REAL-ROOTED PÓLYA-LIKE APPROXIMATIONS TO THE RIEMANN XI-FUNCTION

YAOMING SHI

Abstract. The Riemann Ξ(z) function admits a Fourier transform of a even kernel Φ(t). The latter is related to the derivatives of Jacobi theta function θ(z), a modular form of weight 1/2. Pólya noticed that when t goes to infinity, e^t goes to e^t + e^-t = 2 cosh t. He then approximated the kernel Φ(t) by Φ_P(t) that contained only the leading term and with exp t, exp(9t/4) replaced by 2 cosh t, 2 cos(9t/4). This procedure captured almost all of the contribution from the tail part (i.e., t → ∞) of the kernel Φ(t).

We realize that when t goes to infinity and 0 ≤ b < 1, c ∈ R, cosh t + c cosh(bt) goes to cosh t. Thus we improve Pólya’s approximation by replacing cosh(9t/4) with cosh(9t/4) + ∑ b_k cosh(9kt/(4m)) and adjusting the parameters b, b_k, m such that (A) the approximated kernel Φ_S(b, b_k, m; t) goes to Φ(t) when t goes to infinity; (B) Φ_S(b, b_k, m; t) is identical to Φ(t) at t = 0; (C) the Fourier transform of Φ_S(b, b_k, m; t), like in Pólya’s case, has only real zeros. Since this procedure also captures almost all of the contribution from the head part (i.e., near t = 0) of the kernel Φ(t), we are able to anchor both ends of the kernel Φ(t).

1. Introduction

Let s, z be two complex variables, ζ(s) be the Riemann ζ-function,

\[ \xi(s) = \frac{1}{2}s(s-1)\pi^{-s/2}\Gamma\left(\frac{s}{2}\right) \zeta(s) \]  

be the Riemann (lower case) ξ-function, and

\[ \Xi(z) = \xi(iz + 1/2) \]  

be the Riemann (upper case) Ξ-function, which is an entire function satisfying functional equation \( \Xi(z) = \Xi(-z) \) and \( \Xi(\bar{z}) = \Xi(z) \). Riemann hypothesis is then equivalent to the statement that all the zeros of Ξ(z) are real.

Riemann Ξ(2z) function can be expressed as a Fourier transformation:

\[ \Xi(2z) = \int_{-\infty}^{\infty} \Phi(t) \exp(izt)dt = 2 \int_{0}^{\infty} \Phi(t) \cos(zt)dt, \]  

where

\[ \Phi(t) = 2e^{9t/4}\theta^0(e^t) + 3e^{5t/4}\theta'(e^t) \]

\[ = \sum_{n=1}^{\infty} \left(2\pi^2 n^4 e^{9t/4} - 3\pi n^2 e^{5t/4}\right) \exp\left(-\pi n^2 e^t\right) \]  

\[ = \Phi(-t). \]
And where $\theta(x)$ is the Jacobi theta function defined below in (2.4).

As summarized by Dimitrov [3] and with Rusev [5], then a natural approach to resolving the Riemann hypothesis is to establish criteria for an entire function, or more specifically, a Fourier transform of a kernel, to possess only real zeros and to apply them to the Riemann $\Xi(z)$ function. There is no doubt that this was the main reason why so many celebrated mathematicians have been interested in the zero distribution of entire functions and, in particular, of Fourier transforms. Among them are such distinguished masters of the Classical Analysis as A. Hurwitz, J.L.W. V. Jensen, G. Polya, H.G. Hardy, E. Tichmarsh, W. de Bruin, Newman, N. Obrechkoff, L. Tchakaloff etc.

For complete review we refer the readers to the excellent and 108 page review paper by Dimitrov and Rusev [5]. See also the review paper by Ki [9] and Hallum’s 2014 Master Thesis [7] (an easy-to-read reference).

Pólya noticed that when $t$ goes to infinity, $\exp(at) \to \exp(at) + \exp(-at) = 2\cosh(at)$. He then approximated the kernel $\Phi(t)$ by $\Phi_P(t)$ that contained only the leading term and with $\exp t, \exp(9t/4)$ replaced by $2\cosh t, 2\cosh(9t/4)$. We realize that when $t$ goes to infinity and $0 < b < 1, m \in \mathbb{N}$, $h(t) = \cosh(t/4)(4\cosh^2(t/m) - 4b^2)^m$ goes to $\cosh(9t/4)$. Thus we improve Pólya’s approximation by replacing $\cosh(9t/4)$ with $h(t)$ and adjust the parameters $b, m$ such that (A) the approximated kernel $\Phi_{S3}(b, m; t)$ goes to $\Phi(t)$ when $t$ goes to infinity; (B) $\Phi_{S3}(b, m; t)$ is identical to $\Phi(t)$ at $t = 0$; (C) the Fourier transform of $\Phi_{S3}(b, m; t)$, has only real zeros. Since this procedure also captures almost all of the contribution from the head part (i.e., near $t = 0$) of the kernel $\Phi(t)$, we are able to anchor both ends of the kernel $\Phi(t)$. It remains to see if one can better approximate the body of $\Phi(t)$.

Thus our criteria for picking kernel $K(t)$ to approximate the kernel $\Phi(t)$ of (1.4) are

(i) $K(t) \to \Phi(t), \quad t \to \infty$,
(ii) $K(0) = \Phi(0)$,
(iii) $\int_0^\infty K(t) \cos(zt)dt$ has only real zeros.

Using these criteria, we obtain several new and improved approximations to kernel $\Phi(t)$ and find out that their Fourier transforms have only real zeros.

Here is the outline of the paper. We introduce notations and necessary lemmas in section 2. The approximations to $\Phi(t)$ by Pólya, de Bruijn, and Hejhal related to this paper are introduced in section 3. We also plot these approximated Phi functions and their corresponding Fourier transforms. We present our new approximations to $\Phi(t)$ in section 4. Figures of these new approximated Phi functions and their Fourier transforms are readily compared to those in section 3. In section 5, we provide conclusion.

