Abstract We compute the number of finite dimensional irreducible modules for the algebras quantizing Nakajima quiver varieties. We get a lower bound for all quivers and vectors of framing. We provide an exact count in the case when the quiver is of finite type or is of affine type and the framing is the coordinate vector at the extending vertex. The latter case precisely covers Etingof’s conjecture on the number of finite dimensional irreducible representations for Symplectic reflection algebras associated to wreath-product groups. We use several different techniques, the two principal ones are categorical Kac–Moody actions and wall-crossing functors.

1 Introduction

1.1 Counting problem

Studying irreducible representations of algebraic objects, say of associative algebras, is the most fundamental problem in Representation theory. A basic question is how many there are. For most infinite dimensional algebras, the set of all irreducible representations is wild, in particular, the number is infinite. So it makes sense to restrict the class of representations. The most basic choice is to consider only finite dimensional ones. This is a restriction we impose in the present paper.

A classical infinite dimensional algebra appearing in Representation theory is the universal enveloping algebra \( U(g) \) of a finite dimensional Lie algebra \( g \) over \( \mathbb{C} \). Let us consider the case when the Lie algebra \( g \) is semisimple. In this case, the number of finite dimensional irreducible representations is still infinite: they are classified by dominant weights. More precisely, we consider the Cartan subalgebra \( \mathfrak{h} \subset g \) and fix a system of simple roots. We say that \( \lambda \in \mathfrak{h}^* \) is dominant if \( \langle \alpha^\vee, \lambda \rangle \in \mathbb{Z}_{\geq 0} \) for any simple root \( \alpha \). Then to \( \lambda \) we can assign the irreducible module with highest weight \( \lambda \). Those form a complete and irredundant collection of irreducible finite dimensional representations of \( g \).

However, we can modify the algebra \( U(g) \) to make the counting problem finite. Namely, recall that the center of \( U(g) \) is identified with \( S(\mathfrak{h})^W = \mathbb{C}[\mathfrak{h}^*]^W \) via the Harish-Chandra isomorphism. Here \( W \) is the Weyl group acting on \( \mathfrak{h}^* \) by \( w \cdot \lambda = w(\lambda + \rho) - \rho \), where \( \rho \), as usual, is half the sum of all positive roots. Then, for each \( \lambda \in \mathfrak{h}^*/W \), we can consider the corresponding central reduction, \( U_\lambda \), of \( U(g) \). The classification result above can be restated as follows: the algebra \( U_\lambda \) has a single finite dimensional irreducible representation if \( \langle \lambda + \rho, \alpha^\vee \rangle \) is a nonzero integer for every root \( \alpha \). Otherwise, there are no finite dimensional representations.

Another classical feature of the algebras \( U_\lambda \) is that they have a very nice underlying geometry. These algebras are filtered and the associated graded
algebras \( \text{gr} \mathcal{U}_\lambda \) are all identified with \( \mathbb{C}[\mathcal{N}] \), where \( \mathcal{N} \) stands for the nilpotent cone in \( \mathfrak{g} \). Recall the Springer resolution of singularities \( \rho : \widetilde{\mathcal{N}} \to \mathcal{N} \), where \( \widetilde{\mathcal{N}} \) is the cotangent bundle of the flag variety \( \mathcal{B} \) of \( \mathfrak{g} \). The variety \( \widetilde{\mathcal{N}} \) is smooth and symplectic, while \( \mathcal{N} \) is a singular Poisson variety. The morphism \( \rho \) is therefore a symplectic resolution of singularities.

There is a non-commutative analog of this resolution. Namely, for \( \lambda \in \mathfrak{h}^* \), we can consider the sheaf \( D_\lambda \) of \( \lambda \)-twisted differential operators on \( \mathcal{B} \). Then \( \Gamma(\mathcal{B}, D_\lambda) = \mathcal{U}_\lambda \), while all higher cohomology groups of \( D_\lambda \) vanish. So we have the global section functor \( \Gamma_\lambda : D_\lambda \text{-mod} \to \mathcal{U}_\lambda \text{-mod} \) as well as its derived version \( R\Gamma_\lambda : D^b(\mathcal{B}, \text{-mod}) \to D^b(\mathcal{U}_\lambda \text{-mod}) \). The former is an equivalence if \( \langle \lambda + \rho, \alpha^\vee \rangle / \in \mathbb{Z} \leq 0 \) for all positive roots \( \alpha \), this is the celebrated Beilinson–Bernstein theorem [3]. Its derived version [5], states that \( R\Gamma_\lambda \) is an equivalence if \( \langle \lambda + \rho, \alpha^\vee \rangle \neq 0 \) for all \( \alpha \).

Using the results of the previous paragraph one can give a geometric interpretation of the classification of finite dimensional irreducible representations. Namely, under the abelian Beilinson–Bernstein equivalence, the finite dimensional modules correspond to the \( D_\lambda \)-modules whose singular support is contained in \( \mathcal{B} \subset \widetilde{\mathcal{N}} \), i.e., to the \( \mathcal{O} \)-coherent \( D_\lambda \)-modules. It is easy to see that such a module exists if and only if \( \lambda \) is integral, in which case it is the line bundle on \( \mathcal{B} \) corresponding to \( \lambda \).

### 1.2 Etingof’s conjecture

Another interesting class of associative algebras is Symplectic reflection algebras introduced by Etingof and Ginzburg in [27]. Those are filtered deformations of the skew-group algebras \( S(V)\#\Gamma \), where \( V \) is a symplectic vector space and \( \Gamma \) is a finite subgroup of \( \text{Sp}(V) \). The symplectic reflection algebras \( \mathcal{H}_c \) for the pair \( (V, \Gamma) \) form a family depending on a collection \( c \) of complex numbers.

One especially interesting class of groups \( \Gamma \) comes from finite subgroups of \( \text{SL}_2(\mathbb{C}) \). Namely, pick such a subgroup \( \Gamma_1 \subset \text{SL}_2(\mathbb{C}) \) and form the semidirect product \( \Gamma(\Gamma_1) := \mathcal{S}_n \ltimes \Gamma_1^n \), where \( \mathcal{S}_n \) stands for the symmetric group on \( n \) letters. The group \( \Gamma_1^n \) naturally acts on \( \mathbb{C}^{2n} = (\mathbb{C}^2)^{\oplus n} \) by symplectomorphisms. Here elements of \( \mathcal{S}_n \) permute the \( n \) summands \( \mathbb{C}^2 \), the \( n \) copies of \( \Gamma_1 \) act each on its own summand, and the symplectic form on \( (\mathbb{C}^2)^{\oplus n} \) is obtained as the direct sum of the \( n \) copies of a \( \Gamma_1 \)-invariant symplectic form on \( \mathbb{C}^2 \). For \( n > 1 \), the algebra \( \mathcal{H}_c \) depends on \( r \) parameters, where \( r \) is the number of conjugacy classes in \( \Gamma_1 \) (for \( n = 1 \), the number of parameters is \( r - 1 \)). So one can ask, how many finite dimensional irreducibles does the algebra \( \mathcal{H}_c \) have? The answer, of course, should depend on the parameter \( c \).

In [26, Section 6], Etingof proposed a conjectural answer to this and more general questions. The conjecture takes the following form. Recall that the
finite subgroups of $\text{SL}_2(\mathbb{C})$ are in one-to-one (McKay) correspondence with the affine Dynkin diagrams. Take the affine Dynkin diagram, say $Q$, corresponding to $\Gamma_1$ and form the Kac–Moody algebra $\mathfrak{g}(Q)$ from this diagram. Then Etingof defines a certain subalgebra $\alpha \subset \mathfrak{g}(Q) \times \mathfrak{heis}$ depending on $c$, where $\mathfrak{heis}$ stands for the Heisenberg Lie algebra. Next, he considers the module $V \otimes \mathcal{F}$, where $V$ is the basic representation of $\mathfrak{g}(Q)$ (whose highest weight is the fundamental weight corresponding to the extending vertex of $Q$) and $\mathcal{F}$ is the Fock space representation of $\mathfrak{heis}$. Then Etingof takes an appropriate weight subspace in that representation and considers its intersection with the sum of certain $\alpha$-isotypic components. The conjecture is that the number of finite dimensional irreducibles is the dimension of the resulting intersection.

Etingof’s conjecture (in fact, its more general version dealing with the number of irreducibles with given support in a category $\mathcal{O}$) was proved in the case when $\Gamma_1$ is cyclic by Shan and Vasserot [62, Section 6] (under some technical restrictions on $c$ that were removed in [44, Appendix]). The techniques used in [62] are based on the representation theory of rational Cherednik algebras and do not generalize to the case of non-cyclic $\Gamma_1$.

The main goal of this paper is to prove Etingof’s conjecture on counting finite dimensional irreducibles for all groups $\Gamma_1$. But, first, we put this problem into a more general context: counting finite dimensional irreducible representations over quantizations of symplectic resolutions.

### 1.3 Quantizations of symplectic resolutions

Inside $\mathcal{H}_c$ we can consider the spherical subalgebra, $e\mathcal{H}_c e$, where $e$ is the averaging idempotent. This algebra is a filtered deformation of $S(V)^\Gamma$. By [26, Theorem 5.5], $e\mathcal{H}_c e$ is Morita equivalent to $\mathcal{H}_c$ if and only if $e\mathcal{H}_c e$ has finite homological dimension (the parameter $c$ is called spherical in this case). Under this assumption, the numbers of finite dimensional irreducibles for $\mathcal{H}_c$ and $e\mathcal{H}_c e$ coincide.

When $\Gamma = \Gamma_n$, the variety $V/\Gamma_n$ can be realized as an affine Nakajima quiver variety. It admits a symplectic resolution of singularities that is a smooth Nakajima quiver variety. The algebra $e\mathcal{H}_c e$ can be realized as a quantum Hamiltonian reduction, see [28,42] and references therein (we briefly recall this below in Sect. 2.2.6). Also we can quantize the symplectic resolution getting a sheaf of algebras on that symplectic variety. So we again have a nice geometry as in the case of universal enveloping algebras.

There are other algebras that quantize (i.e., are filtered deformations of) affine Poisson varieties admitting symplectic resolutions and it is natural to expect that the counting problems for these algebras have some nice answers that have to do with the geometry of the resolution. There are three known large classes of resolutions giving rise to interesting algebras. First, there are more
general Nakajima quiver varieties, the corresponding algebras are obtained as quantum Hamiltonian reductions of algebras of differential operators. Second, there are Slodowy varieties that generalize cotangent bundles to (partial) flag varieties. The corresponding algebras are finite W-algebras generalizing the universal enveloping algebras. The counting problem for W-algebras was studied by the second author and Ostrik in [51] (in the case of integral central characters) and by the authors of this paper in [13] (in general), below we will briefly mention how the answer looks like in that case. Third, there are hypertoric varieties that are similar to but much easier than Nakajima quiver varieties, this case is treated in [16].

In this paper we concentrate on the case of Nakajima quiver varieties. In Sect. 1.4 we recall necessary definitions.

1.4 Nakajima quiver varieties and their quantizations

In this section we briefly recall Nakajima quiver varieties and their quantizations. We will elaborate more on their properties in Sect. 2.

Let \( Q \) be a quiver (=oriented graph, we allow loops and multiple edges). We can formally represent \( Q \) as a quadruple \((Q_0, Q_1, t, h)\), where \( Q_0 \) is a finite set of vertices, \( Q_1 \) is a finite set of arrows, \( t, h : Q_1 \to Q_0 \) are maps that to an arrow \( a \) assign its tail and head.

Pick vectors \( v, w \in \mathbb{Z}^{Q_0}_{\geq 0} \) and vector spaces \( V_i, W_i \) with \( \dim V_i = v_i, \dim W_i = w_i \). Consider the (co)framed representation space

\[
R = R(Q, v, w) := \bigoplus_{a \in Q_1} \text{Hom}(V_{t(a)}, V_{h(a)}) \oplus \bigoplus_{i \in Q_0} \text{Hom}(V_i, W_i). 
\]

We will also consider the cotangent bundle \( T^* R = R \oplus R^* \) that can be identified with

\[
\bigoplus_{a \in Q_1} \left( \text{Hom}(V_{t(a)}, V_{h(a)}) \oplus \text{Hom}(V_{h(a)}, V_{t(a)}) \right) \oplus \bigoplus_{i \in Q_0} \left( \text{Hom}(V_i, W_i) \oplus \text{Hom}(W_i, V_i) \right). 
\]

The space \( T^* R \) carries a natural symplectic form, denote it by \( \omega \). On \( R \) we have a natural action of the group \( G := \prod_{i \in Q_0} \text{GL}(v_i) \). This action extends to an action on \( T^* R \) by linear symplectomorphisms. As any action by linear symplectomorphisms, the \( G \)-action on \( T^* R \) admits a moment map, i.e., a \( G \)-equivariant morphism \( \mu : T^* R \to g^* \) with the property that \( \{ \mu^*(x), \bullet \} = x_{T^* R} \) for any \( x \in g \). Here \( \mu^* : g \to \mathbb{C}[T^* R] \) denotes the dual map to \( \mu \), \( \{ \bullet, \bullet \} \) is the Poisson bracket on \( \mathbb{C}[T^* R] \) induced by \( \omega \), and \( x_{T^* R} \) is the vector field
on $T^*R$ induced by $x$ via the $G$-action. Also we consider the dilation action of the one-dimensional torus $\mathbb{C}^\times$ on $T^*R$ given by $t.r = t^{-1}r$. We specify the moment map uniquely by requiring that it is quadratic: $\mu(t.r) = t^{-2}\mu(r)$. In this case $\mu^x(x) = x_R$, where we view $x_R$, an element of $\text{Vect}_R$, as a function on $T^*R$.

In what follows, $Q$ and $w$ are often fixed, but $v$ will vary.

Now let us proceed to the definition of Nakajima quiver varieties. Pick a character $\theta$ of $G$ (below we will often call $\theta$ a stability condition) and also an element $\lambda \in (\mathfrak{g}/[\mathfrak{g}, \mathfrak{g}])^*$. To $\theta$ we associate an open subset $(T^*R)^{\theta-ss}$ of $\theta$-semistable points in $T^*R$ (that may be empty). Recall that a point $r \in T^*R$ is called $\theta$-semistable if there is a $(G, n\theta)$-semiinvariant (with $n > 0$) polynomial $f \in \mathbb{C}[T^*R]$ such that $f(r) \neq 0$.

We can form the GIT quotient $M^\theta_\lambda(v) := (\mu - 1(\lambda) \cap (T^*R)^{\theta-ss})//G$ (we omit the subscript when $\lambda = 0$). This variety is smooth provided $(\lambda, \theta)$ is generic (we will explain the precise meaning of this condition in Sect. 2.1.1). The variety $M^0_\lambda(v)$ is affine and there is a projective morphism $\rho : M^\theta_\lambda(v) \to M^0_\lambda(v)$. There is a sufficient condition for this morphism to be a resolution of singularities that will be recalled in Sect. 2.1.7. We remark that all varieties $M^\theta_\lambda(v)$ carry natural Poisson structures because they are defined as Hamiltonian reductions. For a generic pair $(\lambda, \theta)$, the variety $M^\theta_\lambda(v)$ is symplectic. Also we remark that we have an action of $\mathbb{C}^\times$ on $M^\theta_\lambda(v)$ that comes from the dilation action on $T^*R$ and so rescales the symplectic form.

Now let us briefly recall Nakajima’s construction of a geometric $\mathfrak{g}(Q)$-action on the middle homology groups of the varieties $M^\theta_\lambda(v)$, we assume $Q$ has no loops and $\theta$ is generic. Consider the space $\bigoplus_v H_{\text{mid}}(M^\theta_\lambda(v))$, where the subscript “mid” means the middle dimension, i.e., $\dim_{\mathbb{C}} M^\theta_\lambda(v)$. We remark that these spaces are naturally identified for different $\theta$, see [56, Section 9], this result is recalled in Sect. 2.1.8.

Nakajima [56], defined an action of $\mathfrak{g}(Q)$ on $\bigoplus_v H_{\text{mid}}(M^\theta_\lambda(v))$ turning that space into the irreducible integrable $\mathfrak{g}(Q)$-module $L_\omega$ with highest weight

$$\omega := \sum_{i \in Q_0} w_i \omega^i, \quad (1.1)$$

where we write $\omega^i$ for the fundamental weight corresponding to the vertex $i$. The individual space $H_{\text{mid}}(M^\theta_\lambda(v))$ gets identified with the weight space $L_\omega[v]$ of weight $v$, where

$$v := \omega - \sum_{i \in Q_0} v_i \alpha^i \quad (1.2)$$
(we write $\alpha^i$ for the simple root corresponding to $i$). We note that the identification is determined by the choice of a highest weight vector in $L_\omega[\omega]$ and so is defined up to a scalar multiple.

Now we proceed to the quantum part of this story. Let us start by constructing quantizations of $\mathcal{M}^\theta(v)$ that will be certain sheaves of filtered algebras on $\mathcal{M}^{\theta}(v)$. Namely, consider the algebra $D(R)$ of differential operators on $R$. We can localize this algebra to a microlocal (the sections are only defined on $C^\infty$-stable open subsets) sheaf on $T^*R$ denoted by $D_R$. We have a quantum comoment map $\Phi : g \to D(R)$ quantizing the classical comoment map $g \to C[[T^*R]]$, still $\Phi(x) = x_R$.

Now fix $\lambda \in C^\mathbb{Q}$ and a generic $\theta$. We get the quantum Hamiltonian reduction sheaf $\mathcal{A}_\lambda^\theta(v) := \pi^*[D_R/D_R[\Phi(x) - \langle \lambda, x \rangle | x \in g]]_{(T^*R)^{\theta-ss}}^G$ on $\mathcal{M}^\theta(v)$, here $\pi$ is the quotient morphism $\mu^{-1}(0)^{\theta-ss} \to \mathcal{M}^\theta(v)$. This is a sheaf of filtered algebras with $\text{gr} \mathcal{A}_\lambda^\theta(v) = \mathcal{O}_{\mathcal{M}^\theta(v)}$. In fact, because of this, it has no higher cohomology, and $\Gamma(\mathcal{A}_\lambda^\theta(v))$ satisfies $\text{gr} \Gamma(\mathcal{A}_\lambda^\theta(v)) = \mathbb{C}[\mathcal{M}^\theta(v)]$. Further, one can show that $\Gamma(\mathcal{A}_\lambda^\theta(v))$ is independent of $\theta$, we will write $\mathcal{A}_\lambda(v)$ for that algebra. When $\mu$ is flat or $\lambda$ is Zariski generic, then $\mathcal{A}_\lambda(v)$ coincides with $\mathcal{A}_\lambda^0(v) := [D(R)/D(R)[\Phi(x) - \langle \lambda, x \rangle | x \in g]]^G$, we will elaborate on this in Sect. 2.2.

1.5 Main conjecture

Our ultimate goal is to compute the number of finite dimensional irreducible representations of $\mathcal{A}_\lambda(v)$ or, equivalently, to compute $K_0(\mathcal{A}_\lambda(v) \text{-mod}_{fin})$ (we consider all $K_0$’s over $C$). For this, we need to relate the categories of modules for $\mathcal{A}_\lambda(v)$ and for $\mathcal{A}_\lambda^\theta(v)$ with generic $\theta$. Consider the category $\mathcal{A}_\lambda^\theta(v) \text{-mod}$ of all coherent $\mathcal{A}_\lambda^\theta(v)$-modules and also its derived analog $D^b(\mathcal{A}_\lambda^\theta(v) \text{-mod})$ (see Sect. 2.3 for the definitions). Then we have the derived global sections functor $R\Gamma^\theta_\lambda : D^b(\mathcal{A}_\lambda^\theta(v) \text{-mod}) \to D^b(\mathcal{A}_\lambda(v) \text{-mod})$. As McGerty and Nevins checked in [54, Theorem 1.1] (under some technical conditions [54, Assumptions 3.2]), this functor is an equivalence if and only if the algebra $\mathcal{A}_\lambda(v)$ has finite homological dimension. The inverse of $R\Gamma^\theta_\lambda$ is the derived localization functor $L \text{Loc}^\theta_\lambda := \mathcal{A}_\lambda^\theta(v) \otimes_{\mathcal{A}_\lambda(v)}^L$. In the majority of interesting cases, the precise locus of $\lambda$, where the homological dimension is finite (such $\lambda$ are called regular), is not known. Conjecturally, the regular locus should be the complement of a finite union of hyperplanes, see Sect. 4.3. In this paper we deal with the counting problem only in the case when $\lambda$ is regular, and we make a conjecture on the answer in general, Conjecture 12.8.
For an object in $\mathcal{A}^{\theta}(v)$-mod, one can define its (singular) support, a $\mathbb{C}^\times$-stable coisotropic subvariety of $\mathcal{M}^{\theta}(v)$, and the characteristic cycle, $CC_v(M)$, see Sect. 2.4. The equivalence $R\Gamma^\theta_\lambda$ identifies the following two categories:

- the full subcategory $D^b_{fin}(A_\lambda(v)$-mod) $\subset D^b(A_\lambda(v)$-mod) of all complexes with finite dimensional homology
- and the full subcategory $D^b_{\rho^{-1}(0)}(A_\lambda(v)$-mod) $\subset D^b(A_\lambda(v)$-mod) of all complexes whose homology is supported on (i.e., has support contained in) $\rho^{-1}(0)$.

Since $\rho^{-1}(0)$ is an isotropic subvariety in $\mathcal{M}^{\theta}(v)$, the characteristic cycle of a module supported on $\rho^{-1}(0)$ is a combination of the lagrangian irreducible components of $\rho^{-1}(0)$ (this is a consequence of the Gabber involutivity theorem recalled in Sect. 2.4), let us denote the set of lagrangian components by $\text{comp}$. So we get a linear map

$$CC_\lambda, v : K_0(A_\lambda(v)$-mod $\to \mathbb{C}^{\text{comp}}$. (1.3)$$

The space $\mathbb{C}^{\text{comp}}$ is identified with $H_{\text{mid}}(\mathcal{M}^{\theta}(v)) = L_\omega[v]$ and so is canonically independent of $\theta$. We will see below, Sect. 8.3, that $CC_\lambda, v$ is actually independent of $\theta$. By an unpublished result of Baranovsky and Ginzburg [2], the map $CC_\lambda, v$ is injective (since this result is not published yet, we actually give a proof of this result for quantized quiver varieties in the cases we consider in this paper). So, to solve our counting problem, we just need to describe the image of $CC_\lambda = \bigoplus_v CC_\lambda, v$.

Our conjectural description is inspired by Etingof’s conjecture. Namely, consider the subalgebra $a \subset g(Q)$ constructed from $\lambda$ as follows: the algebra $a$ is generated by the Cartan $h \subset g(Q)$ and all root subspaces $g(Q)_\beta$ for real roots $\beta = \sum_{i \in Q_0} b_i \alpha^i$ with $\sum_{i \in Q_0} b_i \lambda_i \in \mathbb{Z}$. For instance, if $\lambda$ is generic, then $a = h$, while if all $\lambda_i \in \mathbb{Z}$, then $a = g(Q)$ provided $Q$ contains no loops. Let $L^a_\omega$ be the $a$-submodule of $L_\omega$ generated by the weight spaces $L_\omega[\sigma \omega]$ for $\sigma \in W(Q)$, where $W(Q)$ stands for the Weyl group of $g(Q)$.

**Conjecture 1.1** Assume that $Q$ has no loops. Then we have $\text{Im } CC_\lambda = L^a_\omega$.

Let us point out that the case when $Q$ has a loop is non-interesting for our counting problem as stated: the answer is 0 (provided the dimension in the corresponding vertex is positive, if it is zero, then the loop does not matter anyway). In this case, the algebra $A_\lambda(v)$ decomposes into the tensor product of $D(\mathbb{C}^k)$, the algebra of differential operators on $\mathbb{C}^k$, where $k$ is the number of loops, and of another algebra, say $\tilde{A}$. The former has no finite dimensional representations. Of course, it is an interesting question to count the finite dimensional irreducible representations of $\tilde{A}$. At present, the answer to this question is known for the case of Jordan quiver, see [50].
We remark that the dimension vectors \( v \) corresponding to \( \nu = \sigma \omega \) are precisely those with \( M^{\theta}(v) = \{ \text{pt} \} \) and hence \( A_{\lambda}(v) = \mathbb{C} \). In particular, if \( \lambda \) is Weil generic (which, by definition, means a parameter lying outside countably many proper subvarieties), then our conjecture predicts that a non-trivial algebra \( A_{\lambda}(v) \) has no finite dimensional representations, as expected. The other extreme is when \( \lambda \) is integral. Here our conjecture predicts that \( \text{Im} \mathcal{C} = L_{\omega} \). This follows from the work of Webster [63, Section 3], see Sect. 5.2 for details.

Here is the main result of the present paper.

**Theorem 1.2** Conjecture 1.1 is true

- when \( Q \) is of finite type,
- or when \( Q \) is an affine quiver, \( v = n\delta, w = \epsilon_0 \).

Here and below we write \( \delta \) for the indecomposable imaginary root of \( Q \) and \( \epsilon_0 \) for the coordinate vector at the extending vertex.

Let us notice that (ii) precisely covers the algebras of interest for Etingof’s conjecture. In fact, that conjecture follows from Theorem 1.2 and results of [33], we will elaborate on that in Sect. 12.3.

In a subsequent paper [49] the second author proves Conjecture 1.1 for affine type quivers with arbitrary framing.

We also would like to point out that there is a very similar result for finite \( W \)-algebras \( U(\mathfrak{g}, e) \), see [51, Theorem 1.1], [13, Theorem 1.1] (here \( \mathfrak{g} \) is a semisimple Lie algebra and \( e \in \mathfrak{g} \) is a nilpotent element). The role of \( M^{\theta}(v) \) is played by the Slodowy variety \( \tilde{S} \) that is obtained as follows. We take the transversal Slodowy slice \( S \) to the \( G \)-orbit of \( e \) in \( \mathfrak{g} \), and for \( \tilde{S} \) take the preimage of \( S \) in \( \tilde{N} \). The zero fiber \( \rho^{-1}(0) \) becomes the Springer fiber \( B_e \). Therefore \( H_{\text{mid}}(B_e) \) is the Springer representation of the Weyl group \( W(\mathfrak{g}) \) of \( \mathfrak{g} \). So instead of \( \mathfrak{g}(Q) \) we need to consider \( W(\mathfrak{g}) \), and instead of \( \alpha \) we take the integral Weyl group \( W' \) corresponding to a given central character. Then \( K_0 \) of the finite dimensional representations coincides with the sum of certain isotypic components for \( W' \), see [13, Introduction] for details. One could expect that for a general symplectic resolution \( X \) one should be able to state a conjecture on \( K_0 \) of finite dimensional representations using the monodromy representation associated to the quantum connection but specifics of this are not clear at the moment, at least to the authors.

### 1.6 Content of the paper

The paper roughly splits into two parts. The first part, consisting of Sects. 2, 3, 4, 5 is (mostly) preparatory: there we recall known results (or their generalizations to settings we need) as well as prove some technical generalizations
that we will need. In Sect. 2 we recall preliminaries on Nakajima quiver varieties, their quantizations, coherent modules over sheaf quantizations, supports and characteristic cycles and Hamiltonian reduction functors. In Sect. 3 we recall Harish–Chandra (HC) bimodules, construct restriction functors for HC bimodules in our setting and describe some applications of these functors. In Sect. 4 we discuss abelian and derived localization theorems. In Sect. 5 we will introduce two main players in the proof of Theorem 1.2 – the Webster functors and the wall-crossing functors.

Section 6 outlines the main ideas and steps of the proof of Theorem 1.2. We will describe the content of the subsequent sections in the end of Sect. 6.

1.7 Notation

The following table contains various notation used in the paper (we first list the notation starting with Roman letters in, roughly, the alphabetical order and then list the notation starting with a Greek letter).

| Notation | Description |
|----------|-------------|
| \(\hat{\otimes}\) | the completed tensor product of complete topological vector spaces/ modules. |
| \(\mathcal{A}\) \(_{\text{opp}}\) | the opposite algebra of \(\mathcal{A}\). |
| \((a_1, \ldots, a_k)\) | the two-sided ideal in an associative algebra generated by elements \(a_1, \ldots, a_k\). |
| \(A^\wedge\chi\) | the completion of a commutative (or “almost commutative”) algebra \(A\) with respect to the maximal ideal of a point \(\chi \in \text{Spec}(A)\). |
| \(\mathcal{A}_\lambda^\theta(v)\) | := \([\mathcal{Q}_\lambda|_{T^*R^{\theta-ss}}]^G\) |
| \(\mathcal{A}_\lambda(v)\) | := \(\Gamma(\mathcal{A}_\lambda^\theta(v))\). |
| \(\mathcal{A}_{\lambda,\chi}^\theta(v)\) | := \([\mathcal{Q}_\lambda|_{T^*R^{\theta-ss}}]^{G,\chi}\), where \(\chi\) is a character of \(G\), and the superscript \((G, \chi)\) means taking \(\chi\)-semiinvariants. |
| \(a^{(\theta)}\lambda\) | the subalgebra in \(g(Q)\) generated by Cartan \(h\) and real root subspaces \(g(Q)\beta\) with \(\beta \cdot \lambda \in \mathbb{Z}\). |
| \(\mathcal{A}_{\lambda,\chi}^{(\theta)}(v)\) | := \(\Gamma(\mathcal{A}_{\lambda,\chi}^\theta(v))\). |
| \(\mathcal{A}\) \(-\text{mod}\) | the category of finitely generated modules over an associative algebra \(\mathcal{A}\). |
| \(\mathcal{AC}(Y)\) | the asymptotic cone of a subvariety \(Y \subset \mathbb{C}^n\). |
| \(\mathcal{AL}(v)\) | the set of \(\lambda \in \mathfrak{P}\) such that \(\Gamma_\lambda^\theta\) is an abelian equivalence. |
| \(\text{Ann}_{\mathcal{A}}(M)\) | the annihilator of an \(\mathcal{A}\)-module \(M\) in an algebra \(\mathcal{A}\). |
| \(\mathcal{C}\) | the full subcategory of \(\bigoplus_v \mathcal{A}_{\lambda}^\theta(v)\) \(-\text{mod}\) \(_{\rho^{-1}(0)}\) defined in Sect. 6.2. |
| \(\mathcal{CC}(M)\) | the characteristic cycle of a module/sheaf of modules \(M\). |
| \(\mathcal{D}^b_{\text{fin}}(\mathcal{A}_\lambda(v)\) \(-\text{mod}\)) | := \{M \in \mathcal{D}^b(\mathcal{A}_\lambda(v)\) \(-\text{mod}\)) \mid \dim H^*_s(M) < \infty\}. |
| \(\mathcal{D}^b_{\rho^{-1}(0)}(\mathcal{A}_\lambda^\theta(v)\) \(-\text{mod}\)) | := \{M \in \mathcal{D}^b(\mathcal{A}_\lambda^\theta(v)\) \(-\text{mod}\)) \mid \text{Supp} H^*_s(M) \subset \rho^{-1}(0)\}. |
| \(\mathcal{D}(R)\) \(-\text{mod}^{G,\lambda}\) | the category of \((G, \lambda)\)-equivariant finitely generated \(\mathcal{D}(R)\)-modules. |
| \(\mathcal{D}(X)\) | the algebra of differential operators on a smooth affine variety \(X\). |
\( D_X \)
the differential operators on a smooth variety \( X \) viewed as microlocal sheaf on \( T^*X \).

\( \text{Frac}(A) \)
the fraction field of a commutative domain \( A \).

\( G^0 \)
the connected component of unit in an algebraic group \( G \).

\( (G, G) \)
the derived subgroup of a group \( G \).

\( G_x \)
the stabilizer of \( x \) in \( G \).

\( G \times_H V \)
the homogeneous bundle on \( G/H \) with fiber \( V \).

\( g(Q) \)
the Kac–Moody algebra associated to a quiver \( Q \).

\( \gr A \)
the associated graded vector space of a filtered vector space \( A \).

\( \text{Irr}(C) \)
the set of simple objects in an abelian category \( C \).

\( K_0(C) \)
the (complexified) Grothendieck group of an abelian (or triangulated) category \( C \).

\( L_{\omega} \)
the irreducible integrable representation of \( g(Q) \) with highest weight \( \omega \).

\( L_{\omega}[v] \)
the \( v \)-weight space in \( L_{\omega} \).

\( \text{Loc}^\theta \)
localization functor \( \mathcal{A}_{\lambda}(v)^{\text{-mod}} \to \mathcal{A}_\lambda^\theta(v)^{\text{-mod}} \).

\( \Delta_{\lambda}(v)^{\cdot} \)
the derived left adjoint to \( \pi_{\lambda}^\theta(v) \).

\( \mathcal{M}_{\lambda}(v) \)
:= Spec(\mathbb{C}[\mathcal{M}_\lambda^\theta(v)]) for generic \( \theta \).

\( \mathfrak{p} \)
:= \mathbb{C} O^0, the parameter space for classical reduction.

\( \mathfrak{p} \)
:= \mathbb{C} O^0, the parameter space for quantum reduction.

\( \mathfrak{p}^{\text{I}so} \)
the locus of \( \lambda \in \mathfrak{p} \) such that \( \mathcal{A}_\lambda^0(v) \cong \mathcal{A}_\lambda(v) \).

\( \mathfrak{p}^{\text{I}SO} \)
a locus of \( \lambda \in \mathfrak{p}^{\text{I}so} \) with \( \text{Tor}^1_{\mathfrak{g}}(D(R), \mathcal{C}_\lambda) = 0 \) for \( i > 0 \).

\( \mathcal{Q}_{\lambda} \)
:= \( D(R)/D(R)(\Phi(x) - \langle \lambda, x \rangle, x \in \mathfrak{g}) \).

\( R \)
:= \( R(Q, v, w) := \bigoplus_{a \in Q_1} \text{Hom}(V_{(a)}, V_{h(a)}) \oplus \bigoplus_{k \in Q_0} \text{Hom}(V_k, W_k) \), the

coframed representation space of a quiver \( Q \) with dimension \( v \) and framing \( w \).

\( R_h(A) \)
:= \bigoplus_{i \in \mathbb{Z}} h^i F_i A : the Rees \( \mathbb{C}[h] \)-module of a filtered vector space \( A \).

\( \mathcal{G}_n \)
the symmetric group on \( n \) letters.

\( S(V) \)
the symmetric algebra of a vector space \( V \).

\( \text{Supp}(M) \)
the support of the module/sheaf of modules \( M \).

\( \text{Supp}_B^B(B) \)
:= \{ \lambda \in \mathfrak{p} | B \otimes_{\mathbb{C}[\mathfrak{p}]} \mathcal{C}_\lambda \neq \{0\} \}.

\( \mathcal{W}(Q) \)
the Weyl group of \( g(Q) \).

\( \mathcal{W}_{\mathfrak{g}^{\mathfrak{g}^{\text{C}}}}^{\mathfrak{g} \to \lambda'} \)
a wall-crossing functor.

\( \hat{u}_i \)
:= \( u_i + \sum_{a, a(t)(a) = i} v_{h(a)} \) (for a source \( i \in Q_0 ) \).

\( \lambda^{\theta - \text{ss}} \)
the open locus of \( \theta \)-semistable points for an action of a reductive group \( G \) on an

affine algebraic variety \( X \), where \( \theta \) is a character of \( G \).

\( \lambda^{\theta - \text{uns}} \)
:= \( X \setminus \lambda^{\theta - \text{ss}} \).

\( x \cdot y \)
:= \( \sum_{i \in Q_0} x_i y_i \).

\( (x, y) \)
:= \( 2 \sum_{k \in Q_0} x_k y_k - \sum_{a \in Q_1} (x_{t(a)} y_{h(a)} + x_{h(a)} y_{t(a)}) \), the symmetrized Tits form.

\( \Gamma_n \)
:= \( \mathcal{G}_n \ltimes \Gamma_n^1 \) for a finite subgroup \( \Gamma_1 \subset \text{SL}_2(\mathbb{C}) \).

\( \Gamma_\lambda^{\theta} \)
the global section functor \( \mathcal{A}_\lambda^\theta(v)^{\text{-mod}} \to \mathcal{A}_\lambda(v)^{\text{-mod}} \).

\( \mu \)
the moment map \( T^*R \to \mathfrak{g} \).

\( \nu \)
the weight of \( g(Q) \) determined from dimension vector \( v \) and framing \( w \).

\( \pi_{\lambda}^0(v) \)
the natural functor \( D(R)^{\text{-mod}} \to \mathcal{A}_\lambda^0(v)^{\text{-mod}} \) (or its derived analog).

\( \pi_{\lambda}^\theta(v) \)
the natural functor \( D_R^{\text{-mod}} \to \mathcal{A}_\lambda^\theta(v)^{\text{-mod}} \) (or its derived analog).

