We discuss possible constraints on R-parity violation from recently announced Belle/Babar results on the $B \to \tau \nu$ branching fraction, and the bounds on $\tau^{-} \to \ell^{-} K_{S}^{0}$ ($\ell = e$ or $\mu$) from Babar.

PACS numbers: 12.60.Jv,13.20.He,13.35.Dx

I. INTRODUCTION

Measurements of rare decay processes which are small or absent within the Standard Model (SM) provide windows to new physics. During the past year, new measurements and bounds on the decays $B \to \tau \nu$ [1, 2] and $\tau^{-} \to \ell^{-} K_{S}^{0}$ ($\ell = e$ or $\mu$) [3] have been announced from Babar and Belle. In this letter, we discuss what constraints can be placed on new physics from these results using R-parity violating supersymmetry (SUSY) as an example, partially updating the analyses of Dreiner et al. from 2002 [4] and 2006 [5].

II. $B \to \tau \nu$

A. Experimental Value

Babar recently reported their measurement of the $B \to \tau \nu$ branching fraction, using $383 \times 10^{6}$ $B \bar{B}$ pairs and two different methods to reconstruct the tagged $B$, as

$$
B(B \to \tau \nu)_{\text{Babar-hadronic}} = (1.8^{+0.9}_{-0.8} \text{ (stat.)} \pm 0.4 \text{ (bkg.)} \pm 0.2 \text{ (syst.)}) \times 10^{-4},
$$

$$
B(B \to \tau \nu)_{\text{Babar-semileptonic}} = (0.9 \pm 0.6 \text{ (stat.)} \pm 0.1 \text{ (syst.)}) \times 10^{-4},
$$

with the combined value given by [1]

$$
B(B \to \tau \nu)_{\text{Babar}} = (1.2 \pm 0.4 \text{ (stat.)} \pm 0.3 \text{ (bkg.)} \pm 0.2 \text{ (syst.)}) \times 10^{-4}.
$$

Belle also reported a new measurement of $B(B \to \tau \nu)$ using $657 \times 10^{6}$ $B \bar{B}$ pairs and semileptonic tagging as [2]

$$
B(B \to \tau \nu)_{\text{Belle-semileptonic}} = (1.65^{+0.38}_{-0.37} \text{ (stat.)}^{+0.35}_{-0.37} \text{ (syst.)}) \times 10^{-4}.
$$

A previous 2006 Belle result using $449 \times 10^{6}$ $B \bar{B}$ pairs and hadronic tagging yielded [6]

$$
B(B \to \tau \nu)_{\text{Belle-hadronic}} = (1.79^{+0.56}_{-0.46} \text{ (stat.)}^{+0.46}_{-0.51} \text{ (syst.)}) \times 10^{-4}.
$$

Incorporating all these results, the world average for the branching fraction as of August 2009 is [7]

$$
B(B \to \tau \nu)_{\text{exp}} = (1.51 \pm 0.33) \times 10^{-4}.
$$

B. Standard Model Value

In the Standard Model (SM), the decay $B \rightarrow \tau \nu$ proceeds via $s$-channel $W$-exchange which at low energies is described by the effective Lagrangian

$$\mathcal{L}_W = -\sqrt{2} G_F V_{ub} (\overline{u}c^- (1 - \gamma_5) b)(\tau L \gamma_\mu \nu L) + h.c.$$  \hspace{1cm} (6)

This leads to the SM prediction

$$\mathcal{B}(B \rightarrow \tau \nu) = \left(\sqrt{2} G_F V_{ub} m_\tau\right)^2 \frac{m_B}{16\pi} \left(1 - \frac{m_\tau^2}{m_B^2}\right)^2 f_B^2 \tau_B,$$  \hspace{1cm} (7)

where the $B$-decay constant $f_B$ is normalized as

$$\langle 0 | \bar{u}(x) \gamma^\mu \gamma_5 b(x) | B^- (p) \rangle = ip^\mu f_B e^{-ipx}.$$  \hspace{1cm} (8)

Unlike decays into electrons or muons, the chirality-flip factor $(m_\tau/m_B)^2 \approx 0.1$ is not small, but the decay is nevertheless suppressed due to the smallness of $|V_{ub}|$.

