \left[\frac{1}{2} - T(\rho, \phi)\right]
\]

and we propose to expand the integrands of \[(67)\] and \[(68)\] in powers of \( X^I \) and \( X^{II} \) respectively. The boundary \( \rho = S(\phi) \) is chosen as the locus on which \( X^I = X^{II} \), namely \( S(\phi) = 2/\sin^2(2\phi) \), so that the two expansions match term by term on the boundary. With this choice, \( X^I(\rho, \phi) \) and \( X^{II}(\rho, \phi) \) are always smaller than the boundary value \( X^S(\phi) = \frac{1}{2} - T(S(\phi), \phi) \), which itself has a maximum value of approximately 0.18 at \( \phi = 0 \).
and $\phi = \pi/2$. Moreover, the quantities $p^2 s^3 X^A$ are positive, so the expansion of each integrand converges monotonically. This is not necessarily true of the integrals, but in practice we have found that retaining only the first two terms of each expansion yields results that are fairly accurate and match smoothly to the large-$\alpha$ and large-$p$ expansions. It will be seen that each term in the expansion of $\Delta^I_{3R}(p, \theta; \alpha)$ is of the form $(p^2 s^2)^n f_n^I(p^2, \alpha)$, while each term in the expansion of $\Delta^II_{3R}(p, \theta; \alpha)$ is of the form $e^{-p^2/2}(p^2 s^2)^n f_n^I(p^2 c^2, \alpha)$. Each of the functions $f_n^A$ depends only on two variables. We have obtained interpolations for these functions, for $n = 0, 1$, giving final approximations for $\Delta^A_{3R}$ of the form

$$
\Delta^I_{3R}(p, \theta; \alpha) = \left[ \frac{R^I_{1,0}(\alpha)}{1 + \sum_{n=1}^{6} R^I_{1,n}(\alpha)p^{2n}} \right]^{1/6} + p^2 s^2 \left[ \frac{R^I_{2,0}(\alpha)}{1 + \sum_{n=1}^{6} R^I_{2,n}(\alpha)p^{2n}} \right]^{1/2}
$$

$$
\Delta^II_{3R}(p, \theta; \alpha) = \frac{e^{-p^2/2} R^II_{1,0}(\alpha) \left[ 1 + R^II_{1,1}(\alpha)p^{2c^2} \right]}{1 + R^II_{1,2}(\alpha)p^{2c^2} + R^II_{1,3}(\alpha)p^{4c^2}} + p^2 s^2 \frac{e^{-p^2/2} R^II_{2,0}(\alpha)}{1 + R^II_{2,1}(\alpha)p^{2c^2}},
$$

where the $R^A_{i,j}$ are rational approximants obtained from the Thiele interpolation formula. The form of these interpolating functions (and those for $\Pi_R(p; \alpha)$ and $\tilde{\Delta}_R(p; \alpha)$, which we do not give explicitly) is chosen so as to give the correct behaviour at large values of $p$ and to allow the integrals over $\theta$ to be performed analytically in the final calculations of $A_R$ and $\delta_R$.

**VI. RESULTS AND DISCUSSION**

As compared with perturbation theory (the expansion in powers of $\lambda_0$), the $1/N$ expansion has a key advantage when applied to the problem of a superconductor in a magnetic field. At the lowest order of perturbation theory, it is not hard to show that the specific heat behaves as

$$
C \sim B_0(t_0 - t_{0c} + B_0)^{-3/2} \sim B_0 [T - T_{c2}(B_0)]^{-3/2}
$$

in the neighbourhood of the line $T = T_{c2}(B_0)$. In terms of the formalism used in this paper, this approximation corresponds to taking $C \approx \Pi(0)$ in \((29)\) and $\tilde{t}_0 \approx t_0 - t_{0c} + B_0$ in the constraint equation \((22)\). This divergence is entirely spurious. Experimentally, there is no sign of it and theoretically it can be removed by means of a self-energy resummation of the Hartree variety. The $1/N$ expansion incorporates this resummation in a way which allows a renormalization-group analysis of the scaling behaviour to be systematically pursued.