\( \rho \)
the natural projective morphism \( \mathcal{M}_\lambda^\theta(v) \to \mathcal{M}_\lambda^0(v) \) or \( \mathcal{M}_\lambda^\theta(v) \to \mathcal{M}_\lambda(v) \).
\[ \sigma \cdot v \text{ dimension vector corresponding to } \sigma v, \sigma \in W(Q). \]
\[ \sigma \cdot v \lambda \text{ the quantization parameter determined by } \sigma \in W(Q), v \in \mathbb{Z}_{\geq 0}, \lambda \in \Psi. \]
\[ \omega \text{ the dominant weight of } g(Q) \text{ determined from framing } w. \]

## 2 Preliminaries on quiver varieties and their quantizations

### 2.1 Properties of quiver varieties

#### 2.1.1 Generic parameters

First of all, let us recall a description of generic values of \((\lambda, \theta)\), which, by definition, means that the \(G\)-action on \(\mu^{-1}(\lambda)^{\theta-ss}\) is free, due to Nakajima [56, Theorem 2.8]. Namely, \((\lambda, \theta)\) is generic provided there is no \(v' \in \mathbb{Z}_{\geq 0}\) such that

- \(v' \leq v\) (component-wise),
- \(\sum_{i \in Q_0} v_i \alpha_i^t\) is a root for \(g(Q)\),
- and \(v' \cdot \theta = v' \cdot \lambda = 0\) (where we write \(v' \cdot \lambda\) for \(\sum_{i \in Q_0} v'_i \lambda_i\)).

We say that \(\lambda\) (resp., \(\theta\)) is generic if \((\lambda, 0)\) (resp., \((0, \theta)\)) is generic. We write \(p\) for \(\mathbb{C}^{Q_0}\), the space of parameters \(\lambda\). The set of non-generic \(\lambda\)'s will be denoted by \(p^{\text{sing}}\) (or \(p^{\text{sing}}(v)\) when we need to indicate the dependence on \(v\)). It is easy to see that \(p^{\text{sing}}\) is a union of hyperplanes all of which have the form \(\{\lambda | \lambda \cdot v' = 0\}\) for \(v'\) as above, however, a priori, not all \(v'\) as above actually appear.

We note that by results of Crawley-Boevey [23, Section 1, Remarks], \(\mathcal{M}_\lambda^0(v)\) is connected when \((\lambda, \theta)\) is generic.

Since \(\mathcal{M}_\lambda^0(v)\) is defined as a categorical quotient, and \(\mathcal{M}_\lambda^\theta(v)\) is defined as a GIT quotient, we have a natural projective morphism \(\rho : \mathcal{M}_\lambda^\theta(v) \to \mathcal{M}_\lambda^0(v)\). We note that, for a generic \(\lambda\), the open locus \(\mu^{-1}(\lambda)^{\theta-ss}\) coincides with \(\mu^{-1}(\lambda)\). In particular, for a generic \(\lambda\), the morphism \(\rho\) is an isomorphism.

#### 2.1.2 Line bundles

For a character \(\chi\) of \(G\), we consider the line bundle \(\mathcal{O}(\chi)\) on \(\mathcal{M}_\lambda^\theta(v)\) whose sections are given by

\[ \Gamma(U, \mathcal{O}(\chi)) = \mathbb{C}[\pi^{-1}(U)]^{G,K} := \{ f \in \mathbb{C}[\pi^{-1}(U)] | g.f = \chi(g)f, \forall g \in G \}. \]

Here \(g.f\) stands for the function defined by \((g.f)(x) := f(g^{-1}x)\), \(U \subset \mathcal{M}_\lambda^\theta(v)\) is an affine open subset, and \(\pi\) stands for the quotient morphism \(\mu^{-1}(0)^{\theta-ss} \to \mathcal{M}_\lambda^\theta(v)\). By the very definition, \(\mathcal{O}(\theta)\) is an ample line bundle.
2.1.3 LMN isomorphisms

Now let us discuss certain isomorphisms of quiver varieties. For $\sigma \in W(Q)$, we have an isomorphism $M_{\sigma}(v) \cong M_{\sigma \vartheta}(\sigma \bullet v)$, where we assume that $(\lambda, \theta)$ is generic. Here we write $\sigma \bullet v$ for the dimension vector that produces the weight $\sigma v$ via (1.2). For a simple reflection $\sigma = s_k$, we have $(s_k \bullet v)_k = w_k + \sum_{a, t(a) = k} v_h(a) + \sum_{a, h(a) = k} v_t(a) - v_k$.

The existence of such isomorphisms was conjectured by Nakajima in [56] and first proved by Maffei in [53] and, independently, by Nakajima [59], a closely related construction was found by Lusztig [52]. So we call those LMN isomorphisms.

Below we will need a (slightly rephrased) construction of LMN isomorphisms due to Maffei. Let us construct an isomorphism corresponding to a simple reflection $s_i \in W(Q)$ following [53]. We may assume that the vertex $i$ is a source and, since $(\lambda, \theta)$ is generic, that either $\lambda_i \neq 0$ or $\theta_i > 0$ (if $\theta_i < 0$, then we just construct an isomorphism for $s \theta$). Let

$$\tilde{W}_i := W_i \bigoplus \bigoplus_{a, t(a) = i} V_{h(a)}, \tilde{w}_i := \dim \tilde{W}_i$$

so that $v_i + (s_i \bullet v)_i = \tilde{w}_i$. Set

$$R(= R_i) := \bigoplus_{a, t(a) \neq i} \operatorname{Hom}(V_{t(a)}, V_{h(a)}) \bigoplus \bigoplus_{j \neq i} \operatorname{Hom}(V_j, W_j), G := \prod_{j \neq i} \operatorname{GL}(V_j),$$

so that $R = R \bigoplus \operatorname{Hom}(V_i, \tilde{W}_i)$. Consider the Hamiltonian reduction

$$T^* R \parallel_{\lambda_i} \operatorname{GL}(v_i) = T^* \operatorname{Hom}(V_i, \tilde{W}_i) \parallel_{\lambda_i} \operatorname{GL}(v_i) \times T^* R.$$ 

Let us remark that if $\lambda_i = 0$, the reduction $T^* \operatorname{Hom}(V_i, \tilde{W}_i) \parallel_{\lambda_i} \operatorname{GL}(v_i)$ is just $T^* \operatorname{Gr}(v_i, \tilde{w}_i)$.

An easy special case of Maffei’s construction is an isomorphism

$$T^* \operatorname{Hom}(V_i, \tilde{W}_i) \parallel_{\lambda_i} \operatorname{GL}(v_i) \sim T^* \operatorname{Hom}(\tilde{W}_i, V'_i) \parallel_{-\lambda_i} \operatorname{GL}(v'_i),$$

where $v'_i = (s_i \bullet v)_i = \tilde{w}_i - v_i$ and $V'_i$ is a vector space of dimension $v'_i$. When $\lambda_i = 0$, we just have two realizations of $T^* \operatorname{Gr}(v_i, \tilde{w}_i)$ (where $\operatorname{Gr}(v_i, \tilde{w}_i)$ is thought as the variety of $v_i$-dimensional subspaces in $\mathbb{C} \tilde{w}_i$ and as the variety of $(\tilde{w}_i - v_i)$-dimensional quotients), while for $\lambda_i \neq 0$, we get two
equal twisted cotangent bundles on the Grassmanian. These isomorphisms are clearly symplectomorphisms, $\mathbb{C}^\times$-equivariant when $\lambda_i = 0$.

As a consequence, we get a $G$-equivariant symplectomorphism

$$T^* R \parallel_{\lambda_i} \text{GL}(v_i) \sim T^* R' \parallel_{-\lambda_i} \text{GL}(v'_i),$$

where $R' := \text{Hom}(\tilde{W}_i, V'_i) \oplus R$. According to [53, Section 3.1], this isomorphism does not intertwine the moment maps for the $G$-actions. Rather, if $\mu, \mu'$ are the two moment maps, then $\mu = \mu' - s_i \lambda$. The isomorphism does not intertwine the stability conditions either, instead it maps $(T^* R)_{\theta} \parallel_{-\lambda_i} \text{GL}(v_i)$ to $(T^* R')_{s_i \theta} \parallel_{-\lambda_i} \text{GL}(v'_i)$. So, by reducing the $G$-action, we do get a symplectomorphism $\mathcal{M}_\lambda(v) \sim \mathcal{M}_{s_i \lambda}(s_i \cdot v)$. This isomorphism is $\mathbb{C}^\times$-equivariant, if $\lambda = 0$.

We will need a compatibility of the LMN isomorphisms with certain $T$-actions. Namely, the torus $T := (\mathbb{C}^\times)^{Q_1} \times (\mathbb{C}^\times)^{Q_0}$ naturally acts on $R$ (the copy of $\mathbb{C}^\times$ corresponding to an arrow $a$ acts by scalars on $\text{Hom}(V_{i(a)}, V_{h(a)})$), the copy corresponding to $i \in Q_0$ acts on $\text{Hom}(V_i, W_i)$). The lift of this $T$-action to $T^* R$ commutes with $G$ and preserves the moment map and so descends to $\mathcal{M}^\theta(v, w)$. An isomorphism $s_i$ is $T$-equivariant [64, Proposition 4.13].

We will also need to understand the behaviour of line bundles under the LMN isomorphism. Namely, by tracking the construction, we see that $s_i$ maps the line bundle $\mathcal{O}(\chi)$ to $\mathcal{O}(s_i \chi)$.

### 2.1.4 Properties of $\mathcal{M}^0(v)$

Now let us turn to the affine quiver varieties $\mathcal{M}^0(v)$. In [23] Crawley-Boevey found a combinatorial criterion on $v$ for $\mu$ to be flat. Let us state this criterion. Recall the symmetrized Tits form $(\cdot, \cdot)$ for $Q$: $(v^1, v^2) := 2 \sum_{k \in Q_0} v_k^1 v_k^2 - \sum_a (v_{i(a)}^1 v_{h(a)}^2 + v_{h(a)}^1 v_{i(a)}^2)$. We set $p(v) := 1 - \frac{1}{2}(v, v)$ (so if $v$ is a root, then $p(v) \geq 0$). According to [23, Theorem 1.1], the map $\mu$ is flat if and only if

$$p(v) + w \cdot v - (w \cdot v^0 + \sum_{i=0}^k p(v^i)) \geq 0$$

(2.4)

for all decompositions $v = v^0 + \ldots + v^k$ with all $v^i > 0$, equivalently, for the decompositions, where $v^1, \ldots, v^k$ are roots and $v^0 \geq 0$. Note that Crawley-Boevey works with unframed quivers. As usual, one can translate from our setting to his by adding a new vertex $\infty$, as explained in the end of [23, Section 1]. In (2.4) we have restated the Crawley-Boevey inequalities in terms of the original quiver $Q$. 

\( \odot \) Springer
Also if all inequalities for proper decompositions in (2.4) are strict, then \( \mu^{-1}(0) \) is irreducible and contains a free closed orbit [23, Theorem 1.2].

We want to analyze condition (2.4) in the case when \( Q \) is finite or affine and \( \nu \) is dominant.

**Lemma 2.1** Suppose that \( \nu \) is dominant.

1. If \( Q \) is finite, then \( \mu \) is flat, \( \mu^{-1}(0) \) is irreducible and contains a free closed orbit.
2. If \( Q \) is affine, then \( \mu \) is flat. Moreover, if \( (\omega, \delta) > 1 \), then \( \mu^{-1}(0) \) is irreducible and contains a free closed orbit.

**Proof** When \( Q \) is finite, then \( p(v^i) = 0 \) for all \( i > 0 \) and so the left hand side of (2.4) becomes \( 1/2((v^0, v^0) - (v, v)) + \omega \cdot (v - v^0) = (v^0 - v, 1/2(v + v^0)) = 1/2(v^0 - v, v^0 - v) + (v, v^0 - v) \). Here, in the second and the third expressions, \((\cdot, \cdot)\) is the usual form on \( \mathfrak{h}^* \). The first summand is positive if \( v \neq v^0 \), while the second is non-negative. We conclude that \( \mu^{-1}(0) \) is irreducible and contains a free closed orbit.

Now consider the case when \( Q \) is affine. Here \( p(v^i) = 1 \) if \( v^i = a_i\delta \) and \( p(v^i) = 0 \) else, for \( i > 0 \). The left hand side of (2.4) is minimized when all \( a_i = 1 \) and we will assume this. So the left hand side becomes

\[
\frac{1}{2}(v^0 - v, v^0 - v) + (v, v^0 - v) - s
\]

where \( v \geq v^0 + s\delta \). The first summand is non-negative, it equals 0 if and only if \( v - v^0 \) is a multiple of \( \delta \). The second summand is non-negative, it equals 0 if and only if \( v = v^0 + s\delta \). Finally, the third summand is nonnegative, it is 0 if and only if \( (\omega, \delta) = 1 \). So we see that \( \mu \) is flat. The subvariety \( \mu^{-1}(0) \) is irreducible and contains a free closed orbit provided \( (\omega, \delta) > 1 \). \( \square \)

2.1.5 Families

Set \( \mathfrak{p} := \mathbb{C}[Q_0] \cong (\mathfrak{g}^*)^G \) and consider the varieties \( \mathcal{M}_{\mathfrak{p}}^0(v) := \mu^{-1}(\mathfrak{g}^*G) // G \), \( \mathcal{M}_{\mathfrak{p}}^0(v) := \mu^{-1}(\mathfrak{g}^*G)^G-ss // G \).

For a vector subspace \( \mathfrak{p}_0 \subset \mathfrak{p} \), we consider the specializations \( \mathcal{M}_{\mathfrak{p}_0}^0(v) := \mathfrak{p}_0 \times_{\mathfrak{p}} \mathcal{M}_{\mathfrak{p}}^0(v) \), \( \mathcal{M}_{\mathfrak{p}_0}^0(v) \).

2.1.6 Structure of neighborhoods

Pick a point \( x \in \mathcal{M}_{\mathfrak{p}}^0(v) \). Consider the completion \( \mathbb{C}[\mathcal{M}_{\mathfrak{p}}^0(v)]^\wedge_x \) of the algebra \( \mathbb{C}[\mathcal{M}_{\mathfrak{p}}^0(v)] \) at \( x \). Set \( \mathcal{M}_{\mathfrak{p}}^0(v)^\wedge_x := \text{Spec}(\mathbb{C}[\mathcal{M}_{\mathfrak{p}}^0(v)]^\wedge_x) \) (we emphasize that we view \( \mathcal{M}_{\mathfrak{p}}^0(v)^\wedge_x \) as a scheme and not as a formal scheme). Further, set

Springer
\[ \mathcal{M}_p^\theta (v)^{\wedge x} := \mathcal{M}_p^0 (v)^{\wedge x} \times \mathcal{M}_p^\theta (v) \]

In this section, we give a description of the schemes \( \mathcal{M}_p^0 (v)^{\wedge x}, \mathcal{M}_p^\theta (v)^{\wedge x} \) essentially following Nakajima [56, Section 6].

Let \( r \in T^* R \) be a point with closed \( G \)-orbit mapping to \( x \). Then \( r \) is a semisimple representation of the following quiver \( Q^w \). We first adjoin the vertex \( \infty \) to \( Q \) and connect each vertex \( i \in Q_0 \) to \( \infty \) with \( w_i \) arrows. Then we add an opposite arrow to each existing arrow of \( Q^w \). The dimension of \( r \) is \((v,1)\). Let us decompose \( r \) into the sum \( r = r_0 \oplus r_1 \otimes U_1 \oplus \ldots \oplus r_k \otimes U_k \), where \( r_0 \) is an irreducible representation with dimension vector of the form \((v^0,1)\), \( r_1, \ldots, r_k \) are pairwise non-isomorphic irreducible representations with dimensions \((v^i,0)\), \( i = 1, \ldots, k \), and \( U_i \) is the multiplicity space of \( r_i \). In particular, the stabilizer \( G_r \) of \( r \) is \( \prod_{i=1}^k \text{GL}(U_i) \).

Let us define a new quiver \( \hat{Q} \), a dimension vector \( \hat{v} \) and a framing \( \hat{w} \). For the set of vertices \( \hat{Q}_0 \) we take \( \{1, \ldots, k\} \) and we set \( \hat{v} = (\dim U_i)_{i=1}^k \). The number of arrows between \( i, j \in \{1, \ldots, k\} \) is determined as follows. The subspace \( T_r(Gr) \subset T_r(T^* R) \) is contained in its skew-orthogonal complement \( T_r(Gr)^\perp \). So we get a symplectic \( Gr \)-module \( T_r(Gr)^\perp / T_r(Gr) \). We want the \( Gr \)-module \( T^* R_x \), where we write \( R_x \) for \( R(\hat{Q}, \hat{v}, \hat{w}) \), to be isomorphic to \( T_r(Gr)^\perp / T_r(Gr) \). So \( T^* R_x \oplus T^*(g/\mathfrak{g}_r) = T^* R \).

For \( i \neq j \), the multiplicity of the \( Gr \)-module \( \text{Hom}(U_i, U_j) \) in \( T^* R \) equals \( \sum_a (v^i_{l(a)} v^j_{h(a)} + v^j_{l(a)} v^i_{h(a)}) \), while the multiplicity in \( T^*(g/\mathfrak{g}_r) \) equals \( 2 \sum_{k \in Q_0} v^i_k v^j_k \). So the multiplicity of \( \text{Hom}(U_i, U_j) \) in the \( Gr \)-module \( T^* R_x \) has to be equal to \(- (v^i, v^j) \) if \( i \neq j \) and to \( 2 - (v^i, v^i) \) if \( i = j \). Hence the number of arrows between \( i \) and \( j \) in \( \hat{Q} \) has to be \(- (v^i, v^j) \) if \( i \neq j \) and \( p(v^i) = 1 - \frac{1}{2} (v^i, v^i) \) if \( i = j \). Similarly, for \( \hat{w}_i \) we need to take \( w \cdot v^i - (v^0, v^i) \). Finally, we need to add some loops at \( \infty \) but those are just spaces with trivial action of \( G_r \). We will treat them separately: so the symplectic part of the slice module at \( r \) can be written as \( T^* R_x \oplus R_0 \), where \( R_x = \hat{R}(\hat{Q}, \hat{v}, \hat{w}) \) and \( R_0 \) is a symplectic vector space with trivial action of \( G_r \). We choose an orientation on \( \hat{Q} \) in such a way that the \( Gr \)-modules \( R_x \oplus g/\mathfrak{g}_r \) and \( R \) are isomorphic up to a trivial summand. We remark, however, that this choice may violate the condition that the vertex \( \infty \) (corresponding to \( r^0 \)) in \( \hat{Q} \) is a sink.

Consider the homogeneous vector bundle \( G \ast_{G_r} (g/\mathfrak{g}_r \oplus T^* R_x \oplus R_0) \). The symplectic form on the latter comes from a natural identification of that homogenous bundle with \( [T^* G \times (T^* R_x \oplus R_0)] / \theta G_r \) (the action of \( G_r \) is diagonal with \( G_r \) acting on \( T^* G \) from the right). The moment map on the homogeneous bundle is given by \([g, (\alpha, \beta, \beta_0)] \mapsto \text{Ad}(g)(\alpha + \mu(\beta)) \). Here \([g, (\alpha, \beta, \beta_0)] \) stands for the class in \( G \ast_{G_r} (g/\mathfrak{g}_r \oplus T^* R_x \oplus R_0) \) of a point \((g, \alpha, \beta, \beta_0) \in G \times (g/\mathfrak{g}_r \oplus T^* R_x \oplus R_0) \), and \( \mu : T^* R_x \to \mathfrak{g}_r \) is the moment map.
Let $\pi : T^* R \to T^* R//G$ and $\pi' : G*_{G_r} (g/g_r \oplus T^* R_\chi \oplus R_0) \to (g/g_r \oplus T^* R_\chi \oplus R_0)//G_r$ denote the quotient morphisms. The symplectic slice theorem (see, for example [37] where analytic neighborhoods instead of formal ones were used) asserts that there is an isomorphism of formal neighborhoods $U$ of $\pi(r)$ in $T^* R//G$ and $U'$ of $\pi'([1, (0, 0, 0)])$ in $(g/g_r \oplus T^* R_\chi \oplus R_0)//G_r$ that lifts to a $G$-equivariant symplectomorphism $\pi^{-1}(U) \cong \pi'^{-1}(U')$ intertwining the moment maps.

We have the restriction map $p = g^* G \to \hat{p} = g_r^* G_r$. We set $\hat{M}_p^0(\hat{v}) := p \times \hat{p} \hat{M}_\hat{p}^0(\hat{v})$. So we see that (compare with [56, Section 6])

$$M_\hat{p}^0(v)^\wedge = (\hat{M}_\hat{p}^0(\hat{v}) \times R_0)^\wedge_0$$  \hspace{1cm} (2.5)

(an equality of Poisson schemes).

We have a similar decomposition for smooth quiver varieties. First, observe that

$$G*_{G_r} (g/g_r \oplus T^* R_\chi \oplus R_0)_{\theta-ss} = G*_{G_r} ([g/g_r \oplus T^* R_\chi]_{\theta-ss} \times R_0),$$

where in the right hand side we slightly abuse the notation and write $\theta$ for the restriction of $\theta$ to $G_r$. From here it follows that

$$M_\hat{p}^0(v)^\wedge = (\hat{M}_\hat{p}^0(\hat{v}) \times R_0)^\wedge_0, \hspace{1cm} (2.6)$$

where, recall, by definition, $M_\hat{p}^0(v)^\wedge := M_p^0(v)^\wedge \times \hat{M}_p^0(v) \times \hat{M}_p^0(v)$.

Moreover, by the construction, the following diagram commutes

$$\begin{array}{ccc}
M^\theta(v)^\wedge & \cong & (\hat{M}^\theta(\hat{v}) \times R_0)^\wedge_0 \\
\downarrow \rho & & \downarrow \hat{\rho} \times \text{id} \\
M^0(v)^\wedge & \cong & (\hat{M}(\hat{v}) \times R_0)^\wedge_0
\end{array}$$

Let us finish this discussion with a remark.

**Remark 2.2** Let us write $\varpi$ for the restriction map $p \to \hat{p}$. It follows from (2.5) that $\varpi^{-1}(\hat{p}^{\text{sing}}) \subset p^{\text{sing}}$.

2.1.7 Resolution of singularities

**Proposition 2.3** The algebra $\mathbb{C}[M^\theta(v)]$ is finitely generated. The morphism $\rho : M^\theta(v) \to \text{Spec}(\mathbb{C}[M^\theta(v)])$ is a symplectic resolution of singularities.
Proof Fix a generic $\lambda$ and consider the varieties $\mathcal{M}^\theta_{C\lambda}(v)$ and $\mathcal{M}^0_{C\lambda}(v)$. Both are schemes over $C\lambda$. We have a natural morphism $\phi_{C\lambda} : \mathcal{M}^\theta_{C\lambda}(v) \to \mathcal{M}^0_{C\lambda}(v)$ of schemes over $C\lambda$ that is an isomorphism over $C^\times \lambda$ by 2.1.1. Since $\mathcal{M}^\theta_{C\lambda}(v)$ is smooth, connected and has the same dimension for all $z \in C$, we see that $\mathcal{M}^\theta_{C\lambda}(v)$ has dimension $\dim \mathcal{M}^\theta(v) + 1$ and the morphism $\mathcal{M}^\theta_{C\lambda}(v) \to C\lambda$ is dominant.

Let $\tilde{M}_{C\lambda}(v)$ be the image of $\phi_{C\lambda}$, this is a closed subvariety in $\mathcal{M}^0_{C\lambda}(v)$ because $\phi_{C\lambda}$ is projective. So it coincides with the closure of $C^\times \lambda \times C\lambda \tilde{M}_{C\lambda}(v)$ and has dimension $\dim \mathcal{M}^\theta(v) + 1$.

Hence the fiber $\tilde{M}(v)$ of $\tilde{M}_{C\lambda}(v)$ over 0 has dimension $\dim \mathcal{M}^\theta(v)$ and admits a surjective projective morphism from $\mathcal{M}^\theta(v)$. Applying the Stein decomposition to this morphism we decompose it to the composition of a birational morphism $\rho : \mathcal{M}^\theta(v) \to X$ with connected fibers and some finite dominant morphism $X \to \tilde{M}(v)$, where $X$ is necessarily Spec($C[\mathcal{M}^\theta(v)]$).

So $\rho$ has to be (an automatically symplectic) resolution of singularities. \qed

Corollary 2.4 The following claims are true.

(1) The higher cohomology of $O_{\mathcal{M}^\theta(v)}$ vanish.
(2) The algebra $C[\mathcal{M}^\theta(v)]$ is the specialization to 0 of $C[\mathcal{M}^0_p(v)]$. In particular, the latter is finitely generated.
(3) The algebra $C[\mathcal{M}^\theta(v)]$ coincides with the associated graded of $C[\mathcal{M}^0_{\lambda}(v)]$ for a generic $\lambda$ and, in particular, is independent of $\theta$.
(4) The variety Spec($C[\mathcal{M}^\theta(v)]$) is Cohen–Macaulay.

Proof (1) is a corollary of the Grauert-Riemenschneider theorem, and (2) is a corollary of (1). (4) follows from Proposition 2.3 and general properties of symplectic resolutions.

Let us prove (3). Consider the $C^\times$-equivariant morphism $\mathcal{M}^\theta_p(v) \to \mathcal{M}^0_p(v)$. The $C^\times$ action is induced from the action on $T^*R$. Specializing to a generic parameter $\lambda \in p$, we therefore get an isomorphism $C[\mathcal{M}^\theta_\lambda(v)] \to C[\mathcal{M}^0_\lambda(v)]$. The filtrations on both algebras are induced by the grading on $C[T^*R]$, hence the isomorphism intertwines these filtrations. From (2), we deduce that $C[\mathcal{M}^\theta(v)] = \text{gr } C[\mathcal{M}^\theta_\lambda(v)]$. So $C[\mathcal{M}^\theta(v)] = \text{gr } C[\mathcal{M}^0_\lambda(v)]$ and hence $C[\mathcal{M}^\theta(v)]$ is independent of $\theta$. \qed

We write $\mathcal{M}(v)$ for Spec($C[\mathcal{M}^\theta(v)]$) and $\mathcal{M}^\theta_p(v)$ for Spec($C[\mathcal{M}^\theta_p(v)]$), we will later see that $\mathcal{M}^\theta_p(v)$ is independent of the choice of $\theta$ so we will write $\mathcal{M}_p(v)$ for this variety.

Proposition 2.5 Suppose $\mu$ is flat. Then $\rho^* : C[\mathcal{M}^0_p(v)] \to C[\mathcal{M}_p(v)]$ is an isomorphism.
Proof It is enough to show that \( \rho^* : \mathbb{C}[\mathcal{M}^0(v)] \to \mathbb{C}[\mathcal{M}(v)] \) is an isomorphism because \( \mathbb{C}[\mathcal{M}^0_p(v)], \mathbb{C}[\mathcal{M}_p(v)] \) are graded free over \( \mathbb{C}[p] \) and \( \mathbb{C}[\mathcal{M}_0(v)] = \mathbb{C}[\mathcal{M}^0_0(v)]/(p), \mathbb{C}[\mathcal{M}(v)] = \mathbb{C}[\mathcal{M}_p(v)]/(p) \). Now note that both \( \mathbb{C}[\mathcal{M}^0_0(v)], \mathbb{C}[\mathcal{M}_0(v)] \) are identified with the associated graded of \( \mathbb{C}[\mathcal{M}_0^0(\lambda(v))] = \mathbb{C}[\mathcal{M}^0_0(v)]/(p), \mathbb{C}[\mathcal{M}_0(v)] = \mathbb{C}[\mathcal{M}_0^0(\lambda(v))] \) for \( \lambda \) generic and, under this identification, \( \rho^* \) becomes the identity.

\[\square\]

2.1.8 Identification of homology

The purpose of this part is to establish an identification of the homology groups \( H^*_*(\mathcal{M}^\theta_\lambda(v)) \) for different generic \((\lambda, \theta)\).

First, there is a classical way to produce the identification [56, Section 9]. We can view \( \theta \) as an element in \( \mathbb{R}^{Q_0} \), in this case we define \( \mathcal{M}^\theta_\lambda(v) \) as a hyper-Kähler reduction. We get the same varieties as before, the complex structure on \( \mathcal{M}^\theta_\lambda(v) \) depends only on the chamber of \( \theta \). As we have mentioned in Sect. 1.4, this shows that all varieties \( \mathcal{M}^\theta_\lambda(v) \) with generic \( \lambda, \theta \) are diffeomorphic as \( C^\infty \)-manifolds. Consider the generic locus and a bundle with fiber \( H^*_*(\mathcal{M}^\theta_\lambda(v)) \) on this locus. This is a flat bundle with respect to the Gauss-Manin connection. But the generic locus of \( (\lambda, \theta) \) is simply connected so the connection is trivial. Therefore all fibers are canonically identified.

We will need a slightly different description. Pick a generic parameter \( \lambda \in p \). By the end of 2.1.1, we have \( \mathcal{M}^\theta_\lambda(v) = \mathcal{M}^0_\lambda(v) \). Let \( D \) denote the line through \( \lambda \). The inclusions \( \mathcal{M}^\theta(v) \hookrightarrow \mathcal{M}^\theta_D(v), \mathcal{M}^\theta_\lambda(v) \hookrightarrow \mathcal{M}^\theta_D(v) \) induce maps \( H^*(\mathcal{M}^\theta_D(v)) \to H^*(\mathcal{M}^\theta_D(v)), H^*(\mathcal{M}^\theta_\lambda(v)) \to H^*(\mathcal{M}^\theta_\lambda(v)) \). The former is an isomorphism because \( \mathcal{M}^\theta_D(v) \) gets contracted to \( \mathcal{M}^\theta_D(v) \) by a \( C^\infty \)-action. The latter is also an isomorphism because the resulting map \( H^*(\mathcal{M}^\theta_D(v)) \to H^*(\mathcal{M}^\theta_\lambda(v)) \) is precisely the identification in the previous paragraph.

Note that the identification \( H^2(\mathcal{M}^\theta(\lambda,v)) \cong H^2(\mathcal{M}^\theta(v)) \) intertwines the maps from \( p \) by the construction. The variety \( \mathcal{M}^\theta(v) \) admits a universal deformation over \( H^2(\mathcal{M}^\theta(v)) \) whose algebra of global functions is known to be independent of the choice of generic \( \theta \). We conclude that \( \mathbb{C}[\mathcal{M}^\theta_p(v)] \) is independent of \( \theta \).

2.2 Properties of quantizations

In this section, we describe some properties of the algebras \( \mathcal{A}^\lambda_\lambda(v) \) and \( \mathcal{A}^0_\lambda(v) \).

2.2.1 Filtrations

The algebras \( \mathcal{A}^\lambda_\lambda(v), \mathcal{A}^0_\lambda(v) := [D(R)/D(R)\{\Phi(x) - \langle \lambda, x \rangle \}]^G \) can be filtered in different ways, depending on a filtration on \( D(R) \) we consider. First of
all, there is the Bernstein filtration on $A_\lambda(v), A_0^\lambda(v)$ that is induced from the eponymous filtration on $D(R)$ (where $\deg R = \deg R^* = 1$). Let us write $F_i A_\lambda(v)$ for the $i$th filtration component with respect to this filtration. Note that $[F_i A_\lambda(v), F_j A_\lambda(v)] \subset F_{i+j-2} A_\lambda(v)$.

Sometimes, it will be more convenient for us to work with filtrations, where the commutator decreases degrees by 1. Namely, equip $D(R)$ with the filtration by the order of differential operator (where $\deg R^* = 0, \deg R = 1$). We have induced filtrations on $A_\lambda(v), A_0^\lambda(v)$ to be denoted by $F_i^Q$ (the superscript indicates that these filtrations depend on the orientation). Note that $[F_i^Q A_\lambda(v), F_j^Q A_\lambda(v)] \subset F_{i+j-1}^Q A_\lambda(v)$.

The two filtrations are related to each other. Namely, let $e\mu$ denote the Euler vector field in $D(R)$ (so that $[e\mu, \cdot]$ acts by 1 on $R^*$ and by $-1$ on $R$). Since this element is $G$-invariant, it descends to $A_\lambda(v), A_0^\lambda(v)$, we denote the images again by $e\mu$. So we can consider the inner $\mathbb{Z}$-gradings on the algebras of interest by eigenvalues of $[e\mu, \cdot]$, let us write $A_\lambda(v) = \bigoplus_i A_\lambda(v)_i$ and $A_0^\lambda(v) = \bigoplus_i A_0^\lambda(v)_i$ for these gradings. The gradings are compatible with the filtrations $F_i, F_i^Q$ and we have

$$F_i A_\lambda(v) = \bigoplus_{k \in \mathbb{Z}} F_k^Q A_\lambda(v)_{i-2k}.$$  

Thanks to this equality, the associated graded algebras for the two filtrations are the same.

The same considerations apply to $A_0^\lambda(v)$.

In Sect. 1.4 we have mentioned that $\gr A_\lambda(v) = \mathbb{C}[M(v)]$ and $H^i(A_0^\lambda(v)) = 0$. This is because $\gr A_0^\lambda(v) = \mathcal{O}_{\mathcal{M}_\theta(v)}$ and $H^i(\mathcal{O}_{\mathcal{M}_\theta(v)}) = 0$ for $i > 0$.

2.2.2 $A_0^\lambda(v)$ vs $A_\lambda(v), I$

Now we want to relate the algebra $A_\lambda(v)$ to $A_0^\lambda(v)$. We have a natural epimorphism $\mathbb{C}[\mathcal{M}_\theta(v)] \rightarrow gr A_0^\lambda(v)$ to be denoted by $\eta$. Besides, we have a natural homomorphism $\kappa : A_0^\lambda(v) ightarrow A_\lambda(v)$ coming from restricting elements of $D(R)$ to $(T^*R)_{\theta-ss}$. It is clear that $\rho^* : \mathbb{C}[\mathcal{M}_\theta(v)] \rightarrow \mathbb{C}[\mathcal{M}_\theta(v)]$ coincides with the composition $\gr \kappa \circ \eta : \mathbb{C}[\mathcal{M}_\theta(v)] \rightarrow \gr A_\lambda(v)$. It follows that $A_0^\lambda(v) = A_\lambda(v)$ and $\gr A_0^\lambda(v) = \mathbb{C}[\mathcal{M}_\theta(v)]$ when $\mu$ is flat. In particular, $A_\lambda(v)$ is independent of $\theta$ in this case. This is also true for an arbitrary vector $v$ by [18, Proposition 3.8].

2.2.3 Variations

Now let us consider some related constructions. We can consider the quantization
\[ A^\theta_p(v) = D_R \parallel^\theta G := [(D_R / D_R \{ x_R, x \in [g, g] \})|_{T^* R^{g_{ss}}} ]^G \]

of \( M^\theta_p(v) \) and its global section \( A^\theta_p(v) \). For an affine subspace \( \mathfrak{p}_0 \subset \mathfrak{p} \), we consider pull-backs \( A^\theta_{\mathfrak{p}_0}(v) := \mathbb{C}[\mathfrak{p}_0] \otimes_{\mathbb{C}[\mathfrak{p}]} A^\theta_p(v) \), \( A_{\mathfrak{p}_0}(v) := \mathbb{C}[\mathfrak{p}_0] \otimes_{\mathbb{C}[\mathfrak{p}]} A_p(v) \). Those are quantizations of \( M^\theta_p(v), M_p(v) \), where \( \mathfrak{p}_0 \subset \mathfrak{p} \) is the vector subspace corresponding to \( \mathfrak{p}_0 \). Note that \( A^\theta_{\mathfrak{p}_0}(v) = \Gamma(A^\theta_{\mathfrak{p}_0}(v)) \). It also makes sense to speak about \( A^0_{\mathfrak{p}_0}(v) \).

We also consider homogenized versions. Namely, we take the Rees sheaf \( D_{R, \hbar} \) of \( D_R \) (for the filtration by the order of a differential operator) and its reduction \( A^\theta_{\mathfrak{p}_0}(v)_{\hbar} \), it is related to \( A^\theta_p(v) \) via \( A^\theta_{\mathfrak{p}_0}(v) = A^\theta_{\mathfrak{p}_0}(v)/(\hbar - 1) \). Also consider the global sections \( A^\theta_p(v)_{\hbar} \). This is a graded (with positive grading) deformation of \( \mathbb{C}[M(v)] \) over the space \( \mathfrak{p} \oplus \mathbb{C} \). Here we consider the grading coming from the action of \( \mathbb{C}^\times \) on \( T^* R \) by dilations: \( t.(r, \alpha) = (r^{-1}r, t^{-1} \alpha) \) so that the parameter space \( \mathfrak{p} \oplus \mathbb{C} \) is in degree 2.

### 2.2.4 Quantized LMN isomorphisms

The LMN isomorphisms discussed in Sect. 2.1.3 can be quantized. This was done in [42] in a special case (but the construction generalizes in a straightforward way). In fact, the quantum isomorphisms can be obtained by the same reduction in stages construction as before. One either quantizes the steps of that argument or argues similarly to [42, Section 6.4]: for \( \theta \geq 0 \), isomorphism (2.3) can be regarded as an isomorphism of symplectic schemes \( \mathcal{X} := T^* R \parallel^\theta GL(v_k), \mathcal{X}' := T^* R' \parallel^\theta GL(\tilde{w}_k - v_k) \) over \( \mathbb{A}^1 \) that gives the multiplication by \(-1\) on the base. Here we write \( R' \) for \( \text{Hom}(\tilde{W}_k, V_k) \oplus R \). So (2.3) extends to an isomorphism of the canonical (=even+ \( \mathbb{C}^\times \)-equivariant) deformation quantizations \( \mathcal{D}, \mathcal{D}' \) of the schemes \( \mathcal{X}, \mathcal{X}' \) that are defined as follows:

\[
\mathcal{D} := [D_{R, \hbar}/D_{R, \hbar} \Phi^\text{sym}_k(\mathfrak{sl}(v_k))]_{T^* R^{g_{ss}}}^{\text{GL}(v_k)},
\]

\[
\mathcal{D}' := [D_{R', \hbar}/D_{R', \hbar} \Phi^\text{sym}_k(\mathfrak{sl}(\tilde{w}_k - v_k))]_{T^* R^{g_{ss}}}^{\text{GL}(\tilde{w}_k - v_k)}
\]

Here \( \Phi^\text{sym} \), the *symmetrized quantum comoment map*, stands the composition of \( g \to \mathfrak{sp}(T^* R) \) and the natural embedding \( \mathfrak{sp}(T^* R) \hookrightarrow A_h(T^* R) \), where \( A \) denotes the Weyl algebra. For the discussion of canonical and even quantizations and connections between them see [42, Sections 2.2.2.3]. For the definition of a symmetrized quantum comoment map, see [42, Section 5.4].