If we wish to compare the experimental value, Eq. (5), against this SM expression instead of using it to extract $|V_{ub}|f_B$, we must obtain the values of $|V_{ub}|$ and $f_B$ from other sources. The extraction of $|V_{ub}|$ from charmless semileptonic $B$-decays ($B \rightarrow \pi \ell \nu$ with $\ell = e$ or $\mu$) is difficult requiring considerable theoretical input [8-11]. The value quoted in the 2008 Review of Particle Properties [8, 9] is

$$|V_{ub}|_{RPP} = (3.95 \pm 0.35) \times 10^{-3},$$  \hspace{1cm} (9)

with the error dominated by theoretical uncertainty. Note that in using this value as the SM value of $|V_{ub}|$, we are assuming that new physics will not affect charmless semileptonic $B$-decay. The value of $f_B$ is obtained from unquenched lattice QCD. The HPQCD collaboration reports [12]

$$f_B = 0.216 \pm 0.022 \text{ GeV}.$$  \hspace{1cm} (10)

As can be seen, both $|V_{ub}|$ and $f_B$ suffer from uncertainties on the order of 10%. Substituting Eqs. (9) and (10) into Eq. (7), we find

$$\mathcal{B}(B \rightarrow \tau \nu)_{SM} = (1.29 \pm 0.35) \times 10^{-4},$$  \hspace{1cm} (11)

The UTfit [7] and CKMfit [13] collaborations constrain this branching fraction with global SM fits and respectively find

$$\mathcal{B}(B \rightarrow \tau \nu)_{UTfit} = (0.81 \pm 0.12) \times 10^{-4},$$  
$$\mathcal{B}(B \rightarrow \tau \nu)_{CKMfit} = (0.92 \pm 0.10) \times 10^{-4},$$  \hspace{1cm} (12)

as the SM value. Though the errors are much smaller, and the central values in disagreement with the experimental value by almost $2\sigma$, we use neither of these values and adhere to Eq. (11) since the presence of new physics that would shift $B \rightarrow \tau \nu$ away from the SM may affect other observables used in the global fits as well.

C. Constraint on New Physics

The fractional errors on both the experimental value, Eq. (5), and the SM prediction, Eq. (11), are large. However, the constraint on new physics is not necessarily weak since the SM amplitude itself is suppressed by $V_{ub}$ requiring new physics effects to be equally suppressed. We follow Dobrescu and Kronfeld [14] and assume that new physics effects can be expressed in a model independent way with the effective Lagrangian

$$\mathcal{L}_{\text{new}} = \frac{C_A}{M^2} (\overline{u}c^- (1 - \gamma_5) b)(\tau L \gamma_\mu \nu L) + \frac{C_F}{M^2} (\overline{u}c^- (1 - \gamma_5) b)(\tau R \nu L) + h.c.$$  \hspace{1cm} (13)

where $M$ is the scale of new physics, and $C_A$ and $C_F$ are constants that may be complex in general. Only these operators will cause the decay amplitude from new physics to interfere with that from the SM shifting $\sqrt{2} G_F V_{ub} m_\tau$ in Eq. (7) to

$$\sqrt{2} G_F V_{ub} m_\tau \rightarrow \sqrt{2} G_F V_{ub} m_\tau + \frac{1}{M^2} \left( C_A m_\tau - \frac{C_F m_B^2}{m_b} \right),$$  \hspace{1cm} (14)
where the $u$ quark mass has been neglected. Assuming that there is no correlation between the experimental and SM values, Eqs. (5) and (11), we find

$$\frac{B(B \to \tau \nu)_{\text{exp}}}{B(B \to \tau \nu)_{\text{SM}}} = 1.17 \pm 0.41 ,$$

which translates to

$$\left| 1 + \frac{1}{\sqrt{2} G_F V_{ub} M^2} \left( C_A - C_P \frac{m_B^2}{m_b m_\tau} \right) \right|^2 = 1.17 \pm 0.41 .$$

In the standard CKM parametrization we have $V_{ub} = |V_{ub}| e^{-i \delta}$, where $\delta$ is the CP violating phase [15]. Therefore,

$$\left| 1 + \frac{1}{\sqrt{2} G_F V_{ub} M^2} \left( C_A - C_P \frac{m_B^2}{m_b m_\tau} \right) \right|^2 \approx 1 + 2 \frac{\text{Re} \left[ e^{i \delta} (C_A - C_P m_B^2 / m_b m_\tau) \right]}{\sqrt{2} G_F |V_{ub}| M^2} .$$

Setting

$$C \equiv \text{Re} \left[ e^{i \delta} (C_A - C_P m_B^2 / m_b m_\tau) \right] ,$$

the above bound becomes

$$\frac{C}{\sqrt{2} G_F |V_{ub}| M^2} = \left[ (1.53 \pm 0.14) \times 10^3 \right] C \left( \frac{100 \text{ GeV}}{M} \right)^2 = 0.09 \pm 0.20 ,$$

or

$$C \left( \frac{100 \text{ GeV}}{M} \right)^2 = 0.00006 \pm 0.00013 .$$

The $2\sigma$ (95%) range of this ratio is therefore

$$-0.00020 < C \left( \frac{100 \text{ GeV}}{M} \right)^2 < 0.00032 , \hspace{1cm} (95\% \text{ C.L.}) .$$