On the other hand, the $1/N$ expansion has serious drawbacks. Even at the next-to-leading order we have used here, calculations are extremely cumbersome, and this is unfortunate, because the convergence of the expansion is notoriously poor. With the relevant value $N = 1$ for the number of complex order-parameter components, the specific heat exponent given in \((53)\) is $\alpha \approx 0.62$; compared with the best theoretical and experimental value for the XY model $\alpha_{XY} \approx -0.013$, it is about fifty times too large and has the wrong sign! For the correlation-length exponent, we have $\nu \approx 0.46$ compared with $\nu_{XY} \approx 0.67$.

Using the formalism and numerical methods summarized above, we have obtained estimates for the specific-heat scaling function $C(x)$ as given in \((60)\). Here too, we find that
the convergence is poor; for small values of \( N \), the next-to-leading terms are larger than the leading terms. Matters are somewhat improved if the XY exponents \( \nu_{XY} \) and \( \alpha_{XY} \) are substituted in (60) and (61) for those shown in (56). Here, we present only the best results (as judged by their qualitative similarity to experimental data) that we have been able to obtain by this strategy. Figure 3 shows the scaling function calculated for values of \( N \) between 10 and 20 and, for comparison, figure 4 reproduces the experimental data reported in [4]. For more negative values of \( x \) than those shown in figure 3, the calculated curves diverge rapidly, either to large positive values or to large negative values, and our approximations are clearly inadequate in this region. The reason for this is not entirely clear to us. One possibility is that our neglect of the non-zero order parameter \( \langle \phi(r) \rangle \) in the mixed state becomes seriously inadequate at temperatures a little below \( T_{c2}(B_0) \). In the lowest-Landau-level approximation, it seems to be possible to continue the scaling function of the homogeneous normal state to temperatures well below \( T_{c2}(B_0) \), but the same may not be true of the critical-point scaling function.

Since we cannot obtain reliable results for the physically relevant number of order-parameter components \( N = 1 \), a detailed fit of our calculated scaling function to the data would have little meaning, and we have not attempted it. For larger values of \( N \), it is clear that the calculated scaling function does reproduce the qualitative features of the experimentally determined function in the region where our approximations appear to work. Tentatively, at least, it seems reasonable to conclude that the critical-point scaling implied by the Ginzburg-Landau-Wilson model is consistent with what is actually observed. A less tentative conclusion is that some much better method of approximation than those currently available is needed to test this scaling prediction quantitatively.

Whether the scaling observed in YBCO really corresponds to a regime dominated by critical-point fluctuations is another matter. Indeed, the scaling functions exhibited in figure 3 are qualitatively very similar to the 3-dimensional scaling function of the lowest-Landau-level approximation estimated by Tesanović and Andreev [30]. It is far from clear, therefore, that a quantitatively more reliable estimate of the critical-point scaling function, should it be obtainable, would serve to discriminate between the two scaling hypotheses.

In this paper, we have attempted to estimate the scaling function associated with asymptotic critical behaviour, which is controlled by the renormalization-group fixed point \( z = 0 \). In principle, the formalism and numerical approximations described here should also facilitate an investigation of the competition between low-field critical-point scaling and high-field lowest-Landau-level scaling in the intermediate region where neither type of scaling is exactly valid. We plan to address this issue in a future publication.

APPENDIX A: CALCULATION OF VERTEX FUNCTIONS

As explained in detail in [33], the basic elements of Feynman diagrams in the $1/N$ expansion are vertex functions of the form

$$
\Delta_n(r_1, \ldots, r_n) = \Delta(r_1, r_2)\Delta(r_2, r_3) \ldots \Delta(r_n, r_1) .
$$

(A1)

These are gauge-invariant functions, and therefore also translationally invariant, but in the presence of a magnetic field, the form of the propagator (15) makes them somewhat awkward to handle. For the purposes of this paper, the fact that we usually need to integrate over one or more of the arguments $r_i$ leads to some simplification. Let us write

$$
\Delta(r, r') = e^{i(x+x')(y-y')B_0/2} \Delta_2(r - r').
$$

(A2)

where $\Delta_2(r)$ is the function whose Fourier transform is given in (16). We find that

$$
\int d^3r'' \Delta(r, r'')\Delta(r'', r') = e^{i(x+x')(y-y')B_0/2} \Delta_2(r - r') ,
$$