The isomorphism \( \mathcal{D} \sim \mathcal{D}' \) does not intertwine the symmetrized quantum comoment maps for the \( G \)-actions on \( \mathcal{D}, \mathcal{D}' \) but rather does the same change as the with the classical comoment maps.
So we get an isomorphism $A_{\lambda}^\theta(v) \sim A_{\sigma \bullet \lambda}^{\sigma \theta}(\sigma \bullet v)$, where the parameter $\sigma \bullet v \lambda$ is determined as follows. Let $\varrho(v)$ be the character of $g$ equal $-\frac{1}{2} \chi^{\text{top } R}$, where $\chi^{\text{top } R}$ is the character of the action of $g$ on $\bigwedge^{\text{top } R}$. Then $\Phi(x) - \Phi^{\text{sym}}(x) = \langle \varrho(v), x \rangle$. Hence we have

$$\sigma \bullet v \lambda = \sigma(\lambda - \varrho(v)) + \varrho(\sigma \bullet v)$$  \hspace{1cm} (2.7)

We remark that $\Phi(x)$ depends on the orientation of $Q$ (while $\Phi^{\text{sym}}(x)$ does not) and we have

$$\varrho(v)_k = \frac{1}{2} \sum_{a, h(a) = k} v_t(a) - \sum_{a, t(a) = k} v_h(a) - w_k, \quad k \in Q_0.$$  \hspace{1cm} (2.8)

When we change an orientation of $Q$, the character $\varrho(v)$ changes by an element from $\mathbb{Z}^{Q_0}$.

We compute $s_i \bullet v \lambda$ in the case when $i$ is a source so that $\varrho(v)_i = -\frac{1}{2} \tilde{w}_i$. By (2.7), $s_i \bullet v \lambda = s_i \lambda + \varrho(s_i \bullet v) - s_i \varrho(v)$ and what we need to compute is $\varrho(s_i \bullet v) - s_i \varrho(v)$. We have $\rho(s_i \bullet v)_k = (s_i \varrho(v))_k$ when $k$ is different from $i$ and is not adjacent to $i$. When $k = i$, we have $(s_i \varrho(v))_k = -\varrho(v)_k = -s_i \varrho(v)_k$. Finally, let us consider the case when $k$ is adjacent to $i$, say there are $q$ arrows from $i$ to $k$. Then $(s_i \varrho(v))_k = \varrho(v)_k + q \varrho(v)_i = \varrho(v)_k - q \tilde{w}_i$ and $\varrho(s_i \bullet v)_k = \varrho(v)_k + \frac{q}{2}(\tilde{w}_i - v_i - v_i)$. In particular, we deduce that $\varrho(s_i \bullet v) - s_i \varrho(v) \in \mathbb{Z}^{Q_0}$.

Remark 2.6 One conclusion that will be used below is that $\varrho(\sigma \bullet v) - \varrho(v)$ is integral and hence $\sigma \bullet v \lambda - \lambda$ is integral if and only if $\sigma \lambda - \lambda$ is.

An important corollary of $A_{\lambda}^\theta(v) \sim A_{\sigma \bullet \lambda}^{\sigma \theta}(\sigma \bullet v)$ is an isomorphism $A_{\lambda}(v) \sim A_{\sigma \bullet \lambda}(\sigma \bullet v)$.

We also would like to point out that the quantum LMN isomorphisms are $T$-equivariant, this also follows from [64, Proposition 4.13].

2.2.5 $A_{\lambda}^0(v)$ vs $A_{\lambda}(v)$, II

Recall that for a subvariety $Y \subset V$, where $V$ is a vector space, one can define its asymptotic cone $\text{AC}(Y)$ as $\text{Spec} \left( \text{gr } \mathbb{C}[Y] \right) \subset V$, where we take the filtration on $\mathbb{C}[Y]$ induced by the epimorphism $\mathbb{C}[V] \rightarrow \mathbb{C}[Y]$.

A Zariski open subset $\mathfrak{P}^0 \subset \mathfrak{P}$ will be called asymptotically generic if $\text{AC}(\mathfrak{P} \setminus \mathfrak{P}^0) \subset \mathfrak{P}^{\text{sing}}$.

Recall that we write $\mathfrak{P}^{\text{iso}}$ for the set of $\lambda \in \mathfrak{P}$ such that $A_{\lambda}^0(v) \rightarrow A_{\lambda}(v)$ is an isomorphism. The following proposition (to be proved in Sect. 3.5) should be thought as a quantum analog of the isomorphism $M_{\lambda}^0(v) \cong M_{\lambda}(v)$ for a generic $\lambda$. 

\[\text{Comment from Springer}\]
Proposition 2.7  The subvariety $P^{iso} \subset P$ is Zariski open and asymptotically generic.

2.2.6  Spherical symplectic reflection algebras

Here we will discuss the special case when $Q$ is an affine quiver. Let 0 denote the extending vertex (so that $Q \setminus 0$ is a finite Dynkin quiver), and $w = \epsilon_0$, the coordinate vector at the extending vertex.

It is a classical fact that all weights of the irreducible $g(Q)$-module $L_{\omega_0}$ (a.k.a. the basic representation) are conjugate to the weights of the form $\omega_0 - n\delta$, $n \in \mathbb{Z}_{\geq 0}$, under the action of $W(Q)$. Thanks to the quantum LMN isomorphisms it is enough to consider $v = n\delta$. Here the algebra $A_\lambda(v)$ is known to be isomorphic to a certain spherical symplectic reflection algebra.

Let us recall some basics about these algebras. Let $\Gamma_1$ be a finite subgroup in $\text{Sp}(V)$, where $V$ is a symplectic vector space. We choose independent variables $c = (c_0, \ldots, c_r)$, one for each conjugacy class of symplectic reflections in $\Gamma_1$. Then we can consider the algebra $H$, the quotient of $T(V)\#\Gamma_1[c_0, \ldots, c_r]$ by the relations of the form

$$[u, v] = \omega(u, v) + \sum_{i=0}^r c_i \sum_{s \in S_i} \omega_s(u, v), u, v \in V.$$  

Here $S_1, \ldots, S_r$ are the conjugacy classes of symplectic reflections in $\Gamma$, $\omega$ is the symplectic form on $V$, and $\omega_s(u, v) = \omega(\pi_s u, \pi_s v)$, where we write $\pi_s$ for the $s$-invariant projection from $V$ to $\text{im}(s - 1)$. Inside $H$ we can consider the spherical subalgebra $eHe$, where $e = \frac{1}{|\Gamma_1|} \sum_{\gamma \in \Gamma_1} \gamma$. Also, for numerical values of $c$, say $c$, we can consider the specializations $H_c$ of $H$. Recall that a parameter $c$ is called spherical if $eH_ce$ and $H_c$ are Morita equivalent (via the bimodule $H_c,e$).

Examples of $\Gamma$ that are of most interest for us are as follows. Take a finite subgroup $\Gamma_1 \subset \text{SL}_2(\mathbb{C})$ and a positive integer $n$. Then we can form the group $\Gamma = \Gamma_n := \mathfrak{S}_n \ltimes \Gamma_n$ that acts on $V = \mathbb{C}^{2n}$ by linear symplectomorphisms. We have two kinds of symplectic reflections: the conjugacy class $S_0$ containing transpositions in $\mathfrak{S}_n$, and conjugacy classes $S_1, \ldots, S_r$ containing elements from the $n$ copies of $\Gamma$ (here $r$ is the number of the nontrivial conjugacy classes in $\Gamma_1$). We will use the notation $H_{\kappa,c}(n)$ for the algebra corresponding to $c_0 = 2\kappa$ and $c_1, \ldots, c_r$.

Now recall that, by the McKay correspondence, to $\Gamma_1$ we can assign an affine Dynkin quiver $Q$. Take $v = n\delta$, where $\delta$ is the indecomposable imaginary root, and $w = \epsilon_0$, where 0 stands for the extending vertex of $Q$. Then we have isomorphisms $eH_{\kappa,c}(n)e \cong A_\lambda(v)$, where $\lambda$ can obtained from $c$ by formulas.
explained in [28, 1.4]. In particular, \( \kappa = (\lambda, \delta) \). For example, for \( \Gamma_1 = \{1\} \) we just get \( e\mathcal{H}_{\kappa, e}(n)e = A_\kappa(n) \).

The following lemma gives a characterization of spherical values of \( e\mathcal{H}_{\kappa, e}(n)e \).

**Lemma 2.8** The following claims are true.

1. The parameter \((\kappa, c)\) is spherical if and only if \( e\mathcal{H}_{\kappa, c}(n)e \) has finite homological dimension.
2. The parameter \( \kappa \) of the type A Rational Cherednik algebra \( \mathcal{H}_\kappa(n) \) is not spherical if and only if \( \kappa = -\frac{s}{m} \) with \( 1 < m \leq n \) and \( 0 < s < m \).

(1) follows from [26, Theorem 5.5] and (2) is proved in [8, Corollary 4.2].

### 2.3 Coherent modules

Let us proceed to defining suitable categories of sheaves of modules over the sheaves of algebras \( A^\theta_\lambda(v) \). We follow [18, Section 4].

#### 2.3.1 Coherent modules

Now let \( X \) be a smooth symplectic variety (with a \( \mathbb{C}^\times \)-action rescaling the Poisson bracket) and \( D \) be its filtered quantization. Recall that this means that \( D \) is a filtered sheaf of algebras in the conical topology on \( X \) together with an isomorphism \( \text{gr} \ D \cong \mathcal{O}_X \) of sheaves of graded Poisson algebras. We also require that the filtration on \( D \) is complete and separated.

Let \( M \) be a sheaf of \( D \)-modules in the conical topology.

**Definition 2.9** We say that a \( D \)-module \( M \) is coherent if it can be equipped with a global complete and separated filtration such that \( \text{gr} \ M \) is a coherent \( \mathcal{O}_X \)-module (this filtration is called good).

Let us write \( \text{Coh}(D) \) for the category of coherent \( D \)-modules.

We can also consider the completed Rees sheaf \( D_h \) of \( D \). By definition, a coherent \( D_h \)-module \( M_h \) is a coherent sheaf of modules such that the \( \hbar \)-adic filtration on \( M_h \) is complete and separated and \( M_h/hM_h \) is a coherent \( \mathcal{O}_X \)-module.

The notion of coherent modules we use is equivalent to that of [18, Section 4]. They consider the case when \( X \) is a conical symplectic resolution and the action is contracting but the definition generalizes to our setting in a straightforward way. Namely, [18] considers \( \mathbb{C}^\times \)-equivariant \( D_h[\hbar^{-1}] \)-modules. Such a module is called coherent there if it has a coherent \( D_h \)-lattice. From a coherent \( D \)-module \( M \) we can produce a \( \mathbb{C}^\times \)-equivariant coherent \( D_h[\hbar^{-1}] \)-module via \( M \mapsto D_h[\hbar^{-1}] \otimes_D M \) (note that \( D = D_h[\hbar^{-1}]^\mathbb{C}^\times \)). A quasi-inverse functor is given by taking \( \mathbb{C}^\times \)-invariant.
The following lemma contains some basic facts about coherent $D$-modules.

**Lemma 2.10** The following statements are true:

1. Let $X$ be affine, and $A := \Gamma(D)$. Then the functors $M \mapsto M^{loc} := D \otimes_{\mathcal{A}} M$ and $N \mapsto \Gamma(N)$ are mutually inverse equivalences between $A$-mod and $\text{Coh}(D)$. A similar claim holds for the coherent $D_{\hbar}$-modules.

2. $\text{Coh}(D)$ is an abelian subcategory in the category of sheaves of all $D$-modules.

**Proof** Let us prove (1). Note that $\text{gr}(M^{loc})$ is the coherent sheaf on $X$ associated to $\text{gr} M$ and $\text{gr} \Gamma(N) = \Gamma(\text{gr} N)$, the latter is true because $H^1(X, \text{gr} N) = 0$. This shows that the natural homomorphisms $M \mapsto \Gamma(M^{loc}), \Gamma(N)^{loc} \to N$ are isomorphisms after passing to the associated graded modules, hence are isomorphisms because all the filtrations involved are complete and separated.

Let us prove (2). This amounts to prove that for a morphism $\varphi : M \to N$ of coherent sheaves, the kernel and the cokernel are coherent. Choose good filtrations $M = \bigcup_{i \in \mathbb{Z}} M_{\leq i}, N = \bigcup_{i \in \mathbb{Z}} N_{\leq i}$. After shifting a filtration on $N$, we can assume that $\varphi(M_{\leq i}) \subset N_{\leq i}$: this is a local condition and in the case of modules over algebras, this claim is classical. Let $M_{\hbar}, N_{\hbar}$ denote the completed Rees modules of $M, N$. Then $\varphi$ gives rise to a $C^\times$-finite homomorphism $\varphi_{\hbar} : M_{\hbar} \to N_{\hbar}$. Then $\ker \varphi_{\hbar}$ is clearly coherent. The module $\ker \varphi$ is obtained from $\ker \varphi_{\hbar}$ by first taking locally $C^\times$-finite sections and then taking the quotient by $\hbar - 1$. This procedure endows $\ker \varphi$ with a filtration that satisfies the conditions of Definition 2.9. So $\ker \varphi$ is coherent.

Now let us explain why $\text{coker} \varphi$ is coherent. Similarly to the case of kernel, it is enough to show that $\text{coker} \varphi_{\hbar}$ is coherent. This will follow once we know that $\text{im} \varphi_{\hbar}$ is closed in the $\hbar$-adic topology on $N_{\hbar}$. Again, this is a local condition and for modules over an algebra this is easy to show. \(\square\)

### 2.3.2 Derived categories and functors

We consider $X = \mathcal{M}^\theta(v)$ with its contracting $C^\times$-action (we could also consider the action induced by $\deg R = 0, \deg R^* = 1$). Below we write $\mathcal{A}^\theta(v)$ for $\text{Coh}(\mathcal{A}^\theta(v))$. Here we investigate the derived category $D^b(\mathcal{A}^\theta(v)-\text{mod})$ and the derived global section functor. Let us write $\text{Sh}(\mathcal{A}^\theta(v))$ for the category of all sheaves of $\mathcal{A}^\theta(v)$-modules.

**Lemma 2.11** The following statements are true.

1. The natural functor $D^b(\mathcal{A}^\theta(v)-\text{mod}) \to D^b(\text{Sh}(\mathcal{A}^\theta(v)))$ is a full embedding.

2. The derived global section functor $R\Gamma$ takes $D^b(\mathcal{A}^\theta(v)-\text{mod})$ to $D^b(\mathcal{A}(v)-\text{mod})$, where we write $\mathcal{A}(v)-\text{mod}$ for the category of all finitely generated $\mathcal{A}(v)$-modules.
Proof (1) is [18, Corollary 5.11] and (2) is [18, Proposition 4.12]. □

Note that (1) implies that \( R\Gamma \) is given by taking the Čech complex.

2.4 Supports and characteristic cycles

Now let us define the supports of objects in \( \mathcal{A}_\lambda(v)\)-mod and supports and characteristic cycles for objects in \( \text{Coh}(\mathcal{A}_\lambda^\theta(v))\). We also define holonomic modules.

For \( M \in \mathcal{A}_\lambda(v)\)-mod we can define the support, \( \text{Supp} M \), to be the support of the coherent sheaf \( \text{gr} M \) with respect to any good filtration. Similarly, we can define the support of an object in \( \mathcal{A}_\lambda^\theta(v)\)-mod.

We remark that the support of an \( \mathcal{A}_\lambda(v)\)-module (resp., an \( \mathcal{A}_\lambda^\theta(v)\)-module) \( M \) is a coisotropic subvariety in \( \mathcal{M}^\theta(v) \) (resp., \( \mathcal{M}(v) \)) by the Gabber involutivity theorem [29], an easier proof due to Knop can be found in [30, Section 1.2]. If the support of \( M \in \mathcal{A}_\lambda^\theta(v)\)-mod is lagrangian, then we call \( M \) holonomic. An object \( N \in \mathcal{A}_\lambda(v)\)-mod is called holonomic if the intersection of \( \text{Supp} N \) with every symplectic leaf in \( \mathcal{M}(v) \) is isotropic. By [47, Appendix], this is equivalent to \( \rho^{-1}(\text{Supp}(N)) \) to be isotropic.

Let us proceed to characteristic cycles. Suppose \( Y \subset \mathcal{M}^\theta(v) \) is a \( \mathbb{C}^\times \)-stable isotropic subvariety. Recall that to a coherent sheaf \( M_0 \) on \( \mathcal{M}^\theta(v) \) supported on \( Y \) on can assign its characteristic cycle \( \text{CC}(M_0) \) equal to the following formal linear combination of the irreducible components of \( Y \):

\[
\text{CC}(M_0) := \sum_{Y' \subset Y} (\text{grk}_{Y'} M_0)Y',
\]

where \( \text{grk}_{Y'} \) stands for the rank in the generic point of a component \( Y' \). We can define the characteristic cycle \( \text{CC} \) of a coherent \( \mathcal{A}_\lambda^\theta(v)\)-module \( M \) supported on \( Y \) by \( \text{CC}(M) := \text{CC}(\text{gr} M) \), this is easily seen to be well-defined. An alternative definition is given in [18, Section 6.2]. Yet another description of \( \text{CC}(M) \) is as follows. The object \( M \) gives rise to a well-defined class in \( K_0(\text{Coh}_Y(\mathcal{M}^\theta(v))) \), that of \( \text{gr} M \). The map \( [M] \to [\text{gr} M] : K_0(\mathcal{A}_\lambda^\theta(v)\text{-mod}_Y) \to K_0(\text{Coh}_Y \mathcal{M}^\theta(v)) \) will be called the degeneration map in what follows. Applying the Chern character map, we get an element \( \text{CC}'(M) \in H^*(\mathcal{M}^\theta(v), \mathcal{M}^\theta(v)\setminus Y) = H^{BM}_{\text{top}}(Y) \). Then \( \text{CC}(M) \) coincides with the projection of \( \text{CC}'(M) \) to \( H^{BM}_{\text{top}}(Y) \).

When \( Y = \rho^{-1}(0) \), we have \( H^{BM}_{\text{top}}(Y) = H_{\text{top}}(Y) = H_{\text{top}}(\mathcal{M}^\theta(v)) \). The first equality holds because \( \rho^{-1}(0) \) is compact, the second one is true because \( \mathcal{M}^\theta(v) \) is contracted onto \( \rho^{-1}(0) \) by the \( \mathbb{C}^\times \)-action (induced by the dilation action on \( T^*R \)).
Proposition 2.12 [2] The map \( CC : K_0(\mathcal{A}_\lambda^0(v) - \text{mod}_{\rho^{-1}(0)}) \to H_{\text{mid}}(\mathcal{M}^\theta(v)) \) is injective.

The proof of this proposition has not appeared yet, so we will give an independent proof later in the paper in the case when \( Q \) is finite and when \( Q \) is affine with \( w = \epsilon_0 \).

2.5 Various functors

In this section we will study Hamiltonian reduction functors from the category of \((G, \lambda)\)-equivariant \( D \)-modules on \( R \) to the categories of modules over \( \mathcal{A}_\lambda^0(v), \mathcal{A}_\lambda^0(v) \). We will also study the localization and global section functors and their connection to Hamiltonian reduction functors.

2.5.1 Twisted equivariant \( D \)-modules

By a \((G, \lambda)\)-equivariant \( D(R)\)-module one means a weakly \( G \)-equivariant module \( M \) such that \( x_m = \Phi(x)m - \lambda(x)m \) for all \( x \in g, m \in M \). We consider the category \( D(R) \)-\text{Mod}^{G,\lambda} of all \((G, \lambda)\)-equivariant modules over \( D(R) \) and its full subcategory \( D(R) \)-mod^{G,\lambda} of finitely generated modules. Note that, for \( \chi \in \mathbb{Z}^{Q_0} \), the categories \( D(R) \)-\text{Mod}^{G,\lambda} and \( D(R) \)-\text{Mod}^{G,\lambda+\chi} are equivalent, via \( M \mapsto M \otimes \mathbb{C}^{-\chi} : D(R) \)-\text{Mod}^{G,\lambda} \to D(R) \)-\text{Mod}^{G,\lambda+\chi}, where \( \mathbb{C}^{-\chi} \) is the one-dimensional \( G \)-module corresponding to the character \(-\chi\).

2.5.2 Functors for abelian categories

Let us write \( \mathcal{A}_\lambda^0(v) \)-\text{Mod} for the category of all \( \mathcal{A}_\lambda^0(v) \)-modules. We have a functor \( \pi_\lambda^0(v) : D(R) \)-\text{Mod}^{G,\lambda} \to \mathcal{A}_\lambda^0(v) \)-\text{Mod} of taking \( G \)-invariants that restricts to \( D(R) \)-\text{mod}^{G,\lambda} \to \mathcal{A}_\lambda^0(v) \)-\text{mod}. It is a quotient functor, it kills precisely the modules without nonzero \( G \)-invariants. It has a left adjoint (and right inverse)

\[
\pi_\lambda^0(v)^! : \mathcal{A}_\lambda^0(v) \text{-Mod} \to D(R) \text{-Mod}^{G,\lambda},
\]

given by taking the tensor product with the \( D(R)\)-\( \mathcal{A}_\lambda^0(v) \)-bimodule

\[
Q_\lambda := D(R)/D(R)\{\Phi(x) - \langle \lambda, x \rangle, x \in g\}.
\]

This functor restricts to \( \mathcal{A}_\lambda^0(v) \)-\text{mod} \to \( D(R) \)-\text{mod}^{G,\lambda}.

Note that \( Q_\lambda \) is \((G, \lambda)\)-equivariant as a \( D(R) \)-module so \( \pi_\lambda^0(v)^! \) indeed maps to \((G, \lambda)\)-equivariant \( D(R) \)-modules.
Recall that we assume that $\theta$ is generic. We have a functor
\[ \pi^{\theta}_\lambda(v) : D_R -\text{mod}^{G,\lambda} \to \mathcal{A}_\lambda^{\theta}(v) -\text{mod} \]
it first restricts a $D$-module to the $\theta$-semistable locus and then takes the $G$-invariants. The image of $D(R) -\text{mod}^{G,\lambda}$ consists of coherent modules.

**Proposition 2.13** The functor $\pi^{\theta}_\lambda(v)$ is a quotient functor.

In the case when $\mu$ is flat the proof was given in [18, Section 5.5] and also announced in [54, Proposition 4.9]. Below, in Sect. 4.2, we will explain how to generalize the proof from [18] without the flatness assumption.

2.5.3 Reminder on equivariant derived categories

We will need derived versions of the reduction functors considered in Sect. 2.5.2. We can form the derived categories $D^?_G(D(R) -\text{mod}^{G,\lambda})$ (the naive derived categories; here $? \text{ stands for } +, − \text{ or } b$) but we will also need the equivariant derived categories $D^?_{G,\lambda}(D(R) -\text{mod}^{G,\lambda})$. Here we recall some basics regarding equivariant derived categories.

Let $\mathcal{A}$ be an associative algebra equipped with a rational action of a connected reductive algebraic group $G$. Assume that this action is Hamiltonian with quantum comoment map $\Phi$ so it makes sense to speak about weakly $G$-equivariant and $G$-equivariant $\mathcal{A}$-modules. Then the equivariant derived category $D^b_{G,\lambda}(\mathcal{A} -\text{mod})$ is defined as follows. Consider the Chevalley-Eilenberg complex $\tilde{U}(\mathfrak{g})$, a standard resolution of the trivial one-dimensional $\mathfrak{g}$-module, and form the tensor product $\mathcal{A} \otimes \tilde{U}(\mathfrak{g})$. This is a differential graded algebra equipped with a Hamiltonian $G$-action (the diagonal action together with the diagonal quantum comoment map). So it makes sense to speak about $G$-equivariant differential graded $\mathcal{A} \otimes \tilde{U}(\mathfrak{g})$-modules. The category $D^b_{G,\lambda}(\mathcal{A} -\text{mod})$ is obtained from the category of those modules by passing to the homotopy category and localizing the quasi-isomorphisms.

Consider the natural homomorphism $\sigma : \mathcal{A} \otimes \tilde{U}(\mathfrak{g}) \to \mathcal{A}$ of differential graded algebras (taking the 0th homology). The pull-back functor $\sigma^*$ is a natural functor $D^b_{G,\lambda}(\mathcal{A} -\text{mod}) \to D^b_G(\mathcal{A} -\text{mod})$. On the other hand, the category of $G$-equivariant $\mathcal{A} \otimes U(\mathfrak{g})$-modules is the same as the category of weakly $G$-equivariant $\mathcal{A}$-modules. We have a $G$-equivariant homomorphism $\iota : \mathcal{A} \otimes U(\mathfrak{g}) \to \mathcal{A} \otimes \tilde{U}(\mathfrak{g})$ intertwining the quantum moment maps. This gives a pull-back functor $\iota^* : D^b_G(\mathcal{A} -\text{mod}) \to D^b(\mathcal{A} \otimes U(\mathfrak{g}) -\text{mod})$. The composition $\iota^* \circ \sigma^* : D^b(\mathcal{A} -\text{mod}^{G}) \to D^b(\mathcal{A} \otimes U(\mathfrak{g}) -\text{mod}^{G})$ comes from the forgetful functor between abelian categories – from the strongly equivariant category to a weakly equivariant one. Besides, we have left adjoints of $\iota^*, \sigma^*$, the functors $\iota_! : \mathcal{O} \subseteq \mathcal{A} \subseteq \mathcal{A} \otimes \tilde{U}(\mathfrak{g})$ and $\sigma_! : \mathcal{O} \subseteq \mathcal{A} \subseteq \mathcal{A} \otimes \tilde{U}(\mathfrak{g})$.
This discussion implies the following lemma to be used in what follows.

**Lemma 2.14** Let $V$ be a $G$-module. For $M \in D^b_G(A \text{-mod})$, we have a natural isomorphism

$$\text{Hom}_{D^b_G(A \text{-mod})}((A \otimes V) \otimes^L_{U(\mathfrak{g})} \mathbb{C}, M) \cong \text{Hom}_G(V, H_0(M)).$$

### 2.5.4 Functors for derived categories

Let us proceed to derived analogs of $\pi^\theta_\lambda(v), \pi_0^\lambda(v)$ and $\pi_0^\lambda(v)!$.

The functor $\varpi^\star : D^b(D(R) -\text{mod}^{G, \lambda}) \rightarrow D^b_G(D(R) -\text{mod})$ is an equivalence provided $\mu$ is flat, see [7, Theorem 1.6]. This generalizes to any filtered algebra $A$, not just $D(R)$, provided the filtration is complete and separated.

In general, i.e. without additional assumptions on $\mu$, we have the following lemma. Consider the subcategories

$$D^b_{\theta - \text{uns}}(D(R) -\text{mod}^{G, \lambda}), D^b_{G, \lambda, \theta - \text{uns}}(D(R) -\text{mod})$$

of all all objects with (singular) supports of homology contained in $(T^*R)^{\theta - \text{uns}}$.

**Lemma 2.15** The induced functor

$$D^b(D(R) -\text{mod}^{G, \lambda})/D^b_{\theta - \text{uns}}(D(R) -\text{mod}^{G, \lambda}) \rightarrow D^b_{G, \lambda}(D(R) -\text{mod})/D^b_{G, \lambda, \theta - \text{uns}}(D(R) -\text{mod})$$

is a category equivalence.

**Proof** Let $U$ be a $G$-stable open affine subvariety of $T^* R$. Recall from [7, Theorem 1.6] that if $G$ acts freely on $U$, then the functors $\varpi^*_U \circ \varpi_U$, $\varpi_U$ for the algebra $A = D_R(U)$ are mutually inverse equivalences. We have t-exact functors

$$D^b(D(R) -\text{mod}^{G, \lambda}) \rightarrow D^b(A -\text{mod}^{G, \lambda}), D^b_{G, \lambda}(D(R) -\text{mod})$$

induced by microlocalization. They intertwine $\varpi^*_U$ with $\varpi^*_U$ and $\varpi_U$ with $\varpi_U!$.

We need to show that for all $M \in D^b(D(R) -\text{mod}^{G, \lambda}), N \in D^b_{G, \lambda}(D(R) -\text{mod})$ the cones of the adjunction morphisms $\omega_U \circ \omega^*_U(M) \rightarrow M$ and $N \rightarrow \omega_U \circ \omega_U!(N)$ have cohomology supported on $\mu^{-1}(0)^{\theta - \text{uns}}$. Indeed, this precisely means that $\omega^*_U, \omega_U$ give mutually quasi-inverse equivalences between the quotient categories.

Let $\omega_U \circ \omega^*_U(M) \rightarrow M \rightarrow M_0 \xrightarrow{+1} M_U$ be a distinguished triangle. By the first paragraph of the proof, $\omega_U \circ \omega^*_U(M|U) \xrightarrow{\sim} M_U$. It follows that the microlocalization $M_0|_U$ is zero, equivalently, the cohomology of $M_0$ are supported away
from $U$. Note that $(T^*R)^{\theta-ss}$ is covered by open affine $G$-stable subvarieties of the form $(T^*R)_f$, where $f$ is a $G$-semiinvariant. It follows that the cohomology of $M_0$ are supported on $\mu^{-1}(0)^{\theta-uns}$. The statement for $N \to \omega^* \circ \omega_!(N)$ is established similarly. 

So we can extend the functor $\pi^\theta_!(v)$ to a t-exact functor $D^b_{G,\lambda}(D_R \text{-Mod}) \to D^b(A^0_\lambda(v) \text{-Mod})$. Assuming the former is a quotient functor, so is the latter.

Let us consider a derived version of $\pi^0_!(v)$. This functor extends to $D^b(D(R) \text{-mod}^{G,\lambda}) \to D^b(A^0_\lambda(v) \text{-mod})$ and we have the derived left adjoint functor $L\pi^0_!(v)^! : D^b(A^0_\lambda(v) \text{-mod}) \to D^b(D(R) \text{-mod}^{G,\lambda})$.

When $\lambda$ is Zariski generic, we can also lift $\pi^0_!(v)$ to a quotient functor $D^-(D(R) \text{-mod}) \to D^-(A^0_\lambda(v) \text{-mod})$. For this, we need the following proposition.

**Proposition 2.16** The following is true:

1. There is a Zariski open asymptotically generic subset $P_{ISO} \subset P_{iso}$ such that $\text{Tor}^i_{U(\mathfrak{g})}(D(R), C_\lambda) = 0$ for all $i > 0$ and $\lambda \in P_{iso}$.

2. For $\lambda \in P_{ISO}$, the functor $\pi^0_!(v) := \text{Hom}_{D^b_{G,\lambda}(D(R) \text{-mod})}(Q_\lambda, \bullet)$ maps $M \in D(R) \text{-mod}^{G,\lambda}$ to $H^0(M)^G$. It is a quotient functor $D^b_{G,\lambda}(D_R \text{-mod}) \to D^b(A^0_\lambda(v) \text{-mod})$ with a left adjoint and right inverse functor $L\pi^0_!(v)^!$ given by $Q_\lambda \otimes^L A^0_\lambda(v) \bullet$.

**Proof** (1) will be proved below, see Sect. 3.6. (2) follows from (1) and Lemma 2.14 applied to the trivial $G$-module $V$. 

### 2.5.5 Global section and localization functors

We write $R\Gamma^\theta_\lambda : D^b(A^\theta_\lambda(v) \text{-mod}) \to D^b(A^\theta_\lambda(v) \text{-mod})$ for the derived global sections functor, this makes sense by (2) of Lemma 2.11. The functor extends also to bounded above derived category. There it has a left adjoint, the derived localization functor,

$$L\text{Loc}^\theta_\lambda : A^\theta_\lambda(v) \otimes^L A^0_\lambda(v) \bullet : D^-(A^0_\lambda(v) \text{-mod}) \to D^-(A^\theta_\lambda(v) \text{-mod}).$$

We will also consider the abelian versions of these functors: $\Gamma^\theta_\lambda$ and its left adjoint $\text{Loc}^\theta_\lambda$.

**Lemma 2.17** Assume that $\lambda \in P^{ISO}$. Then $L\text{Loc}^\theta_\lambda = \pi^\theta_!(v) \circ L\pi^0_!(v)$. 

\[ \square \]
Proof The functor $L\pi^0_\lambda(v)^!$ is the derived tensor product with $Q_\lambda$. The functor $\pi^\theta_\lambda(v)$ is the composition of three functors, $\pi^\theta_\lambda(v) = \pi_3 \circ \pi_2 \circ \pi_1$, where the functors $\pi_1, \pi_2, \pi_3$ are as follows. First, we have the quotient functor

$$\pi_1 : D^-_{G,\lambda}(D(R) - \text{mod}) \twoheadrightarrow D^-_{G,\lambda}(D(R) - \text{mod}) / D^-_{G,\lambda}(D(R) - \text{mod})_{\theta - \text{uns}}.$$ 

Second, we have the identification

$$\pi_2 : D^-_{G,\lambda}(D(R) - \text{mod}) / D^-_{G,\lambda,\theta - \text{uns}}(D_R - \text{mod}) \sim D^-(D_R - \text{mod}^{G,\lambda}) / D^-_{\theta - \text{uns}}(D_R - \text{mod}^{G,\lambda}),$$

see Lemma 2.15. Third, we have the equivalence

$$\pi_3 : D^- (D_R - \text{mod}^{G,\lambda}) / D^-_{\theta - \text{uns}}(D_R - \text{mod}^{G,\lambda}) \sim D^-(A^\theta_\lambda(v) - \text{mod})$$

that is realized by taking $G$-invariants. The functor

$$\pi_2 \circ \pi_1 \circ L\pi^0_\lambda(v)^! : D^- (A^\lambda_\lambda(v) - \text{mod})$$

$$\rightarrow D^- (D_R - \text{mod}^{G,\lambda}) / D^-_{\theta - \text{uns}}(D_R - \text{mod}^{G,\lambda})$$

is isomorphic to $\pi_3^{-1}(Q_\lambda \otimes^L_{A^\lambda_\lambda(v)} \bullet)$. From here we deduce that

$$\pi^\theta_\lambda(v) \circ L\pi^0_\lambda(v)^! = [Q_\lambda|_{T^* R^{\theta - \text{ss}}} \otimes A^0_\lambda(v) (\bullet)]^G = A^\theta_\lambda(v) \otimes^L_{A^0_\lambda(v)} \bullet.$$

But the functor $L\text{Loc}^\theta_\lambda$ is $A^\theta_\lambda(v) \otimes^L_{A^0_\lambda(v)} \bullet$, by its definition. □

Let $D^b_Y(A^\lambda_\lambda(v) - \text{mod}) \subset D^b(A^\lambda_\lambda(v) - \text{mod})$, $D^b_{\rho^{-1}(Y)}(A^\lambda_\lambda(v) - \text{mod}) \subset D^b(A^\lambda_\lambda(v) - \text{mod})$ denote the full subcategories consisting of all objects whose homology have support contained in $Y$, $\rho^{-1}(Y)$, respectively.

Lemma 2.18 The functor $R\Gamma^\theta_\lambda$ maps $D^b_{\rho^{-1}(Y)}(A^\lambda_\lambda(v))$ to $D^b_Y(A^\lambda_\lambda(v) - \text{mod})$, while $L\text{Loc}^\theta_\lambda$ sends $D^-_Y(A^\lambda_\lambda(v))$ to $D^-_{\rho^{-1}(Y)}(A^\theta_\lambda(v))$.

Proof Note that for an open affine $U \subset M(v)$ the microlocalization functors to $U$ and $\rho^{-1}(U)$ intertwine the functor $L\text{Loc}^\theta_\lambda$ with its counterpart for the restriction of $\rho$ to $\rho^{-1}(U)$. So if $M \in A^\lambda_\lambda(v) - \text{mod}$ is supported away from $U$, then $L\text{Loc}^\theta_\lambda(M)$ is supported away from $\rho^{-1}(U)$.

To prove the corresponding statement for $R\Gamma^\theta_\lambda$, we need to use that $\rho$ is proper so that $R\rho_*$ maps coherent sheaves to coherent ones. Using this it is easy to prove that $R\Gamma$ maps sheaves supported away from $\rho^{-1}(U)$ to complexes with homology supported away from $U$. □
In particular, \( R\Gamma^\theta_\lambda \) maps \( D^b_{\rho-1(0)}(A^\theta_\lambda(v)\mod) \) to \( D^b_0(A^\theta_\lambda(v)\mod) \), while \( L\text{Loc}^\theta_\lambda \) maps \( D^-_{\rho-1(0)}(A^\theta_\lambda(v)\mod) \) to \( D^-_0(A^\theta_\lambda(v)\mod) \). In the case when \( R\Gamma^\theta_\lambda \) is an equivalence

\[
D^b(A^\theta_\lambda(v)\mod) \simto D^b(A^\theta_\lambda(v)\mod),
\]

it restricts to an equivalence

\[
D^b_{\rho-1(0)}(A^\theta_\lambda(v)\mod) \simto D^b_0(A^\theta_\lambda(v)\mod)
\]

with quasi-inverse \( L\text{Loc}^\theta_\lambda \).