The bound on the scale of new physics $M$ will depend on the sign of $C$:

$$\frac{M}{\sqrt{+C}} \geq 6 \text{ TeV} \hspace{1cm} \text{if } C > 0 ,$$

$$\frac{M}{\sqrt{-C}} \geq 7 \text{ TeV} \hspace{1cm} \text{if } C < 0 , \hspace{1cm} (95\% \text{ C.L.}) .$$

### D. Constraints on R-parity violation

The new physics to which the above bounds apply must distinguish among fermion flavors since it must affect $B \to \tau \nu_\tau$ without affecting $B \to \pi \ell \nu_\ell$ ($\ell = e$ or $\mu$). As an example, we consider R-parity violating supersymmetry (SUSY), the superpotential of which is given by [16, 17]

$$W_R = \frac{1}{2} \lambda_{ijk} \hat{L}_i \hat{L}_j \hat{E}_k + \lambda'_{ijk} \hat{L}_i \hat{Q}_j \hat{D}_k + \frac{1}{2} \lambda''_{ijk} \hat{U}_i \hat{D}_j \hat{D}_k .$$

Here $i, j, k$ are generation indices, while $SU(2)$-weak isospin and $SU(3)$-color indices are suppressed. The coefficients $\lambda_{ijk}$ are antisymmetric in the first two indices, while $\lambda'_{ijk}$ are antisymmetric in the latter two. Consequently, there are 9 independent $LLE$ couplings, 27 independent $LQD$ couplings, and 9 independent $UDD$ couplings. The decay $B \to \pi \ell \nu_\ell$ ($\ell = e$ or $\mu$) can be affected by the coupling combinations $\lambda'_{1ik} \lambda''_{1jk}$ ($i = 1$ or 2, $k$ arbitrary) and $\lambda_{ijk} \lambda''_{1ik}$ ($j = 1$ or 2, $i = 3$ or $3 - j$) so these are assumed to be sufficiently small. The coupling combinations which affect $B \to \tau \nu_\tau$ are shown in Figure 1. The decay can proceed either via $t$-channel sdown exchange, or via $s$-channel selectron exchange.
FIG. 1: Possible R-parity violating contributions to $B^- \rightarrow \tau^- \bar{\nu}_\tau$. The index is $k = 1, 2, \text{or } 3$ in (a), while $i = 1 \text{ or } 2$ in (b) due to the anti-symmetry of $\lambda_{ijk}$ in the first two indices.

1. $t$-channel sdown exchange

$t$-channel exchange of $\tilde{d}_{kR}$ ($k = 1, 2, \text{or } 3$) is described by the effective operator

$$\mathcal{L}_{\tilde{d}_{kR}} = -\frac{\lambda'_{33k} \lambda'_{31k}}{M^2_{\tilde{d}_{kR}}} (u_L^\taurites \nu_L^\taurites b_L) .$$

(24)

A Fierz transformation allows us to rewrite

$$\overline{(u_L^\taurites \nu_L^\taurites b_L)} = -\frac{1}{2} (u_L^\taurites \gamma_\mu b_L) (\nu_L^\taurites \gamma^\mu \nu_L^\taurites) = +\frac{1}{4} (\overline{\nu}_\tau^\mu (1 - \gamma_5) b) (\tau_L^\gamma \nu^{\tau_L} .$$

(25)

The relevant part of the operator Eq. (24) is therefore

$$+\frac{\lambda'_{33k} \lambda'_{31k}}{4M^2_{\tilde{d}_{kR}}} (\overline{\nu}_\tau^\mu (1 - \gamma_5) b) (\tau_L^\gamma \nu^{\tau_L} .$$

(26)

Comparison with Eqs. (13) and (18) leads to the identifications

$$M = M_{\tilde{d}_{kR}} , \quad C_A = \frac{\lambda'_{33k} \lambda'_{31k}}{4} , \quad C = \text{Re}[e^{i\delta} C_A] = \frac{\text{Re}[e^{i\delta} \lambda'_{33k} \lambda'_{31k}]}{4} .$$

(27)

Allowing only one sdown contribution to be non-zero at a time, the bounds of Eq. (21) translate to

$$-0.0008 < \text{Re}[e^{i\delta} \lambda'_{33k} \lambda'_{31k}] \left(\frac{100 \text{ GeV}}{M_{\tilde{d}_{kR}}}\right)^2 < +0.0013 , \quad (95\% \text{ C.L.}) .$$

(28)