(A3)

with

$$
\Delta_2(r) = \int d^3r' e^{i(x'y' - x'y)B_0/2} \Delta(r - r') \tilde{\Delta}(r') .
$$

(A4)

A lengthy, but straightforward calculation shows that the Fourier transform of $\Delta_3(k)$ defined in (25) is

$$
\tilde{\Delta}_3(k) = -\frac{1}{2} \frac{\partial \Delta(k)}{\partial \tilde{t}_0} .
$$

(A5)

When $B_0 = 0$, this reduces to the familiar fact that $\partial[(k^2 + \tilde{t}_0)^{-1}]/\partial \tilde{t}_0 = -(k^2 + \tilde{t}_0)^{-2}$. The function $\Delta_3(k)$ defined in [25] is equivalent to

$$
\Delta_3(k) = \int \frac{d^3k'}{(2\pi)^3} \Delta(k') \tilde{\Delta}_2(k + k') = -\frac{1}{2} \frac{\partial \Delta(k)}{\partial \tilde{t}_0} .
$$

(A6)

In the same way, we can define $\tilde{\Delta}_3(r - r')$ by

$$
\int d^3r'' d^3r''' \Delta(r, r'')\Delta(r'', r''')\Delta(r''', r') = e^{i(x+x')(y-y')B_0/2} \tilde{\Delta}_3(r - r') ,
$$

(A7)

and find that its Fourier transform is

$$
\tilde{\Delta}_3(k) = -\frac{1}{2} \frac{\partial \Delta_2(k)}{\partial \tilde{t}_0} = -\frac{1}{2} \frac{\partial \Delta(k)}{\partial \tilde{t}_0} .
$$

(A8)

Consider now the self-energy diagrams shown in figure 2, which are to be evaluated with the external wavevector equal to zero. The first one is

$$
\Pi_\psi^{(1)}(0) = \int \frac{d^3k}{(2\pi)^3} \frac{d^3k'}{(2\pi)^3} D(k)\Delta_2(k') \tilde{\Delta}_2(k + k')
$$

$$
= -\int \frac{d^3k}{(2\pi)^3} \frac{d^3k'}{(2\pi)^3} D(k) \frac{\partial \Delta(k)}{\partial \tilde{t}_0} \tilde{\Delta}_2(k + k')
$$

(A9)
and the second is
\[
\Pi_{\psi}^{(2)}(0) = \int \frac{d^3k}{(2\pi)^3} \frac{d^3k'}{(2\pi)^3} D(k) \Delta(k') \tilde{\Delta}(k+k')
= -\frac{1}{2} \int \frac{d^3k}{(2\pi)^3} \frac{d^3k'}{(2\pi)^3} D(k) \Delta(k') \frac{\partial \Delta_2(k+k')}{\partial \tilde{t}_0} \quad (A10)
\]
so we can use (A6) to write
\[
\Pi_{\psi}^{(1)}(0) + 2\Pi_{\psi}^{(2)}(0) = -\int \frac{d^3k}{(2\pi)^3} D(k) \frac{\partial \Delta_3(k)}{\partial \tilde{t}_0} \quad (A11)
\]
Using the expression (18) for \(D(k)\) and the first expression in (A6) for \(\Delta_3(k)\), we find that
\[
\frac{\partial D(k)}{\partial \tilde{t}_0} = -D(k)^2 \Delta_3(k), \quad (A12)
\]
so the third diagram of figure 2 is
\[
\Pi_{\psi}^{(3)}(0) = \int \frac{d^3k}{(2\pi)^3} \Delta_3(k) D(k)^2 \Delta_3(k)
= -\int \frac{d^3k}{(2\pi)^3} \frac{\partial D(k)}{\partial \tilde{t}_0} \Delta_3(k) \quad (A13)
\]
and we obtain
\[
\Pi_{\psi}^{(1)}(0) + 2\Pi_{\psi}^{(2)}(0) - \Pi_{\psi}^{(3)}(0) = -\frac{\partial}{\partial \tilde{t}_0} \int \frac{d^3k}{(2\pi)^3} D(k) \Delta_3(k) = -\frac{\partial A(t_0, \lambda_0, B_0)}{\partial \tilde{t}_0} \quad (A14)
\]
The final diagram in figure 2 is
\[
\Pi_{\psi}^{(4)}(0) = \Delta_3(0) = -\frac{\partial \Pi(0)}{\partial \tilde{t}_0} \quad (A15)
\]