2. NOTATIONS AND DEFINITIONS

Almost all of the material in this section can be found in [7, 5] or references therein. The complex function

$$\theta_3(z, \tau) := \sum_{n=-\infty}^{\infty} \exp(i\pi n^2 \tau + 2i\pi nz), z \in \mathbb{C}, \text{Im}\tau > 0,$$

(2.1)
is one of the Jacobi theta-functions [10, 18]. The function $\theta_3(0, \tau)$ is holomorphic in the upper half-plane ($\text{Im}\tau > 0$) and satisfies the relations

$$\theta_3(0, \tau + 1) = \theta_3(0, \tau - 1),$$

(2.2)
\[ \theta_3(0, -1/\tau) = (-i\tau)^{1/2} \theta_3(0, \tau), \quad (2.3) \]

where \((-i\tau)^{1/2} := \exp((1/2) \log(-i\tau))\). Thus \(\theta_3(0, \tau)\) is a modular form of weight \(1/2\).

For simplification, a Jacobi \(\theta(x)\) function is often defined by setting \(\tau = ix\) in \(\theta_3(0, \tau)\) as:

\[ \theta(x) := \theta_3(0, ix) = \sum_{n=-\infty}^{\infty} \exp(-\pi n^2 x), \quad x > 0. \quad (2.4) \]

It satisfies relations

\[ \theta(x) = \theta(x + 2i), \quad (2.5) \]
\[ \theta(1/x) = x^{1/2} \theta(x). \quad (2.6) \]

**Definition 1.** A real entire function \(f(z) = \sum_{k=0}^{\infty} \gamma_k z^k\) is in the Laguerre-Pólya class, written \(f(z) \in \mathcal{LP}\), if

\[ f(z) = cz^m \exp(-az^2 + bz) \prod_{k=1}^{\omega} \left(1 + \frac{z}{z_k}\right) \exp(-z/z_k) \quad (2.7) \]

where \(b, c, z_k \in \mathbb{R}\) (i.e., all the zeros are real), \(m \in \mathbb{N}_0, a \geq 0, 0 \leq \omega \leq \infty\) and \(\sum_{k=1}^{\omega} \frac{1}{z_k^2} < \infty\).

G. Pólya [14] introduced a class of functions he termed universal factors. Let \(K(t)\) be an even and real-valued function that is absolutely integrable over \(R\). Also, suppose, for \(b > 2, K(t) = O(\exp(-|t|^b)), t \to \pm \infty\).

**Definition 2.** Universal factors are the collection of functions, \(\{\phi(t)\}\), such that if the integral

\[ \int_{-\infty}^{\infty} K(t) \exp(izt) dt \in \mathcal{LP}, \quad (2.8) \]

then the integral

\[ \int_{-\infty}^{\infty} \phi(t) K(t) \exp(izt) dt \in \mathcal{LP}. \quad (2.9) \]

G. Pólya was able to completely characterize the functions, \(\phi(t)\), that comprise this class.

**Lemma 1** (Pólya’s Universal Factor Theorem). If \(\phi(iz) \in \mathcal{LP}\), then \(\phi(t)\) is a universal factor. If the real analytic function \(\phi(t)\) is a universal factor, then \(\phi(it) \in \mathcal{LP}\).

**Lemma 2** (Eneström-Kakeya Theorem). If \(0 < a_0 < a_1 < a_2 < \cdots < a_n\), then the polynomial \(p_n(z) = \sum_{k=0}^{n} a_k z_k\) has all of its zeros in the closed unit disk \(D = z : |z| < 1\).

**Lemma 3** (Hermite-Biehler theorem). If the zeros of the algebraic polynomial with complex coefficients \(p_n(z) = \sum_{k=0}^{n} c_k z_k\) belong to unit disk \(D\) and if we set \(z = \cos \alpha + i \sin \alpha\) and separate the real and the imaginary parts, \(p_n(z) = A(\alpha) + iB(\alpha)\), then the trigonometric polynomials \(A(\alpha) \in \mathcal{LP}\) and \(B(\alpha) \in \mathcal{LP}\) and their zeros interlace.

The Lemma 2 and Lemma 3 already imply
Lemma 4. If $0 < a_0 < a_1 < a_2 < \cdots < a_n$, then
\[
A(\alpha) = \sum_{k=0}^{n} a_k \cos(k\alpha) \in \mathcal{L}\mathcal{P},
\]
\[
B(\alpha) = \sum_{k=1}^{n} a_k \sin(k\alpha) \in \mathcal{L}\mathcal{P},
\]
and their zeros are interlace. Thus $B(it), t \in \mathbb{R}$ is a universal factor.

Let $K_{iz}(a)$ be the Modified Bessel function of the second:
\[
K_{iz}(a) = \int_{0}^{\infty} \exp(-a \cosh t) \cosh(tz) dt = K_{-iz}(a).
\]
Lemma 5. \[13 \ 14\]
\[
K_{iz}(2\pi) = K_{-iz}(2\pi) \in \mathcal{L}\mathcal{P}.
\]
Lemma 6. \[13 \ 14\] Let $A, c > 0$, then
\[
K_{iz+c}(A) + K_{iz-c}(A) \in \mathcal{L}\mathcal{P}.
\]