In what follows, we will write \( D^b_{\text{fin}} \) instead of \( D^b_0 \).

3 Harish–Chandra bimodules and restriction functors

Harish–Chandra (shortly, HC) bimodules and restriction functors between the categories of HC bimodules play a crucial role in this paper. In this section we review a definition and basic properties of these bimodules (Sects. 3.1, 3.2). In the remaining sections, we construct restriction functors for HC bimodules over quantized quiver varieties, study their basic properties and provide some applications. In particular, we prove Proposition 2.7 and part (1) of Proposition 2.16.

3.1 Harish–Chandra bimodules

Let us start with a general definition of a Harish–Chandra bimodule, compare to [18, 31, 38, 41]. Let \( \mathcal{A} = \bigcup_{i \leq 0} \mathcal{A}^{\leq i} \), \( \mathcal{A}' = \bigcup_{i = 0} \mathcal{A}'^{\leq i} \) be \( \mathbb{Z}_{\geq 0} \)-filtered algebras such that the algebras \( \text{gr} \mathcal{A} \), \( \text{gr} \mathcal{A}' \) are identified with graded Poisson quotients of the same finitely generated commutative graded Poisson algebra \( \mathcal{A} \). Below we will always consider graded Poisson algebras, where the bracket has degree \(-1\).

We will take \( \mathcal{A} = A^0_\lambda(v) \), \( \mathcal{A}' = A^0_{\lambda'}(v) \) or sometimes \( \mathcal{A} = A^0_\lambda(v) \), \( \mathcal{A}' = A^0_{\lambda'}(v) \) (the filtration on \( \mathcal{A} \) is induced from the differential operator filtration on \( D(R) \)). In the first case, we take \( A := \mathbb{C}[\mathcal{M}^0_0(v)] \) (where we consider \( \mathcal{M}^0_0(v) \) with its natural scheme structure), in the second case put \( A := \mathbb{C}[\mathcal{M}(v)] \) so that \( \text{gr} \mathcal{A} = \text{gr} \mathcal{A}' = A \).

3.1.1 Definition

By a Harish–Chandra (HC) \( \mathcal{A}'\mathcal{A} \)-bimodule we mean a bimodule \( \mathcal{B} \) that can be equipped with a bimodule \( \mathbb{Z} \)-filtration bounded from below, \( \mathcal{B} = \bigcup_i \mathcal{B}^{\leq i} \), such
that \( \text{gr} \ B \) is a finitely generated \( A \)-module (meaning, in particular, that the left and the right actions of \( A \) coincide). Such a filtration on \( B \) is called \textit{good}. We remark that every HC bimodule is finitely generated both as a left \( A' \)-module and as a right \( A \)-module. We also remark that, although \( \text{gr} \ B \) does depend on the choice of a filtration on \( B \), the support of \( \text{gr} \ B \) in \( \text{Spec}(A) \) depends only on \( B \), this support is called the \textit{associated variety} of \( B \) and is denoted by \( V(B) \). We remark that \( V(B) \) is always a Poisson subvariety of \( \text{Spec}(A) \).

By a homomorphism of HC bimodules we mean a bimodule homomorphism. Given a homomorphism \( \varphi : B \to B' \) we can find good filtrations \( B = \bigcup_i B^{\leq i} \) and \( B' = \bigcup_i B'^{\leq i} \) with \( \varphi(B^{\leq i}) \subset B'^{\leq i} \) for all \( i \). Indeed, if \( \text{gr} \ B \) is generated by homogeneous elements of degree up to \( d \) then we can use any good filtration on \( B' \) such that \( \varphi(B^{\leq i}) \subset B'^{\leq i} \) for \( i \leq d \).

For example, both \( A_{\lambda}(v) \), \( A_{\lambda'}(v) \) are HC \( A_{\lambda}(v) \)-bimodules. It follows that any HC \( A_{\lambda'}(v) \)-\( A_{\lambda}(v) \)-bimodule is HC also when viewed as a \( A_{\lambda'}(v) \)-\( A_{\lambda'}(v) \)-bimodule.

### 3.1.2 Rees construction

Starting from \( A \), we can form the Rees algebra \( \bar{A}_\hbar := \bigoplus_i A^{\leq i} \hbar^i \) that is graded with \( \deg \hbar = 1 \).

We can introduce a notion of a Harish–Chandra \( A'_{\hbar'} \)-\( A_{\hbar} \)-bimodule: those are finitely generated graded \( A'_{\hbar'} \)-\( A_{\hbar} \)-bimodules \( B_\hbar \) with \( a m - ma \subset \hbar B_\hbar \) (for \( a, a' \) such that \( a + \hbar A_{\hbar}, a' + \hbar A'_{\hbar} \) are the images of a single element \( \tilde{a} \in A \)) that are free over \( \mathbb{C}[\hbar] \). To pass from HC \( A_{\hbar} \)-bimodules to HC \( A \)-bimodules with a fixed good filtration, one mods out \( \hbar - 1 \). To get back, one takes the Rees bimodule.

### 3.1.3 Derived categories

Consider the category \( \mathcal{D}^{-}_{HC}(A' - A \text{-bimod}) \) consisting of all bounded above complexes of \( A' - A \)-bimodules whose homology are Harish–Chandra. Similarly to [18, Proposition 6.3], the subcategories \( \mathcal{D}^{-}_{HC}(...) \subset \mathcal{D}^{-}(...) \) are closed with respect to

\[
\otimes^L_{A'} : \mathcal{D}^{-}(A'' - A' \text{-bimod}) \times \mathcal{D}^{-}(A' - A \text{-bimod}) \to \mathcal{D}^{-}(A'' - A \text{-bimod}).
\]

The same argument implies that \( R \text{Hom}_A \) sends \( \mathcal{D}^{-}_{HC}(A - A' \text{-bimod}) \times \mathcal{D}^{+}_{HC}(A' - A'' \text{-bimod}) \) to \( \mathcal{D}^{+}_{HC}(A' - A'' \text{-bimod}) \).
3.1.4 Translation bimodules

Let us provide two closely related examples of HC bimodules over the algebras \( A_0(v) \): translation bimodules.

Recall the \( D(R)\)-\( A_0(v) \)-bimodule \( Q_0 \) from 2.5.2. Pick \( \chi \in \mathbb{Z}Q_0 \). We can consider the \( A_0(v) \)-\( A_0(v) \)-bimodule \( A^0_{\lambda,\chi}(v) = Q^G_{\lambda,\chi} \). This bimodule is HC, the filtration on \( A^0_{\lambda,\chi}(v) \) induced from the filtration on \( D(R) \) by the order of a differential operator is good.

Now consider the restriction \( Q_0 |_{T^* R^{\theta-ss}} \) and set \( A^0_{\lambda,\chi}(v) := [Q_0 |_{T^* R^{\theta-ss}}]^G_{\lambda,\chi} \). This is a sheaf on \( M^{\theta}(v) \) that is an \( A^0_{\lambda,\chi}(v) \)-\( A^0_{\lambda,\chi}(v) \)-bimodule. Set \( \Gamma(A^0_{\lambda,\chi}(v)) := \Gamma(A^0_{\lambda,\chi}(v)) \). That it is HC was demonstrated in [18, Section 6.3] but we want to sketch a proof. Namely, notice that \( \text{gr } A^0_{\lambda,\chi}(v) = \mathcal{O}(\chi) \). Consider the Rees bimodule \( A^0_{\lambda,\chi}(v)h \) that is a deformation of \( \mathcal{O}(\chi) \). Then \( \Gamma(A^0_{\lambda,\chi}(v))h \) is the Rees bimodule for \( A^0_{\lambda,\chi}(v) \). But \( \Gamma(A^0_{\lambda,\chi}(v))/h \) embeds into \( \Gamma(\mathcal{O}(\chi)) \), the latter is a \( \mathbb{C}[\mathcal{M}^{\theta}(v)] \)-module rather than just a bimodule. This completes the proof.

We have a natural bimodule homomorphism

\[
A^0_{\lambda,\chi}(v) \to A^0_{\lambda,\chi}(v) \tag{3.1}
\]

induced by the restriction map \( Q_0 \to Q_0 |_{T^* R^{\theta-ss}} \). A priori, (3.1) is neither injective, not surjective. In Sect. 4 we will get some sufficient conditions for (3.1) to be an isomorphism.

3.1.5 Further properties

Finally, we need some results from [47]. The next lemma follows from Theorems 1.2, 1.3 or Section 4.3 there.

**Lemma 3.1** Every HC \( A^0_{\lambda,\chi}(v) \)-\( A^0_{\lambda,\chi}(v) \)-bimodule has finite length.

The following claim is [47, Lemma 4.2].

**Lemma 3.2** Let \( B \) be a HC \( A^0_{\lambda,\chi}(v) \)-\( A^0_{\lambda,\chi}(v) \) bimodule and \( J_\ell, J_r \) be its left and right annihilators. Then \( V(B) = V(A^0_{\lambda,\chi}(v)/J_\ell) = V(A^0_{\lambda,\chi}(v)/J_r) \).

3.2 Families of Harish–Chandra bimodules

Recall from 2.1.5 that we have the scheme \( \mathcal{M}^0_{\mathfrak{p}}(v) = \mu^{-1}(\mathfrak{g}^*G)^{\theta-ss} / G \) over \( p \). In Sect. 2.2 we have introduced the sheaf of \( \mathbb{C}[\mathfrak{M}] \)-algebras

\[
A^0_{\mathfrak{p}}(v) := [Q_{\mathfrak{p}} |_{T^* R^{\theta-ss}}]^G,
\]

\( \odot \) Springer
where we write $\mathcal{Q}_\mathfrak{P}$ for $D(R)/D(R)\Phi([\mathfrak{g}, \mathfrak{g}])$, on $\mathcal{M}_p^\theta(v)$, and the $\mathbb{C}[\mathfrak{P}]$-algebra $\mathcal{A}_\mathfrak{P}(v) = \Gamma(\mathcal{A}_\mathfrak{P}^\theta(v)).$ We also consider the global Hamiltonian reduction $\mathcal{A}_\mathfrak{P}^0(v) := [\mathcal{Q}_\mathfrak{P}]^G$. Also, for a vector subspace $p_0 \subset p$, we can consider the specialization $\mathcal{A}_p^\theta(v)$ and, for an affine subspace $\mathfrak{P}_0 \subset \mathfrak{P}$, we consider the specializations $\mathcal{A}_\mathfrak{P}_0^\theta(v), \mathcal{A}_\mathfrak{P}_0(v), \mathcal{A}_\mathfrak{P}^0(v)$.

The algebra $\mathcal{A}_{\mathfrak{P}_0}(v)$ is filtered with commutative associated graded (equal to $\mathbb{C}[\mathcal{M}_{p_0}(v)]$, where $p_0$ is the vector subspace of $p$ parallel to $\mathfrak{P}_0$). The algebra $\mathcal{A}_{\mathfrak{P}_0}^0(v)$ is filtered as well with $\mathbb{C}[\mathcal{M}_{p_0}^0(v)]$ denoted as graded associated of $(\mathcal{A}_{\mathfrak{P}_0}^0(v)).$ So it makes sense to speak about HC $\mathcal{A}_{\mathfrak{P}_0}(v)$-bimodules or HC $\mathcal{A}_{\mathfrak{P}_0}^0(v)$-bimodules. Also for two parallel affine subspaces $\mathfrak{P}_0 \subset, \mathfrak{P}_0 \subset$ one can speak about HC $\mathcal{A}_{\mathfrak{P}_0}(v)$ $\mathcal{A}_{\mathfrak{P}_0}(v)$-bimodules or about HC $\mathcal{A}_{\mathfrak{P}_0}^0(v)-\mathcal{A}_{\mathfrak{P}_0}^0(v)$-bimodules.

For $\mathcal{A}_{\mathfrak{P}_0}^0(v)-\mathcal{A}_{\mathfrak{P}_0}^0(v)$-bimodules we can still consider the corresponding derived category of all complexes with HC homology. These categories are closed under derived tensor products or under $R$ Hom’s of left or right modules. The proofs are as for $\mathcal{A}_{\lambda,\chi}(v)-\mathcal{A}_{\lambda,\chi}^0(v)$-bimodules.

### 3.2.1 Translation bimodules

For example, we have the HC $\mathcal{A}_{\mathfrak{P}_0}(v)-\mathcal{A}_{\mathfrak{P}_0}(v)$-bimodule $\mathcal{A}_{\mathfrak{P}_0,\chi}(v)$ (where $\mathfrak{P}_0 = \chi + \mathfrak{P}_0$). This is the most important family of HC bimodules considered in this paper. Obviously, the specialization of $\mathcal{A}_{\mathfrak{P}_0,\chi}(v)$ to $\lambda \in \mathfrak{P}_0$ coincides with $\mathcal{A}_{\lambda,\chi}(v)$.

Yet another family that we will need for technical reasons is $\mathcal{A}_{\mathfrak{P}_0,\chi}^{(\theta)}(v)$ defined analogously to $\mathcal{A}_{\lambda,\chi}^{(\theta)}(v)$. This is a HC $\mathcal{A}_{\mathfrak{P}_0+\chi}(v)-\mathcal{A}_{\mathfrak{P}_0}(v)$-bimodule and hence also a HC $\mathcal{A}_{\mathfrak{P}_0+\chi}(v)-\mathcal{A}_{\mathfrak{P}_0}(v)$-bimodule. An important result here is as follows [18, Proposition 6.23].

**Proposition 3.3** The $\mathcal{A}_{\mathfrak{P}}(v)$-bimodule $\mathcal{A}_{\mathfrak{P},\chi}^{(\theta)}(v)$ is independent of $\theta$.

Let us provide the proof for readers convenience, since it is omitted in [18].

**Proof** Recall the variety $\mathcal{M}_p(v)$ introduced after Corollary 2.4 that comes with a projective morphism $\mathcal{M}_p^\theta(v) \rightarrow \mathcal{M}_p(v)$. This morphism is Poisson by construction and is a fiberwise resolution of singularities. Let us write $\mathcal{M}_p(v)^{reg}$ for the union of open symplectic leaves in the fibers of $\mathcal{M}_p(v) \rightarrow p$. This is an open subvariety of $\mathcal{M}_p(v)$ because the dimension of a symplectic leaf is an upper-semicontinuous function. Let $\mathcal{M}_p^\theta(v)^{reg}$ denote its preimage in $\mathcal{M}_p^\theta(v)$. Then $\mathcal{M}_p^\theta(v)^{reg} \cong \mathcal{M}_p(v)^{reg}$ is an isomorphism. In particular, the varieties $\mathcal{M}_p^\theta(v)^{reg}$ are identified for different generic $\theta$.

The sheaf $\mathcal{A}_{\mathfrak{P},\chi}^\theta|\mathcal{M}_p(v)^{reg}$ is a quantization of $\mathcal{O}_p(\chi)|\mathcal{M}_p(v)^{reg}$. 

\[ \text{Springer} \]
The 1st cohomology of the structure sheaf of $M_p(v)^{reg}$ vanish. This is because $H^1(M_p^0(v), \mathcal{O}) = 0$, $M_p(v)$ is Cohen–Macaulay, and the complement of $M_p(v)^{reg}$ in $M_p(v)$ has codimension 3, compare to the proof of Proposition of [18, Proposition 3.7]. It follows that there is a unique microlocal deformation of $\mathcal{O}(\chi)|_{M_p(v)^{reg}}$ to an $A_{\mathfrak{p}, \chi}^\theta(v)|_{M_p(v)^{reg}}$-bimodule. So the restrictions of all $A_{\mathfrak{p}, \chi}^\theta(v)$ to $M_p(v)^{reg}$ coincide. Since the codimension of $M_p^0(v) \setminus M_p^0(v)^{reg}$ is bigger than 2, we have $\Gamma(M_p^0(v)^{reg}, A_{\mathfrak{p}, \chi}^\theta(v)) = \Gamma(M_p^0(v), A_{\mathfrak{p}, \chi}^\theta(v))$. The left hand side is independent of $\theta$ and so we get the claim of the proposition.

We would like to point out that the specialization $A_{\mathfrak{p}, \chi}^\theta(v)$ admits a natural homomorphism to $A_{\chi, \chi}^\theta(v)$. This homomorphism is injective because $\Gamma$ is left exact. We do not know if this is an isomorphism in general, but this is so under additional assumptions:

**Lemma 3.4** Let $\mathfrak{p}_0 \subset \mathfrak{p}$ be an affine subspace and pick $\chi \in \mathbb{Z}^Q_0$. Suppose that one of the following conditions holds:

1. $H^1(M^0(v), \mathcal{O}(\chi)) = 0$.
2. $(\lambda + \chi, \theta) \in \mathfrak{N}(v)$.

Then $A_{\chi, \chi}^\theta(v) = A_{\chi, \chi}^\theta(v)$.

**Proof** We can view $A_{\chi, \chi}^\theta(v)$ as a sheaf on $M^0(v)$ quantizing $\mathcal{O}(\chi)$. Let us show that both our assumptions imply that $H^1(A_{\chi, \chi}^\theta(v)) = 0$. Then we can apply [18, Proposition 6.26] to deduce $A_{\chi, \chi}^\theta(v) = A_{\chi, \chi}^\theta(v)\chi$.

The filtration on $A_{\chi, \chi}^\theta(v)$ induces a separated filtration on $H^1(M^0(v), A_{\chi, \chi}^\theta(v))$ (the claim that the filtration is separated is proved similarly to the proof of [33, Lemma 5.6.3]) with $H^1(M^0(v), \mathcal{O}(\chi)) \rightarrow \text{gr} H^1(M^0(v), A_{\chi, \chi}^\theta(v))$. So the equality $H^1(M^0(v), \mathcal{O}(\chi)) = 0$ implies $H^1(M^0(v), A_{\chi, \chi}^\theta(v)) = 0$.

Now assume that $(\lambda + \chi, \theta) \in \mathfrak{N}(v)$. Then any object in $A_{\chi}^\theta(v)$-mod has no higher cohomology, and we are done.

3.2.2 Supports in parameters

We also have the following elementary but important property. By the right $\mathfrak{p}$-support of an $A_{\mathfrak{p}}(v)$-bimodule $B$ (denoted by $\text{Supp}^r_{\mathfrak{p}}(B)$), we mean the set of all $\lambda \in \mathfrak{p}$ such that the specialization $B_\lambda$ is nonzero. Analogously, we can speak about the left support $\text{Supp}^l_{\mathfrak{p}}(B)$.
Lemma 3.5 For a reduced closed subscheme $Y$ of $\mathcal{P}$, set $A^0_Y(v) := \mathbb{C}[Y] \otimes_{\mathbb{C}[\mathcal{P}]} A^0_\mathcal{P}(v)$. Any finitely generated right $A^0_Y(v)$-module $B$ is generically free over $\mathbb{C}[Y]$, i.e., there is a non zero divisor $f \in \mathbb{C}[Y]$ such that the localization $B_f$ is a free $\mathbb{C}[Y]_f$-module.

Proof We will need to modify a filtration on $A^0_Y(v)$ so that $\mathbb{C}[Y]$ lives in degree 0. Consider the Rees algebra $\tilde{A}^0_\mathcal{P}(v)_h$ and its base change $\tilde{A}^0_\mathcal{P}(v)_{\bar{h}} = \mathbb{C}[\mathcal{P}, h] \otimes_{\mathbb{C}[\mathcal{P}, h]} A^0_\mathcal{P}(v)_h$, where the endomorphism of $\mathbb{C}[\mathcal{P}, h]$ used to form the tensor product is given by $\bar{h} \mapsto h, \alpha \mapsto \bar{h} \alpha$ for $\alpha \in \mathcal{P}^*$. The algebra $\tilde{A}^0_\mathcal{P}(v)_{\bar{h}}$ is graded with $\deg \bar{h} = 1$, $\deg \mathbb{C}[\mathcal{P}] = 0$. Also the specializations of $\tilde{A}^0_\mathcal{P}(v)_h, A^0_\mathcal{P}(v)_h$ at $\bar{h} = 1$ are the same and so coincide with $A^0_\mathcal{P}(v)$. We equip $A^0_\mathcal{P}(v)$ with the filtration coming from the grading on $\tilde{A}^0_\mathcal{P}(v)_h$ and we equip the quotient $A^0_Y(v)$ of $A^0_\mathcal{P}(v)$ with the induced filtration. We remark that $\text{gr} A^0_Y(v)$ is now a quotient of $\mathbb{C}[M^0(v)] \otimes \mathbb{C}[Y]$.

A finitely generated right module $B$ admits a good filtration. By a general commutative algebra result [25, Theorem 14.4], $\text{gr} B$ is generically free over $\mathbb{C}[Y]$. So there is a non zero divisor $f$ such that $(\text{gr} B)_f$ is free over $\mathbb{C}[Y]_f$. It follows that $B_f$ and $(\text{gr} B)_f$ are isomorphic free $\mathbb{C}[Y]_f$-modules, and we are done.

There is a trivial but very important corollary of this lemma.

Corollary 3.6 Let $B$ be a Harish–Chandra $A^0_{\mathcal{P}'}(v) - A^0_{\mathcal{P}_0}(v)$-bimodule. Then the following claims hold:

1. There is $f \in \mathbb{C}[\mathcal{P}_0]$ such that $B_f$ is a free $\mathbb{C}[\mathcal{P}_0]_f$-module.
2. $\text{Supp}_{\mathcal{P}_0}(B)$ is a constructible set.

We also have left-handed analogs of these claims.

Proof A Harish–Chandra bimodule is finitely generated as a right $A_{\mathcal{P}_0}(v)$-module (this was noted in the beginning of Sect. 3.1). So (1) follows from Lemma 3.5.

To prove (2) we note that the support of any finitely generated right $A_Y(v)$-module is a constructible subset of $Y$. This follows from Lemma 3.5.

Below, Proposition 3.13, we will see that $\text{Supp}_{\mathcal{P}_0}(B)$ is actually a closed subset.

Here is how we are going to use (2). Let $B$ be a HC $A_{\mathcal{P}_0} - A_{\mathcal{P}_0}$-bimodule, where $\mathcal{P}_0 \subset \mathcal{P}$ is an affine subspace. Then if $B_{\lambda} = 0$ for a Weil generic $\lambda \in \mathcal{P}_0$ (we say that a parameter is Weil generic if it lies outside of the countable union of algebraic subvarieties), then $B_{\lambda} = 0$ for a Zariski generic
λ as well. HC $A_{\lambda + \chi}(v)$-bimodules for $\lambda$ Weil generic are easier then for an arbitrary (even Zariski generic) $\lambda$. We will use this observation many times in our discussion of short wall-crossing functors through the affine wall, Sect. 11.

### 3.3 Restriction functors: construction

We want to define restriction functors for Harish–Chandra bimodules over $A^0_\mathbb{P}(v)$ (or over $A^\theta_\mathbb{P}(v)$) similar to the functors $\bullet_3$ used in [38,41]. Those will be exact $C[\mathbb{P}]$-linear functors mapping HC bimodules over $A^0_\mathbb{P}(v)$ to those over $\hat{A}^0_\mathbb{P}(v)$, an algebra defined similarly to $A^0_\mathbb{P}(v)$ but for the quiver $\hat{Q}$ and vectors $\hat{v}, \hat{w}$ that were constructed in Sect. 2.1.6 (in fact, we will sometimes need to modify the algebras $\hat{A}^0_\mathbb{P}(\hat{v})$, see below).

#### 3.3.1 Algebras $\hat{A}^0_\mathbb{P}(\hat{v})$, etc.

Let us proceed to the construction of $\hat{A}^0_\mathbb{P}(\hat{v})$. Let $\hat{\mathbb{P}} = \hat{g}G^*$ be the parameter space for the quantizations associated to $(\hat{Q}, \hat{v}, \hat{w})$. Let us define an affine map $\hat{r} : \mathbb{P} \to \hat{\mathbb{P}}$ whose differential is the restriction map $r : gG^* \to \hat{g}G^*$. Namely, recall that we have elements $\varrho(v), \hat{\varrho}(\hat{v})$ (the former is defined by (2.8) and the latter is defined analogously). Now set

$$\hat{r}(\lambda) := r(\lambda - \varrho(v)) + \hat{\varrho}((\hat{v}). \tag{3.2}$$

Further, set $\hat{A}^0_\mathbb{P}(\hat{v}) := C[\hat{\mathbb{P}}] \otimes_{C[\mathbb{P}]} \hat{A}^0_\mathbb{P}(\hat{v})$ and define $\hat{A}^\theta_\mathbb{P}(\hat{v})$ in a similar way. Here

$$\hat{A}^0_\mathbb{P}(\hat{v}) := [D(\hat{R})/D(\hat{R})\Phi([\hat{g}, \hat{g}])]\hat{G},$$

where $\hat{R} = R(\hat{Q}, \hat{v}, \hat{w})$.

We want to get decompositions similar to (2.5),(2.6) at the quantum level. For this, we consider the Rees sheaves and algebras $A^0_\mathbb{P}(v)_\hbar, A^\theta_\mathbb{P}(v)_\hbar$. $\hat{A}^0_\mathbb{P}(v)_\hbar$ defined for the filtrations by the order of a differential operator. We can complete those at $x$ getting the algebras $A^0_\mathbb{P}(v)^\wedge_x$, $A^\theta_\mathbb{P}(v)^\wedge_x$ with $A^0_\mathbb{P}(v)^\wedge_x / (\hbar) = C[M^0_\mathbb{P}(v)^\wedge_x], C[M^\theta_\mathbb{P}(v)^\wedge_x]$ $\to A^0_\mathbb{P}(v)^\wedge_x / (\hbar)$ and the sheaf of algebras $A^\theta_\mathbb{P}(v)^\wedge_x$ on $M^\theta_\mathbb{P}(v)^\wedge_x$ obtained by the $\hbar$-adic completion of

$$A^0_\mathbb{P}(v)^\wedge_x \otimes A^\theta_\mathbb{P}(v)_\hbar \otimes A^\theta_\mathbb{P}(v)_\hbar$$
Note that $A^\theta_\mathfrak{p}(v)^\wedge_x / (\hbar) = O_{A^\theta_\mathfrak{p}(v)^\wedge_x}$.

**Lemma 3.7** We have the following decompositions.

\begin{align}
A^0_\mathfrak{p}(v)^\wedge_x &= \hat{A}^0_\mathfrak{p}(v)^\wedge_0 \otimes_{\mathbb{C}[\hbar]} A^{\wedge_0}_\hbar, \\
A_\mathfrak{p}(v)^\wedge_x &= \hat{A}_\mathfrak{p}(v)^\wedge_0 \otimes_{\mathbb{C}[\hbar]} A^{\wedge_0}_\hbar, \\
A^\theta_\mathfrak{p}(v)^\wedge_x &= \left( \hat{A}^\theta_\mathfrak{p}(v)^\wedge_0 \otimes_{\mathbb{C}[\hbar]} A^{\wedge_0}_\hbar \right)^\wedge_0.
\end{align}

Isomorphisms (3.3), (3.5) become (2.5), (2.6) after setting $\hbar = 0$. (3.4) is obtained from (3.5) by taking global sections.

By $A_\hbar$ we denote the homogenized Weyl algebra of $R_0$ and we write $A^{\wedge_0}_\hbar$ for the quantization of the symplectic formal polydisk $R^{\wedge_0}_0$.

**Proof** The proof follows that of [42, Lemma 6.5.2]. We provide it for reader’s convenience.

Let $U$ denote the symplectic part of the slice module for $r$. Then, as we have mentioned in Sect. 2.1.6,

\[(T^* R)^{\wedge G_r} \cong ((T^* G \times U) / G_r)^{\wedge G / G_r},\]

where $G_r$ acts diagonally on $T^* G \times U$. We can consider the quantization $D_\hbar (R)^{\wedge G_r}$ of $(T^* R)^{\wedge G_r}$ obtained by the completion of the homogenized Weyl algebra on $T^* R$. Also we can consider the quantization

\[\left[ D_\hbar (G)^{\wedge G} \otimes_{\mathbb{C}[\hbar]} A_\hbar (U)^{\wedge_0} \right] / 0 G_r\]

of $([T^* G \times U] / G_r)^{\wedge G / G_r}$ (where we use the symmetrized quantum comoment map for $G_r$). Those are canonical quantizations in the sense of [11] (for the second quantization this follows from [42, Section 5.4]) and so they are isomorphic. Consequently, their reductions (both affine and GIT) for the $G$-action (again, with respect to the symmetrized quantum comoment map $\Phi^{sym}$) are isomorphic. But the reduction of the quantization of the right hand side of (3.6) coincides with

\[\mathbb{C}[\{p, \hbar\}] \otimes_{\mathbb{C}[\{p, \hbar\}]} \left[ A^{\wedge_0}_\hbar (U) / A^{\wedge_0}_\hbar (U) \hat{\Phi}^{sym} ([\hat{\mathfrak{g}}, \hat{\mathfrak{g}}]) \right]^{\hat{G}}.\]

Since $\Phi - \varrho (v), \hat{\Phi} - \hat{\varrho} (\hat{v})$ are the symmetrized quantum comoment maps, (3.3) and (3.5) follow. (3.4) is obtained from (3.5) via taking the global sections on both sides. \[\square\]
Let us observe that

$$r(q(v)) - \hat{q}(v) \in \mathbb{Z}^\hat{Q}_0. \quad (3.7)$$

Indeed, by reversing some arrows in $\hat{Q}$ (the quiver obtained from $\hat{Q}$ by adjoining the new vertex $\infty$, see 2.1.6), we can arrange (by reversing some arrows, perhaps, including arrows coming from $\infty$) that $R, R_x \oplus g/g_r$ are isomorphic up to a trivial direct summand. Since $g/g_r$ is an orthogonal $G_r$-module, we see that $\bigwedge^{top} R \cong \bigwedge^{top} R_x$ as $G_r$-modules. Then we need to turn $\infty$ back to a sink, so we have to reverse some arrows. Reversing an arrow in a quiver results in adding an integral character to the quantum comoment map, and so (3.7) follows.

3.3.2 Euler derivations

The sheaf $A^\theta_p(v)_h$ comes with a $\mathbb{C}^\times$-action (that is induced now by the fiberwise dilation action on $T^*R$) and hence with the Euler derivation $\mathfrak{e}u$ satisfying $\mathfrak{e}u(h) = h$. This derivation extends to the completion $A^\theta_p(v)_h^\times$. On the other hand, the product $\hat{A}_p^\theta(v)_h^\times \otimes_{\mathbb{C}[h]} A^\theta_0$ comes with a $\mathbb{C}^\times$-action, and hence with the Euler derivation $\hat{\mathfrak{e}}u$ again satisfying $\hat{\mathfrak{e}}u(h) = h$. We want to compare derivations $\mathfrak{e}u$ and $\hat{\mathfrak{e}}u$ of $A^\theta_p(v)_h^\times$ (and similarly defined derivations of $A^\theta_0(v)_h^\times$).

Lemma 3.8 There is an element $a \in A^\theta_p(v)_h^\times$ such that $\mathfrak{e}u - \hat{\mathfrak{e}}u = \frac{1}{h}[a, \cdot]$ on $A^\theta_p(v)_h^\times$ and on $A^\theta_0(v)_h^\times$.

Proof Consider a more general setting. Let $R$ be a vector space, $G$ be a reductive group acting on $R$, $v \in \mu^{-1}(0) \subset T^*R$ be a point such that $Gv$ is closed and $G_v$ is connected (for simplicity). Let $\Phi : g \to D_h(R)$ be a symmetrized quantized comoment map and let $\theta : G \to \mathbb{C}^\times$ be a character. Consider the quantum Hamiltonian reduction $(D_h(R)_\theta G)^\wedge_v$ (there the completion is taken at the image $x$ of $v$ in $T^*R/\mathcal{O}_G$). Let $d$ be a $G$-invariant $\mathbb{C}[h]$-linear derivation of $D_h(R)^{G_v}$ such that $d \circ \Phi = 0$ so that $d$ induces derivations $d^\theta$ on $(D_h(R)_\theta G)^\wedge_v$ and $d^0$ on $(D_h(R)_0 G)^\wedge_v$. We claim that

(*) there is an element $a \in (D_h(R)_\theta G)^\wedge_v$ such that $d^\theta = \frac{1}{h}[a, \cdot]$ and $d^0 = \frac{1}{h}[a, \cdot]$.

To apply (*) in our situation, we take $d = \mathfrak{e}u - \hat{\mathfrak{e}}u$. Here $\mathfrak{e}u$ is the derivation of $D_h(R)^{G_v}$ induced by the fiberwise $\mathbb{C}^\times$-action on $T^*R$ and $\hat{\mathfrak{e}}u$ is the derivation induced by the fiberwise $\mathbb{C}^\times$-action on $T^*(G \times G_v R_x)$.

To prove (*) note that we can replace $G$ with a finite central extension and assume that $G = G_0 \times T$, where $T$ is a torus and $G_0$ satisfies
$G_0 = (G_0, G_0)G_v$. So $D_h(R)^{\wedge G_v} = D_h(T)^{\wedge T} \widehat{\otimes}_{\mathbb{C}[\hbar]} D_h(Y)^{\wedge G_0 Y}$, where $Y = G_0 \ast_{G_v} R_x$ and $y$ is the point $[1, 0] \in Y$. The algebra $D_h(Y)^{\wedge G_0 Y}$ is the reduction of $D_h(R)^{\wedge G_v}$ by the action of $T$ and so $d$ descends to $D_h(Y)^{\wedge G_0 Y}$. Furthermore, $(D_h(R)^{\wedge G}Y)^{\wedge v} = D_h(Y)^{\wedge G_0 Y} \otimes^\theta G_0$. Let us note that $H^1_{DR}(T^*Y) = 0$ because of the assumption $G_0 = (G_0, G_0)G_v$. Modulo $\hbar$, the derivation $d$ is a symplectic vector field on the formal neighborhood of $G_0 y$ in $T^*Y$. So it is Hamiltonian. From here we deduce that $d = \frac{1}{\hbar} [\bar{a}, \cdot]$ for some element $\bar{a} \in D_h(Y)^{\wedge G_0 Y}$. This element commutes with $\Phi(\bar{g}_0)$ and hence is $G_0$-invariant. For $a$ we take its image in $(D_h(R)^{\wedge G}Y)^{\wedge \cdot}$. It is straightforward to see that this element satisfies $(\ast)$. 

\[\square\]

3.3.3 Construction of $\bullet_{\uparrow, x}$

Let us now proceed to constructing $\bullet_{\uparrow, x} : \text{HC}(A_\mathbb{F}(v)) \to \text{HC}(\hat{A}_\mathbb{F}(\hat{v}))$. Define the category $\text{HC}(A_\mathbb{F}(v)^{\wedge x})$ as the category of $A_\mathbb{F}(v)^{\wedge x}$-bimodules $B'_h$ that are

- finitely generated as bimodules,
- flat over $\mathbb{C}[\hbar]$ and complete and separated in the $\hbar$-adic topology,
- satisfy $[a, b] \in \hbar B'_h$ for all $a \in A_\mathbb{F}(v)^{\wedge x}$, $b \in B'_h$,
- and come equipped with a derivation $\tilde{\mathfrak{e}}u$ compatible with $\mathfrak{e}u$ on $A_\mathbb{F}(v)^{\wedge x}$.

Similarly, we can define the category $\text{HC}(\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0})$ (we need to have a derivation compatible with $\tilde{\mathfrak{e}}u$). The categories $\text{HC}(A_\mathbb{F}(v)^{\wedge x})$ and $\text{HC}(\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0})$ are equivalent as follows. Using the decomposition (3.4), we view $B'_h \in \text{HC}(A_\mathbb{F}(v)^{\wedge x})$ as a bimodule over $\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0} \widehat{\otimes}_{\mathbb{C}[\hbar]} \mathbb{A}_h^{\wedge 0}$. Similarly to [38, Proposition 3.3.1], this bimodule splits as $\hat{B}'_h \widehat{\otimes}_{\mathbb{C}[\hbar]} \mathbb{A}_h^{\wedge 0}$, where $\hat{B}'_h$ is an $\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0}$-bimodule. The derivation $\tilde{\mathfrak{e}}u := \mathfrak{e}u - \frac{1}{\hbar} [a, \cdot]$ on $B'_h$ is compatible with the derivation $\mathfrak{e}u$ on $\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0} \widehat{\otimes}_{\mathbb{C}[\hbar]} \mathbb{A}_h^{\wedge 0}$ and so restricts to $\hat{B}'_h$ making it an object of $\text{HC}(\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0})$. An equivalence $\text{HC}(A_\mathbb{F}(v)^{\wedge x}) \sim \text{HC}(\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0})$ we need maps $B'_h$ to $\hat{B}'_h$. A quasi-inverse equivalence sends $\hat{B}'_h$ to $\hat{B}'_h \widehat{\otimes}_{\mathbb{C}[\hbar]} \mathbb{A}_h^{\wedge 0}$.