The bounds on the sdown mass are

$$\sqrt{+\text{Re}[e^{i\delta} \lambda'_{33k} \lambda'_{31k}]} \geq 3 \text{ TeV} \quad \text{if } \text{Re}[e^{i\delta} \lambda'_{33k} \lambda'_{31k}] > 0 ,$$

$$\sqrt{-\text{Re}[e^{i\delta} \lambda'_{33k} \lambda'_{31k}]} \geq 4 \text{ TeV} \quad \text{if } \text{Re}[e^{i\delta} \lambda'_{33k} \lambda'_{31k}] < 0 , \quad (95\% \text{ C.L.}) .$$

(29)

2. $s$-channel selectron exchange

$s$-channel exchange of $\tilde{e}_{iL}$ ($i = 1 \text{ or } 2$) is described by the effective operator

$$\mathcal{L}_{\tilde{e}_{iL}} = \frac{\lambda'_{13i} \lambda'_{r31}}{M^2_{\tilde{e}_{iL}}} (\overline{\nu}_L^\taurites \nu^{\tau_L} \overline{\nu}_R^\nu_L \nu_L^\taurites) = \frac{\lambda'_{13i} \lambda'_{r13}}{2M^2_{\tilde{e}_{iL}}} (\overline{\nu}_L^\taurites \nu^{\tau_L} \overline{\nu}_R^\nu_L \nu_L^\taurites) .$$

(30)
the relevant part of which is

\[ \frac{\lambda_{333}^L \lambda_{113}^L}{2M_{\bar{e}L}^2}(\pi_7b)(\tau_R \nu_{\tau L}) . \]  

(31)

Comparison with Eqs. (13) and (18) leads to the identifications

\[ M = M_{\bar{e}L} , \quad C_P = \frac{\lambda_{333}^L \lambda_{113}^L}{2} , \quad C = \frac{m_B^2}{m_b m_{\tau}} \text{Re} \left[ -e^{i\delta} C_P \right] = \frac{m_B^2}{2m_b m_{\tau}} \text{Re} \left[ -e^{i\delta} \lambda_{333}^L \lambda_{113}^L \right] . \]  

(32)

The factor \( m_B^2/m_b m_{\tau} \) is equal to \[18]\]

\[ \frac{m_B^2}{m_b m_{\tau}} = \frac{(5.27917 \pm 0.00029 \text{ GeV})^2}{(1.77684 \pm 0.00017 \text{ GeV})(4.79^{+0.19}_{-0.09} \text{ GeV})} = 3.27^{+0.06}_{-0.12} , \]  

where we have used the pole mass for \( m_b \). Allowing only one selectron contribution to be non-zero at a time, the bounds of Eq. (21) translate to

\[-0.00012 < \text{Re} \left[ -e^{i\delta} \lambda_{333}^L \lambda_{113}^L \right] (\frac{100 \text{ GeV}}{M_{\bar{e}L}})^2 < +0.00020 , \quad (95\% \text{ C.L.}) . \]  

(34)

The corresponding bounds on the selectron mass are

\[ \frac{M_{\bar{e}L}}{\sqrt{\text{Re} \left[ -e^{i\delta} \lambda_{333}^L \lambda_{113}^L \right]}} \geq 7 \text{ TeV} \quad \text{if} \quad \text{Re} \left[ -e^{i\delta} \lambda_{333}^L \lambda_{113}^L \right] > 0 , \]  

(35)

III. \( \tau^\pm \to \ell^\pm K_S^0 \)

A. Experimental Bounds on Lepton Flavor Violating \( \tau \) Decays

Babar recently reported their measurements for tau lepton-flavor-violating decays \( \tau^- \to \ell^- K_S^0 (\ell = e \text{ or } \mu) \) using a data sample corresponding to an integrated luminosity of 469 fb\(^{-1}\). The upper limits on the branching fractions for the two channels, at 90% confidence level, are \[3\]

\[ B(\tau^- \to \mu^- K_S^0)_{\text{Babar}} < 4.0 \times 10^{-8} , \quad (90\% \text{ C.L.}) , \]  

(36)

\[ B(\tau^- \to e^- K_S^0)_{\text{Babar}} < 3.3 \times 10^{-8} , \]  

These supersede the previous 90% bounds from Belle based on 281 fb\(^{-1}\) of data, which were \[19\]

\[ B(\tau^- \to \mu^- K_S^0)_{\text{Belle}} < 4.9 \times 10^{-8} , \]  

(37)

\[ B(\tau^- \to e^- K_S^0)_{\text{Belle}} < 5.6 \times 10^{-8} , \]  

For the sake of comparison with the bounds from \( B \to \tau \nu \) we derived in the previous section, and also with the previous bounds from Ref. \[5\], we will use the 95% confidence level bounds from Babar, which can be read off from Fig. 4 of Ref. \[3\] as

\[ B(\tau^- \to \mu^- K_S^0)_{\text{Babar}} < 5.2 \times 10^{-8} , \quad (95\% \text{ C.L.}) . \]  

(38)

\[ B(\tau^- \to e^- K_S^0)_{\text{Babar}} < 4.3 \times 10^{-8} , \]  

Since there exist no SM contribution to these processes, these bounds translate directly into bounds on new physics.