APPENDIX B: LARGE-MOMENTUM EXPANSIONS

To verify that the constraint equation and the specific heat can be correctly renormalized, and also to assist the numerical estimation of the renormalized quantities, we require expansions of the subintegrals \(\Pi_R(p; \alpha), \Delta_{3R}(p; \alpha)\) and \(\tilde{\Delta}_R(p; \alpha)\). We use the notation indicated in (44) and the abbreviations \(s = \sin \theta\) and \(c = \cos \theta\). For \(\tilde{\Delta}_R(p; \alpha)\), the expansion
\[
\tilde{\Delta}_R(p, \theta; \alpha) = \int_0^\infty du \exp \left[-(p^2 c^2 + \alpha)u - \frac{1}{2}(1 - e^{-2u})p^2 s^2\right]
= p^{-2} - (\alpha - 2s^2)p^{-4} + \left[\alpha^2 - (6\alpha + 4)s^2 + 12s^4\right]p^{-6} + O(p^{-8}) \quad (B1)
\]
follows trivially from the change of variable \(u = v/p^2\). For \(\Delta_{3R}(p; \alpha)\) we have the expression...
where \( \tau = \tanh u \) and \( \tau' = \tanh u' \). By virtue of the symmetry of the integrand under interchange of \( u \) and \( u' \), the region of integration \( 0 \leq u' \leq u \) yields exactly half of the integral. In this region, we can make the change of variable

\[
u + u' = v + v', \quad 4uu'/(u + u') = v'
\]

to obtain

\[
\Delta_{3R} = \frac{1}{2(4\pi)^{3/2}} \int_0^\infty du \, du' \frac{(u + u')^{1/2} \exp \left[-(\alpha - 1)(u + u') - \frac{uu'}{(u + u')p^2c^2} - \frac{\tau\tau'}{(\tau + \tau')p^2s^2} \right]}{\sinh(u + u')} \tag{B2}
\]

where

\[
\sigma(v, v') = \left[ \cosh(v + v') - \cosh \left( \sqrt{v(v + v')} \right) \right] / 2 \sinh(v + v').
\] \( \tag{B5} \)

A further change of variable \( v' = v''/p^2 \) facilitates an expansion in powers of \( p^{-2} \), with a result of the form

\[
\Delta_{3R}(p, \theta; \alpha) = Q_0(\alpha)p^{-2} + \left[ Q_1(\alpha) + Q_2(\alpha)s^2 \right] p^{-4} + \left[ Q_3(\alpha) + Q_4(\alpha)s^2 + Q_5(\alpha)s^4 \right] p^{-6} + O(p^{-8}). \tag{B6}
\]

The coefficients \( Q_i(\alpha) \) are

\[
Q_i(\alpha) = \left( \frac{1}{4\pi} \right)^{3/2} \int_0^\infty dv \frac{v^{1/2} \exp[-(\alpha - 1)v]}{\sinh v} Q_i(v, \alpha) \tag{B7}
\]

with

\[
Q_0(v, \alpha) = 1, \quad Q_1(v, \alpha) = 4(v^{-1} - \coth v + 1 - \alpha), \quad Q_2(v, \alpha) = 2(\coth v - v^{-1}) \nn Q_3(v, \alpha) = 16 \left[ \alpha^2 - 2\alpha + 2(\coth v - 1 + \alpha)(\coth v - v^{-1}) \right] \nn Q_4(v, \alpha) = 4 \left[ 5 + 3(\coth v - v^{-1})v^{-1} - 4 \coth v + 2 - 2\alpha \right] \nn Q_5(v, \alpha) = 12(\coth v - v^{-1})^2.
\]