Now we construct the functor $\bullet_{\uparrow}$. Pick $B \in \text{HC}(A_\mathbb{F}(v))$. Choose a good filtration on $B$ and let $B_h \in \text{HC}(A_\mathbb{F}(v)_h)$ be the Rees bimodule. So the completion $B^{\wedge x}_h$ is an $A_\mathbb{F}(v)^{\wedge x}_h$-bimodule. By the construction, $B_h$ comes with the derivation $\mathfrak{e}u := \hbar \partial_h$ compatible with the derivation $\mathfrak{e}u$ on $A_\mathbb{F}(v)_h$. The derivation $\mathfrak{e}u$ extends to $B^{\wedge x}_h$ that makes the latter an object of $\text{HC}(A_\mathbb{F}(v)^{\wedge x}_h)$. From this object we get $\hat{B}'_h \in \text{HC}(\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0}_h)$.

By [38, Proposition 3.3.1], the $\tilde{\mathfrak{e}}u$-finite part $\hat{B}'_h$ is dense in $\hat{B}'_h$. Since $\hat{B}'_h$ is a finitely generated bimodule over $\hat{A}_\mathbb{F}(\hat{v})^{\wedge 0}_h$, and $\hat{B}'_h$ is dense, we can choose generalized $\tilde{\mathfrak{e}}u$-eigen-vectors for generators of $\hat{B}'_h$. Now it is easy to see that

\[\text{Springer}\]
\[ \hat{B}_h \text{ is finitely generated over } \hat{A}_\mathcal{P}(\hat{v})_h. \] In its turn, this implies that \( \hat{B}_h \) can be made into a graded \( \hat{A}_\mathcal{P}(\hat{v})_h \)-bimodule.

We set \( \mathcal{B}_{\hat{\tau}, x} := \hat{B}_h/(h - 1) \), it is a Harish–Chandra \( \hat{A}_\mathcal{P}(\hat{v}) \)-bimodule, a good filtration comes from the \( C^\infty \)-action on \( \hat{B}_h \). Similarly to [38, Section 3.4], we see that the assignment \( \mathcal{B} \to \mathcal{B}_{\hat{\tau}, x} \) is functorial.

Let us note that the functor is independent (up to an isomorphism) of the choice of \( a \) (which is defined uniquely up to a summand from \( C[\mathcal{P}, \hbar] \)). This is because the spaces of \( C^\times \)-finite sections arising from \( a \) and \( a + f \) with \( f \in C[\mathcal{P}, \hbar] \) are obtained from one another by applying \( \exp([F, \cdot]) \), where \( F := \frac{1}{\hbar} \int_0^\hbar f \, dh \).

So we have constructed \( \bullet_{\hat{\tau}, x} : \text{HC}(\mathcal{A}_\mathcal{P}(v)) \to \text{HC}(\hat{A}_\mathcal{P}(\hat{v})). \)

### 3.3.4 Variations

The functor \( \bullet_{\hat{\tau}, x} : \text{HC}(\mathcal{A}_\mathcal{P}^0(v)) \to \text{HC}(\hat{A}_\mathcal{P}^0(\hat{v})) \) is constructed completely analogously. Similarly to Sect. 3.1.1, any HC \( \mathcal{A}_\mathcal{P}(v) \)-bimodule \( \mathcal{B} \) is also HC over \( \mathcal{A}_\mathcal{P}^0(v) \) and \( \mathcal{B}_{\hat{\tau}, x} \) does not depend on whether we consider \( \mathcal{B} \) as an \( \mathcal{A}_\mathcal{P}(v) \)-bimodule or as a \( \mathcal{A}_\mathcal{P}^0(v) \)-bimodule.

Note also that above we have established a functor \( \text{HC}(\mathcal{A}_\mathcal{P}(v)^{\wedge x}) \to \text{HC}(\hat{A}_\mathcal{P}(\hat{v})). \) Denote it by \( \Psi \). We also have a version of this functor for the \( \mathcal{A}^0 \)-algebras (again, denoted by \( \Psi \)).

In the case of affine quivers, we sometimes will need a slight modification of the target category for \( \bullet_{\hat{\tau}, x} \). Namely, we remark that 0 does not need to be a single symplectic leaf in \( \hat{\mathcal{M}}(\hat{v}) \). This happens, for example, when the quiver \( \hat{Q} \) is a single loop or is a union of such. Let \( \mathcal{L}_0 \) be a leaf through \( 0 \in \hat{\mathcal{M}}(\hat{v}) \), this is an affine space. So the algebra \( \hat{A}_\mathcal{P}(v) \) splits into the product of the Weyl algebra \( \mathcal{A}_0 \) quantizing \( \mathcal{L}_0 \) and of some other algebra \( \hat{A}_\mathcal{P}(\hat{v}) \). The latter is obtained by the same reduction but from the space where we replace all summands of the form \( \text{End}(\mathbb{C}^{\hat{v}}) \) with \( \mathfrak{sl}_{\hat{v}} \). We have a category equivalence \( \text{HC}(\hat{A}_\mathcal{P}(\hat{v})) \sim \text{HC}(\hat{A}_\mathcal{P}(\hat{v})) \) sending \( \hat{B} \) to the centralizer \( \mathcal{B}_0 \) of \( \mathcal{A}_0 \) in \( \hat{B} \) (so that \( \hat{B} = \mathcal{A}_0 \otimes \mathcal{B} \)). We will view \( \bullet_{\hat{\tau}, x} \) as a functor with target category \( \text{HC}(\hat{A}_\mathcal{P}(\hat{v})). \)

### 3.4 Restriction functors: properties

It is straightforward from the construction that \( \bullet_{\hat{\tau}, x} \) is exact and \( \mathbb{C}[\mathcal{P}] \)-linear, compare to [38, Section 3.4] or [43, Section 4.1.4].

Now let us describe the behavior of the functor \( \bullet_{\hat{\tau}, x} \) on the associated varieties. The following lemma follows straightforwardly from the construction (compare with (4) of [41, Proposition 3.6.5]).
Lemma 3.9 Let $B$ be a HC $A_{\mathfrak{p}}(v)$-bimodule. Then the associated variety of $B_{\xi,x}$ is uniquely characterized by $(\mathcal{V}(B_{\xi,x}) \times \mathcal{L})^{\wedge x} = \mathcal{V}(B)^{\wedge x}$, where $\mathcal{L}$ is the symplectic leaf through $x$. A similar claim holds for HC $A_0^0(\mathfrak{p})(v)$-bimodules.

Now let us proceed to the compatibility of $\bullet_{\xi,x}$ with the Tor’s and Ext’s.

Lemma 3.10 We have a functorial isomorphism

$$\text{Tor}_i \hat{A}_{\mathfrak{p}_0}^0(v)(B^1, B^2)_{\xi,x} = \text{Tor}_i \hat{A}_{\mathfrak{p}_0}(v)(B^1_{\xi,x}, B^2_{\xi,x}).$$

Here $B^1 \in \text{HC}(A_0^0(\mathfrak{p}_0) - A_0^0(\mathfrak{p}_0)(v))$ and $B^2 \in \text{HC}(A_0^0(\mathfrak{p}_0)(v) - A_0^0(\mathfrak{p}_0')(v))$, where $\mathfrak{p}_0, \mathfrak{p}_0', \mathfrak{p}_0''$ are three parallel affine subspaces in $\mathfrak{p}$. Similarly, we have

$$\text{Ext}^i \hat{A}_{\mathfrak{p}_0}^0(v)(B^1, B^2)_{\xi,x} = \text{Ext}^i \hat{A}_{\mathfrak{p}_0}(v)(B^1_{\xi,x}, B^2_{\xi,x}),$$

where $B^1 \in \text{HC}(A_0^0(\mathfrak{p}_0) - A_0^0(\mathfrak{p}_0)(v))$ and $B^2 \in \text{HC}(A_0^0(\mathfrak{p}_0)(v) - A_0^0(\mathfrak{p}_0')(v))$.

Proof We will deal with the case when $\mathfrak{p}_0 = \mathfrak{p}$, the general case is similar. We will do Tor’s, the case of Ext’s is similar.

Consider the bounded derived category $D^b(A_0^0(\mathfrak{p})(v))$ of the category $A_0^0(\mathfrak{p})(v)$-bimod of finitely generated $A_0^0(\mathfrak{p})(v)$-bimodules and its subcategory $D^b_{HC}(A_0^0(\mathfrak{p})(v))$ of all complexes with HC homology. Similarly, consider the bounded derived category $D^b(A_0^0(\mathfrak{p})(\hbar))$ of the category $A_0^0(\mathfrak{p})(\hbar)$-bimod of graded finitely generated $A_0^0(\mathfrak{p})(\hbar)$-bimodules and its subcategory $D^b_{HC}(A_0^0(\mathfrak{p})(\hbar))$ of all complexes whose homology mod $\hbar$ are $\mathbb{C}[\mathcal{M}_0(\mathfrak{p})]$-modules (rather than just arbitrary bimodules). We have a functor $\mathbb{C}_1 \otimes \mathbb{C}[\hbar] \bullet : A_0^0(\mathfrak{p})(\hbar)$-bimod $\to A_0^0(\mathfrak{p})(v)$-bimod whose kernel is the subcategory $A_0^0(\mathfrak{p})(\hbar)$-bimod$_{tor}$ of all bimodules where $\hbar$ acts nilpotently. This gives rise to the equivalence

$$\mathbb{C}_1 \otimes \mathbb{C}[\hbar] \bullet : D^b(A_0^0(\mathfrak{p})(\hbar))/D^b_{tor}(A_0^0(\mathfrak{p})(\hbar)) \to D^b(A_0^0(\mathfrak{p})(v)) \quad (3.8)$$

that restricts to an equivalence of the HC subcategories and clearly intertwines the derived tensor product (or Hom) functors.

Let us proceed to the completed setting. Consider the algebra

$$\mathfrak{A} := \mathbb{C}[[x]] \otimes (A_0^0(\mathfrak{p})(\hbar)^{\wedge x} \otimes \mathbb{C}[\hbar], A_0^0(\mathfrak{p})(\hbar)^{\wedge x, opp}),$$

where $[x, a] = \hbar \partial_h a$ for $a \in A_0^0(\mathfrak{p})(\hbar)^{\wedge x} \otimes \mathbb{C}[\hbar], A_0^0(\mathfrak{p})(\hbar)^{\wedge x, opp}$. Any module over $\mathfrak{A}$ is a $A_0^0(\mathfrak{p})(\hbar)^{\wedge x}$-bimodule equipped with an Euler derivation (but not vice
versa). Let $D^b(A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}}) \subset D^b(\mathfrak{A} - \text{mod})$ stand for the full subcategory of all objects whose homology is a HC $A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}}$-bimodule. We have the completion functor

$$
\bullet^\wedge := (A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}})^\wedge \otimes_{\mathbb{C}[h]} A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \otimes A^0_{\mathfrak{P}^1}(v)^{opp} \bullet : A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}} - \text{grbimod} \to \mathfrak{A} - \text{mod}
$$

We remark that, for a HC bimodule $\mathcal{M}$, we have $\mathcal{M}^\wedge = A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \otimes A^0_{\mathfrak{P}^1}(v)^{opp} \mathcal{M}$ because the right hand side is already complete as a right $A^0_{\mathfrak{P}^1}(v)^{\wedge, opp}$-module. The completion functor restricts to a functor

$$
\bullet^\wedge : D^b_{HC}(A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}}) \to D^b_{HC}(A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \otimes A^0_{\mathfrak{P}^1}(v)^{opp}).
$$

(3.9)

This functor preserves the $\mathfrak{h}$-torsion subcategories. It intertwines $\bullet \otimes A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}} \bullet$ with $\bullet \otimes A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \bullet$. It is t-exact. And since it sends $A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}}$ to $A^0_{\mathfrak{P}^1}(v)^{\wedge, opp}$, it intertwines the derived tensor product functors as well.

Now let us equip $B^1, B^2$ with good filtrations and consider the corresponding Rees bimodules $B^1_{\hat{\mathfrak{h}}}, B^2_{\hat{\mathfrak{h}}}$. Since $\bullet^\wedge$ is a t-exact functor, we see that

$$
H_i(B^1_{\hat{\mathfrak{h}}} \otimes L^0_{A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}}} B^2_{\hat{\mathfrak{h}}})^\wedge = H_i(B^1^\wedge \otimes L^0_{A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \otimes A^0_{\mathfrak{P}^1}(v)^{opp}}, i \wedge \wedge). \quad (3.10)
$$

the equality of HC $A^0_{\mathfrak{P}^1}(v)^{\wedge, opp}$-bimodules.

Recall the functor $\Psi : HC(A^0_{\mathfrak{P}^1}(v)_{\hat{\mathfrak{h}}}) \to HC(\hat{\mathfrak{A}}_{\mathfrak{P}^1}(\hat{v}))$ from Sect. 3.3. Applying $\Psi$ to the left hand side of (3.10), we get $H_i(B^1 \otimes L^0_{A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \otimes A^0_{\mathfrak{P}^1}(v)^{opp}}, i \wedge \wedge)$.

Let us see what happens when we apply $\Psi$ to the right hand side. Note that $B^1_{\hat{\mathfrak{h}}} = A^0_{\hat{\mathfrak{h}}} \otimes_{\mathbb{C}[h]} R_h(B^1_{\hat{\mathfrak{h}}})^\wedge$ that yields

$$
B^1_{\hat{\mathfrak{h}}} \otimes L^0_{A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \otimes A^0_{\mathfrak{P}^1}(v)^{opp}}, i \wedge \wedge = A^0_{\hat{\mathfrak{h}}} \otimes_{\mathbb{C}[h]} \left( R_h(B^1_{\hat{\mathfrak{h}}})^\wedge \otimes L^0_{A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \otimes A^0_{\mathfrak{P}^1}(v)^{opp}}, i \wedge \wedge \right).
$$

So if we apply $\Psi$ to the right hand side of (3.10) we get $H_i(B^1 \otimes L^0_{A^0_{\mathfrak{P}^1}(v)^{\wedge, opp} \otimes A^0_{\mathfrak{P}^1}(v)^{opp}}, i \wedge \wedge)$. This completes the proof. □

Another important property of the restriction functor is the equality

$$
A^0_{\mathfrak{P}^1, \mathfrak{V}}(v)_{\hat{\mathfrak{h}}} = \hat{\mathfrak{A}}^0_{\mathfrak{P}^1, \mathfrak{V}}(\hat{v}). \quad (3.11)
$$

This follows from the decomposition $A^0_{\mathfrak{P}^1, \mathfrak{V}}(v)_{\hat{\mathfrak{h}}} \simeq \hat{\mathfrak{A}}^0_{\mathfrak{P}^1, \mathfrak{V}}(\hat{v})^\wedge \otimes_{\mathbb{C}[h]} A^0_{\hat{\mathfrak{h}}}$ that is proved similarly to (3.3).

Springer
We finish this section with two remarks.

**Remark 3.11** Let us explain why in Lemma 3.10 we deal with Tor’s rather than with the derived tensor products. The reason is that we do not have the derived version of the functor $\bullet_{\hat{v}, x}$. The difficulty here is to pass between the derived version of the category $HC(\hat{A}_P(\hat{v})^\wedge_0)$ to that of the category $HC(\hat{A}_P(\hat{v})_h)$. For the latter derived version we take the subcategory in the derived category of the category of graded $\hat{A}_P(\hat{v})_h$-bimodules with HC homology. For the former version we need to use the subcategory in the derived category of modules over

$$\mathbb{C}[\hat{u}] \ltimes \left( \mathbb{C}((h)) \otimes \mathbb{C}[[h]] \left( \hat{A}_P(\hat{v})^\wedge_0 \hat{\otimes} \mathbb{C}[[h]] \hat{A}_P(\hat{v})^{\wedge_0, opp} \right) \right)$$

with homology that is a localization (from $\mathbb{C}[[h]]$ to $\mathbb{C}((h))$) of a HC bimodule. We need to localize to $\mathbb{C}((h))$ because the operator $\frac{1}{\hbar} [\alpha, \cdot]$ is not defined on an arbitrary $\hat{A}_P(\hat{v})^\wedge_0$-bimodule. Of course, we still have a completion functor

$$D_{HC}^b(\hat{A}_P(\hat{v})_h, grbimod) / D_{HC}^b(\hat{A}_P(\hat{v})_h, grbimod)_{tor} \rightarrow$$

$$D_{HC}^b(\mathbb{C}[\hat{u}] \ltimes \mathbb{C}((h)) \otimes \mathbb{C}[[h]] \left( \hat{A}_P(\hat{v})^\wedge_0 \hat{\otimes} \mathbb{C}[[h]] \hat{A}_P(\hat{v})^{\wedge_0, opp} \right))$$

(here grbimod means graded bimodules). A problem with this functor is that it is not an equivalence, the target category has more Hom’s, which has to do with the fact that we do not require the action of a derivation $\hat{e}u$ to be diagonalizable (and we do not see any way to impose this condition).

Let us point out that this problem does not occur in the W-algebra setting [38,43] because there we have a Kazhdan torus action that fixes a point where we complete. So in that case it is enough to deal with weakly $\mathbb{C}^\times$-equivariant derived categories.

**Remark 3.12** Let $\tilde{HC}(A_0^0)_{prism}$ denote the category of locally HC $A_0^0$-bimodules (i.e., bimodules that are sums of their Harish–Chandra subbimodules), the ind completion of $HC(A_0^0)_{prism}$. Then, similarly to [38, Section 3.4], [41, Section 3.7], we have a functor $\bullet_{\hat{v}, x} : HC(A_0^0)_{prism} \rightarrow \tilde{HC}(A_0^0)_{prism}$ that is right adjoint to $\bullet_{\hat{v}, x}$. This functor is automatically $\mathbb{C}[\mathfrak{P}]$-linear. It is likely that the image of $\bullet_{\hat{v}, x}$ actually lies in $HC(A_0^0)_{prism}$ but we do not know the proof of this claim. Below we will see $B_{\hat{v}, x}$ lies in $HC(A_0^0)_{prism}$ provided $B$ is finitely generated over $\mathbb{C}[\mathfrak{P}]$.

### 3.5 Restriction functors: applications

Our first application will be to $\mathfrak{P}$-supports of HC bimodules.
Proposition 3.13 Let $B$ be a HC $\mathcal{A}_\mathfrak{p}^0(v)$-bimodule. Then $\text{Supp}_\mathfrak{p}^r(B)$ is closed and

$$\text{AC}(\text{Supp}_\mathfrak{p}^r(B)) = \text{Supp}_\mathfrak{p} (\text{gr } B).$$

Recall that $\text{AC}$ stands for the asymptotic cone.

Proof Pick a generic point $x$ in an irreducible component of $V(B) \cap \mathcal{M}_0^0(v)$ and consider the HC $\mathcal{A}_\mathfrak{p}^0(v)$-bimodule $B_{\mathfrak{t},x}$. By the choice of $x$, $B_{\mathfrak{t},x}$ is finitely generated over $\mathbb{C}[\mathfrak{p}]$. This follows from Lemma 3.9. Moreover, since $\bullet_{\mathfrak{t},x}$ is $\mathbb{C}[\mathfrak{p}]$-linear (and is $\mathbb{C}[\mathfrak{p}]$-linear after passing to the associated graded bimodules) by the construction, we have

$$\text{Supp}_\mathfrak{p}^r(B_{\mathfrak{t},x}) \subset \text{Supp}_\mathfrak{p}^r(B), \quad \text{Supp}_\mathfrak{p}(\text{gr } B_{\mathfrak{t},x}) \subset \text{Supp}_\mathfrak{p}(\text{gr } B).$$

Since $B_{\mathfrak{t},x}$ is finitely generated over $\mathbb{C}[\mathfrak{p}]$, we see that $\text{AC}(\text{Supp}_\mathfrak{p}^r(B_{\mathfrak{t},x})) = \text{Supp}_\mathfrak{p}(\text{gr } B_{\mathfrak{t},x})$. Hence $\text{AC}(\text{Supp}_\mathfrak{p}^r(B_{\mathfrak{t},x})) \subset \text{Supp}_\mathfrak{p}(\text{gr } B)$. There is the unique maximal subbimodule $B' \subset B$ with $B'_{\mathfrak{t},x} = 0$. Clearly, $\text{Supp}_\mathfrak{p}^r(B_{\mathfrak{t},x}) \subset \text{Supp}_\mathfrak{p}^r(B/B')$. On the other hand, let $I$ be the right annihilator of $B_{\mathfrak{t},x}$ in $\mathbb{C}[\mathfrak{p}]$. Then $BI \subset B'$ and $\text{Supp}_\mathfrak{p}^r(B/B') \subset \text{Supp}_\mathfrak{p}^r(B/B) \subset \text{Supp}_\mathfrak{p}^r(B_{\mathfrak{t},x})$.

So we see that $\text{Supp}_\mathfrak{p}^r(B_{\mathfrak{t},x}) = \text{Supp}_\mathfrak{p}^r(B/B')$ is a closed subvariety in $\mathfrak{p}$ whose asymptotic cone coincides with $\text{Supp}_\mathfrak{p}(\text{gr } (B/B')) = \text{Supp}_\mathfrak{p}(\text{gr } B_{\mathfrak{t},x})$.

Now let us observe that

$$\text{Supp}_\mathfrak{p}^r(B) = \text{Supp}_\mathfrak{p}^r(B/B') \cup \text{Supp}_\mathfrak{p}^r(B'). \quad (3.12)$$

The inclusion of the left hand side into the right hand side is clear. Now we just need to show that if $z \in \text{Supp}_\mathfrak{p}^r(B') \setminus \text{Supp}_\mathfrak{p}^r(B/B')$, then $z \in \text{Supp}_\mathfrak{p}^r(B)$. Recall that $\text{Supp}_\mathfrak{p}^r(B/B')$ is closed. So if $z \notin \text{Supp}_\mathfrak{p}^r(B/B')$, then $\text{Tor}^1_{\mathbb{C}[\mathfrak{p}]}(B/B', C_z) = 0$. Hence if $z \in \text{Supp}_\mathfrak{p}^r(B')$, then $z \in \text{Supp}_\mathfrak{p}^r(B)$. Similarly,

$$\text{Supp}_\mathfrak{p}(\text{gr } B) = \text{Supp}_\mathfrak{p}(\text{gr } B/B') \cup \text{Supp}_\mathfrak{p}(\text{gr } B'). \quad (3.13)$$

Thanks to (3.12) and (3.13), it remains to prove that $\text{Supp}_\mathfrak{p}^r(B')$ is closed and its asymptotic cone is $\text{Supp}_\mathfrak{p}(\text{gr } B')$. The variety $\mathcal{M}_0^0(v)$ has finitely many symplectic leaves. Since $\text{Supp}_\mathfrak{p}^r(B') \subset \text{Supp}_\mathfrak{p}^r(B)$, we can use the induction on the maximal dimension of a symplectic leaf in the support to finish the proof of the proposition. \qed

Now we are ready to prove Proposition 2.7.
Proof of Proposition 2.7 Consider the natural homomorphism \( \mathcal{A}_λ(\mathfrak{p}) \to \mathcal{A}_λ(\mathfrak{p}) \) and let \( K, C \) denote its kernel and cokernel. Both \( \mathcal{A}_λ(\mathfrak{p}) \) and \( \mathcal{A}_λ(\mathfrak{p}) \) are HC bimodules over \( \mathcal{A}_λ(\mathfrak{p}) \) and therefore \( K, C \) are HC bimodules as well. By Proposition 3.13, \( \text{Supp}_\mathfrak{p}(K) \) and \( \text{Supp}_\mathfrak{p}(C) \) are closed.

The homomorphism \( \mathcal{A}_λ(\mathfrak{p}) \to \mathcal{A}_λ(\mathfrak{p}) \) is an isomorphism if and only if \( \lambda \notin \text{Supp}_\mathfrak{p}(K) \cup \text{Supp}_\mathfrak{p}(C) \). Indeed, the homomorphism is surjective if and only if \( \lambda \notin \text{Supp}_\mathfrak{p}(C) \). Further, if \( \lambda \notin \text{Supp}_\mathfrak{p}(C) \), then, similarly to the proof of Proposition 3.13, we get \( \mathcal{A}_λ(\mathfrak{p}) \cong \mathcal{A}_λ(\mathfrak{p}) \) if and only if \( \lambda \notin \text{Supp}_\mathfrak{p}(K) \).

Consider the homomorphism \( \text{gr} \mathcal{A}_λ(\mathfrak{p}) \to \text{gr} \mathcal{A}_λ(\mathfrak{p}) = \mathbb{C}[\mathcal{M}_p(\mathfrak{p})] \) and compose it with the epimorphism \( \mathbb{C}[\mathcal{M}_p(\mathfrak{p})] \to \mathcal{A}_λ(\mathfrak{p}) \). Let \( K^0, C^0 \) denote the kernel and the cokernel of the resulting homomorphism \( \mathbb{C}[\mathcal{M}_p(\mathfrak{p})] \to \mathbb{C}[\mathcal{M}_p(\mathfrak{p})] \). The latter coincides with \( p^{\text{sing}} \). It follows that \( \text{Supp}_p(K^0 \oplus C^0) \subset p^{\text{sing}} \). Let \( \mathbb{C}^0 = \text{gr} \mathbb{C} \), while \( \text{gr} \mathbb{C} \) is a subquotient of \( K^0 \). Because of this, we have \( \mathbb{A}(\text{Supp}_\mathfrak{p}(C)) \subset \text{Supp}_\mathfrak{p}(C^0) \) and \( \mathbb{A}(\text{Supp}_\mathfrak{p}(K)) \subset \text{Supp}_p(K^0) \). The claim of the proposition follows.

Next we will show that the algebra \( \mathcal{A}_λ(\mathfrak{p}) \) is simple for a Weil generic \( \lambda \), compare with [41, Section 4.2].

Proposition 3.14 The algebra \( \mathcal{A}_λ(\mathfrak{p}) \) is simple for a Weil generic \( \lambda \).

We will obtain a more precise description of the locus, where \( \mathcal{A}_λ(\mathfrak{p}) \) is simple, using wall-crossing functors below, Proposition 9.6.

Proof Step 1. Let us show that, for a Weil generic \( \lambda \), the algebra \( \mathcal{A}_λ(\mathfrak{p}) \) has no finite dimensional representations. Let \( \mathfrak{p}_d \) denote the set of points \( \lambda \in \mathfrak{p} \) such that \( \mathcal{A}_λ(\mathfrak{p}) \) has a \( d \)-dimensional representation or, in other words, there is a homomorphism \( \mathcal{A}_λ(\mathfrak{p}) \to \text{Mat}_d(\mathbb{C}) \). Consider the ideal \( I_d \subset \mathcal{A}_λ(\mathfrak{p}) \) generated by the elements

\[
\alpha_{2d}(x_1, \ldots, x_{2d}) = \sum_{\sigma \in S_{2d}} \text{sgn}(\sigma)x_{\sigma(1)} \ldots x_{\sigma(2d)}.
\]

Any homomorphism \( \mathcal{A}_λ(\mathfrak{p}) \to \text{Mat}_d(\mathbb{C}) \) factors through \( \mathcal{A}_λ(\mathfrak{p})/I_d \), this is the Amitsur-Levitski theorem. The support of \( \mathcal{A}_λ(\mathfrak{p})/I_d \) in \( \mathfrak{p} \) is closed by Proposition 3.13. If a Weil generic element of \( \mathfrak{p} \) belongs to \( \bigcup_d \text{Supp}_\mathfrak{p}(\mathcal{A}_λ(\mathfrak{p})/I_d) \), then \( \text{Supp}_p(\mathcal{A}_λ(\mathfrak{p})/I_d) = \mathfrak{p} \) for some \( d \). By Proposition 3.13, \( \text{Supp}_p(\mathbb{C}[\mathcal{M}_p(\mathfrak{p})]/\text{gr} I_d) = p \). However, this is impossible. Indeed, for a Zariski generic \( \lambda \), the variety \( \mathcal{M}_λ(\mathfrak{p}) \) is symplectic, so \( \mathbb{C}[\mathcal{M}_λ(\mathfrak{p})] \) has no proper Poisson ideals. Since \( \text{gr} I_d \) is a Poisson ideal, we get a required contradiction.
Step 2. By the previous step, for a Weil generic \( \lambda \) and all \( x \in \mathcal{M}(v) \backslash \mathcal{M}(v)^{reg} \), the algebra \( \hat{A}_x(\hat{v}) \) defined from \( x \) has no finite dimensional irreducible representations. It follows from Lemma 3.9 that the algebra \( A_\lambda(v) \) has no ideals \( I \) such that \( V(A_\lambda(v)/I) \) is a proper subvariety of \( \mathcal{M}(v) \). Indeed, for \( x \) that is generic in an irreducible component of \( V(A_\lambda(v)/I) \), the ideal \( I_{x,x} \subset \hat{A}_x(\hat{v}) \) is of finite codimension. On the other hand, if \( I \) is a proper ideal, then \( V(A_\lambda(v)/I) \) is also proper, this is consequence of [15, Corollary 3.6]. The proposition follows.

\[ \square \]

3.6 Applications to derived Hamiltonian reduction

In this section we prove part (1) of Proposition 2.16. The proof does not have to do with HC bimodules but involves techniques similar to what was used in Sects. 3.3–3.5.

We will prove the following claim that implies (1) of Proposition 2.16:

(*) There is an asymptotically generic open affine subset \( U \subset \mathcal{P}^{iso} \) such that \( Q_U := \mathcal{Q} \otimes_{\mathcal{P}} \mathbb{C}[U] \) is flat over \( \mathbb{C}[U] \) and \( \text{Tor}^i(U(g), \mathbb{C}[U]) = 0 \) for \( i > 0 \).

Let \( r \in T^*R \) be a point with closed \( G \)-orbit and let \( \hat{R}, R_0 \) have the same meaning as in Sect. 2.1.6. We need to relate \( \text{Tor}^i(U(g), \mathbb{C}[\mathcal{P}]) \) to \( \text{Tor}^i(U(r), \mathbb{C}[\mathcal{P}]) \), where \( \mathbb{C}[\mathcal{P}] \) becomes a \( U(g_r) \)-module via the inclusion \( U(g_r) \hookrightarrow U(g) \).

Lemma 3.15 We have a natural \( \mathbb{C}[\mathcal{P}, \hbar] \)-linear isomorphism

\[
\text{Tor}^i(U(h), \mathbb{C}[\mathcal{P}, \hbar])^{\wedge G_r} \\
\cong \Gamma \left( G / G_r, G *_{G_r} \text{Tor}^i(U(h), \mathbb{C}[\mathcal{P}, \hbar]) \right)^{\wedge G_r} \otimes_{\mathbb{C}[\hbar]} A_h(R_0)^{\wedge 0}. \tag{3.14}
\]

Proof Recall the isomorphism

\[
D_h(R)^{\wedge G_r} \cong \left( \left[ D_h(G)^{\wedge G} \otimes_{\mathbb{C}[\hbar]} D_h(\hat{R})^{\wedge 0} \right] \otimes_{\mathbb{C}[\hbar]} A_h(R_0)^{\wedge 0} \right). \tag{3.15}
\]

that has appeared in the proof of Lemma 3.7. Note also that

\[
\text{Tor}^i(U(h), \mathbb{C}[\mathcal{P}, \hbar])^{\wedge G_r} \cong \text{Tor}^i(U(h), D_h(R)^{\wedge G_r}, \mathbb{C}[\mathcal{P}, \hbar]).
\]
So we need to check that the right hand side of (3.14) coincides with the \( \text{Tor} \) of the right hand side of (3.15). This will follow if we check that

\[
\text{Tor}_i^{U_h(\mathfrak{g})} \left( \left[ D_h(G) \otimes_{\mathbb{C}[h]} D_h(\hat{R}) \right] \left/ 0G_r \right. \right), \mathbb{C}[\mathfrak{g}, h] \right) \cong \Gamma \left( G/G_r, G \ast G_r \text{Tor}_i^{U_h(\mathfrak{g}_r)} (D_h(\hat{R}), \mathbb{C}[\mathfrak{g}, h]) \right).
\] (3.16)

Since the actions of \( G_r \) and \( U_h(\mathfrak{g}) \) commute and

\[
[D_h(G) \otimes_{\mathbb{C}[h]} D_h(\hat{R})] \left/ 0G_r = \left( [D_h(G) \otimes_{\mathbb{C}[h]} D_h(\hat{R})] \otimes_{U_h(\mathfrak{g}_r)} \mathbb{C}[\mathfrak{g}, h] \right)^{G_r},
\]

we see that the left hand side of (3.16) coincides with

\[
\text{Tor}_i^{U_h(\mathfrak{g} \times \mathfrak{g}_r)} (D_h(G) \otimes_{\mathbb{C}[h]} D_h(\hat{R}), \mathbb{C}[\mathfrak{g}, h])^{G_r}.
\]

Here \( \mathbb{C}[\mathfrak{g}, h] \) is viewed as the diagonal \( \mathfrak{g} \times \mathfrak{g}_r \)-module. But to compute \( \text{Tor}_i^{U_h(\mathfrak{g} \times \mathfrak{g}_r)} (D_h(G) \otimes_{\mathbb{C}[h]} D_h(\hat{R}), \mathbb{C}[\mathfrak{g}, h]) \) we can take the derived tensor product with \( U_h(\mathfrak{g}) \) and after that the derived tensor product with \( U_h(\mathfrak{g}_r) \). What we get is exactly the right hand side of (3.16). \( \square \)

**Lemma 3.16** We have \( \text{AC} \left( \text{Supp}_{\mathfrak{p}} \left( \text{Tor}_i^{U_h(\mathfrak{g})} (D(R), \mathbb{C}[\mathfrak{g}]) \right) \right) \subset \mathfrak{p}^{\text{sing}} \) provided \( i > 0 \).

**Proof** Set \( M := \text{Tor}_i^{U_h(\mathfrak{g})} (D(R), \mathbb{C}[\mathfrak{g}]) \), we view it as a \( D(R) \otimes \mathbb{C}[\mathfrak{g}] \)-module. It is supported on \( \mu^{-1}(\mathfrak{p}) \times_p \mathfrak{p} \). Let \( N \) be the maximal submodule of \( M \) with the property that \( V(N) \cap (\mu^{-1}(0) \times \{0\}) \) is contained in the nilpotent cone of \( \mu^{-1}(0) \), equivalently, \( N^{\text{sing}} = 0 \) for all nonzero \( x \in \mathcal{M}_0(v) \). Note that we have only finitely many possible \( G_r \subset G \) and hence finitely many possible spaces \( \mathfrak{g}^{\text{sing}} \). Moreover, under the natural projection \( p \to \hat{p} \), the preimage of \( \hat{p}^{\text{sing}} \) lies in \( \mathfrak{p}^{\text{sing}} \) by Remark 2.2. From this observation combined with Lemma 3.15 and an induction argument, it follows that \( \text{AC}(\text{Supp}_{\mathfrak{p}}(M/N)) \subset \mathfrak{p}^{\text{sing}} \).

The space \( M \) is naturally filtered and there is an inclusion \( \text{gr} M \hookrightarrow M^0 \), where \( M^0 \) is a \( G \)-equivariant quotient of \( \text{Tor}_i^{U_h(\mathfrak{g})} (\mathbb{C}[T^*R], \mathbb{C}[\mathfrak{p}]) \). Inside \( M^0 \) we can consider the maximal submodule \( N^0 \) defined similarly to \( N \subset M \). Note that \( \text{Supp}_{\mathfrak{p}} \left( \text{Tor}_i^{U_h(\mathfrak{g})} (\mathbb{C}[T^*R], \mathbb{C}[\mathfrak{p}]) \right) \subset \mathfrak{p}^{\text{sing}} \) and therefore \( \text{Supp}_{\mathfrak{p}}(M^0) \subset \mathfrak{p}^{\text{sing}} \) and \( \text{Supp}_{\mathfrak{p}}(M^0/N^0) \subset \mathfrak{p}^{\text{sing}} \). From here we deduce that

\[
\text{Supp}_{\mathfrak{p}}(N^0) \subset \mathfrak{p}^{\text{sing}}.
\] (3.17)

Clearly, \( \text{gr} N \subset N^0 \) (a \( G \)-equivariant embedding).
The $D(R)$-module $N$ is weakly $G$-equivariant and finitely generated. So it is generated by finitely many $G$-isotypic components, say, corresponding to $G$-irreps $V_1, \ldots, V_k$. We can assume that the corresponding isotypic components generate $N^0$ as well ($N^0$ is also finitely generated). Let $N_V \subset N$, $N^0_V \subset N^0$ denote the sum of these isotypic components so that $\text{gr} N_V \subset N^0_V$. We have

$$\text{Supp}_p^r(N_V) = \text{Supp}_p^r(N), \text{Supp}_p(N^0_V) = \text{Supp}_p(N^0). \quad (3.18)$$

Since $V(N^0) \cap (\mu^{-1}(0), 0)$ lies in the nilpotent cone, we see that any $G$-isotypic component in $N^0$ is finitely generated over $\mathbb{C}[p]$. A similar claim holds for $N$. From here and the inclusion $\text{gr} N_V \subset N^0_V$ we deduce that $\text{AC}(\text{Supp}_p(N_V)) \subset \text{Supp}_p(N^0_V)$. Combining (3.17) with (3.18), we see that $\text{AC}(\text{Supp}_p(N)) \subset p^{\text{sing}}$. Since $\text{Supp}_p^r(M) \subset \text{Supp}_p^r(N) \cup \text{Supp}_p^r(M/N)$, we get $\text{AC}(\text{Supp}_p(M)) \subset p^{\text{sing}}$. \hfill \Box

Now let us show that there is an asymptotically generic $U \subset \mathfrak{P}$ such that $Q_U$ is flat over $U$. For this, we consider various modules $\text{Tor}_{C[\mathfrak{P}]}^i(Q_\mathfrak{P}, C[Y])$, where $Y$ is a closed irreducible subvariety in $\mathfrak{P}$. Since $Q_\mathfrak{P}$ is a finitely generated $D(R)$-module, there is an affine Zariski open subset $U \subset \mathfrak{P}$ (not asymptotically generic, a priori) such that $Q_U$ is free over $U$, this is proved analogously to Lemma 3.5. Let $Z$ denote the Zariski closure of the union of the supports of various $\text{Tor}_{C[\mathfrak{P}]}^i(Q_\mathfrak{P}, C[Y])$. So $Z \subset \mathfrak{P}\setminus U$. We need to check that $\text{AC}(Z) \subset p^{\text{sing}}$. This is done as in the proof of Lemma 3.16, now we need to consider $M := \text{Tor}_{C[\mathfrak{P}]}^i(Q_\mathfrak{P}, C[Z])$. This finishes the proof of (1) of Proposition 2.16.