B. Constraints on R-parity violation

As in the \( B \to \tau \nu \) analysis, we use R-parity violating SUSY as an example. Possible contributions to the process \( \tau^- \to \ell^- K_S^0 \) from R-parity violation are shown in Figure 2. The decay can proceed either via sup exchange, or sneutrino exchange.
A Fierz transformation allows us to rewrite

\[ \lambda_{ijk}^s = \frac{\lambda_{3ik}^s \lambda_{2ij}^s}{M_{\tilde{u}_{ijL}}^2} \left( \frac{d_{kR} \gamma_{1L}}{d_{kR} \gamma_{1L}} \right) \left( \frac{\mu_{L} \gamma_{\mu} \tau_{L}}{\mu_{L} \gamma_{\mu} \tau_{L}} \right) . \]  

(39)

A Fierz transformation allows us to rewrite

\[ \left( \frac{d_{kR} \gamma_{1L}}{d_{kR} \gamma_{1L}} \right) \left( \frac{\mu_{L} \gamma_{\mu} \tau_{L}}{\mu_{L} \gamma_{\mu} \tau_{L}} \right) = \frac{1}{2} \left( \frac{d_{kR} \gamma_{\mu} \tau_{L}}{d_{kR} \gamma_{\mu} \tau_{L}} \right) \left( \frac{\mu_{L} \gamma_{\mu} \tau_{L}}{\mu_{L} \gamma_{\mu} \tau_{L}} \right) = \frac{1}{4} \left( \frac{d_{kR} \gamma_{\mu}(1 + \gamma_5)d_{\ell}}{d_{kR} \gamma_{\mu}(1 + \gamma_5)d_{\ell}} \right) \left( \frac{\mu_{L} \gamma_{\mu} \tau_{L}}{\mu_{L} \gamma_{\mu} \tau_{L}} \right) , \]

and the part of the operator relevant for the decay in question

\[ \frac{\lambda_{3ik}^s \lambda_{2ij}^s}{4M_{\tilde{u}_{ijL}}^2} \left( \frac{d_{kR} \gamma_{\mu} \gamma_5 d_{k}}{d_{kR} \gamma_{\mu} \gamma_5 d_{k}} \right) \left( \frac{\mu_{L} \gamma_{\mu} \tau_{L}}{\mu_{L} \gamma_{\mu} \tau_{L}} \right) . \]

(41)

The matrix element of \( d_{kR} \gamma_{\mu} \gamma_5 d_{k} \) between the vacuum and the \( K_0^0 = (K^0 + \bar{K}^0)/\sqrt{2} \) state can be expressed as

\[ \langle K_0^0(p) | \bar{d}_{kR}(x) \gamma_{\mu} \gamma_5 d_{k}(x) | 0 \rangle = -\frac{i}{\sqrt{2}} p^\mu f_{K^0} e^{ipx} , \]

(42)

where the \( K^0 \) decay constant \( f_{K^0} \) is defined as

\[ \langle 0 | \bar{s}(x) \gamma_{\mu} \gamma_5 s(x) | K^0(p) \rangle = i p^\mu f_{K^0} e^{-ipx} . \]

(43)

The \( \tau^- \rightarrow \mu^- K_0^0 \) branching fraction due to the operator Eq. (41) is then expressed as \([5]\)

\[ B(\tau^- \rightarrow \mu^- K_0^0) = \frac{|\lambda_{3ik}^s \lambda_{2ij}^s|}{M_{\tilde{u}_{ijL}}^2} \sqrt{\frac{\Lambda(m_0^2, m_\mu^2, m_K^2)}{1024 \pi m_\mu^2}} \left( \frac{(m_\tau^2 - m_\mu^2)^2 - m_K^2(m_\tau^2 + m_\mu^2)}{1024 \pi m_\mu^2} \right) (f_{K^0})^2 \tau_\tau , \]

(44)

where

\[ \Lambda(a, b, c) \equiv a^2 + b^2 + c^2 - 2ab - 2bc - 2ca . \]

(45)

Invoking isospin symmetry, we assume that \( f_{K^0} \) is equal to the decay constant of the charged Kaons \( f_{K^\pm} = 0.1555 \pm 0.0008 \text{ GeV} \) \([20]\) and find

\[ B(\tau^- \rightarrow \mu^- K_0^0) = (0.1561 \pm 0.0017) |\lambda_{3ik}^s \lambda_{2ij}^s|^2 \left( \frac{100 \text{ GeV}}{M_{\tilde{u}_{ijL}}} \right)^4 . \]