The function \( \Pi_R(p; \alpha) \) satisfies \( \partial \Pi_R(p; \alpha) / \partial \alpha = -\Delta_{3R}(p; \alpha) \), but does not itself have an expansion in powers of \( p^{-2} \). At \( B = 0 \), we have the exact result

\[
\Pi(k; \tilde{\ell}, 0) = (8\pi k)^{-1} \tan^{-1}(k/2\tilde{\ell}^{1/2}) = bk^{-1} - 4a\tilde{\ell}^{1/2}k^{-2} + O(k^{-4}) \tag{B8}
\]

with \( k = |k| \), which implies that \( \Pi_R(p; \alpha) \) has the limiting form

\[
\Pi_R(p; \alpha) = bp^{-1} - 4ac^{1/2}p^{-2} + O(p^{-4}) \tag{B9}
\]
as \( \alpha \to \infty \). By integrating \( \Delta_{3R}(p; \alpha) \) with this boundary condition, we obtain the expansion

\[
\Pi_R(p; \alpha) = bp^{-1} + \Delta_R(\alpha)p^{-2} + O(p^{-4}),
\]

which is sufficient for our purposes.

In the constraint equation (46) and the specific heat (49), singularities at \( z \to 0 \) arise from the large-\( p \) region of integration in integrals of the form

\[
\int \frac{d^3p}{(2\pi)^3} D_R(p; \alpha, z, B)f(p; \alpha).
\]

By restricting the range of integration to \( |p| \geq p_0 \), where the value of \( p_0 \) is immaterial, the leading singularities can be extracted by means of the power-series expansions given above. Using the expansion \( D_R^{-1}(p; \alpha, z, B) = z + B^{-1/2}bp^{-1} + B^{-1/2}\Delta_R(\alpha)p^{-2} + O(p^{-4}) \), we encounter the three divergent integrals

\[
\int \frac{d^3p}{(2\pi)^3} \frac{1}{(z + B^{-1/2}bp^{-1})p^4} = -B^{1/2}S_3 \frac{S_3}{b} \ln z + \ldots
\]  

\[
\int \frac{d^3p}{(2\pi)^3} \frac{1}{(z + B^{-1/2}bp^{-1})^2p^4} = B^{1/2}S_3 \frac{S_3}{b} z^{-1} + \ldots
\]  

\[
\int \frac{d^3p}{(2\pi)^3} \frac{1}{(z + B^{-1/2}bp^{-1})^3p^4} = -B^{3/2}S_3 \frac{S_3}{b^3} \ln z + \ldots
\]

where the ellipses represent less singular terms. These results, together with straightforward, though tedious, manipulations of the integrals (B7) suffice to verify that the functions \( \Phi, E_1 \) and \( E_2 \) have finite limits and, in (46), that \( z_0_R = -\Delta_RS_3/2b + \ldots \).

FIGURES

FIG. 1. Diagrammatic representation of (a) the order-parameter 2-point function and (b) the expectation value $\langle \psi(r) \rangle$ at next-to leading order.

FIG. 2. Diagrammatic representation of the 2-point function for the auxiliary field $\psi$ at next-to-leading order.

FIG. 3. Numerical results for the specific-heat scaling function $C(x)$ for several values of $N$.

FIG. 4. Experimental data for the specific-heat scaling function as reported in Ref. [4].
\[ G^{(2)} = -\frac{1}{2N} + \frac{1}{N} \delta \] (a)

\[ \langle \psi \rangle = f \otimes + \frac{i}{2} \] (b)

Figure 1
\[ \langle \psi(r) \psi(r') \rangle = \quad \quad + \quad \frac{1}{4N} \quad \quad - \quad \frac{1}{4N} \quad \quad + \quad \frac{1}{2N} \quad \quad - \quad \frac{1}{N^\delta} \quad \quad - \quad \quad \]