### 4 Localization theorems and translation bimodules

In this section we deal with (abelian and derived) localization theorems. These theorems allow to relate the category of finitely generated modules over $A_\lambda(v)$ to the category of coherent sheaves over $A_\lambda^\theta(v)$. We also study more closely translation bimodules introduced in Sect. 3.1.4 that play a crucial role in the abelian localization theorems.

#### 4.1 Abelian and derived localization

Let $\theta$ be a generic stability condition and $\lambda \in \mathfrak{P}$. We say that $(\lambda, \theta)$ satisfies abelian (resp., derived) localization if the functors $\Gamma_\lambda^\theta$ and $\text{Loc}_\lambda^\theta$ are mutually inverse equivalences between $A_\lambda(v)$-mod and $A_\lambda^\theta(v)$-mod (resp., $R\Gamma_\lambda^\theta$ and $L\text{Loc}_\lambda^\theta$ are mutually inverse equivalences between $D^b(A_\lambda(v)$-mod) and
We will write $\mathfrak{AL}(v)$ for the set of all $(\lambda, \theta)$ satisfying abelian localization.

**Proposition 4.1** Suppose that the moment map $\mu$ is flat or $Q$ has finite or affine type. Then $(\lambda, \theta)$ satisfies derived localization if and only if the homological dimension of $A_\lambda(v)$ is finite.

**Proof** The case when $\mu$ is flat follows from [54, Theorem 1.1].

In general, we can apply a quantum LMN isomorphism and assume that $\nu$ is dominant. If $Q$ is of finite or affine type, then by 2.1.4, $\mu$ is flat. $\square$

Sufficient conditions (in greater generality) for abelian localization to hold were studied in [18, Section 5.3]. Let us recall some results from there. For this we need some terminology. By a classical wall for $v$ we mean a hyperplane of the form $\{\theta | \theta \cdot v' = 0\}$, where $v'$ is as in 2.1.1. So if $\theta$ does not lie on a classical wall, it is generic. By a classical chamber we mean the closure of a connected component of the complement to the union of classical walls in $\mathbb{R}^Q$. Let $C = C_\theta$ be the classical chamber of $\theta$.

**Proposition 4.2** (Corollary 5.17 in [18]) For every $\lambda$ and any $\chi \in \mathbb{Z}^Q \cap \text{int} C$ there is $n_0 \in \mathbb{Z}$ such that the $(\lambda + n\chi, \theta) \in \mathfrak{AL}(v)$ for any $n > n_0$.

Here we write $\text{int} C$ for the interior of $C$.

Unfortunately, Proposition 4.2 is not good enough for our purposes, as we will need a stronger version. We will also need to relate abelian localization to the functors $\pi^0_\lambda(v), \pi^\theta_\lambda(v)$. Recall the open subset $\Psi^{iso}$ of all parameters $\lambda$ such that $A^0_\lambda(v) \sim A_\lambda(v)$.

**Proposition 4.3** The following statements are true.

1. Suppose $\lambda \in \Psi^{iso}$. We have $(\lambda, \theta) \in \mathfrak{AL}(v)$ if and only if the functors $\pi^0_\lambda(v)$ and $\pi^\theta_\lambda(v)$ are isomorphic.
2. For every $\lambda$, there is $\chi \in \mathbb{Z}^Q$ such that $(\lambda', \theta) \in \mathfrak{AL}(v)$ for every $\lambda' \in \lambda + \chi + (C \cap \mathbb{Z}^Q)$.

To prove (2) (that will be used when we discuss wall-crossing functors), we will also need a more technical version of (2), which is the following lemma.

**Lemma 4.4** For every $\lambda$, there are

- $\lambda' \in \lambda + \mathbb{Z}^Q$,
- and a subset $Y(\lambda') \subset \lambda' + (C \cap \mathbb{Z}^Q)$

such that $\lambda'' \in \Psi^{iso}$, $(\lambda'', \theta) \in \mathfrak{AL}(v)$ for all $\lambda'' \in Y(\lambda')$ and the intersection of $Y(\lambda')$ with every codimension 1 face of the cone $\lambda' + C$ is Zariski dense in that face.
4.2 Translation bimodules

In this subsection we will apply results from Sects. 3.4 and 3.5 to studying translation bimodules $A^0_{\lambda,\chi}(v), A^{(\theta)}_{\lambda,\chi}(v)$ and a connection between them. In particular, here we will prove Propositions 2.13 and 4.3(1) as well as Lemma 4.4.

The next two propositions investigate when various versions of translations coincide.

Proposition 4.5 Let $\chi, \chi' \in \mathbb{Z}^{Q_0}$. Then the following subsets of $\Psi$ are Zariski open and asymptotically generic.

1. The set of $\lambda$ such that $A^0_{\lambda,\chi}(v) \rightarrow A^{(\theta)}_{\Psi,\chi}(v)$ is an isomorphism.
2. The set of $\lambda$ such that the multiplication homomorphism $A^0_{\lambda,\chi}(v) \otimes A^0_{\lambda,\chi}(v) \rightarrow A^0_{\lambda,\chi}(v)$ is an isomorphism.

Proof Let us prove (1). We have a natural surjection $\mathbb{C}[\mu^{-1}(p)]^{G,\chi} \rightarrow \text{gr} A^0_{\Psi,\chi}(v)$ and a natural inclusion $\text{gr} A^{(\theta)}_{\Psi,\chi}(v) \hookrightarrow \mathbb{C}[\mu^{-1}(p)^{\theta-ss}]^{G,\chi}$. Further, the following diagram is commutative (microlocalization commutes with taking the associated graded)

\[
\begin{array}{ccc}
\mathbb{C}[\mu^{-1}(p)]^{G,\chi} & \longrightarrow & \mathbb{C}[\mu^{-1}(p)^{\theta-ss}]^{G,\chi} \\
\downarrow & & \downarrow \\
\text{gr} A^0_{\Psi,\chi}(v) & \longrightarrow & \text{gr} A^{(\theta)}_{\Psi,\chi}(v)
\end{array}
\]  

Now the top horizontal arrow becomes an isomorphism when localized to the generic locus in $p$. (1) follows from Proposition 3.13, as in the proof of Proposition 2.7.

Let us prove (2). We have natural epimorphisms

\[
\begin{array}{ccc}
\mathbb{C}[\mu^{-1}(p)]^{G,\chi} & \rightarrow & \text{gr} A^0_{\Psi,\chi}(v), \mathbb{C}[\mu^{-1}(p)]^{G,\chi'} \\
\rightarrow & \rightarrow & \text{gr} A^0_{\Psi,\chi}(v), \mathbb{C}[\mu^{-1}(p)]^{G,\chi+\chi'} \rightarrow \text{gr} A^0_{\Psi,\chi+\chi'}(v).
\end{array}
\]  

Note that

\[
\text{gr} Q_{\Psi}|_{\mathcal{M}^0_{p\text{reg}}(v)} = \mathbb{C}[\mu^{-1}(p)]|_{\mathcal{M}^0_{p\text{reg}}(v)}
\]  

(4.2)
as \( \mu : \mu^{-1}(p) \to p \) is flat over \( p^{reg} := p \setminus p^{sing} \). So the kernels of these epimorphisms are supported on \( p^{sing} \). From here we see that the kernel of

\[
\mathbb{C}[\mu^{-1}(p)]^{G, x'} \otimes_{\mathbb{C}[\mathcal{M}_{p}^{0}(v)]} \mathbb{C}[\mu^{-1}(p)]^{G, x} \to \text{gr} \mathcal{A}_{p, x'}^{0} \otimes_{\mathbb{C}[\mathcal{M}_{p}^{0}(v)]} \text{gr} \mathcal{A}_{p, x}^{0}
\]
is also supported on \( p^{sing} \). (4.2) also shows that the kernel of

\[
\text{gr} \mathcal{A}_{p, x'}^{0} \otimes_{\mathbb{C}[\mathcal{M}_{p}^{0}(v)]} \text{gr} \mathcal{A}_{p, x}^{0} \to \text{gr} \left( \mathcal{A}_{p, x'}^{0} \otimes \mathcal{A}_{p}^{0} \right) \mathcal{A}_{p, x}^{0}(v)
\]
is supported on \( p^{sing} \). So the kernel of the composition

\[
\mathbb{C}[\mu^{-1}(p)]^{G, x'} \otimes_{\mathbb{C}[\mathcal{M}_{p}^{0}(v)]} \mathbb{C}[\mu^{-1}(p)]^{G, x} \to \text{gr} \left( \mathcal{A}_{p, x'}^{0} \otimes \mathcal{A}_{p}^{0} \right) \mathcal{A}_{p, x}^{0}(v)
\]
is supported on \( p^{sing} \). Let \( \sigma, \sigma^{0} \) denote the natural homomorphisms

\[
\mathcal{A}_{p, x'}^{0} \otimes \mathcal{A}_{p}^{0} \to \mathcal{A}_{p, x'}^{0} \otimes \mathcal{A}_{p}^{0},
\]

\[
\mathbb{C}[\mu^{-1}(p)]^{G, x'} \otimes_{\mathbb{C}[\mathcal{M}_{p}^{0}(v)]} \mathbb{C}[\mu^{-1}(p)]^{G, x} \to \text{gr} \mathcal{A}_{p, x'}^{0} \otimes \mathcal{A}_{p}^{0} \mathcal{A}_{p, x}^{0}(v)
\]

We have \( \sigma^{0} = \text{gr} \sigma \circ \eta \). It follows that both the kernel and the cokernel of \( \text{gr} \sigma \) are supported on \( p^{sing} \). Now we can argue as in the proof of Proposition 2.7 to finish the proof of (2).

\[\Box\]

**Proposition 4.6** Suppose that \( \chi \) lies in the interior of the chamber of \( \theta \) and satisfies \( H^{1}(\mathcal{M}^{\theta}(v), \mathcal{O}(\chi)) = 0 \). Then we have \( \mathcal{A}_{p, x}^{0}(v) \xrightarrow{\sim} \mathcal{A}_{p, x}^{(\theta)}(v) \). Moreover, this isomorphism is filtered and induces an isomorphism

\[
\text{gr} \mathcal{A}_{p, x}^{0}(v) \xrightarrow{\sim} \text{gr} \mathcal{A}_{p, x}^{(\theta)}(v).
\]

Both these \( \mathbb{C}[\mu^{-1}(p)]^{G, x} \) modules are identified with \( \mathbb{C}[\mu^{-1}(p)]^{G, x} \).

**Proof** Note that the restriction map \( \mathbb{C}[\mu^{-1}(p)]^{G, x} \to \mathbb{C}[\mu^{-1}(p)^{\theta, ss}]^{G, x} \) is injective because \( \chi \) is in the chamber of \( \theta \). The left vertical arrow in diagram (4.1) is surjective. We conclude that it is an isomorphism. From \( H^{1}(\mathcal{M}^{\theta}(v), \mathcal{O}(\chi)) = 0 \) it follows that the right vertical arrow in (4.1) is an isomorphism. For the same reasons, the same true for the specialization of (4.1) to any value of \( \lambda \). For \( \lambda \) Zariski generic, the natural map \( \mathcal{A}_{p, x}^{0}(v) \to \mathcal{A}_{p, x}^{(\theta)}(v) \) is an isomorphism. This follows from (1) of Proposition 4.5 combined with Lemma 3.4. Since the induced map of the associated graded modules is an embedding, it is forced to be an isomorphism. So \( \mathcal{A}_{p, x}^{0}(v) \to \mathcal{A}_{p, x}^{(\theta)}(v) \) is an isomorphism for all \( \lambda \). From here we deduce that \( \mathcal{A}_{p, x}^{0}(v) \leftrightarrow \mathcal{A}_{p, x}^{(\theta)}(v) \) is an isomorphism. The claim about the associated graded follows from here. \[\Box\]

Let us deduce a corollary of the previous proposition.
Corollary 4.7 Let $\theta$ be a generic stability condition. Let $\chi$ be generic. Then $\mathcal{A}_{\emptyset, \chi}^0 (v) = \mathcal{A}_{\emptyset, \chi}^0 (v)$ provided $H^1 (\mathcal{M}^0 (v), \mathcal{O}(\chi)) = 0$.

Proof This is a consequence of Propositions 3.3, 4.6.

Proof of Proposition 2.13 The claim of the proposition is equivalent for any two parameters with difference in $\mathbb{Z} \mathcal{O}_0$. Recall, Proposition 2.7, that $\mathcal{P}^{iso}$ is asymptotically generic. Therefore, after adding an element of $\mathbb{Z} \mathcal{O}_0$ to $\lambda$, we can assume that $\lambda + n \chi \in \mathcal{P}^{iso}$ for all $n \geq 0$. By Proposition 4.6, $\mathcal{A}_{\lambda + n \chi}^0 (v) \sim \mathcal{A}_{\lambda + m \chi, m \chi}^0 (v)$ for all $n, m \geq 0$. So the $\mathbb{Z}$-algebra $\mathcal{Z}_{\lambda, \chi} := \bigoplus_{n, n' \geq 0} \mathcal{A}_{\lambda + n \chi, n' \chi}^0$ is the same as the one appearing in [18, Section 5.3].

Thanks to Proposition 4.2, replacing $\lambda$ with $\lambda + m \chi$ for some $m$, we may assume that the $\mathbb{Z}$-algebra $\mathcal{Z}_{\lambda, \chi}$ is Morita, see, e.g., [18, Section 5.3] for the definition. Therefore, $\mathcal{A}_{\lambda}^0 (v)$ -mod is equivalent to the category $\mathcal{Z}_{\lambda, \chi}$ -mod of finitely generated graded $\mathcal{A}$-modules.

Now the claim that $\pi_{\lambda}^0 (v)$ is a quotient functor is proved as in [18, Section 5.5]. Let us provide details of the argument. Consider the functor $\pi_{\emptyset}^\mathbb{Z} := \bigoplus_{n=0}^\infty \mathcal{A}_{\lambda + n \chi}^0 (v) : \mathcal{D}(\mathcal{R})$ -mod$^{G, \lambda} \rightarrow \mathcal{Z}_{\lambda, \chi}$ -mod$^{gr}$. By [18, Proposition 5.28] (that only uses the assumption $\lambda + n \chi \in \mathcal{P}^{iso}$ for all $n \geq 0$ and not the flatness of the moment map), the equivalence $\mathcal{A}_{\lambda}^0 (v)$ -mod $\sim \mathcal{Z}_{\lambda, \chi}$ -mod$^{gr}$ intertwines the functors $\pi_{\lambda}^0 (v)$ and $\pi_{\emptyset}^\mathbb{Z}$. The latter is a quotient functor by [18, Lemma 5.29].

Proof of (1) Proposition 4.3 The proof is in several steps.

Step 1. We can choose $\chi$ in the interior of the chamber of $\theta$ satisfying the following three conditions:

(i) $H^1 (\mathcal{M}^\theta (v), \mathcal{O}(n \chi)) = 0$ for all $n \geq 1$.
(ii) $H^1 (\mathcal{M}^{-\theta} (v), \mathcal{O}(-n \chi)) = 0$ for all $n \geq 1$.
(iii) $\lambda + n \chi \in \mathcal{P}^{iso}$ and $(\lambda + n \chi, \theta) \in \mathcal{A} \mathcal{L}(v)$ for all $n \geq 0$.

Namely, choose $\chi$ in the chamber of $\theta$. Multiplying $\chi$ by a positive integer, we achieve (i) and (ii). Then we can rescale $\chi$ again and achieve (iii) thanks to Proposition 2.7 and Proposition 4.2.

Step 2. By Corollary 4.7, $\mathcal{A}_{\emptyset, m \chi}^0 (v)_{\lambda + n \chi} = \mathcal{A}_{\lambda + n \chi, m \chi}^0 (v)$ for all $m \geq -n$. Since $\lambda + n \chi \in \mathcal{A} \mathcal{L}(v)$, we see that $\mathcal{A}_{\emptyset, m \chi}^0 (v)_{\lambda + n \chi} = \mathcal{A}_{\lambda + n \chi, m \chi}^0 (v)$ thanks to Lemma 3.4. Therefore $\mathcal{A}_{\lambda + n \chi, m \chi}^0 (v) = \mathcal{A}_{\lambda + n \chi, m \chi}^0 (v)$ for all $m \geq -n$. We are going to deduce (1) of Proposition 4.3 from this equality.

Step 3. Consider the $\mathbb{Z}$-algebra $\mathcal{Z}_{\lambda, \chi} := \bigoplus_{n, m \geq 0} \mathcal{A}_{\lambda + n \chi, m \chi}^0 (v)$ and an “extended” $\mathbb{Z}$-algebra $\tilde{\mathcal{Z}}_{\lambda, \chi} := \bigoplus_{n \geq 0, m \geq -n} \mathcal{A}_{\lambda + n \chi, m \chi}^0 (v)$. For $M \in \mathcal{D}(\mathcal{R})$ -mod$^{G, \lambda}$, the sum $\bigoplus_{n \geq 0} M_{\mathcal{G}, n \chi}$ is a module over $\tilde{\mathcal{Z}}_{\lambda, \chi}$. But since $(\lambda + n \chi, \theta) \in \mathcal{A} \mathcal{L}(v)$ for all $n \geq 0$, all bimodules $\mathcal{A}_{\lambda + n \chi, m \chi}^0 (v) = \mathcal{A}_{\lambda + n \chi, m \chi}^0 (v)$.
\(A_{\lambda+(n+m)\chi, m\chi}(v)\) are Morita equivalences with inverse \(A_{\lambda+(n+m)\chi, -m\chi}(v) = A_{\lambda+(n+m)\chi, -m\chi}(v)\).

Step 4. We have an isomorphism \(A_{\lambda+(n+m)\chi, -m\chi}(v) \otimes A_{\lambda+(n+m)\chi}(v) \sim A_{\lambda+n\chi}(v)\) hence the map \(A_{\lambda+(n+m)\chi, -m\chi}(v) \otimes A_{\lambda+(n+m)\chi}(v) \rightarrow M^{G,n\chi}\) is an isomorphism as well. But this map comes from taking products by elements of \(D(R)\) in \(M\) and hence factors as

\[
A_{\lambda+(n+m)\chi, -m\chi}(v) \otimes A_{\lambda+(n+m)\chi}(v) \rightarrow A_{\lambda+(n+m)\chi, -m\chi}(v) \otimes A_{\lambda+(n+m)\chi}(v) \rightarrow M^{G,n\chi}\.
\]

So we see that the second map is surjective. Similarly, so is the first one. It follows that all maps \(A_{\lambda+(n+m)\chi, -m\chi}(v) \otimes A_{\lambda+(n+m)\chi}(v) \rightarrow M^{G,n\chi}\) are isomorphisms. A conclusion is that the spaces \(M^{G,n\chi}\) are either all zero or all nonzero.

Step 5. As described in [18, Section 5.3], the category \(A_{\chi}(v)\) -mod is equivalent to \(Z_{\lambda, \chi}\) -mod, where the latter stands for the quotient of the category of graded \(Z_{\lambda, \chi}\) -modules by the subcategory of all bounded modules. Under this equivalence, the functor \(\pi_{\lambda}(v)\) becomes \(M \mapsto \bigoplus_{n \geq 0} M^{G,n\chi}\) by [18, Proposition 5.28] (we remark that \(\pi_{\lambda}(v) \cong \pi_{\lambda}(v)\)). The conclusion of Step 4 now implies that the kernels of \(\pi_{\lambda}(v)\) and of \(\pi_{\lambda}(v)\) coincide. This proves (1). \(\square\)

Proof of Lemma 4.4 The proof is in several steps.

Step 1. Pick \(\chi \in \mathbb{Z}_{\lambda, \chi}\) lying in the interior of the chamber of \(\theta\) and satisfying \(H^1(\mathcal{M}(v), \mathcal{O}(\chi)) = 0\). Consider the subset \(\mathfrak{P}^{0} \subset \mathfrak{P}\) consisting of all parameters \(\lambda\) such that \(\lambda, \lambda+\chi \in \mathfrak{P}_{iso}\) and \(A_{\lambda, \chi}(v), A_{\lambda, -\chi}(v)\) are mutually inverse Morita equivalences. By Proposition 2.7 and (2) of Proposition 4.5, \(\mathfrak{P}^{0}\) is Zariski open and asymptotically generic.

Step 2. We claim that \((\lambda, \theta) \in \mathfrak{A}\mathcal{L}(v)\) provided \(\lambda + n\chi \in \mathfrak{P}^{0}\) for all \(n \geq 0\). As was mentioned in Step 2 of the proof of (1) of Proposition 4.3, \(A_{\lambda+m\chi,n\chi}^{0} = A_{\lambda+m\chi,n\chi}^{0}\) (we will drop “(v)” from the notation). So \(A_{\lambda+m\chi,n\chi}^{0}\) is a Morita equivalence bimodule for all \(m \geq 0\). By [18, Proposition 5.13] what remains to be checked is that the natural homomorphism

\[
A_{\lambda+(n+m)\chi, \chi}^{0} \otimes A_{\lambda+(n+m)\chi}^{0} \rightarrow A_{\lambda+m\chi,(n+1)\chi}^{0} \quad (4.3)
\]

is an isomorphism. Note that we also have a natural homomorphism

\[
A_{\lambda+(m+n+1)\chi, \chi}^{0} \otimes A_{\lambda+(m+n+1)\chi}^{0} \rightarrow A_{\lambda+m\chi,(n+1)\chi}^{0} \quad (4.4)
\]
Since $\mathcal{A}_{\lambda+(m+n)\chi,\chi}^{0}$ is a Morita equivalence bimodule with inverse $\mathcal{A}_{\lambda+(m+n+1)\chi,-\chi}^{0}$, (4.4) gives rise to

$$\mathcal{A}_{\lambda+m\chi,(n+1)\chi}^{0} \rightarrow \mathcal{A}_{\lambda+(m+n)\chi,\chi}^{0} \otimes \mathcal{A}_{\lambda+(m+n)\chi}^{0} \mathcal{A}_{\lambda+m\chi,n\chi}^{0} \quad (4.5)$$

It is easy to see from the construction that (4.5) and (4.3) are mutually inverse to each other. This completes the proof of the claim in the beginning of the paragraph and the proof of the lemma.

Step 3. Let us finish the proof of lemma. Let $f$ denote the product of the linear functions defining the singular hyperplanes in $\text{p}^\text{sing}$. Since $\mathfrak{p}^0$ is asymptotically generic, there is a polynomial $F \in \mathbb{C}[\mathfrak{p}]$ that vanishes on $\mathfrak{p} \setminus \mathfrak{p}^0$ and has the form $f^d + \ldots$, where $\ldots$ denote the terms of smaller degree. We can assume that the top degree term of $F$ is positive on the interior of $C$. Pick a codimension 1 face $\Gamma$ of $C$ and let $p_0$ denote the hyperplane in $p$ spanned by $\Gamma$. We can write an arbitrary element $\lambda \in \mathfrak{p}$ as $\lambda = \lambda' + z\chi + \lambda_0$ with $\lambda'$ being a fixed element, $z \in \mathbb{C}, \lambda_0 \in p_0$ (here we use the identifications $\mathfrak{p} \cong \mathbb{C}^{Q_0} \cong p$). So we can view $F$ as an element of $\mathbb{C}[p_0][z]$. We can shift $\lambda'$ by an integer so that $F|_{z=n}$ is a nonzero element of $\mathbb{C}[p_0]$ for all $n \in \mathbb{Z}_{\geq 0}$. This is our choice of $\lambda'$.

Let $Y(\lambda')$ consist of all $\lambda \in \lambda' + (C \cap Z^{Q_0})$ such that $\lambda + n\chi \in \mathfrak{p}^0$ for all $n \in \mathbb{Z}_{\geq 0}$. Now pick a Zariski generic primitive element $\psi \in \Gamma \cap Z^{Q_0}$. We claim that for infinitely many elements $m \in \mathbb{Z}_{\geq 0}$, we have $F(m\psi + n\chi) \neq 0$ for all $n \in \mathbb{Z}_{\geq 0}$. This will imply the required properties of $Y(\lambda')$.

Let $e$ denote the degree of $F$. Let us write $F_e$ for the homogeneous degree $e$ part of $F$ and $F_{<e}$ for the sum of degree $< e$ parts so that $F = F_e + F_{<e}$ and $F_e = f^d$. By the construction of $f$, we have $F_e(m\psi + n\chi) > A_1 n^e$, where $A_1$ is some positive constant. On the other hand, $|F_{<e}(m\psi + n\chi)| < A_2 \max(m, n)^{e-1}$, where $A_2$ is some positive constant. We conclude that $F(m\psi + n\chi) \neq 0$ as long as $n \geq A_3 m^{1-1/e}$, where $A_3$ is some positive constant. On the other hand, for fixed $n$, the number of solutions $m$ to $F(m\psi + n\chi) = 0$ cannot exceed $e$, because the degree of $F$ is $e$. So for $M \in \mathbb{Z}_{>0}$, the number of pairs $m \in [0, M], n \in \mathbb{Z}_{>0}$ such that $F(m\psi + n\chi) = 0$ is bounded by $A_4 M^{1-1/e}$, where $A_4$ is some positive constant. This finishes the proof of the claim in the beginning of the paragraph and the proof of the lemma.

4.3 Conjectures on localization

We would like to finish this section by stating conjectures on the precise loci, where abelian and derived localizations hold.

Let us state the main conjecture.

Conjecture 4.8 The following is true:
(1) The locus $\mathcal{P}^{\text{sing}}(v)$ of $\lambda \in \mathcal{P}$ such that the algebra $A_{\lambda}(v)$ has infinite homological dimension is the union of hyperplanes each parallel to some $\ker \alpha$, where $\alpha$ is a root of $g(Q)$ with $\alpha \leq v$.

(2) Let $\theta$ be a generic stability condition lying in the classical chamber $C$. Then $(\lambda, \theta) \in \mathcal{AL}(v)$ if and only if $(\lambda + (C \cap \mathbb{Z}^{Q_0})) \cap \mathcal{P}^{\text{sing}}(v) = \emptyset$.

We would like to point out that the main challenge in (a) is to prove that $\mathcal{P}^{\text{sing}}(v)$ is a finite union of hyperplanes, it should not be hard to determine the hyperplanes in $\mathcal{P}^{\text{sing}}(v)$. Let us give a more detailed conjectural description of $\mathcal{P}^{\text{sing}}(v)$. Assume, for simplicity, that the moment map $\mu$ is flat so that $\mathcal{M}(v) = \mathcal{M}^0(v)$.

For a root $\alpha$, let $\Sigma_{\alpha}$ denote the union of hyperplanes parallel to $\ker \alpha$ that are contained in $\mathcal{P}^{\text{sing}}(v)$ so that, according to Conjecture 4.8, $\mathcal{P}^{\text{sing}}(v) = \bigcup_{\alpha \leq v} \Sigma_{\alpha}$. Let us explain how to compute $\Sigma_{\alpha}$.

Pick a generic point $p \in \ker \alpha$ and assume that $\alpha$ is indecomposable. Let $k$ be maximal such that $(v, 1) - k\alpha$ is a root of the quiver $Q^w$. Then, in the terminology of 2.1.6, we can pick $x \in \mathcal{M}_p(v)$ that corresponds to the decomposition $r = r_0 \oplus r_1 \otimes \mathbb{C}^k$, where $\dim r_1 = \alpha$ and $\dim r_0 = (v^0, 1)$. Then we get the quiver $\hat{Q}$ that has a single vertex and $1 - (\alpha, \alpha)/2$ loops. We consider the dimension $\hat{v} = k$ and the framing $\hat{w} = w \cdot \alpha - (v^0, \alpha)$. Recall the affine map $\hat{r} : \mathcal{P} \to \hat{\mathcal{P}} = \mathbb{C}$ from 3.3.1.

**Conjecture 4.9** We have $\Sigma_{\alpha} = \hat{r}^{-1}(\mathcal{P}^{\text{sing}}(\hat{\nu}))$ (where the locus $\mathcal{P}^{\text{sing}}(\hat{\nu})$ is formed for the framing $\hat{w}$).

Conjectures 4.8 and 4.9 reduce the computation of the locus where abelian/derived localization holds to quivers with a single vertex. Let us explain what is known there.

In the case when there are no loops, the algebra $A_{\lambda}(v)$ is $D^{\lambda}(\text{Gr}(v, w))$, the algebra of global $\lambda$-twisted differential operators on the grassmanian $\text{Gr}(v, w)$. In this case, analogs of the abelian/derived Beilinson–Bernstein theorems (stated originally for the flag varieties) hold. We have $\mathcal{P}^{\text{sing}}(v) = \{-1, -2, \ldots, 1 - w\}$ and (2) of Conjecture 4.8 holds.

Let us consider the situation when there is one loop. A classical case is when $w = 1$. Here $A_{\lambda}(v)$ is the spherical rational Cherednik algebra for $(S_n, C^n)$, see 2.2.6. The subset $\mathcal{P}^{\text{sing}}(v)$ consists of all rational $\lambda \in (-1, 0)$ with denominator not exceeding $n$, see e.g. [8, Corollary 4.2]. Moreover, (2) of Conjecture 4.8 holds, this follows from [34,36], the case of half-integer parameters was completed in [8].

When $w > 1$, we have that $\mathcal{P}^{\text{sing}}(v)$ consists of all rational numbers $\lambda \in (-w, 0)$ with denominator not exceeding $v$. Moreover, (2) of Conjecture 4.8 holds. These results are obtained in the subsequent paper [50] by the second named author.
Finally, let us mention that derived and/or abelian localization is known for some \((Q, v, w)\) with \(|Q_0| > 1\). For example, much is known about the case when \(Q\) is of finite Dynkin type A. The case when the corresponding variety \(M^\theta(v)\) is the cotangent bundle to a partial flag variety follows similarly to the Beilinson–Bernstein theorem. The case when \(M^\theta(v)\) is the preimage of the Slodowy slice in the cotangent bundle of the full flag variety follows as in [31].

Now let \(Q\) be an affine quiver with extending vertex 0. Assume that \(w = \epsilon_0\) so that \(A^\lambda(v)\) is the spherical subalgebra in an SRA. In this case there was a conjecture describing the singular (=aspherical) locus in \(P^{\text{sing}}(n\delta)\) [26, Conjecture 5.3], based on the cyclic case done before that in [24]. It is easy to see that (after relating the parameterizations) (1) of Conjecture 4.8 reduces to [26, Conjecture 5.3] for \(v = n\delta\). Moreover, part (2) in the cyclic case should follow from results of [45].

5 Wall-crossing and Webster functors

In this section we will recall/introduce two different (but related) families of functors that are the main ingredients of the proof of Theorem 1.2.

We will consider functors categorifying the action of \(a\) on the cohomology of \(\bigsqcup_\theta M^\theta(v)\). In special cases (for example, when \(\lambda\) is integral and all components of \(\theta\) are positive) these functors were constructed by Webster in [63] and our general construction is built on his. So we call these Webster functors. The second family of functors was introduced in [18, Section 6] under the name of twisting functors. In this paper we call them wall-crossing functors.

Roughly, the Webster functors should be thought as induction functors that allow to produce new finite dimensional modules from existing ones, proving a “lower bound” of Theorem 1.2. The wall-crossing functors are used to establish the “upper bound”.

5.1 Wall-crossing functors

Here we define wall-crossing functors and study some of their properties. In what follows we assume that the functor \(L\text{Loc}_{\lambda}^\theta\) is a derived equivalence provided the homological dimension of \(A^\lambda(v)\) is finite (this is always the case when the quiver \(Q\) is of finite or affine type, see Proposition 4.1).

5.1.1 Construction of the functor

Pick \(\lambda \in \mathfrak{P}, \chi \in \mathbb{Z}^{Q_0}\). Recall, 3.1.4, the \(A^\theta_{\lambda+\chi}(v) - A^\theta_{\lambda}(v)\)-bimodule \(A^\theta_{\lambda, \chi}(v) := [Q_{\lambda} | T^* R^{\theta - ss}]^{G, \chi}\) and its global sections \(A^\theta_{\lambda, \chi}(v)\). Note that the
functor $T_{\lambda, \chi} : \mathcal{A}_{\lambda, \chi}^\theta (v) \otimes \mathcal{A}_\lambda^\eta(v) \bullet : \mathcal{A}_\lambda^\theta(v) \text{-mod} \to \mathcal{A}_{\lambda+\chi}^\theta(v) \text{-mod}$ is an equivalence. We remark that
\[ T_{\lambda, \chi} \circ \pi^\theta_\lambda(v) = \pi^\theta_{\lambda+\chi}(v) \circ (\mathbb{C}_{-\chi} \otimes \bullet). \] (5.1)

Now let $\lambda', \lambda$ be such that $\chi := \lambda - \lambda' \in \mathbb{Z}Q^0$, the algebra $\mathcal{A}_{\lambda'}(v)$ has finite homological dimension (and so $L \text{Loc}_{\lambda'}^\theta$ is a derived equivalence), and $(\lambda, \theta) \in \mathfrak{A}(v)$. Following [18, Section 6.4], we define a functor $\mathcal{MC}_{\lambda' \to \lambda} : \mathcal{D}^b(\mathcal{A}_{\lambda'}(v) \text{-mod}) \sim \to \mathcal{D}^b(\mathcal{A}_\lambda(v) \text{-mod})$ by
\[ \mathcal{MC}_{\lambda' \to \lambda} := \Gamma^\theta_\lambda \circ T_{\lambda', \chi} \circ L \text{Loc}_{\lambda'}^\theta. \] (5.2)

We remark that this functor is right $t$-exact. If $(\lambda', \theta') \in \mathfrak{A}(v)$, then we can also consider the functor $\mathcal{MC}_{\lambda' \to \lambda} = T_{\lambda', \chi} \circ (R \Gamma_{\lambda'})^{-1} \circ \Gamma_{\lambda'}^\theta : \mathcal{D}^b(\mathcal{A}_{\lambda'}(v) \text{-mod}) \sim \to \mathcal{D}^b(\mathcal{A}_{\lambda}(v) \text{-mod})$. When $(\lambda', \theta') \in \mathfrak{A}(v)$, we often write $\mathcal{MC}_{\theta' \to \theta}$ instead of $\mathcal{MC}_{\lambda' \to \lambda}$. We note that under the identifications
\[ \mathcal{A}_{\lambda_1}^\eta(v) \text{-mod} \sim \to \mathcal{A}_\lambda^\eta(v) \text{-mod}, \mathcal{A}_{\lambda_1'}^\eta(v) \text{-mod} \sim \to \mathcal{A}_{\lambda'}^\eta(v) \text{-mod} \]
with $\lambda_1 \in \lambda + \mathbb{Z}Q^0, \lambda_1' \in \lambda' + \mathbb{Z}Q^0$, the functor $\mathcal{MC}_{\theta' \to \theta}$ is independent of the choice of $\lambda_1, \lambda_1'$ provided $(\lambda_1, \theta), (\lambda_1', \theta') \in \mathfrak{A}(v)$.

5.1.2 Alternative realizations

Here is another formula for $\mathcal{MC}_{\theta' \to \theta}$ that holds when $\lambda \in \mathcal{P}^{ISO}$ (and $(\lambda, \theta) \in \mathfrak{A}(v)$):
\[ \mathcal{MC}_{\theta' \to \theta} = \pi^\theta_\lambda(v) \circ (\mathbb{C}_{-\lambda} \otimes \bullet) \circ L \pi^\theta_{\lambda'}(v)^\dagger. \] (5.3)

This formula follows from (5.1),(5.2) and Lemma 2.17. Here we use the isomorphism $\pi^\theta_{\lambda'}(v) = \pi^\theta_\lambda(v)$ to produce the functor $L \pi^\theta_{\lambda'}(v)^\dagger$.

A connection of $\mathcal{A}_{\lambda, \chi}^{(\theta)}$ to the wall-crossing functor is provided by the following assertion.