(46)
Then, the 95% Babar bound, Eq. (38), translates to
\[ \sqrt{\frac{\lambda_{3ik}^t \lambda_{1i\ell}^*}{M_{\tilde{u}_{iL}}} \left( \frac{100 \text{ GeV}}{M_{\tilde{u}_{iL}}} \right)} < 0.024 \text{ , or } \frac{M_{\tilde{u}_{iL}}}{\sqrt{\lambda_{3ik}^t \lambda_{1i\ell}^*}} > 4.2 \text{ TeV} \text{ , (95\% C.L.)} \] (47)

Similarly, the branching fraction of \( \tau^- \to e^- K_S^0 \) proceeding via the subprocesses \( \tau_L^- \to e_L^- s_R d_R \) and \( \tau_L^- \to e_L^- d_R s_R \) is given by
\[
\mathcal{B}(\tau^- \to e^- K_S^0) = \frac{|\lambda_{3ik}^t \lambda_{1i\ell}^*|^2}{M_{\tilde{u}_{iL}}} \left( \frac{100 \text{ GeV}}{M_{\tilde{u}_{iL}}} \right)^2 \left[ \left( m_{\tau}^2 - m_{\mu}^2 \right)^2 - m_{K}^2 (m_{\mu}^2 + m_{e}^2) \right] \frac{1024 \pi m_{\tau}^2}{(f_{K^0})^2} \tau_{\tau}.
\]
(48)

The constraint from the 95% Babar bound, Eq. (38), is then
\[
\sqrt{\frac{\lambda_{3ik}^t \lambda_{1i\ell}^*}{M_{\tilde{u}_{iL}}} \left( \frac{100 \text{ GeV}}{M_{\tilde{u}_{iL}}} \right)} < 0.023 \text{ , or } \frac{M_{\tilde{u}_{iL}}}{\sqrt{\lambda_{3ik}^t \lambda_{1i\ell}^*}} > 4.4 \text{ TeV} \text{ , (95\% C.L.)} \] (49)

2. sneutrino exchange

Next, we consider the decay \( \tau^- \to \mu^- K_S^0 \) via the sneutrino exchange subprocess \( \tau_R^- \to \mu_R^- s_R d_R \) or \( \tau_R^- \to \mu_R^- d_R s_R \) shown in Figure 2(b). The indices for these subprocesses are \( j = 2 \) with \( (k\ell) = (12) \) or \( (21) \). The effective operator induced by \( \tilde{\nu}_{iL} \) \( (i = 1 \text{ or } 2) \) exchange is
\[
\mathcal{L}_{\tilde{\nu}_{iL}} = \frac{\lambda_{3ij}^t \lambda_{1i\ell}^*}{M_{\tilde{\nu}_{iL}}} \left( \frac{m_{\nu_{R}} \gamma_{\tau} \tau_{\nu_{R}}}{2M_{\tilde{\nu}_{iL}}} \right) \frac{d_{k\ell} d_{R}}{d_{k} (1 + \gamma_{5}) d_{\ell}}.
\]
(50)

The part of this operator that is relevant for the decay is
\[
\frac{\lambda_{3ij}^t \lambda_{1i\ell}^*}{2M_{\tilde{\nu}_{iL}}} \left( \frac{m_{\nu_{R}} \gamma_{\tau} \tau_{\nu_{R}}}{2M_{\tilde{\nu}_{iL}}} \right) \frac{d_{k} (1 + \gamma_{5}) d_{\ell}}{d_{k} (1 + \gamma_{5}) d_{\ell}}.
\]
(51)

leading to the branching fraction [5]
\[
\mathcal{B}(\tau^- \to \mu^- K_S^0) = \frac{|\lambda_{3ij}^t \lambda_{1i\ell}^*|^2}{M_{\tilde{\nu}_{iL}}} \left( \frac{100 \text{ GeV}}{M_{\tilde{\nu}_{iL}}} \right)^2 \left[ \left( m_{\mu}^2 - m_{\mu}^2 \right)^2 - m_{K}^2 (m_{\mu}^2 + m_{e}^2) \right] \frac{256 \pi m_{\mu}^2}{(f_{K^0})^2} \tau_{\tau},
\]
(52)

where the factor \( \xi \) is defined as:
\[
\xi = \frac{m_{K}}{m_{d} + m_{e}} \approx \frac{m_{K}}{m_{s}} = \frac{496.614 \pm 0.024 \text{ MeV}}{105.625 \text{ MeV}} = 4.7.
\]
(53)