3. Approximations to $\Phi(t)$ by Pólya, de Bruijn, and Hejhal

Pólya \[13 \ 14\] approximated $\Phi(t)$ with $\Phi_P(t)$ and $\Phi_{P2}(t)$ by keeping only the leading $(n = 1)$ term in (1.4) and replaced $e^{at}$ with $(e^{at} + e^{-at}) = 2 \cosh(at)$:
\[
\Phi_P(t) = 4\pi^2 \cosh(9t/4) \exp(-2\pi \cosh t),
\]
\[
\Phi_{P2}(t) = (4\pi^2 \cosh(9t/4) - 6\pi \cosh(5t/4)) \exp(-2\pi \cosh t).
\]
Thus when $t \to \infty$, $\Phi(t) \to \Phi_P(t), \Phi_{P2}(t) \to \Phi_P(t)$. The Fourier transforms of $\Phi_P(t)$ and $\Phi_{P2}(t)$, are given by:
\[
\Xi_P(2z) = 4\pi^2 \left( K_{iz+9/4}(2\pi) + K_{iz-9/4}(2\pi) \right),
\]
\[
\Xi_{P2}(2z) = 4\pi^2 \left( K_{iz+9/4}(2\pi) + K_{iz-9/4}(2\pi) \right)
- 6\pi \left( K_{iz+5/4}(2\pi) + K_{iz-5/4}(2\pi) \right).
\]
Pólya proved that $\Xi_P(2z)$ and $\Xi_{P2}(2z)$ have only real zeros.
de Bruijn \[4\] approximated $\Phi(t)$ with $\Phi_{dB}(t)$:
\[
\Phi_{dB}(t) = \exp(-2\pi \cosh t)
\]
\[
\times \left( 4\pi^2 \cosh(t/4) + (4\pi^3 - 6\pi) \cosh(5t/4) + 4\pi^2 \cosh(9t/4) \right)
\]
The Fourier transform of $\Phi_{dB}(t)$ is given by:
\[
\Xi_{dB}(2z) = 4\pi^2 \left( K_{iz+9/4}(2\pi) + K_{iz-9/4}(2\pi) \right)
+ (4\pi^3 - 6\pi) \left( K_{iz+5/4}(2\pi) + K_{iz-5/4}(2\pi) \right)
+ 4\pi^2 \left( K_{iz+1/4}(2\pi) + K_{iz-1/4}(2\pi) \right),
\]
de Bruijn proved that the function $\Xi_{dB}(2z)$ has only real zeros.
Hejhal \[8\] approximated $\Phi(t)$ with $\Phi_{H,n}(t)$:
\[
\Phi_{H,n}(t) = \sum_{n=1}^{m} (4\pi^2 n^4 \cosh(9t/4) - 6\pi n^2 \cosh(5t/4)) \exp(-2\pi n^2 \cosh t)
\]
The resulting $\Xi_{H,m}(z)$ is given by:

$$\Xi_{H,m}(2z) = \sum_{n=1}^{m} 4n^4 \pi^2 \left( K_{iz+9/4}(2\pi n^2) + K_{iz-9/4}(2\pi n^2) \right)$$

$$- \sum_{n=1}^{m} 6n^2 \pi \left( K_{iz+5/4}(2\pi n^2) + K_{iz-5/4}(2\pi n^2) \right).$$

(3.8)

Clearly when $m \rightarrow \infty$, $\Phi_{H,m}(t) \not\rightarrow \Phi(t)$, and $\Xi_{H,m}(2z) \not\rightarrow \Xi(2z)$. Thus the study of this general approximation is often considered not to be directly related to a possible proof of the Riemann hypothesis. Nevertheless Hejhal proved that almost all the zeros of the function $\Xi_{H,m}(2z)$ are real.

We notice that there is one thing in common in Pólya’s approximation $\Phi_P(t)$, $\Phi_{P_2}(t)$ of (3.1) and (3.2), de Bruijn’s approximation $\Phi_{dB}(t)$ of (3.5), and Hejhal’s approximation $\Phi_{H,m}(t)$ of (3.7), that they all captured the contribution of the tail part (at $t \rightarrow \infty$) of $\Phi(t)$ in the Fourier transformation. But none of them converges to $\Phi(t)$ near $t=0$. This aspect is clearly shown in Figure 1. Thus they can hardly capture the contribution of the head part (at $t=0$) of $\Phi(t)$ in the Fourier transformation.

A natural question then arises: Is it possible to find approximations to $\Phi(t)$ such that they converge to $\Phi(t)$ at $t \rightarrow \infty$ and $t=0$, and the corresponding Fourier transforms have only real zeros? We will give positive answers to this question in the next subsection.

In Figures 2 below we compare $\Xi_P(z)$ (Blue) against $\Xi(z)$ (Red). It showed that there existed 29 zeros for both $\Xi_P(z)$ and $\Xi(z)$.
Figure 2. Plots of various Xi functions vs. $z$. This includes: $|\Xi_P(z)|/N(z)$ (Blue); $-|\Xi(z)|/N(z)$ (Red). Here and after $N(z) = \exp(-\pi z/4)(z + 1)^2$ is a scale normalization function.

In Figures 3 below we compare $\Xi_{P_2}(z)$ (Purple) against $\Xi(z)$ (Red). It showed that there existed 29 zeros for both $\Xi_{P_2}(z)$ and $\Xi(z)$.

Figure 3. Plots of various Xi functions vs. $z$. This includes: $|\Xi_{P_2}(z)|/N(z)$ (Purple); $-|\Xi(z)|/N(z)$ (Red).

In Figures 4 below we compare $\Xi_{dB}(z)$ (Brown) against $\Xi(z)$ (Red). It showed that there existed 29 zeros for both $\Xi_{dB}(z)$ and $\Xi(z)$.

In Figures 5 below we compare $\Xi_{H,1}(z)$ (Green) and $\Xi_{H,4}(z)$ (Blue) against $\Xi(z)$ (Red). It showed that there existed 29 zeros for $\Xi_{H,1}(z)$, $\Xi_{H,4}(z)$, and $\Xi(z)$.

Figure 5. Plots of various $\Xi$ functions vs. $z$. This includes: $|\Xi_{H,1}(z)|/N(z)$ (Green); $|\Xi_{H,4}(z)|/N(z)$ (Blue); $-|\Xi(z)|/|N(z)|$ (Red).