**Lemma 5.1** (Proposition 6.31 in [18]) If $(\lambda, \theta) \in \mathfrak{A}(v)$, then
\[ \mathcal{MC}_{\lambda \to \lambda'}(\bullet) = \mathcal{A}_{\lambda, \chi}^{(\theta)}(v) \otimes_{\mathcal{A}_\lambda(v)} L \bullet. \]

In fact, under the assumptions of Lemma 5.1, $\mathcal{A}_{\lambda, \chi}^{(\theta)}(v) = \mathcal{A}_{\lambda, \chi}^0(v)$, as the following proposition shows.
Proposition 5.2 Suppose that $\lambda, \lambda + \chi \in \mathcal{P}^{iso}$ and $(\lambda + \chi, \theta) \in \mathcal{A}(v)$. Then the natural homomorphism $A^0_{\lambda, \chi}(v) \rightarrow A^{(\theta)}_{\lambda, \chi}(v)$ is an isomorphism.

Proof By (1) of Proposition 4.3, the functors $\pi^\theta_{\lambda + \chi}(v), \pi^0_{\lambda + \chi}(v)$ are isomorphic (below we suppress $v$ and write $\pi^\theta_{\lambda + \chi}, \pi^0_{\lambda + \chi}$, etc.). Moreover, $\pi^0_{\lambda + \chi} = \Gamma^\theta_{\lambda + \chi} \circ \pi^\theta_{\lambda + \chi}$. Then we have

\[
\begin{align*}
A^0_{\lambda, \chi}(v) \otimes \Lambda_{\lambda}(v) &\cong \text{[Lemma 5.1]} \\cr
\Gamma^\theta_{\lambda + \chi} \circ (A^\theta_{\lambda, \chi} \otimes \Lambda^\theta_{\lambda}) &\circ \text{Loc}^\theta_{\lambda} \cong \text{[Lemma 2.17]} \\cr
\Gamma^\theta_{\lambda + \chi} \circ \pi^\theta_{\lambda + \chi} \circ (\mathbb{C}_{-\chi} \otimes \bullet) &\circ (\pi^0_{\lambda})^!.
\end{align*}
\]

Also it is easy to see that $A^0_{\lambda, \chi}(v) \otimes \Lambda_{\lambda}(v) \bullet = \pi^0_{\lambda + \chi} \circ (\mathbb{C}_{-\chi} \otimes \bullet) \circ (\pi^0_{\lambda})^!$. So the functors $A^0_{\lambda, \chi}(v) \otimes \Lambda_{\lambda}(v)$ and $A^0_{\lambda, \chi}(v) \otimes \Lambda_{\lambda}(v) \bullet$ are isomorphic. It follows that the bimodules $A^0_{\lambda, \chi}(v)$ and $A^0_{\lambda, \chi}(v)$ are isomorphic. Let us see why the corresponding isomorphism coincides with (3.1).

Consider the functor $(\pi^\theta_{\lambda})^! : A^\theta_{\lambda}(v) \text{-mod} \rightarrow D(R) \text{-Mod}^{G, \lambda}$ defined by

\[
(\pi^\theta_{\lambda})^! := \Gamma(Q_{\lambda} |_{(T^* R)^{ss}} \otimes A^\theta_{\lambda}(v) \bullet)
\]

We have a natural isomorphism

\[
\begin{align*}
\text{Hom}_{A^\theta_{\lambda}(v)}(\pi^\theta_{\lambda}(N), M) &\cong \text{Hom}_{D(R)}(N, (\pi^\theta_{\lambda})^!(M)), \\
N \in D(R) \text{-mod}^{G, \lambda}, M \in A^\theta_{\lambda}(v) \text{-mod}.
\end{align*}
\]

By the definition, (3.1) coincides with the natural homomorphism

\[
\begin{align*}
\pi^0_{\lambda + \chi} \circ (\mathbb{C}_{-\chi} \otimes \bullet) &\circ (\pi^0_{\lambda})^! \circ (A_{\lambda}(v)) \rightarrow [\pi^0_{\lambda + \chi} \circ (\pi^\theta_{\lambda + \chi})^!] \\cr
\circ \pi^\theta_{\lambda + \chi} \circ (\mathbb{C}_{-\chi} \otimes \bullet) &\circ (\pi^0_{\lambda})^! \circ (A_{\lambda}(v)).
\end{align*}
\]

It follows from Lemma 2.17 and (5.4) that the composition in the brackets in (5.5) is $\Gamma^\theta_{\lambda + \chi}$. Also (5.4) gives rise to a functor morphism $\text{id} \rightarrow (\pi^\theta_{\lambda + \chi})^! \circ \pi^\theta_{\lambda + \chi}$, which is nothing else but the restriction homomorphism of a module in $D(R) - \text{mod}^{G, \lambda}$ to its sections on the semistable locus. (5.5) is induced by this functor morphism. So (5.5) is the homomorphism $A^0_{\lambda, \chi}(v) \rightarrow A^{(\theta)}_{\lambda, \chi}(v)$ constructed before in this proof.

The importance of this proposition is that the bimodules $A^0_{\lambda, \chi}(v)$ are better than $A^{(\theta)}_{\lambda, \chi}(v)$ in several aspects: for example, the former behave well under...
restriction functors, (3.11). This will allow to study wall-crossing functors inductively.

5.1.3 Composition of wall-crossing functors

It turns out that, under additional restrictions, a composition of wall-crossing functors is again a wall-crossing functor.

More precisely, suppose that we have two generic stability conditions \( \theta, \theta' \).

Suppose that \( \theta_i, i = 0, \ldots, q \), are such that \( \theta_0 = \theta, \theta_q = \theta' \), \( \theta_i \) and \( \theta_{i+1} \) are separated by a single wall and \( q \) is minimal with these properties.

**Theorem 5.3** We have an isomorphism of functors

\[
WC_{\theta_0} \to_{\theta} \to_{\theta_q} \circ \ldots \circ WC_{\theta_1} \to_{\theta} \to_{\theta_2} \circ WC_{\theta_0} \to_{\theta} \to_{\theta_1}.
\]

**Proof** This is established in the proof of [18, Theorem 6.35]. \( \square \)

5.1.4 Non-essential walls

Sometimes a wall-crossing functor between two different chambers happens to be an abelian equivalence. We will be interested in the situation when this happens for two chambers sharing a wall.

Namely, we say that a classical wall \( \ker \alpha \) is *non-essential* (for the parameter \( \lambda \)) if for every two classical chambers \( C, \ C' \) separated by \( \ker \alpha \) only, the wall-crossing functor \( WC_{\lambda} \to_{\lambda'} \) is an abelian equivalence for \( \theta \in C, \theta' \in C' \) (and \( (\lambda, \theta), (\lambda', \theta') \in \mathcal{AL}(v) \)).

Here is an important example of a non-essential wall.

**Proposition 5.4** Suppose \( \alpha \) is a real root and \( \langle \alpha, \lambda \rangle \notin \mathbb{Z} \). Assume also that the intersections of \( P^{iso} \) with \( \lambda + \ker \alpha, \lambda' + \ker \alpha \) are nonempty. Then the wall ker \( \alpha \) is non-essential for \( \lambda \).

**Proof** Let \( \mathfrak{p}_0 := \lambda + \ker \alpha, \mathfrak{p}_0' := \lambda' + \ker \alpha \). Consider the translation bimodules \( B_{\mathfrak{p}_0} := A_{\mathfrak{p}_0, \chi}(v), B_{\mathfrak{p}_0}' := A_{\mathfrak{p}_0', -\chi}(v) \) and the algebras \( A_{\mathfrak{p}_0} := A_{\mathfrak{p}_0}(v), A_{\mathfrak{p}_0}' := A_{\mathfrak{p}_0'}(v) \), where \( \chi = \lambda' - \lambda \).

**Step 1.** We claim that for a Zariski generic \( \lambda_1 \in \mathfrak{p}_0 \) the specializations \( B_{\lambda_1}, B'_{\lambda_1} \) are mutually inverse Morita equivalences. Similarly to the proof of Proposition 2.7 (Sect. 3.5), this amounts to checking that the kernels and the cokernels of the natural homomorphisms

\[
B'_{\mathfrak{p}_0} \otimes A'_{\mathfrak{p}_0} B_{\mathfrak{p}_0} \to A_{\mathfrak{p}_0} \quad \text{and} \quad B_{\mathfrak{p}_0} \otimes A_{\mathfrak{p}_0} B'_{\mathfrak{p}_0} \to A'_{\mathfrak{p}_0}
\]

have proper supports in \( \mathfrak{p}_0 \). This will be proved in subsequent steps.

\( \square \)
Step 2. Pick a Zariski generic \( p \in \ker \alpha \) and consider \( x \in \mathcal{M}_p^0(v) \). The corresponding representation \( r \) of \( Q^w \) decomposes into irreducibles as \( r = r_0 \oplus r_1 \oplus \ldots \oplus r_k \), where \( r_0 \) has dimension \( (v - k \alpha, 1) \) and all \( r_i \) have dimension \((\alpha, 0)\). By [23, Theorem 1.2], the representations \( r_1, \ldots, r_k \) are all isomorphic. The corresponding quiver \( \hat{Q} \) (see 2.1.6) has one vertex and no loops, \( \hat{v} = k \) and \( \hat{w} = w \cdot \alpha - (v - k \alpha, \alpha) = (v, \alpha) + 2k \). We claim that \( \hat{r}(\lambda) = \langle \alpha, \lambda \rangle + s \), where \( s \in \mathbb{Z} \). Indeed, this boils down to \( \langle \varrho(v), \alpha \rangle - \frac{1}{2}(v, \alpha) \in \mathbb{Z} \) that is a straightforward check. So the parameter \( \hat{\lambda} := \hat{r}(\lambda) \) is not an integer. Also since \( \lambda \in \mathcal{P}_{iso} \), we see that \( \hat{\lambda} \) is an integer. Therefore the bimodules \( \hat{A}_0^\lambda(v) \) are mutually inverse Morita equivalences. Proposition 5.2 implies that the bimodules \( \hat{A}_0^\lambda(v) \) are Morita equivalences. Equivalently, the kernels and cokernels of the homomorphisms in (5.6) vanish under the functor \( \bullet \circ_{\text{t}, \chi} \). By Lemma 3.9, the associated varieties of these kernels and cokernels do not intersect \( \mathcal{M}_p(v) \). Since \( p \) was chosen to be Zariski generic, the \( \mathcal{P}_0 \)-supports of the kernels and cokernels are proper. The claim in the beginning of Step 1 follows.

Step 3. Let \( \hat{\chi} = \langle \chi, \alpha \rangle \), this is an integer. So both \( \hat{\lambda}, \hat{\lambda} + \hat{\chi} \) are not integers. A version of the Beilinson–Bernstein abelian localization theorem for twisted differential operators on grassmanians implies that abelian localization holds for \( (\hat{\lambda}, \hat{\theta}) \) and \( (\hat{\lambda} + \hat{\chi}, \hat{\theta}) \). Therefore the bimodules \( \hat{A}_{\hat{\lambda}, \hat{\chi}}^0(\hat{v}), \hat{A}_{\hat{\lambda} + \hat{\chi}, -\hat{\chi}}^0(\hat{v}) \) are mutually inverse Morita equivalences. Proposition 5.2 implies that the bimodules \( \hat{A}_{\hat{\lambda}, \hat{\chi}}^0(\hat{v}), \hat{A}_{\hat{\lambda} + \hat{\chi}, -\hat{\chi}}^0(\hat{v}) \) are Morita equivalences. Equivalently, the kernels and cokernels of the homomorphisms in (5.6) vanish under the functor \( \bullet \circ_{\text{t}, \chi} \). By Lemma 3.9, the associated varieties of these kernels and cokernels do not intersect \( \mathcal{M}_p(v) \). Since \( p \) was chosen to be Zariski generic, the \( \mathcal{P}_0 \)-supports of the kernels and cokernels are proper. The claim in the beginning of Step 1 follows.

Step 4. Let us finish the proof. By applying integral shifts to \( \mathcal{P}_0, \mathcal{P}_0' \) (and, in particular, modifying \( \chi \)), thanks to Lemma 4.4, we may assume that there is \( \lambda_0 \in \lambda + (\mathbb{Z} \cap \ker \alpha) \) such that \( (\lambda_1, \theta), (\lambda_1 + \chi, \theta') \in \mathcal{A}_\mathcal{L}(v) \) for \( \lambda_1 \in \lambda_0 + (C \cap \ker \alpha) \) in some Zariski dense subset of \( \ker \alpha \). As was mentioned in Sect. 5.1.1, the functor \( \mathcal{M}_\mathcal{C}_{\lambda_1 \to \lambda_1 + \chi} \) becomes \( \mathcal{M}_\mathcal{C}_{\lambda \to \lambda + \chi} \) up to pre- and post-composing with equivalences of abelian categories. Since \( \lambda_0 + (C \cap \ker \alpha) \) is Zariski dense, we use Proposition 5.2 together with Lemma 5.1 to see that \( \mathcal{M}_\mathcal{C}_{\lambda_1 \to \lambda_1 + \chi} = \mathcal{A}_{\lambda_1 + \chi}^0(v) \otimes_{\mathcal{A}_{\lambda_1}^0(v)} \bullet \) is an abelian equivalence. This completes the proof.

So the only non-trivial wall-crossing functors corresponding to the walls \( \ker \alpha \) with real \( \alpha \) are for \( \alpha \) that are roots of \( \alpha^\lambda \). This is the first indication that the representation theory of the algebras \( A_{\lambda}(v) \) is controlled by the algebras \( \alpha^\lambda \).
5.2 Webster functors

5.2.1 Special case: Webster’s construction

In [63], Webster introduced a quantum categorical version of Nakajima’s construction [56, Section 10]. In the case when all $\theta_k$ are positive and for $i \in Q_0$ such that $\lambda_i \in \mathbb{Z}$, he produced functors $F_i : D^b(A_\lambda^i(v) \text{-mod}) \cong D^b(A_\lambda^i(v + \epsilon_i) \text{-mod}) : E_i$ and studied their properties. We will need the construction so we recall it first.

We start with the simplest possible case when $Q$ is a single vertex without arrows. In this case, $M^0(v) = T^* \text{Gr}(v, w)$ and $\lambda$ has to be an integer (for $\alpha$ to be different from the Cartan subalgebra). Our exposition follows [21].

Pick $r > 0$ and set $d = w - 2v + r$. Consider the incidence subvariety $C^r(d) := \text{Fl}(v, v - r, w) \subset \text{Gr}(v, w) \times \text{Gr}(v - r, w)$. Consider the $\delta$-function $D_{\text{Gr}(v,w) \times \text{Gr}(v-r,w)}$-module $\delta_{C^r(d)}$ on $C^r(d)$ (the image of the structure sheaf on $C^r(d)$ under the Kashiwara equivalence). Then we consider the following objects:

$$E^{(r)}(d) = \delta_{C^r(d)}[v(w - v)] \in D^b(D_{\text{Gr}(v,w) \times \text{Gr}(v-r,w)} \text{-mod}),$$

$$F^{(r)}(d) = \delta_{C^r(d)}[(v - r)(w - v + r)] \in D^b(D_{\text{Gr}(v-r,w) \times \text{Gr}(v,w)} \text{-mod}).$$

The object $E^{(r)}(d)$ defines a functor $E^{(r)}(d) : D^b(D_{\text{Gr}(v,w)} \text{-mod}) \to D^b(D_{\text{Gr}(v-r,w)} \text{-mod})$ by convolving with $E^{(r)}(d)$. Similarly, we get a functor $F^{(r)}(d) : D^b(D_{\text{Gr}(v-r,w)} \text{-mod}) \to D^b(D_{\text{Gr}(v,w)} \text{-mod})$. We write $E^{(r)}$ for $\bigoplus_d E^{(r)}(d)$, and $F^{(r)}$ for $\bigoplus_d F^{(r)}(d)$.

The functors $E^{(r)}(d), F^{(r)}(d)$ are adjoint to one another up to homological shifts. Namely, let us write $E^{(r)}(d)_L, E^{(r)}(d)_R$ for the left and right adjoint functors of $E^{(r)}(d)$. We have

$$E^{(r)}(d)_L \cong F^{(r)}(d)[-rd], \quad E^{(r)}(d)_R \cong F^{(r)}(d)[rd]. \quad (5.7)$$

This construction has several extensions. For example, we get functors

$$F : D^b(D_{\text{Gr}(\bullet,w)} \otimes D_{\mathbb{R}} \text{-mod}) \cong D^b(D_{\text{Gr}(\bullet+1,w)} \otimes D_{\mathbb{R}} \text{-mod}) : E$$

for any vector space $R$. Also if $H$ is a reductive group equipped with homomorphisms $H \to \text{GL}(w), \text{GL}(R)$ and $\lambda$ is a character of $\mathfrak{h}$, then we get functors

$$F : D^b_{H,\lambda}(D_{\text{Gr}(\bullet,w)} \otimes D_{\mathbb{R}} \text{-mod}) \cong D^b_{H,\lambda}(D_{\text{Gr}(\bullet+1,w)} \otimes D_{\mathbb{R}} \text{-mod}) : E \quad (5.8)$$
Now let us proceed to the case of a general quiver. We assume that \( \theta_k > 0 \) for all \( k \in Q_0 \). Let \( R, G \) be as in (2.2), \( \theta \) be the collection of \( \theta_j \) with \( j \neq i \) and \( \lambda \) have the similar meaning to \( \theta \). We reverse arrows if necessary and assume that \( i \) is a source in \( Q \).

Since \( \theta_i > 0 \), we have \( R_{/\theta_i} G_i = \text{Gr}(v_i, \bar{w}_i) \times R \), where \( \bar{w}_i \) is defined by (2.1). The group \( G \) acts on \( \text{Gr}(v_i, \bar{w}_i) \times R \) diagonally, the action on \( \text{Gr}(v_i, \bar{w}_i) \) is via a natural action of \( G \) on \( \bar{w}_i \). Then we have

\[
D_{R_{/\theta_i} \lambda_i} \text{GL}(v_i) = D_{\text{Gr}(v_i, \bar{w}_i)}^{\lambda_i} \otimes D_R, \quad A_{\lambda}^\theta(v) = [D_{\text{Gr}(v_i, \bar{w}_i)}^{\lambda_i} \otimes D_R]_{/\theta_i} G_i.
\]

Let us write \( A_{\lambda_i}^{\theta_i}(v) \) for the former reduction.

It follows from Proposition 2.13 that the category \( A_{\lambda}^\theta(v) \)-mod is the quotient of the category \( A_{\lambda_i}^{\theta_i}(v) \)-mod\( G, \lambda \) (of \( (G, \lambda) \)-equivariant \( A_{\lambda_i}^{\theta_i}(v) \)-modules) by the Serre subcategory of all modules whose singular support is contained in the image of \( \mu^{-1}(0)^{\theta_i - ss} \setminus \mu^{-1}(0)^{\theta - ss} \) in \( T^* R_{/\theta_i} \text{GL}(v_i) \). Lemma 2.15 shows that the same is true on the level of (equivariant) derived categories.

As was checked by Webster [63, Section 4], the functors

\[
F : D^b_{G, \lambda}(A_{\lambda_i}^{\theta_i}(v) \text{-mod}) \rightleftharpoons D^b_{G, \lambda}(A_{\lambda_i}^{\theta_i}(v + \epsilon_i) \text{-mod}) : E
\]

preserve the subcategories of all complexes whose homology are supported on the image of \( \mu^{-1}(0)^{\theta_i - ss} \setminus \mu^{-1}(0)^{\theta - ss} \) in \( T^* R_{/\theta_i} \text{GL}(v_i) \) (it is important here that all \( \theta_k \) are positive). So they descend to endo-functors of \( \bigoplus_v D^b(A_{\lambda}^\theta(v) \text{-mod}) \) to be denoted by \( E_i, F_i \).

**Remark 5.5** Let \( \chi \in \mathbb{Z} Q_0 \). By the very definition of the functors \( E_i, F_i \), the equivalences

\[
A_{\lambda}^\theta(v) \text{-mod} \sim A_{\lambda + \chi}^\theta(v) \text{-mod}, \quad A_{\lambda}^\theta(v + \epsilon_i) \text{-mod} \sim A_{\lambda + \chi}^\theta(v + \epsilon_i) \text{-mod}
\]

intertwine these functors.

### 5.2.2 Properties

Let us explain some properties of the functors \( E, F \) (and also of \( E_i, F_i \)).

The proof of the next lemma is a part of that for [63, Theorem 3.1].

**Lemma 5.6** The functors (5.8) define a categorical action of the 2-Kac–Moody algebra \( \mathcal{U}(sl_2) \) (we use the same version as in [63, Section 1]) on the category

\[
\bigoplus_{v=0}^w D^b_{H, \lambda}(D^\lambda_{\text{Gr}(v, w)} \otimes D_R \text{-mod}). \quad (5.9)
\]
The divided power functors are $E^{(r)}$, $F^{(r)}$.

Consider a 2-category $Q$, a “single vertex analog” of the 2-category $Q_\lambda$ introduced in the end of [63, Section 2] (so that the 1-morphisms $E^{(r)}$, $F^{(r)}$ in $\mathcal{U}(\mathfrak{sl}_2)$ map to $E^{(r)}$, $F^{(r)}$) that we are going to define now. In our definition of $Q$ we will need a version of the Steinberg variety. By definition, this is the subvariety $St \subset T^* Gr(v, w) \times T^* Gr(v', w)$ that is the preimage of the diagonal in $\mathfrak{gl}(w) \times \mathfrak{gl}(w)$ under the moment map $T^* Gr(v, w) \times T^* Gr(v', w) \to \mathfrak{gl}(w) \times \mathfrak{gl}(w)$.

To define $Q$, it is enough to restrict to the case $\lambda = 0$. The collection of objects in that category is $\{0, \ldots, w\}$, and the 1-morphisms from $v'$ to $v$ are the objects from

$$D^b_H(\mathcal{D}_{Gr(v', w)} \otimes \mathcal{D}_{Gr(v, w)} \otimes D_{R^2})$$

with homology supported (in the sense of the singular support) on $St \times \mathcal{N}^0_{diag}$, where $\mathcal{N}^0_{diag}$ stands for the conormal bundle to the diagonal $R \subset R^2$. We remark that Webster’s 2-category has, in a sense, more 1-morphisms but what we have above is sufficient for our purposes. The description of 2-morphisms in $Q$ is similar to [63, Section 2]. The action of $Q$ on (5.9) (as well as the tensor structure on $Q$) is defined via convolution of D-modules. The grading shift in $\mathcal{U}(\mathfrak{sl}_2)$ corresponds to the homological shift in $Q$.

The construction of [63, Section 4] shows that the action in Lemma 5.6 factors through a homomorphism $\psi$ of 2-algebras $\mathcal{U}(\mathfrak{sl}_2) \to Q$.

Let us point out several other important properties of the functors $E_i$, $F_i$ that are due to Webster.

**Lemma 5.7** The following claims are true:

1. The functors $E_i$, $F_i$ preserve the subcategory

$$\bigoplus_v D^b_{\rho^{-1}(0)}(\mathcal{A}_\lambda^\theta(v) \text{-mod}) \subset \bigoplus_v D^b(\mathcal{A}_\lambda^\theta(v) \text{-mod}).$$

2. Moreover, for $M \in D^b_{\rho^{-1}(0)}(\mathcal{A}_\lambda^\theta(v) \text{-mod})$, we have

$$\text{CC}(E_i M) = e_i \text{CC}(M), \text{CC}(F_i M) = f_i \text{CC}(M),$$

where $e_i$, $f_i$ stand for the Nakajima operators.

For the proof, see [63, Corollary 3.4, Proposition 3.5]. In particular, if $\lambda \in \mathbb{Z}^{Q_0}$, we see that $\text{CC} : K_0(\mathcal{A}_\lambda^\theta(v) \text{-mod}) \to L_{\omega \lfloor \nu \rfloor}$ is surjective.
5.2.3 General case

Now let us explain how to generalize Webster’s functors to the case when \( \lambda \) is not necessarily integral and \( \theta \) is not necessarily positive. We will assume that \( \theta \) lies in the Tits cone (which puts no restrictions for finite type \( Q \) and results in \((\theta, \delta) > 0\) for affine type \( Q \)). We will also assume that \( \theta \) is generic for all \( v \), in fact, for every given \( v \) and every classical chamber there is such an element there.

The element \( \theta \) defines a Weyl chamber for the algebra \( a \) and hence a system of simple roots \( \Pi_\theta \) for \( a \). For \( \alpha \in \Pi_\theta \) (and all \( v \)) we will define functors

\[
F_\alpha : D^b(A^\theta_\lambda(v) \text{-mod}) \rightleftarrows D^b(A^\theta_\lambda(v + \alpha) \text{-mod}) \text{ : } E_\alpha
\]

generalizing the functors constructed by Webster.

Now we proceed to constructing \( E_\alpha, F_\alpha \). Let \( \theta^+ \) denote a stability condition with all entries positive. Let \( \sigma \in W(Q) \) be such that \( \sigma \theta^+ \) lies in the same Weyl chamber for \( a \) as \( \theta \). The stability conditions \( \theta, \sigma \theta^+ \) are separated only by non-essential walls of the form \( \ker \beta \) for real roots \( \beta \) and so, by Proposition 5.4 and Theorem 5.3, we can identify the categories \( A^\theta_\lambda(v) \text{-mod} \) and \( A^{\sigma \theta^+}_\lambda(v) \text{-mod} \) by means of the wall-crossing functor \( WC_{\theta \to \sigma \theta^+} \) (for all \( v \)). Also recall, 2.2.4, that \( \sigma \) gives rise to the quantum LMN isomorphism \( \sigma : A^{\theta^+}_{\lambda'}(v') \to A^{\sigma \theta^+}_{\lambda'}(v) \), where \( v' := \sigma^{-1} \cdot v \), \( \lambda' := \sigma^{-1} \cdot v \lambda \), and hence an abelian equivalence \( \sigma_* : A^{\theta^+}_{\lambda'}(v') \text{-mod} \rightleftarrows A^{\sigma \theta^+}_{\lambda'}(v) \text{-mod} \).

Now let \( \alpha \in \Pi_\theta \). In general, \( \sigma^{-1} \alpha \) is not a simple root. However, we can modify \( \theta \) staying in the same Weyl chamber for \( a \) and in the Tits cone for \( g(Q) \) (using a wall-crossing functor through non-essential walls) so that the \( g(Q) \)-chamber of \( \theta \) is adjacent to a wall for \( a \). Then we can, in addition, assume \( \sigma^{-1}(\alpha) \) is a simple root for \( g(Q) \), say \( \alpha_i \).

**Definition 5.8** The functors \( F_\alpha, E_\alpha \) are, by definition, obtained by transferring Webster’s functors \( F_i, E_i \) using equivalences

\[
\sigma_* : A^{\theta^+}_{\lambda'}(v') \text{-mod} \rightleftarrows A^{\sigma \theta^+}_{\lambda'}(v) \text{-mod},
\]

\[
\sigma_* : A^{\theta^+}_{\lambda''}(v' + \alpha) \text{-mod} \rightleftarrows A^{\sigma \theta^+}_{\lambda''}(v + \alpha) \text{-mod}.
\]

Here \( \lambda', \lambda'' \) are given by \( \lambda' = \sigma^{-1} \cdot v \lambda \), \( \lambda'' = \sigma^{-1} \cdot v + \alpha \lambda \). Note that \( \lambda'' - \lambda' \in \mathbb{Z}Q_0 \).

More precisely,

\[
F_\alpha := \sigma_* \circ F_i \circ T_{\lambda', \lambda'' - \lambda'} \circ \sigma_*^{-1}
\]

and \( E_\alpha \) is defined in a similar fashion.
By the construction and (1) of Lemma 5.7 the functors $E_\alpha, F_\alpha$ preserve
\[ \bigoplus_v D^b_{\rho-1(0)}(A_\lambda^\theta(v) \text{-mod}). \]

Remark 5.9 Of course, our construction of the functors $E_\alpha, F_\alpha$ depends on the choice of a suitable $g(Q)$-chamber in the $a$-chamber of $\theta$. In a subsequent paper the second named author plans to check that the functors $E_\alpha, F_\alpha$ are well-defined and, in fact, give a categorical $a$-action on $\bigoplus_v D^b_{\rho-1(0)}(A_\lambda^\theta(v) \text{-mod})$, at least when $a$ is simply laced. It is expected that this result will allow to compute the Euler characteristics of $R\Gamma(M)$ for $M \in \text{Irr}(A_\lambda^\theta(v) \text{-mod}_{\rho-1(0)})$.

6 Roadmap

In this section we will explain key ideas and steps in the proof of Theorem 1.2 that will be carried out in the subsequent sections.

Recall that $\lambda \in \mathfrak{P}$ is chosen in such a way that $A_\lambda(v)$ has finite homological dimension. By Proposition 4.2 we can always achieve that by replacing $\lambda$ with some element of $\lambda + \mathbb{Z}Q_0$.

Conjecture 1.1 boils down to the following three claims.

(I) The image of $CC_\lambda^\theta$ contains $L_\omega^\alpha[v]$.

(II) The image of $CC_\lambda^\theta$ is contained in $L_\omega^\alpha[v]$.

(III) The map $CC_\lambda^\theta : K_0(A_\lambda(v) \text{-mod}_{\text{fin}}) \to L_\omega[v]$ is injective.

6.1 Outline of proof: lower bound on the image

We proceed to outlining the key ideas of our proof of Theorem 1.2 starting with (I): $\text{im } CC_\lambda^\theta \supset L_\omega^\alpha$ (we will also see that $CC_\lambda^\theta$ does not depend on the choice of $\theta$). For this we need to establish a generalization of (2) of Lemma 5.7 that will be proved in Sect. 8.4.

Proposition 6.1 For $M \in D^b(A_\lambda^\theta(v) \text{-mod}_{\rho-1(0)})$, we have $CC(E_\alpha M) = \pm e_\alpha CC(M)$ and $CC(F_\alpha M) = \pm f_\alpha CC(M)$.

In fact, we can do even better and prove an analog of this proposition for $K_0(\text{Coh}_{\rho-1(0)}(M^\theta(v)))$ instead of $H_{\text{mid}}(M^\theta(v))$ and the degeneration map $[M] \mapsto [\text{gr } M]$ instead of $CC$, this is done in Sect. 8.4.

Let us explain ideas behind a proof of Proposition 6.1 (similar ideas are used to prove a stronger result from Sect. 8.4, Proposition 8.13). Since the homologies of all $M^\theta(v)$, for generic $\theta$, are identified (see 2.1.8), the LMN isomorphisms give rise to a $W(Q)$-action on $L_\omega$. We also have an action of a suitable extension (by a 2-torsion group) of $W(Q)$ on $L_\omega$ coming from the
g(Q)-action. If we knew that on each weight space the two actions coincide up to a sign, then we would have $\sigma^{-1}_v \mathbb{C}C(E_\alpha) \sigma_\ast = c_v e_{\sigma^{-1}(\alpha)} = c_v e_\alpha$ (for $c_v = \pm 1$) and similarly for $F$’s. So, to prove Proposition 6.1, we need to establish the coincidence of the two group actions. Of course, it is enough to check the equality for simple reflections, $s_i$.

We will check that rather indirectly: on a categorical level. Namely, assume that $\theta_k > 0$ for all $k$ and $\lambda_i$ is integral. Set $v' := s_i \cdot v$. Recall that the functors $E_i$, $F_i$ give rise to a categorical $sl_2$-action and hence produce derived equivalences (convolutions with Rickard complexes) $\Theta_i : D^b(A_\lambda^\theta(v) - \text{mod}) \sim D^b(A_\lambda^\theta(s_i \cdot v) - \text{mod})$. On the other hand, suppose that $(\lambda, \theta) \in A\mathcal{L}(s_i \cdot v)$ (and hence $(\lambda', s_i \theta) \in A\mathcal{L}(v)$ for $\lambda' = s_i \cdot v' \lambda$). Then we can consider the wall-crossing functor

$\mathcal{WC}_{\lambda \to \lambda'} : D^b(A_\lambda^\theta(v) - \text{mod}) \sim D^b(A_{\lambda'}^{s_i \theta}(v) - \text{mod}).$

**Theorem 6.2** Assume that $(\lambda, \theta) \in A\mathcal{L}(v)$, $\lambda_i \in \mathbb{Z}_{\geq 0}$ and $\theta_k > 0$ for all $k \in Q_0$. Then we have an isomorphism of functors $\Theta_i = s_i \ast \circ \mathcal{WC}_{\lambda \to \lambda'}$.

We are going to use Theorem 6.2 to show that $\mathbb{C}C(E_\alpha)$ acts as $\pm e_\alpha$ on $\text{Im} \mathbb{C}C_v$ and that $\mathbb{C}C(F_\alpha)$ acts as $\pm f_\alpha$ on $\text{Im} \mathbb{C}C_{v+e_i}$. For this we need to check that $\mathbb{C}C(\Theta_i)$ acts by $\text{Im} \mathbb{C}C_v$ by $\pm s_i$ (by $s_i$ we denote an operator on $L_\omega$ induced by the $g(Q)$-action, it is defined up to a sign). This follows from (2) of Lemma 5.7 when we use the stability condition $\theta^+$ but this is not straightforward for $\sigma \theta$. On the other hand, we need to show that $\mathbb{C}C(s_i \ast \circ \mathcal{WC}_{\lambda \to \lambda'})$ coincides with $s_i \ast$ (the operator of the $W(Q)$-action on the middle homology). Both claims follow from the next proposition. Let us write $\mathbb{C}C_\theta^\lambda, v$ for the characteristic cycle map $K_0(A_\lambda^\theta(v) - \text{mod}_{fin}) \to L_\omega[v]$ defined using the stability condition $\theta$.

**Proposition 6.3** The following statements are true:

1. If the homological dimension of $A_\lambda(v)$ is finite and $\lambda \in \mathbb{P}^{ISO}$, then the map $\mathbb{C}C_\theta^\lambda, v$ is independent of $\theta$.
2. For $M \in D^b_{\rho^{-1}(0)}(A_\lambda^\theta(v) - \text{mod})$ we have $\mathbb{C}C(M) = \mathbb{C}C(\mathcal{WC}_{\lambda \to \lambda'} M)$.

Again, we have an analog of this proposition (and of the equality $s_i = \pm [s_i \ast]$) on $\bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(M^\theta(v)))$, see Sects. 8.3 and 8.4.

We will deduce the coincidence of the two group actions from Theorem 6.2 and Proposition 6.3. Also Theorem 6.2 that can be regarded as a formula for $\mathcal{WC}_{\lambda \to v}$ will play an important role in proving (II), see the next section.

### 6.2 Outline of proof: upper bound on the image

We prove (II), the inclusion $\text{im} \mathbb{C}C_\lambda \subset L_\omega^a$, using wall-crossing functors.
More precisely, we will prove the following claim. Let $C$ denote the full subcategory of $\bigoplus_v A^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}$ consisting of all modules that appear in the homology of complexes of the form $FL_0$, where $F$ is a monomial in the functors $E_\alpha, F_\alpha, \alpha \in \Pi^\theta$, (here, as usual, $\Pi^\theta$ is the simple root system for $a$ defined in Sect. 5.2.3) and $L_0 \in A^\theta_\lambda(\sigma \cdot w)$, where $\sigma \in W(Q)$ is such that $\sigma \omega$ is dominant for $a$.

**Proposition 6.4** We have $C = \bigoplus_v A^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}$.

This proposition will be proved in Section 12. In Sect. 10, we will see that Proposition 6.4 implies (II). Conversely, one can show that, modulo (III), (II) implies Proposition 6.4.

A basic strategy of proving Proposition 6.4 is as follows (we will elaborate on the strategy below in this section).

1. Characterize the finite dimensional modules using a “long wall-crossing functor”.
2. Reduce the study of the “long wall-crossing functor” to the study of “short wall-crossing functors” – between chambers sharing an essential wall.
3. Study short wall-crossing functors using Theorem 6.2 and categorical $\mathfrak{sl}_2$-actions.
4. In the case of affine quivers, study the wall-crossing functor crossing the affine wall ker $\delta$.

### 6.2.1 Long wall-crossing functor

Our first goal is to characterize the dimension of support of a simple $A_\lambda(v)$-module in terms of a functor. It turns out that the functor we need is a “long wall-crossing functor” defined as follows. Let $\lambda, \theta$ be such that $(\lambda + k\theta, \theta) \in \mathfrak{A}\mathfrak{L}(v)$ for any $k \in \mathbb{Z}_{\geq 0}$. Thanks to Proposition 4.2, we can find $\lambda^- \in \lambda + \mathbb{Z}^Q_{\geq 0}$ such that $(\lambda^- - k\theta, -\theta) \in \mathfrak{A}\mathfrak{L}(v)$ for any $k \geq 0$. By a long wall-crossing functor we mean $\mathfrak{M}\mathfrak{C}_{\lambda \rightarrow \lambda^-} : D^b(A_\lambda(v)\text{-mod}) \sim D^b(A_{\lambda^-}(v)\text{-mod})$.

We have recalled the definition of holonomic modules for $A_\lambda(v), A^\theta_\lambda(v)$ in Sect. 2.4. In particular, modules from $A_\lambda(v)\text{-mod}_{\text{fin}}, A^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}$ are holonomic.

The following proposition is inspired by a similar result on the BGG category $O$, see [10, Proposition 4.7].