Here, we have used the \( \overline{\text{MS}} \) mass at \( \mu = 2 \text{ GeV} \) for \( m_{s} \). The error introduced by the neglect of \( m_{d} \) is only about 5\%. Allowing \( \xi \) to sweep this range, we find
\[
\mathcal{B}(\tau^- \to \mu^- K_S^0) = (0.8 \sim 2.4) \frac{|\lambda_{3ij}^t \lambda_{1i\ell}^*|^2}{M_{\tilde{\nu}_{iL}}} \left( \frac{100 \text{ GeV}}{M_{\tilde{\nu}_{iL}}} \right)^2,
\]
(54)

and Eq. (38) translates to
\[
\sqrt{\frac{\lambda_{3ij}^t \lambda_{1i\ell}^*}{M_{\tilde{\nu}_{iL}}} \left( \frac{100 \text{ GeV}}{M_{\tilde{\nu}_{iL}}} \right)} < 0.012 \sim 0.016 \text{ , or } \frac{M_{\tilde{\nu}_{iL}}}{\sqrt{\lambda_{3ij}^t \lambda_{1i\ell}^*}} > (6 \sim 8) \text{ TeV} \text{ , (95\% C.L.)}.
\]
(55)

The branchinger fraction due to the subprocesses \( \tau_R^- \to \mu_R^- s_R d_R \) or \( \tau_R^- \to \mu_R^- d_R s_R \) shown in Figure 2(c) is the same as Eq. (52) except with the coupling constants replaced by the combination \( \lambda_{323}^t \lambda_{1i\ell}^* \) with \( i = 1 \text{ or } 3 \), to which the exact same bounds apply.

The analysis for the decay \( \tau^- \to e^- K_S^0 \) proceeds in an exactly analogous fashion and the results are
\[
\sqrt{\frac{\lambda_{3ij}^t \lambda_{1i\ell}^*}{M_{\tilde{\nu}_{iL}}} \left( \frac{100 \text{ GeV}}{M_{\tilde{\nu}_{iL}}} \right)} < 0.011 \sim 0.015 \text{ , or } \frac{M_{\tilde{\nu}_{iL}}}{\sqrt{\lambda_{3ij}^t \lambda_{1i\ell}^*}} > (7 \sim 9) \text{ TeV} \text{ , (95\% C.L.)}.
\]
(56)

with \( i = 1 \text{ or } 2 \). The same bounds apply to \( \lambda_{113}^t \lambda_{1i\ell}^* \) with \( i = 2 \text{ or } 3 \).
IV. SUMMARY & DISCUSSION

In Table I we list the bounds on various R-parity violating coupling combinations obtained in this work against those obtained by Dreiner et al. in 2002 [4] and in 2006 [5]. All sfermion masses have been set to 100 GeV. The bounds from both $B \to \tau \nu_{\tau}$ and $\tau \to \ell K^0_S$ have all improved by factors of $4 \sim 5$. The corresponding lower bound on the scale of new physics is in the 4 to 10 TeV range if we set all coupling constants to one.

The current single-coupling bounds on the individual R-parity violating couplings that appear in Table I are listed in Table II. The numbers have been updated from those in Table 6.1 on page 110 of Ref. [17] using the most recent data [8, 21, 25]. Detailed derivations will be provided elsewhere [27, 28]. The products of these single-coupling bounds are listed in the rightmost column of Table I with all sparticle masses set to 100 GeV. As can be seen, the bounds from $B \to \tau \nu_{\tau}$ and $\tau \to \ell K^0_S$ are much stronger than the products of the single-coupling bounds with the exception of the combination $|\lambda'_{111}\lambda'_{312}|$ for which $|\lambda'_{111}|$ is strongly constrained by neutrinoless double beta-decay.

The experimental error on $B \to \tau \nu_{\tau}$ can be expected to be reduced further as more Belle and Babar data is analyzed. However, unless the theoretical uncertainty of its SM prediction based on charmless semileptonic $B$ decay and lattice calculations can be reduced also, any improvement on the new physics bounds will be limited. The decay $\tau \to \ell K^0_S$, on the other hand, has no SM counterpart, and any reduction of its experimental upper bound will translate directly into an improvement of the bounds on new physics.

Acknowledgements

We thank Swagato Banerjee, Marcella Bona, Herbert Dreiner, and Martin Hirsch for helpful discussions and communications. A portion of this work was presented by Kao at Pheno 2009. We thank the organizers for providing us with the opportunity to present our results. This work was supported by the U.S. Department of Energy, grant DE-FG05-92ER40709, Task A.