4. OUR APPRXMIATIONS TO THE KERNEL $\Phi(t)$

Let $\lambda > 0$, $\alpha = \alpha_n$ and

$$f(t) = \exp(-\lambda \cosh t) \sum_{n=-N}^{N} \alpha_n \exp(nt), \quad (4.1)$$

$$\Psi(z) = \int_{-\infty}^{\infty} f(t) \exp(itz) dt. \quad (4.2)$$

de Bruijn proved that $\Psi(z)$ of (4.2) has $N$ pair of non-real zeros at most [4] (Theorem 21). de Bruijn commented that function $\Psi(z)$ may be of some interest since the Riemann Xi-function can be approximated by functions of this type.
We would like to point out that with $a_{-n} = a_n \in \mathbb{R}$, $\lambda = 2\pi$, when $t \to \infty$, because $N$ is a positive integer, $\cosh(Nt) \neq \cosh(9t/4)$, so

$$f(t) \to 2a_N \cosh(Nt) \exp(-2\pi \cosh t) \neq 4\pi^2 \cosh(9t/4) \exp(-2\pi \cosh t) = \Phi_P(t)$$

Thus $f(t)$ does not have the proper behavior near $t \to \infty$. But we can remedy this problem. Let $\lambda = 2\pi$, $\alpha_{-n} = \alpha_n \in \mathbb{R}$, $0 \leq \beta_{-n} = \beta_n < 1$ and

$$K(t) = \Phi_P(t) + \exp(-2\pi \cosh t) \sum_{n=-N}^{N} \alpha_n \exp(9\beta_n t/4).$$

(4.4)

So when $t \to \infty, K(t) \to \Phi_P(t)$. Thus criteria (i) $K(t) \to \Phi(t), t \to \infty$, mentioned in the introduction, is satisfied. The actual values of parameters $\alpha_n$ and $\beta_n$ are then used to satisfy the other two criteria; namely (ii) $K(0) = \Phi(0)$, (iii) $\int_0^\infty K(t) \cos(zt) dt$ has only real zeros.

In theory one can also use the following $K(t)$ to approximate $\Phi(t)$.

$$K(t) = \Phi_P(t) + \exp(-2\pi \cosh t) \sum_{n=-N}^{N} \alpha_n \exp(9\beta_n t/4)$$

$$+ \exp(-2\pi \cosh t) \int_{-A}^{A} \gamma(\mu) \exp(9\delta(\mu) t/4) dt.$$ (4.5)

Where $A > 0, \mu \in \mathbb{R}, \gamma(-\mu) = \gamma(\mu) \in \mathbb{R}, \delta(\mu) = \delta(\mu) \in \mathbb{R}.$

In all of our approximations below, we will use the $K(t)$ of the type (4.4) to approximate $\Phi(t)$.

Let

$$\Phi(0) = \theta''(1) + (3/2)\theta'(1) \approx 0.446696$$ (4.6)

where $\theta(x)$ is defined in (2.4).

We first approximate $\Phi(t)$ with $\Phi_S(t)$.

**Theorem 1.** Let

$$\Phi_S(m; t) = 4\pi^2 f_m(t) \exp(-2\pi \cosh t),$$

(4.7)

$$f_m(t) = \cosh(9t/4) + b \sum_{k=0}^{m-1} b_k \cosh(9kt/(4m)),$$ (4.8)

where $0 < b_k = \frac{k+1}{m+1} < 1, k = 0, 1, \ldots m - 1$. The Fourier transform of $\Phi_S(m; t)$ is:

$$\Xi_S(m; 2z) = 4\pi^2 (G_{2\pi}(iz + 9/4) + G_{2\pi}(iz - 9/4))$$

$$+ 4\pi^2 b \sum_{k=0}^{m-1} b_k (G_{2\pi}(iz + 9k/(4m)) + G_{2\pi}(iz - 9k/(4m))),$$

(4.9)

where $G_a(z) := K_a(a)$.

If $m \geq 11$ and $b$ is determined by

$$bm = 2\beta, \quad \beta := (4\pi^2)^{-1}(e^{2\pi} \Phi(0) - 1) \approx 5.059069$$

(4.10)

then

(A) $\Phi_S(m; t) \to \Phi(t)$, when $t \to \infty$;

(B) $\Phi_S(m; 0) = \Phi(0)$;

(C) the entire function $\Xi_S(m; 2z)$ has only real zeros.
Proof. Since \(0 < \frac{k}{m} < 1\), \(f_m(t) \to \cos(9t/4)\) and \(\Phi_S(m; t) \to \Phi(t)\) when \(t \to \infty\). Thus we proved (A). Setting \(\Phi_S(m; 0) = \Phi(0)\) leads to (4.10), thus we proved (B).

Because of Lemma 5, it suffice to prove that \(f_m(t)\) is a universal factor, or \(f_m(it) \in \mathcal{LP}\). Defining \(x = \frac{9t}{4m}\), then we obtain:

\[
f_m(it) = \tilde{f}(x) = \cos(mx) + b \sum_{k=0}^{m-1} b_k \cos(kx), \quad (4.11)
\]

Comparing \(\tilde{f}(x)\) with \(f_c(x)\) of (2.10) and realizing that \(0 < b_k < b_{k+1} < 1\) we conclude that it is now suffice to prove that \(0 < b < 1\). If we pick an integer \(m \geq 11\) in (4.10), then \(0 < b < 1\). This proved (C). \(\square\)

Figure 6 below showed comparison of \(\Phi(t)\)(Red) with \(\Phi_S(m = 11; t)\)(Green), and \(\Phi_S(m = 100; t)\)(Blue).

![Figure 6](image)

**Figure 6.** Plots of various Phi functions vs. \(t\). This includes \(\Phi(t)\)(Red), \(\Phi_S(m = 11; t)\) \((b = 0.919830)\) (Green), \(\Phi_S(m = 100; t)\) \((b = 0.101181)\) (Blue).