**TABLE I:** The 2$\sigma$ (95% C.L.) bounds on R-parity violating couplings with the mediating sparticle masses set to 100 GeV. The indices on $\lambda$ have been reordered using the anti-symmetry in the first two indices. The rightmost column shows the product of the 2$\sigma$ single-coupling bounds listed in Table II. The observables that provide the individual constraints are shown in brackets.
| Coupling  | 2σ bound | Observable |
|-----------|-----------|------------|
| $\lambda_{12k}$ | 0.03 $\tilde{\epsilon}_{kR}$ | $V_{ud}$ |
| $\lambda_{13k}$ | 0.05 $\tilde{\epsilon}_{kR}$ (0.03 $\tilde{\epsilon}_{kR}^*$) | $R_\tau = \Gamma(\tau \to e\nu_\tau\nu_\tau)/\Gamma(\tau \to \mu\nu_\mu\nu_\tau)$ |
| $\lambda_{23k}$ | 0.05 $\tilde{\epsilon}_{kR}$ | $R_\tau$ |
| $\lambda_{111}$ | $7 \times 10^{-1} \tilde{q}^2\tilde{g}^{1/2}$ | $0\nu\beta\beta^{(76 Ge)}$ |
| $\lambda_{11k}$ | 0.03 $\tilde{\epsilon}_{kR}$ | $V_{ud}; R_\pi = \Gamma(\pi \to e\nu_e\nu_\pi)/\Gamma(\pi \to \mu\nu_\mu\pi)$ |
| $\lambda_{12k}$ | 0.2 $\tilde{d}_{kR}$ | $R_{D^+} = \Gamma(D^+ \to \mu^+\nu_\mu K^0)/\Gamma(D^+ \to e^+\nu_e K^0)$ |
| $\lambda_{11j}$ | 0.03 $\tilde{a}_{jL}$ | $Q_{W^{(133 Cs)}}$ |
| $\lambda_{12j}$ | 0.28 $\tilde{a}_{jL}$ | $A^\mu_{13}$ |
| $\lambda_{21k}$ | 0.06 $\tilde{d}_{kR}$ (0.04 $\tilde{d}_{kR}^*$) | $R_\tau (R_{\tau\tau} = \Gamma(\tau \to \pi\nu_\pi)/\Gamma(\pi \to \mu\nu_\mu\pi))$ |
| $\lambda_{22k}$ | 0.1 $\tilde{d}_{kR}$ | $R_{D^0} = \Gamma(D^0 \to \mu^+\nu_\mu K^-)/\Gamma(D^0 \to e^+\nu_e K^-)$ |
| $\lambda_{23k}$ | 0.45 ($m_{d_{kR}} = 100 \text{ GeV}$) | $R_\mu^0 = \Gamma(Z \to \text{had})/\Gamma(Z \to \mu^+\mu^-$ |
| $\lambda_{13k}$ | 0.06 $\tilde{d}_{kR}$ (0.08 $\tilde{d}_{kR}^*$) | $R_{\tau\tau}$ |
| $\lambda_{12k}$ | 0.3 $\tilde{d}_{kR}$ | $R_{D_s}(\tau\mu) = \Gamma(D_s \to \tau\nu_\tau)/\Gamma(D_s \to \mu\nu_\mu)$ |
| $\lambda_{13k}$ | 0.58 ($m_{d_{kR}} = 100 \text{ GeV}$) | $R_\tau^\pm = \Gamma(Z \to \text{had})/\Gamma(Z \to \tau^+\tau^-)$ |

TABLE II: The 2σ bounds on single R-parity violating couplings from a variety of sources. The notation follows that of Ref. [17] with the sparticle symbol representing the sparticle mass divided by 100 GeV. Only the current best bounds are shown. The numbers have been updated from those given in Table 6.1 of Ref. [17] (page 110) taking into account the most recent data available in the Review of Particle Properties [8] and elsewhere. In particular, the bound on $\lambda_{111}$ from the weak charge of Cesium-133 uses the result of Ref. [21]. The bound on $\lambda_{111}$ from neutrinoless double beta decay uses the result of Ref. [22], utilizing the nuclear matrix elements calculated in Ref. [23]. It does not account for the pion-exchange contribution discussed in Ref. [24]. The bounds on $\lambda_{13k}$, $\lambda_{21k}$, and $\lambda_{11j}$ inside parentheses with asterisks are what they would be if the preliminary $\tau$-decay data from Babar [25] are taken into account. They are not used to calculate the numbers in the rightmost column of Table I. The bounds based on LEP data, namely those on $\lambda_{11j2}$, $\lambda_{23k}$, and $\lambda_{13k}$, have not been updated. The bounds on $\lambda_{12k}$ and $\lambda_{13k}$ are from loop effects and do not scale linearly with the squark mass. To rescale to squark masses other than $m_{d_{kR}} = 100 \text{ GeV}$, see Ref. [26]. The detailed derivation of these bounds is presented in Ref. [27], except for the bound on $\lambda_{111}$ from neutrinoless double beta decay which will be discussed separately in Ref. [28].