To quantify the goodness of the approximation, we define and numerically calculate the following relative differences in percentage:

\[
\frac{\int_0^\infty |\Phi(t) - \Phi_S(m = 11; t)|dt}{\int_0^\infty \Phi(t)du} \approx 7.949691\% \quad (4.12)
\]

\[
\frac{\int_0^\infty |\Phi(t) - \Phi_S(m = 100; t)|dt}{\int_0^\infty \Phi(t)du} \approx 9.091720\% \quad (4.13)
\]

In Figure 7 below we compare \(\Xi_S(m = 11; z)\)(Purple) against \(\Xi(z)\)(Red). It showed that there existed 29 zeros for both \(\Xi_S(m = 11; z)\) and \(\Xi(z)\).
Figure 7. Plots of various Xi functions vs. $z$. This includes: $|\Xi_S(m=11,z)|/|N(z)|$ (Purple); $-|\Xi(z)|/|N(z)|$ (Red).

In Figure 8 below we compare $\Xi_S(m=21,z)$ (Blue) against $\Xi(z)$ (Red). It showed that there existed 29 zeros for both $\Xi_S(m=21,z)$ and $\Xi(z)$.

Figure 8. Plots of various Xi functions vs. $z$. This includes: $|\Xi_S(m=21,z)|/|N(z)|$ (Blue); $-|\Xi(z)|/|N(z)|$ (Red).

We next approximate $\Phi(t)$ with $\Phi_{S2}(m,a,t)$.

**Theorem 2.** Let

$$\Phi_{S2}(m,a,t) = 4\pi^2 g(m,a;u) \exp (-2\pi \cosh t),$$

$$g(m,a;u) = \cosh (9t/4) + c \sum_{k=0}^{m-1} c_k(a) \cosh (9kt/(4m)),$$

where $0 < c_k(a) = 1 - a^{m+1} < 1$, $0 < a < 1$, $k = 0, 1, \ldots m - 1$.

The Fourier transform of $\Phi_{S2}(m,a,t)$ is:

$$\Xi_{S2}(m,a;2z) = 4\pi^2 (G_{2\pi}(iz + 9/4) + G_{2\pi}(iz - 9/4)) + 4\pi^2 c \sum_{k=0}^{m-1} c_k(a)(G_{2\pi}(iz + 9k/(4m)) + G_{2\pi}(iz - 9k/(4m))),$$

(4.16)
For a given parameter $0 < a < 1$, if $\mu, m$ satisfies the equations:

\[
\mu(1 - a^\mu) = \beta, \tag{4.17}
\]

\[
m \geq \lceil \mu \rceil, \tag{4.18}
\]

where the constant $\beta$ is defined in (4.10), Then

(A) $\Psi_{S2}(m, a; t) \to \Phi(t)$, when $t \to \infty$;

(B) $\Psi_{S2}(m, a; 0) = \Phi(0)$;

(C) the entire function $\Xi_{S2}(m, a; z)$ has only real zeros.

Proof. The proof is similar to that for theorem 1. Since $0 < \frac{k}{m} < 1$, $g(m, a; t) \to \cos(9t/4)$ and $\Psi_{S2}(m; t) \to \Phi(t)$ when $t \to \infty$. Thus we proved (A). Setting $\Psi_{S2}(m, a; 0) = \Phi(0)$ leads:

\[
c = \left( e^{2\pi \Phi(0)} - 4\pi^2 \right) \frac{(1 - a)}{m(1 - a) - a(1 - a^m)} = \frac{\beta}{m - \sum_{k=1}^{m} a^k} > 0. \tag{4.19}
\]

If we determined $c$ from (4.19), then we proved (B).

Because of Lemma 5, it suffice to prove that $g(m, a; t)$ is a universal factor, or $g(m, a; it) \in \mathcal{LP}$. Defining $x = \frac{9t}{4m}$, then we obtain:

\[
g(m, a; it) = \tilde{g}(x) = \cos(mx) + c \sum_{k=0}^{m-1} c_k \cos(kx), \tag{4.20}
\]

Comparing $\tilde{g}(x)$ with $f_c(x)$ of (2.10) and realizing that $0 < c_k(a) < c_{k+1}(a) < 1$ we conclude that it is now suffice to prove that $0 < c < 1$.

If we want that $c < 1$, then we need to require

\[
m - \sum_{k=1}^{m} a^k > \beta \tag{4.21}
\]

Since $0 < a < 1$, we have $\sum_{k=1}^{m} a^k < ma^m$. Thus we may require $m$ to satisfy

\[
m(1 - a^m) > m - \sum_{k=1}^{m} a^k > \beta \tag{4.22}
\]

If we select $m$ that satisfies (4.18), then (4.22) and (4.21) are satisfied. Thus the parameter $c$ determined by (4.19) satisfies $0 < c < 1$. Thus we proved (C). □

Figure 9 below showed comparison of $\Phi(t)$(Red) with $\Psi_{S2}(m = 6, a = 1/100; t)$(Green), and $\Psi_{S2}(m = 7, a = 1/2; t)$(Blue).
Figure 9. Plots of various Phi functions vs. $t$. This includes $\Phi(t)$ (Red), $\Phi_S(m = 6, a = 1/100; t)$ ($b = 0.844600$) (Green), $\Phi_S(m = 7, a = 1/2; t)$ ($b = 0.842081$) (Blue).

The relative differences in percentage:

\[
\frac{\int_0^\infty |\Phi(t) - \Phi_S(m = 6, a = 1/100; t)|dt}{\int_0^\infty \Phi(t)dt} \approx 2.497861\% \quad (4.23)
\]

\[
\frac{\int_0^\infty |\Phi(t) - \Phi_S(m = 7, a = 1/2; t)|dt}{\int_0^\infty \Phi(t)dt} \approx 3.916332\% \quad (4.24)
\]

In Figure 10 below we compare $\Xi_S(m = 6, a = 1/100; z)$ (Purple) against $\Xi(z)$ (Red). It showed that there existed 29 zeros for both $\Xi_S(m = 6, a = 1/100; z)$ and $\Xi(z)$.

Figure 10. Plots of various Xi functions vs. $z$. This includes: $|\Xi_S(m = 6, a = 1/100; z)|/N(z)$ (Purple); $-|\Xi(z)|/N(z)$ (Red).

In Figure 11 below we compare $\Xi_S(m = 7, a = 1/2; z)$ (Blue) against $\Xi(z)$ (Red). It showed that there existed 29 zeros for both $\Xi_S(m = 7, a = 1/2; z)$ and $\Xi(z)$. 
Lemma 7. Let $k \in \mathbb{N}$, then

$$
\sinh^{2k}(x) = \sum_{j=0}^{k} a_{k,j} \cosh(2jx) \tag{4.25}
$$

where $a_{k,0} = (-1)^k 2^{2k} \binom{2k}{k}$, $a_{k,k} = 2^{1-2k}$, $a_{k,j} = (-1)^{k-j} 2^{1-2k} \binom{2k}{k-j}$, $0 < j < k$.

Lemma 8. Let $m \in \mathbb{N}$, then

$$
h_m(t) = 4^m \cosh(t/4)(\sinh^2(t/m) + 1 - a^2)^m
= \sum_{j=0}^{m} b_{m,j}(\cosh(2jt/m + t/4) + \cosh(2jt/m - t/4)) \tag{4.26}
$$

where

$$
b_{m,j} = \frac{1}{2} 4^m \sum_{k=j}^{m} \binom{m}{k} (1 - a^2)^{m-k} a_{k,j} \tag{4.27}
$$
Proof. 
\[ h_m(t) = 4^m \cosh(t/4)(\cosh^2(t/m) - a^2)^m \]
\[ = 4^m \cosh(t/4)(\sinh^2(t/m) + 1 - a^2)^m \]
\[ = 4^m \cosh(t/4) \sum_{k=0}^{m} \left( \begin{array}{c} m \\ k \end{array} \right) (1 - a^2)^{m-k} \sinh^{2k}(t/m) \]
\[ = 4^m \cosh(t/4) \sum_{k=0}^{m} \sum_{j=0}^{k} \left( \begin{array}{c} m \\ k \end{array} \right) (1 - a^2)^{m-k} a_{k,j} \cosh(t/4) \cosh(2jt/m) \]
\[ = \frac{1}{2} 4^m \sum_{k=0}^{m} \sum_{j=0}^{k} \left( \begin{array}{c} m \\ k \end{array} \right) (1 - a^2)^{m-k} a_{k,j} \]
\[ \times (\cosh(2jt/m + t/4) + \cosh(2jt/m - t/4)) \]
\[ = \frac{1}{2} 4^m \sum_{j=0}^{m} \sum_{k=j}^{m} \left( \begin{array}{c} m \\ k \end{array} \right) (1 - a^2)^{m-k} a_{k,j} \]
\[ \times (\cosh(2jt/m + t/4) + \cosh(2jt/m - t/4)) \]
\[ = \sum_{j=0}^{m} b_{m,j} (\cosh(2jt/m + t/4) + \cosh(2jt/m - t/4)). \]

We next approximate \( \Phi(t) \) with \( \Phi_{S3}(m;t) \).

**Theorem 3.** Let
\[ \Phi_{S3}(m;t) = 2\pi^2 h_m(t) \exp(-2\pi \cosh t), \tag{4.29} \]
\[ h_m(t) = \cosh(t/4)(4 \cosh^2(t/m) - 4a^2)^m; \tag{4.30} \]
where \( a \in \mathbb{R}, m \in \mathbb{N} \).

The Fourier transform of \( \Phi_{S3}(m;t) \) is:
\[ \Xi_{S3}(m; 2z) = 2\pi^2 \sum_{k=0}^{m} b_{m,k} (G_{2\pi}(iz + 2k/m + 1/4) + G_{2\pi}(iz - 2k/m - 1/4)) \]
\[ + 2\pi^2 \sum_{k=0}^{m} b_{m,k} (G_{2\pi}(iz + 2k/m - 1/4) + G_{2\pi}(iz - 2k/m + 1/4)) \]
\[ \tag{4.31} \]

If parameter \( a \) is determined by
\[ a = \left( 1 - \frac{1}{4}(1 + \beta)^{1/m} \right)^{1/2} \tag{4.32} \]
where the constant \( \beta \) is defined in (4.10), then
(A) \( \Phi_{S3}(m;t) \to \Phi(t) \), when \( t \to \infty \);
(B) \( \Phi_{S3}(m; 0) = \Phi(0) \);
(C) the Fourier transform of \( \Phi_{S3}(m;t) \) has only real zeros.

Proof. Since
\[ \cosh(t/4) (4 \cosh^2(t/m) - 4a^2)^m \to \cosh(9t/4), \quad \text{when} \ t \to \infty, \tag{4.33} \]
We proved (A).
Setting $\Phi_S(3; 0) = \Phi(0)$ leads to Eq. (4.32), thus we proved (B).

Because of Lemma 5 it suffice to prove that $h_m(t)$ is a universal factor, or $h_m(\text{i}t) \in L\mathcal{P}$. Since:

$$h_m(\text{i}t) = \tilde{h}(t) = \cos(t/4) \left(2 \cos(t/m) - 2a\right)^m \left(2 \cos(t/m) + 2a\right)^m,$$

(4.34) and $\cos(t/4) \in L\mathcal{P}$, it is suffice to prove that $0 < a < 1$.

When $m = 2$, $a^2 \approx 0.384621 < 1$; when $m \to \infty$, $a^2 \to 1^-$. Since

$$\frac{da^2}{dm} = \frac{(1 + \beta)^{1/m} \log(1 + \beta)}{4m^2} > 0,$$

(4.35) $a^2(m)$ is monotonically increasing from 0.384621 to 1$^-$ when $m$ varies in the range $[2, \infty)$. Therefore $0 < a^2 < 1$ and $0 < a < 1$. Thus $\tilde{h}(t) \in L\mathcal{P}$. This proved (C).

Because these Phi functions are so close to each other, we can not readily see their differences in a figure like Figures 1,2,3. So in Figure 4 below we showed comparison of differences: $\Phi_S(m = 2; t) - \Phi(t),(b = 0.620177)$(Green); $\Phi_S(m = 3; t) - \Phi(t),(b = 0.737722)$(Blue).

The relative differences in percentage are:

$$\frac{\int_0^\infty |\Phi(t) - \Phi_S(3; t)| dt}{\int_0^\infty \Phi(t) dt} \approx 0.402822\% \quad (4.37)$$

In Figure 13 below we compare $\Xi_S(m = 2; z)$(Blue) against $\Xi(z)$(Red). It showed that there existed 29 zeros for both $\Xi_S(m = 2; z)$ and $\Xi(z)$.
Figure 13. Plots of various Xi functions vs. $z$. This includes: $|\Xi_{S3}(m = 2; z)|/|N(z)|$(Blue); $-|\Xi(z)|/|N(z)|$(Red).

In Figure 14 below we compare $\Xi_{S3}(m = 3; z)$(Blue) against $\Xi(z)$(Red). It showed that there existed 29 zeros for both $\Xi_{S3}(m = 3; z)$ and $\Xi(z)$.

Figure 14. Plots of various Xi functions vs. $z$. This includes: $|\Xi_{S3}(m = 3; z)|/|N(z)|$(Blue); $-|\Xi(z)|/|N(z)|$(Red).

Lemma 9. Let $m \in \mathbb{N}$, then

$$ j_m(t) = \cosh(t/4)(4 \sinh^2(t/(2m)) + 4a)^m(4 \sinh^2(t/(2m)) + 4b)^m $$

$$ = \sum_{j=0}^{m} \sum_{l=0}^{m} d_{m,j,l} p_{m,j,l}(t) \quad (4.38) $$
where
\[ d_{m,j,l} = 4^{2m-1} \sum_{k=j}^{m} \sum_{n=l}^{m} \binom{m}{k} \binom{m}{n} a^{-k}b^{m-n}a_{k,j}a_{n,l} \]
\[ p_{m,j,l}(t) = 4 \cosh(t/4) \cosh(jt/m) \cosh(lt/m) \]
\[ = \cos \left( \frac{t}{4} + \left( +j + l \right) \frac{t}{m} \right) + \cos \left( \frac{t}{4} + \left( +j - l \right) \frac{t}{m} \right) \]
\[ + \cos \left( \frac{t}{4} + \left( -j + l \right) \frac{t}{m} \right) + \cos \left( \frac{t}{4} + \left( -j - l \right) \frac{t}{m} \right). \]

\textbf{Proof.}
\[ j_m(t) = \cosh(t/4)(4 \sinh^2(t/(2m)) + 4a)^m(4 \sinh^2(t/(2m)) + 4b)^m \]
\[ = 4^{2m} \cosh(t/4) \sum_{k=0}^{m} \left( \binom{m}{k} \right) a^{-k} \sinh(2k(t/(2m))) \sum_{n=0}^{m} \left( \binom{m}{n} \right) b^{m-n} \sinh(2l(t/(2m))) \]
\[ = 4^{2m} \sum_{k=0}^{m} \sum_{n=0}^{m} \sum_{j=0}^{k} \sum_{l=0}^{n} \left( \binom{m}{k} \right) \left( \binom{m}{n} \right) a^{-k}b^{m-n}a_{k,j}a_{n,l} \times (\cosh(t/4) \cosh(jt/m) \cosh(lt/m)) \]
\[ =: 4^{2m-1} \sum_{k=0}^{m} \sum_{n=0}^{m} \sum_{j=0}^{k} \sum_{l=0}^{n} \left( \binom{m}{k} \right) \left( \binom{m}{n} \right) a^{-k}b^{m-n}a_{k,j}a_{n,l} \cdot \sum_{k=0}^{m} \sum_{n=0}^{m} \sum_{j=0}^{k} \sum_{l=0}^{n} \left( \binom{m}{k} \right) \left( \binom{m}{n} \right) a^{-k}b^{m-n}a_{k,j}a_{n,l} \cdot p_{m,j,l}(t) \]
\[ =: \sum_{j=0}^{m} \sum_{l=0}^{m} d_{m,j,l} p_{m,j,l}(t) \] (4.40)

We next approximate \( \Phi(t) \) with \( \Phi_{S4}(m,t) \).

\textbf{Theorem 4.} \textit{Let}
\[ \Phi_{S4}(m,u) = 2\pi^2 j_m(t) \exp \left( -2\pi \cosh t \right), \]
\[ j_m(t) = \cosh(t/4)(4 \sinh^2(t/(2m)) + 4a)^m(4 \sinh^2(t/(2m)) + 4b)^m, \]
\textit{where} \( a < b; m \in \mathbb{N}. \) \textit{The Fourier transform of} \( \Phi_{S4}(m;t) \) \textit{is:}
\[ \Xi_{S4}(m;2z) = 2\pi^2 \sum_{j=0}^{m} \sum_{l=0}^{m} d_{m,j,l} P(m,j,l;z) \]
\[ P(m,j,l;z) = (G_{2\pi}(iz + 1/4 + 2(j + l)/m) + G_{2\pi}(iz + 1/4 - 2(j + l)/m)) \]
\[ = (G_{2\pi}(iz + 1/4 + 2(j - l)/m) + G_{2\pi}(iz - 1/4 - 2(j - l)/m)) \]
\[ = (G_{2\pi}(iz + 1/4 + 2(j - l)/m) + G_{2\pi}(iz - 1/4 - 2(j - l)/m)) \]
\[ = (G_{2\pi}(iz + 1/4 + 2(j - l)/m) + G_{2\pi}(iz - 1/4 - 2(j - l)/m)). \] (4.43)
If \( m = 2, 3 \) and the parameters \(-1 < a < b < 1\) are determined by

\[
\Phi(0) = \Phi_{S4}(m, 0) = \pi^2 e^{-2\pi} 2^{3+4m} (ab)^m
\]

\[
\Phi''(0) = \Phi''_{S4}(m, 0) = -\pi^2 e^{-2\pi} 2^{1+4m} (ab)^{m-1} (abm(32\pi - 1) - 8(a+b))
\]

then

\( (A) \Phi_{S4}(m; t) \to \Phi(t) \), when \( t \to \infty; \)

\( (B) \Phi_{S4}(m; 0) = \Phi(0), \quad \Phi''_{S4}(m; 0) = \Phi''(0); \)

\( (C) \) the Fourier transform of \( \Phi_{S4}(m; t) \) has only real zeros.

Proof. When \( t \to \infty, \)

\[
\cosh(t/4) \left(4 \sinh^2(t/(2m) + 4a)^m \left(4 \sinh^2(t/(2m) + 4b)^m \to \cosh(9t/4).\right) \right. \]

We proved (A).

Setting \( \Phi_{S4}(m; 0) = \Phi(0) \) and \( \Phi''_{S4}(m; 0) = \Phi''(0) \) leads to (4.44) and (4.45), thus we proved (B).

Because of Lemma 5, it suffice to prove that \( j_m(t) \) is a universal factor, or \( j_m(it) \in \mathcal{LP} \). Since:

\[
j_m(it) = \hat{j}(t) = \cos(t/4) \left(4 - 4 \sin^2(t/(2m)) \right)^m \left(4b - 4 \sin^2(t/(2m)) \right)^m, \]

and \( \cos(t/4) \in \mathcal{LP} \), it is suffice to prove that \( 0 < a < b < 1 \). From (4.44) and (4.45), we obtain:

\[
a + b = m\gamma \delta^{1/m}, \quad ab = (1/16)\delta^{1/m}
\]

where

\[
\gamma = \frac{4\Phi''(0) + \Phi(0)(32\pi - 1)}{128\Phi(0)} \approx 0.192369
\]

\[
\delta = 2^{-3}\pi^{-2} e^{2\pi} \Phi(0) \approx 6.059069
\]

From (4.48), we can solve for \( a, b \) and obtain:

\[
a(m) = \frac{1}{2} m\gamma \delta^{1/m} - \frac{1}{4} \left(\delta^{1/m} \left(4m^2\gamma^2 \delta^{1/m} - 1 \right) \right)^{1/2},
\]

\[
b(m) = \frac{1}{2} m\gamma \delta^{1/m} + \frac{1}{4} \left(\delta^{1/m} \left(4m^2\gamma^2 \delta^{1/m} - 1 \right) \right)^{1/2}.
\]

When \( m = 2, \) we find numerically the solution: \( a(2) \approx 0.208233 < b(2) \approx 0.738810 < 1. \) When \( m = 3, \) we find numerically the solution: \( a(3) \approx 0.122579 < b(3) \approx 0.929527 < 1. \) Thus \( j(t) \in \mathcal{LP} \). This proved (C).

We also find out that \( a(1), b(1) \in \mathbb{C} \) and \( 0 < a(m) < 1 < b(m), m > 3. \)

In Figure 15 below we showed comparison of differences: \( \Phi_{S4}(m = 2; t) - \Phi(t), (a = 0.208233, b = 0.738810)(Green); \Phi_{S4}(m = 3; t) - \Phi(t), (a = 0.122579, b = 0.929527)(Blue). \)
Figure 15. Plots of various differences among Phi functions vs. \( t \). This includes: \( \Phi_{S4}(m = 2; t) - \Phi(t), (a = 0.208233, b = 0.738810) \) (Green); \( \Phi_{S4}(m = 3; t) - \Phi(t), (a = 0.122579, b = 0.929527) \) (Blue).

The relative differences in percentage are:

\[
\frac{\int_0^{\infty} |\Phi(t) - \Phi_{S4}(m = 2; u)|dt}{\int_0^{\infty} \Phi(t)dt} \approx 0.835144\% \quad (4.51)
\]

\[
\frac{\int_0^{\infty} |\Phi(t) - \Phi_{S4}(m = 3; t)|dt}{\int_0^{\infty} \Phi(t)dt} \approx 0.402822\% \quad (4.52)
\]

In Figure 16 below we compare \( \Xi_{S4}(m = 2; z) \) (Purple) against \( \Xi(z) \) (Red). It showed that there existed 29 zeros for both \( \Xi_{S4}(m = 2; z) \) and \( \Xi(z) \).

Figure 16. Plots of various Xi functions vs. \( z \). This includes: \( |\Xi_{S4}(m = 2; z)|/N(z) \) (Purple); \( -|\Xi(z)|/N(z) \) (Red).

In Figure 17 below we compare \( \Xi_{S4}(m = 3; z) \) (Blue) against \( \Xi(z) \) (Red). It showed that there existed 29 zeros for both \( \Xi_{S4}(m = 3; z) \) and \( \Xi(z) \).
5. CONCLUDING REMARKS

Our criteria for picking kernel $K(t)$ to approximate the kernel $\Phi(t)$ of (1.4) for Riemann $\Xi(z)$ function are

(i) $K(t) \to \Phi(t), \quad t \to \infty,$

(ii) $K(0) = \Phi(0),$

(iii) $\int_0^\infty K(t) \cos(zt) dt$ has only real zeros.

Using these criteria, we obtain several new and improved approximations to kernel $\Phi(t)$ and find out that their Fourier transforms have only real zeros.

Thus this method is quite general and it remains to be seen if one can better approximate the body of the kernel $\Phi(t)$.

6. ACKNOWLEDGMENT

We appreciate the continuing support and help from Prof. Jie QING (math dept. of University of California at Santa Cruz), Prof. Zixiang ZHOU (math dept. of Fudan University), Prof. Xinyi YUAN, (math dept. of University of California at Berkeley), Dr. Xiaoyi WU.