**Proposition 6.5** Let $M$ be a holonomic $A_\lambda(v)$-module. Then

1. $H_i(\mathfrak{M}\mathfrak{C}_{\lambda \rightarrow \lambda^-} M) = 0$ if $i < \frac{1}{2} \dim \mathcal{M}^\theta(v) - \dim \text{Supp } M$ or $i > \frac{1}{2} \dim \mathcal{M}^\theta(v)$. Moreover, $H_i(\mathfrak{M}\mathfrak{C}_{\lambda \rightarrow \lambda^-} M) \neq 0$ for $i = \frac{1}{2} \dim \mathcal{M}^\theta(v) - \dim \text{Supp } M$.
2. The functor $\mathfrak{M}\mathfrak{C}_{\lambda \rightarrow \lambda^-} [-\frac{1}{2} \dim \mathcal{M}^\theta(v)]$ is an abelian equivalence $A_\lambda(v)\text{-mod}_{\text{fin}} \sim A_{\lambda^-}(v)\text{-mod}_{\text{fin}}$. 
The minimal number \( i \) such that \( H_i(\mathbb{W}_{\lambda \to \lambda_\lambda} L) \neq 0 \) will be called the **homological shift** (of \( L \) under the functor \( \mathbb{W}_{\lambda \to \lambda_\lambda} \)).

The proof to be given below, Sect. 9, is based on using abelian localization as well as a connection between the long wall-crossing functor and a homological duality functor.

One problem with the wall-crossing functor is that it is quite hard to study it (in particular, computing the homological shifts) directly. Instead, we will decompose \( \mathbb{W}_{\lambda \to \lambda_\lambda} \) into a composition of short wall-crossing functors (i.e., functors crossing a single wall between two adjacent chambers) using Theorem 5.3. The information about homological shifts under the short wall-crossing functors together with Theorem 5.3 turn out to be enough to establish (II) for finite and affine quivers \( Q \), see Sect. 12.2 (in this paper we only deal with very special framing in the affine case but this can be generalized to arbitrary framing by suitably generalizing techniques that we use here, see the subsequent paper [49]). The case of wild quivers poses some additional essential difficulties, we will discuss why in Sect. 6.2.3.

### 6.2.2 Short wall-crossing through real wall

We want to characterize objects with zero homological shift under the short wall-crossing functor through a wall defined by a real root.

Let \( \alpha \in \Pi^\theta \). We say that an object \( L \in \text{Irr}(\mathcal{A}_\lambda^\theta(v) - \text{mod}_{\rho^{-1}(0)}) \) is \( \alpha \)-**singular** if

1. \( (\nu, \alpha) \geq 0 \) and \([L] \notin \text{im}[F_\alpha] \) or
2. \( (\nu, \alpha) \leq 0 \) and \([L] \notin \text{im}[E_\alpha] \).

Here and below we write \([L]\) for the class of \( L \) in \( K_0(\mathcal{A}_\lambda^\theta(v) - \text{mod}_{\rho^{-1}(0)}) \). We write \([E_\alpha] \), \([F_\alpha] \) for the maps between the \( K_0 \) spaces induced by the functors \( E_\alpha \), \( F_\alpha \).

There is an important alternative characterization of \( \alpha \)-singular objects based on Theorem 6.2. Namely, suppose that \( \theta' \) is a generic stability condition separated from \( \theta \) by the single wall \( \ker \alpha \) (meaning the chambers of \( \theta, \theta' \) share the common wall \( \ker \alpha \)).

**Proposition 6.6** Let \( L \in \text{Irr}(\mathcal{A}_\lambda^\theta - \text{mod}_{\rho^{-1}(0)}) \). The following conditions are equivalent:

1. \( L \) is \( \alpha \)-singular.
2. \( H_0(\mathbb{W}_{\theta \to \theta'} L) \neq 0 \).

Moreover, under these equivalent conditions there is a unique \( \alpha \)-singular simple constituent of \( H_*(\mathbb{W}_{\theta \to \theta'} L) \), say \( L' \), and it is a quotient of \( H_0(\mathbb{W}_{\theta \to \theta'} L) \). The map \( L \mapsto L' \) is a bijection between the sets of \( \alpha \)-singular simples in \( \mathcal{A}_\lambda^\theta - \text{mod}_{\rho^{-1}(0)}, \mathcal{A}_\lambda^{\theta'} - \text{mod}_{\rho^{-1}(0)} \).

This proposition will be proved in Sect. 10.2.
6.2.3 Short wall-crossing through affine wall

Thanks to the previous paragraph, we only need to show (modulo technicalities to be addressed later) that the wall-crossing functor through ker $\delta$ cannot homologically shift a simple by more than $\dim \mathcal{M}^\theta(v)/2 - 1$.

Let us explain an idea of the proof of this claim, which is an extension of what was done in the proof of Proposition 5.4. By Proposition 5.2, the wall-crossing functor through ker $\delta$ is given by $A^0_{\lambda,\chi}(v) \otimes L_{A^0_{\lambda}(v)} \bullet$ (here we assume that $\lambda, \lambda + \chi \in \mathfrak{P}_{iso}$ and there are generic stability conditions $\theta, \theta'$ separated by ker $\delta$ such that $(\lambda, \theta), (\lambda + \chi, \theta') \in \mathfrak{M}(v)$). Now let us set $\mathfrak{P}_0 := \lambda + \ker \delta, \mathfrak{P}_0' := \lambda + \chi + \ker \delta$. Then $A^0_{\lambda,\chi}(v)$ is the specialization of $A^0_{\mathfrak{P}_0,\chi}(v)$. We will show that “homological shift behavior” of the functors $A^0_{\lambda_1,\chi}(v) \otimes A^0_{\lambda_1}(v) \bullet$ is the same for Zariski generic parameters $\lambda_1 \in \mathfrak{P}_0$ (this is the most non-trivial part of the proof; the very first step here is results from 3.2.2). Then we need to show that for a Weil generic $\lambda_1$ the homological shifts under the functor $A^0_{\lambda_1,\chi}(v) \otimes L_{A^0_{\lambda_1}(v)} \bullet$ are less than $\frac{1}{2} \dim \mathcal{M}^\theta(v)$ (recall that “Weil generic” means “lying outside of countably many proper closed algebraic subvarieties”). The point of considering Weil generic parameters is that here the functor $A^0_{\lambda_1,\chi}(v) \otimes L_{A^0_{\lambda_1}(v)} \bullet$ becomes the long wall-crossing functor (indeed, all walls but possibly ker $\delta$ are non-essential). Basically, we prove that the algebra $A^0_{\lambda_1}(v)$ has no finite dimensional simples, and our claim about homological shifts follows from Proposition 6.5.

In fact, we show more than the bound for homological shifts, we prove that $\mathcal{WC}_{\lambda \to \lambda + \chi}$ is perverse in the sense of Chuang and Rouquier [60, Section 2.6]. We characterize filtrations on the categories $A^0_{\lambda}(v)$-mod, $A^0_{\lambda + \chi}(v)$-mod that make $\mathcal{WC}_{\lambda \to \lambda + \chi}$ perverse and deduce our claim about homological shifts from there. We use results on the representation theory of type A Rational Cherednik algebras to establish the perversity, which leads to restrictions on the framing.

Let us explain the most essential reason why we restrict to finite and affine quivers. In fact, as shown in the subsequent paper [49], wall-crossing functors are perverse in a much more general situation (including all wall-crossings through hyperplanes for wild quivers). A difficulty of dealing with wild quivers is that one may need to cross many walls defined by imaginary roots and we do not know how to control the homological shifts of compositions in that case.

6.2.4 Completion of the proof

Let us define extremal objects.
**Definition 6.7** We say that \( L \in \operatorname{Irr}(\mathcal{A}^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}) \) is extremal if \( L \) does not lie in the category \( \mathcal{C} \) from 6.2 and \( v \) is minimal such that \( L \) exists.

Of course, (II) is equivalent to the claim that no extremal objects exist.

Here are two important properties of extremal objects.

**Lemma 6.8** An extremal object is singular for all \( \alpha \).

**Proof** Let \( L \in \operatorname{Irr}(\mathcal{A}^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}) \) be extremal. By the minimality assumption on \( v \), we see that \( v \) is dominant and \( [L] \notin \sum_\alpha \text{im}[F_\alpha] \). In particular, \( L \) is \( \alpha \)-singular for all \( \alpha \in \Pi^\theta \). \( \square \)

The following is a crucial property of extremal objects. It will be proved in Sect. 12.

**Proposition 6.9** The bijection \( L \mapsto L' \) from Proposition 6.6 restricts to a bijection between the sets of extremal simples in \( \mathcal{A}^\theta_\lambda\text{-mod}_{\rho^{-1}(0)}, \mathcal{A}^\theta_{\lambda'}\text{-mod}_{\rho^{-1}(0)} \).

We conclude that extremal objects are not homologically shifted by short wall-crossing functors through real walls (=walls defined by real roots). This finishes the proof of (II) in the case when \( Q \) is finite. To deal with the case of affine \( Q \) (under our restrictions on the framing) one uses results outlined in Sect. 6.2.3.

### 6.3 Outline of proof: injectivity of \( CC \)

Now we will explain how Proposition 6.4 implies (III).

Suppose first, that we know that

\(*\) the endomorphisms \([E_\alpha], [F_\alpha], \alpha \in \Pi^\theta\), define a representation of the Lie algebra \( \mathfrak{a} \) in \( \bigoplus_v K_0(\mathcal{A}^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}) \)

(so far we know that each pair \([E_\alpha], [F_\alpha]\) defines a representation of \( \mathfrak{sl}_2 \)). So \( CC_\lambda \) becomes an epimorphism of \( \mathfrak{a} \)-modules. Using Proposition 6.4 we will show that it is an isomorphism.

It remains to establish \(*\). In fact, this reduces to the case when \( \lambda \) is rational (where we have a powerful tool – reduction to positive characteristic). The general case will be deduced from there and Proposition 6.4.

To prove \(*\) we will argue more or less as follows. We will show that the degeneration map, \([M] \mapsto [\text{gr } M]\) defines an embedding \( K_0(\mathcal{A}^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}) \hookrightarrow K_0(\text{Coh}_{\rho^{-1}(0)}, \mathcal{M}^\theta(v)) \). We will see that \( \mathfrak{a} \) naturally acts on \( K_0(\text{Coh}_{\rho^{-1}(0)}, \mathcal{M}^\theta(v)) \) (in fact, the whole algebra \( \mathfrak{g}(Q) \) does) and our embedding (after some twist) intertwines \([E_\alpha]\) with \( e_\alpha \), \([F_\alpha]\) with \( f_\alpha \). The proofs here are based on \( K \)-theory version of results mentioned in Section 6.1. This proves \(*\) and finishes the proof of Theorem 1.2.
6.4 Subsequent content

Let us describe the content of the following sections. Section 7 is preparatory, there we discuss some relatively standard results based on the reduction to characteristic \( p \). Then, in Sect. 8 we prove (I) (the inclusion \( L_\omega^\theta [v] \subset \text{im } C_C(\lambda) \)) as well as some stronger results needed in the proofs of (II) and (III) (concerning \( K \)-theory rather than middle homology).

In the subsequent three sections we study wall-crossing functors. In Sect. 9 we study the long wall-crossing functor and relate the homological shifts under this functor to codimension of support. In Sect. 10 we study short wall-crossing functors through walls defined by real roots and their interactions with singular simples. In Sect. 11 we study the short wall-crossing functor through the wall \( \ker \delta \) and prove that it is a perverse equivalence.

Finally, in Sect. 12 we finish the proofs of (II) and (III) and hence of Theorem 1.2. We also discuss some generalizations of Conjecture 1.1.

7 Quantizations in positive characteristic and applications

In this section we deal with quantizations in positive characteristic and their applications to characteristic 0.

Let us explain two main applications first. They concern the existence of tilting generators on \( \mathcal{M}^\theta (v) \) with some special properties and the injectivity of a natural map \( K_0(\mathcal{A}_\lambda(v) \text{-mod}_{fin}) \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \) that is the composition of the localization and degeneration (here we assume that the homological dimension of \( \mathcal{A}_\lambda(v) \) is finite and \( \lambda \in \mathbb{Q}^0 \)).

Let us state a result about a tilting bundle. We say that a vector bundle \( \mathcal{P} \) on a smooth algebraic variety \( X \) is a tilting generator if \( \text{Ext}^i(\mathcal{P}, \mathcal{P}) = 0 \) for \( i > 0 \) and the homological dimension of the algebra \( \text{End}(\mathcal{P}) \) is finite. When \( X \) is a Nakajima quiver variety (in fact, under some more general assumptions) and \( \mathcal{P} \) is a tilting generator, the functor \( R\text{Hom}_{\mathcal{O}_X}(\mathcal{P}, \bullet) \) is an equivalence \( D^b(\text{Coh } X) \sim D^b(\text{End}(\mathcal{P})^{opp} \text{-mod}) \) (see [12, Proposition 2.2]).

Here is our main result on the existence of compatible tilting generators on the quiver varieties \( \mathcal{M}^\theta(v) \).

**Proposition 7.1** There is a \( \mathbb{C}^\times \)-equivariant (with respect to the contracting action) tilting generator \( \mathcal{P}^\theta \) on \( \mathcal{M}^\theta(v) \) such that the algebra \( \text{End}(\mathcal{P}^\theta) \) is independent of \( \theta \).

Such a bundle \( \mathcal{P}^\theta \) is constructed by Kaledin in [35]. Our construction is quite similar to Kaledin’s and is also inspired by an earlier construction in [12]. Namely, one fixes a suitable quantization of \( \mathcal{M}^\theta(v) \) over an algebraically closed field \( \mathbb{F} \) of positive characteristic. It is an Azumaya algebra on the Frobe-
Etingof’s conjecture for quantized quiver varieties

The splitting bundle then extends to a vector bundle that is shown to be tilting. Our proof of the splitting result is easier than Kaledin’s. Besides, for our next main result of this section we need to use a particular choice of a quantization: one obtained by Hamiltonian reduction.

Now let us proceed to the second main result in this section: on the injectivity of the natural map $K_0(A_\lambda(v)\text{-mod}_{\text{fin}}) \to K_0(\text{Coh}_{\rho^{-1}(0)}(M^{\theta}(v)))$. Let $\lambda$ be such that $A_\lambda(v)$ is regular so that the localization functor $L \text{Loc}^\theta_\lambda$ gives rise to an identification $K_0(A_\lambda(v)\text{-mod}_{\text{fin}}) \sim K_0(A^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)})$. We have a well-defined map

$$[M] \mapsto [\text{gr } M] : K_0(A^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}) \to K_0(\text{Coh}_{\rho^{-1}(0)}(M^{\theta}(v))).$$

Let us denote the composition

$$K_0(A_\lambda(v)\text{-mod}_{\text{fin}}) \to K_0(A^\theta_\lambda(v)\text{-mod}_{\rho^{-1}(0)}) \to K_0(\text{Coh}_{\rho^{-1}(0)}(M^{\theta}(v)))$$

by $\gamma^\theta_\lambda$.

**Proposition 7.2** Suppose, in addition, that $\lambda \in \mathbb{Q}^{Q_0}$. Then $\gamma^\theta_\lambda$ is injective.

The proposition is true for any $\lambda$ and, in fact, follows from the injectivity of the characteristic cycle map. But at this point we are only prove it for rational $\lambda$.

### 7.1 Quiver varieties and quantizations in characteristic $p$

We can define the GIT quotient $M^{\theta}(v)$ in characteristic $p$ for $p$ large enough. More precisely, the moment map $\mu : T^*R \to \mathfrak{g}$ is defined over $\mathbb{Z}$. So we can reduce it modulo $p$ and get $\mu_F : T^*R_F \to \mathfrak{g}_F$. For $p$ large enough, this is still a moment map and we can form the Hamiltonian reduction $M^{\theta}(v)_F$ that is a smooth symplectic algebraic variety over $\mathbb{F}$.

**Lemma 7.3** There is a finite localization $S$ of $\mathbb{Z}$ and a smooth symplectic scheme $M^{\theta}(v)_S$ over $\text{Spec}(S)$ with the following properties:

1. $M^{\theta}(v)_S, M^{\theta}(v)_F$ are obtained from $M^{\theta}(v)_S$ by base change (for every $S$-algebra $\mathbb{F}$ that is an algebraically closed field).
2. $\mathbb{C}[M^{\theta}(v)_S], \mathbb{F}[M^{\theta}(v)_F]$ are obtained from $S[M^{\theta}(v)_S]$ by base change.
3. $H^i(M^{\theta}(v)_S, \mathcal{O}_{M^{\theta}(v)_S}) = 0$, $H^i(M^{\theta}(v)_F, \mathcal{O}_{M^{\theta}(v)_F}) = 0$ for $i > 0$, where $\mathbb{F}$ is as in (1).
Proof We remark that $\mu^{-1}(0)^{\theta-ss} \to M^\theta(v)$ is a principal $G$-bundle, in particular, it is locally trivial in the Zariski topology. It is defined over some finite localization $S$ of $\mathbb{Z}$. After a finite localization, $\mu_S^{-1}(0)^{\theta-ss}$ – the stable locus of $\text{Spec}(S[T^*R_S]/(\mu_S^*(g_S)))$ – becomes the total space of this principal bundle. (i) follows.

Fix an open affine cover of $M^\theta(v)_S$. After a finite localization all cocycle groups in the positive degree part of the Čech complex for $O_{M^\theta(v)_S}$ coincide with the corresponding coboundary groups and they are free over $S$. (2) and (3) follow. \hfill \Box

This result can be generalized to $M^\theta_p(v)$ in a straightforward way.

Quantizations of $M^\theta(v)_F$ were studied in [9], see Sections 3, 4, 6 there.

Take $\lambda \in \mathbb{F}^{Q_0}_{p}$. The algebra $D(R)_F$ is Azumaya over the Frobenius twist $\mathbb{F}[T^*R]^{(1)}$ so we can view $D_{R,F}$ as a coherent sheaf on $(T^*R_F)^{(1)}$.

According to [9, Section 3],

$$A^\theta_\lambda(v)_F := [Q_{F,\lambda}|(T^*R_F)^{(1)},\theta-ss]^G_F$$

is a sheaf of Azumaya algebras on $M^\theta(v)_F^{(1)}$. If we consider this sheaf in the conical topology, it becomes filtered, and the associated graded is $\text{Fr}_* O_{M^\theta(v)_F}$.

There is an extension of this construction to $\lambda \in \mathbb{F}^{Q_0}_{p}$. The difference is that $A^\theta_\lambda(v)_F$ is now an Azumaya algebra over $M^\theta_{AS(\lambda)}(v)$, where $AS$ is the Artin-Schreier map, see [9, Section 3.2]. We also have a version that works in families. We get a sheaf $A^\theta_p(v)_F$ of Azumaya algebra over $p_F \times p_F^{(1)} M^\theta_p(v)_F^{(1)}$ that specializes to $A^\theta_\lambda(v)_F$ for any $\lambda \in \mathbb{F}^{Q_0}$.

Let us write $A_\lambda(v)_F$ for the global sections of $A^\theta_\lambda(v)_F$.

Lemma 7.4 Fix $\lambda^\circ \in \mathbb{Q}^{Q_0}$. There is a finite localization $S$ of $\mathbb{Z}$ with the following property: for any $\lambda \in \lambda^\circ + \mathbb{Z}^{Q_0}$ there exists a filtered $S$-algebra $A_\lambda(v)_S$ such that

1. $\text{gr} A_\lambda(v)_S = S[M^\theta(v)_S]$.
2. $\mathbb{C} \otimes_S A_\lambda(v)_S = A_\lambda(v)$.
3. $F \otimes_S A_\lambda(v)_S = A_\lambda(v)_F$.

Proof We may assume that Lemma 7.3 holds for $S$ and moreover that $\lambda^\circ \in S^{Q_0}$ and that $\mu_S$ is flat. We can define the microlocal quantizations $A^\theta_\lambda(v)_S$ of $M^\theta(v)_S$ in the same way as was done for the complex numbers. Set $A_\lambda(v)_S := \Gamma(A^\theta_\lambda(v)_S)$.

(1) follows from (2) and (3) of Lemma 7.3. The microlocal quantization $A^\theta_\lambda(v)$ is obtained from $A^\theta_\lambda(v)_S$ by the base change to $\mathbb{C}$ followed by a suitable completion (needed to preserve the condition that the sheaf is still...
complete and separated with respect to the filtration). Note that the algebras $A_\lambda(v)_S$, $A_\lambda(v)_F$ are $\mathbb{Z}_{\geq 0}$-filtered so completing with respect to the filtration does not change these algebras. (2) follows. To prove (3), we notice that we have a natural homomorphism $A_\theta^\theta(v)_F \to \text{Fr}_* (\mathbb{F} \otimes_S A_\lambda^0(v)_S)$. On the level of the associated graded sheaves, it is the identity automorphism of Fr$_* O_{\mathcal{M}_\theta(v)}$. So it gives rise to an isomorphism $A_\lambda(v)_F = \Gamma (\mathcal{M}_\theta(v)_F, \mathbb{F} \otimes_S A_\lambda^0(v)_S) = \mathbb{F} \otimes_S A_\lambda(v)_S$. 

7.2 Splitting

We set $M(v)_F := \text{Spec}(\mathbb{F}[M_\theta(v)(1)_F])$, $M_p(v)_F := p_F \times_{p_F(1)} \text{Spec}(\mathbb{F}[M_p(v)^{1}_F])$.

In this section and the next one we write $M_\theta p(v)(1)^\wedge_0$ for the formal neighborhood of $M_\theta(v)(1)^\wedge_0$ in $M_\theta p(v)(1)_F \times M_0 p(v)(1)_F$. (7.1)

In particular, $M_\theta p(v)^{(1)}_{F} \wedge_0$ is a formal scheme and not a scheme.

Proposition 7.5 The restrictions $A_\theta^\theta(v)^{1}_{F} \wedge_0$ of $A_\lambda^\theta(v)_F$ to $M_\theta^\theta(v)^{(1)}_{F} \wedge_0$ and $A_\theta^\theta(p)_F(v)^{1}_{F} \wedge_0$ of $A_\theta^\theta(p)_F(v)$ to $M_\theta^\theta(p)^{(1)}_{F} \wedge_0$ (where the fiber of $A_\theta^\theta(p)_F(v)$ over $0 \in p$ is $A_\lambda^\theta(v)_F$) split.

Proof Let us prove the claim about $A_\lambda^\theta(v)^{1}_{F} \wedge_0$ first.

Step 1. Consider the one-form $\beta$ on $M_\theta(v)^{(1)}_{F}$ obtained by pairing of the symplectic form $\omega$ with the vector field for the $F$-action (induced from the fiberwise dilation action on $T^* R$). We claim that the class of $A_\lambda^\theta(v)_F$ in the Brauer group $\text{Br}(M_\theta(v)^{(1)}_{F})$ comes from $\beta$ (see [55, III.4] for a general discussion of Azumaya algebras coming from 1-forms). Let us prove this claim. Let $\pi$ denote the quotient morphism $Z := (\mu_{F}^{(1)})^{-1}(0)^{\theta-ss} \to M_\theta(v)^{(1)}_{F}$ (by the $G^1_F$-action). By [9, Remark 4.1.5], $\pi^*(A_\lambda^\theta(v)_F)$ is Morita equivalent to $D_{R,F}|Z$. The class of $D_{R,F}|Z$ comes from the canonical 1-form $\tilde{\beta}$ on $(T^* R)^{(1)}$. The restriction of $\tilde{\beta}$ to $Z$ coincides with $\pi^* \beta$. It follows that the class of $\pi^* A_\lambda^\theta(v)_F$ in the Brauer group coincides with the class defined by $\pi^* \beta$. Now recall that $Z$ is a principal $G^1_F$-bundle on $M_\theta^\theta(v)^{(1)}_{F}$ hence it is locally trivial in Zariski topology. It follows that the restriction of the class of $A_\lambda^\theta(v)$ to an open subset $U \subset M_\theta^\theta(v)^{(1)}_{F}$ (where the bundle trivializes) coincides with

\[\square\]
the restriction of the class of $\beta$. Since the restriction induces an embedding $\operatorname{Br}(\mathcal{M}^\theta(v)_{F}^{(1)}) \hookrightarrow \operatorname{Br}(U)$ ([55, III.2.22]), the claim in the beginning of the paragraph is proved.

Step 2. An Azumaya algebra defined by a one-form $\beta'$ splits provided $\beta' = \alpha - C(\alpha)$ for some 1-form $\alpha$, where $C$ stands for the Cartier map $\Omega_{cl}^1 \to \Omega^1$ (here we write $\Omega^1$ for the bundle of 1-forms and $\Omega_{cl}^1$ for the bundle of closed 1-forms). We claim that $C : \Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega_{cl}^1) \to \Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega^1)$ is surjective. This follows from the following exact sequences of sheaves:

$$0 \to \Omega_{ex}^1 \to \Omega_{cl}^1 \xrightarrow{C} \Omega^1 \to 0, \quad (7.2)$$

$$0 \to \mathcal{O}^p \to \mathcal{O} \to \Omega_{ex}^1 \to 0. \quad (7.3)$$

Since $H^i(\mathcal{M}^\theta(v)_{F}^{(1)}, \mathcal{O}) = H^i(\mathcal{M}^\theta(v)_{F}, \mathcal{O}) = 0$ for $i = 1, 2$, (7.3) implies $H^1(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega_{cl}^1) = 0$. Hence, using (7.2), we see that

$$C : \Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega_{cl}^1) \to \Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega^1).$$

Step 3. The global sections $\Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega_{cl}^1)$, $\Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega^1)$ are graded with respect to the $\mathbb{F}^\times$-action (coming from the dilation action on $T^*R$), let $\Gamma(\ldots)$ denote the $d$th graded component. The map $C$ sends $\Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega_{cl}^1)_d$ to $\Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega^1)_{d/p}$ if $d$ is divisible by $p$ and to 0 else. Pick $\mathbb{F}$-linear sections $C^{-1} : \Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega^1)_d \to \Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega_{cl}^1)_{pd}$.

Let us point out that the degree of $\beta$ is 1. It follows that $\alpha := \sum_{i=0}^{+\infty} C^{-i}(\beta)$ is a well-defined 1-form on $\mathcal{M}^\theta(v)_{F}^{(1)} \wedge 0$. Indeed the $i$th summand has degree $p^i$ and so $C^{-i}(\beta)$ converges to zero in the topology defined by the maximal ideal of 0 in $\mathbb{F}[\mathcal{M}(v)_{F}^{(1)}]$ because $\Gamma(\mathcal{M}^\theta(v)_{F}^{(1)}, \Omega^1)$ is a finitely generated $\mathbb{F}[\mathcal{M}^\theta(v)_{F}^{(1)}]$-module. Clearly, $\beta = \alpha - C(\alpha)$.

This finishes the proof of the claim that $\mathcal{A}^\theta_{\mathbb{F}}(v)_{F}^{(1)} \wedge 0$ splits.

Let us proceed to the splitting of $\mathcal{A}^\theta_{\mathbb{F}}(v)_{F}^{(1)} \wedge 0$.

Step 4. We will prove a stronger statement. Let $\tilde{A}$ be an Azumaya algebra over scheme (7.1) whose restriction to $\mathcal{M}^\theta(v)_{F}^{(1)} \wedge 0$ splits. We will show that then the restriction of $\tilde{A}$ to $\mathcal{M}^\theta_p(v)_{F}^{(1)} \wedge 0$ splits as well.

Let $\mathcal{M}^\theta_p(v)_{F}^{(1)k}$ denote the $k$th infinitesimal neighborhood of $\mathcal{M}^\theta(v)_{F}^{(1)} \wedge 0$ in (7.1), a scheme over $\text{Spec}(\mathbb{F}[p]/m^{k+1})$, where $m$ is the maximal ideal of 0 in $\mathbb{F}[p]$. We remark that

$$H^i(\mathcal{M}^\theta(v)_{F}^{(1)} \wedge 0, \mathcal{O}) = 0, \text{ for } i > 0.$$
(to simplify the notation we just write $\mathcal{O}$ for the structure sheaf). This follows from $H^i(\mathcal{M}_\theta^\theta(v)_{\mathbb{P}^1}^{(1)}, \mathcal{O}) = 0$ and the formal function theorem.

Step 5. We have a short exact sequence of sheaves on $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)\wedge 0}$:

$$0 \to S^k \mathcal{N} \to \mathcal{O}_\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k+1} \to \mathcal{O}_\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k} \to 0,$$

where $\mathcal{N}$ is the normal bundle to $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)}$ in $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)}$.

We claim that $\mathcal{N} = \mathfrak{p} \otimes \mathcal{O}$. First, note that the conormal bundle to $\mu^{-1}(0)\theta - ss$ in $T^*\mathbb{R}$ is the trivial bundle with the fiber $\mathfrak{g}$: if $\xi_1, \ldots, \xi_m$ is a basis in $\mathfrak{g}$, then $d\mu^*(\xi_1), \ldots, d\mu^*(\xi_m)$ is a basis in the conormal bundle. It follows the conormal bundle to $\mu^{-1}(0)\theta - ss$ in $\mu^{-1}(\mathfrak{g}^*G)\theta - ss$ is trivial with fiber $\mathfrak{g}^G$. Since $\mathcal{N}$ is the equivariant descent of the latter bundle, we get $\mathcal{N} = \mathfrak{p} \otimes \mathcal{O}$.

This implies

$$H^i(\mathcal{M}_\theta^\theta(v)_{\mathbb{F}}^{(1)\wedge 0}, S^k \mathcal{N}) = 0 \text{ for } i > 0.$$

In particular, the Picard groups of the schemes $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}$ equal to $H^1_{et}(\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}, \mathcal{O}^\times)$ are naturally identified.

Step 6. To check that the restriction of $\tilde{\mathcal{A}}$ to $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)\wedge 0}$ splits, it is enough to show that $\tilde{\mathcal{A}}|_{\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}}$ splits for each $k$. Indeed, let $\mathcal{P}_k$ denote a splitting bundle for $\tilde{\mathcal{A}}|_{\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}}$. Such a bundle is defined up to a twist with a line bundle. So the restriction of $\mathcal{P}_{k+1}$ to $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}$ is isomorphic to $\mathcal{P}_k \otimes \mathcal{L}_k$ for some line bundle $\mathcal{L}_k$. By the last paragraph of Step 5, $\mathcal{L}_k$ lifts to a line bundle $\mathcal{L}_{k+1}$ on $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k+1}$. Replacing $\mathcal{P}_{k+1}$ with $\mathcal{P}_{k+1} \otimes \mathcal{L}_{k+1}$ we achieve that the restriction of $\mathcal{P}_{k+1}$ to $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}$ coincides with $\mathcal{P}_k$.

We show that $\tilde{\mathcal{A}}|_{\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}}$ splits by using induction on $k$. The base, $k = 1$, has been established before in this proof. Let us establish the induction step. Recall that $\text{Br}(\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}) \hookrightarrow H^2_{et}(\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}, \mathcal{O}^\times)$, see [55, Theorem 2.5]. From (7.4), (7.5), it follows that $H^2_{et}(\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}, \mathcal{O}^\times)$ and $H^2_{et}(\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k+1}, \mathcal{O}^\times)$ are naturally identified. In particular, the claim that the restriction of $\tilde{\mathcal{A}}$ to $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}$ splits is equivalent to the vanishing of the class of this restriction in $H^2_{et}(\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k}, \mathcal{O}^\times)$. Then the class in $H^2_{et}(\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k+1}, \mathcal{O}^\times)$ of the restriction of $\tilde{\mathcal{A}}$ to $\mathcal{M}_p^\theta(v)_{\mathbb{F}}^{(1)k+1}$ vanishes as well, hence that restriction splits.

$\square$
7.3 Comparison for different resolutions

Let \( \hat{P}_p^\theta \) denote a splitting bundle for \( \mathcal{A}_p^\theta (v)^{\wedge 0}_F \). The bundle \( \hat{P}_p^\theta \) has trivial higher self-extensions, compare with [12, Section 2.3], and hence has an \( \mathbb{F}^\times \)-equivariant structure, see [65].

We remark that since \( \mathcal{M}_p^\theta (v)_F \) is defined over \( \mathbb{F}_p \), we have an isomorphism \( \mathcal{M}_p^\theta (v)_F \cong \mathcal{M}_p^\theta (v)_F^{(1)} \) of \( \mathbb{F} \)-schemes. Therefore we can view \( \hat{P}_F^\theta \) (the specialization of \( \hat{P}_p^\theta \) to \( 0 \in p_F \)) as a bundle on \( \mathcal{M}_p^\theta (v)^{\wedge 0}_F \). Similarly, we can view \( \hat{P}_p^\theta \) as a bundle on \( \mathcal{M}_p^\theta (v)^{\wedge 0}_F \). This is because the Artin-Schreier map \( p_F \to \mathbb{F}_F^{(1)} \) is etale and so induces an isomorphism of \( \mathbb{F}[p]^{\wedge 0} \) with itself. Since the bundle \( \hat{P}_p^\theta \) has no higher self-extensions, we can extend it to a unique \( \mathbb{F}^\times \)-equivariant vector bundle on \( \mathcal{M}_p^\theta (v)_F \) to be denoted by \( \mathcal{P}_p^\theta \).

One can lift \( \mathcal{P}_p^\theta \) to characteristic 0 as explained in [12]. Let us recall how to do this. The bundle \( \mathcal{P}_p^\theta \) is defined over some finite field \( \mathbb{F}_q \). Let \( \tilde{S} \) be an algebraic extension of the ring \( S \) from Sect. 7.1 that has \( \mathbb{F}_q \) as a quotient field. Set \( \mathcal{M}_p^\theta (v)_\tilde{S} := \text{Spec}(\tilde{S}) \times_{\text{Spec}(S)} \mathcal{M}_p^\theta (v)_S \). Since the bundle \( \mathcal{P}_p^\theta \) has no higher Ext’s it can be extended to a unique \( \mathbb{G}_m \)-equivariant bundle \( \mathcal{P}_{\tilde{S}}^\theta \) on the formal neighborhood \( \mathcal{M}_p^{\wedge q}_\tilde{S} \) of \( \mathcal{M}_p^\theta (v)_\mathbb{F}_q \) in \( \mathcal{M}_p^\theta (v)_\tilde{S} \) (the existence is guaranteed by vanishing of \( \text{Ext}^2 \), and the uniqueness by the vanishing of \( \text{Ext}^1 \)). Since the bundle \( \mathcal{P}_p^\theta \) is \( \mathbb{G}_m \)-equivariant, and the action is contracting, this bundle is the completion of a unique \( \mathbb{G}_m \)-equivariant bundle \( \mathcal{P}_{\tilde{S}^{\wedge q}}^\theta \) on \( \mathcal{M}_p^\theta (v)_\tilde{S}^{\wedge q} \), where \( \tilde{S}^{\wedge q} \) stands for the completion of \( S \) with respect to the kernel of \( S \to \mathbb{F}_q \).

Since the quotient field of \( \tilde{S}^{\wedge q} \) embeds into \( \mathbb{C} \), we get a bundle \( \mathcal{P}_p^\theta \) on \( \mathcal{M}_p^\theta (v)_\mathbb{F}_q \). This bundle is \( \mathbb{C}^\times \)-equivariant and has no higher self-extensions. We remark that its restriction to \( \mathcal{M}_p^\theta (v) \) has no higher self-extensions because \( \mathcal{P}_p^\theta \) and \( \text{End}(\mathcal{P}_p^\theta) \) are flat over \( \mathbb{C}[p] \), and \( \mathcal{P}_p^\theta \) has no higher self-extensions.

Now we want to compare the endomorphism algebras of the bundles \( \mathcal{P}_p^\theta \) for different \( \theta \).

**Proposition 7.6** For any (generic) \( \theta, \theta' \), we have \( \text{End}(\mathcal{P}_p^\theta) \cong \text{End}(\mathcal{P}_p^{\theta'}) \), an isomorphism of graded \( \mathbb{C}[p] \)-algebras.

**Proof** The proof is in several steps.

**Step 1.** Consider the locus \( \mathcal{M}_p^\theta (v)_F^{(1)\text{reg}} \subset \mathcal{M}_p^\theta (v)_F^{(1)} \) that is the union of open symplectic leaves in the Poisson varieties \( \mathcal{M}_p^\theta (v)_F^{(1)} \). As in the proof of Proposition 3.3, \( \mathcal{M}_p^\theta (v)_F^{(1)\text{reg}} \) is an open subvariety in \( \mathcal{M}_p^\theta (v)_F^{(1)} \). Further, the morphism \( \mathcal{M}_p^\theta (v)_F^{(1)} \to \mathcal{M}_p^\theta (v)_F^{(1)\text{reg}} \) is an isomorphism over \( \mathcal{M}_p^\theta (v)_F^{(1)\text{reg}} \) because it is a fiberwise symplectic resolution of singularities. Let \( \mathcal{M}_p^\theta (v)_F^{(1)\text{reg}} \)
denote the isomorphic preimage of \( \mathcal{M}_p(v^{(1)}_{\mathbb{F}})^{reg} \) in \( \mathcal{M}_p^{\theta}(v^{(1)}_{\mathbb{F}}) \). In particular, we see that \( \mathcal{M}_p^{\theta}(v^{(1)}_{\mathbb{F}})^{reg} \) and \( \mathcal{M}_p^{\theta'}(v^{(1)}_{\mathbb{F}})^{reg} \) are naturally identified.

We claim that the restrictions of the bundles \( \mathcal{P}^{\theta}_{p,\mathbb{F}}, \mathcal{P}^{\theta'}_{p,\mathbb{F}} \) to this open subvarieties differ by a twist with a line bundle. The latter will follow if we check that

\[
\text{End}(\mathcal{P}^{\theta}_{p,\mathbb{F}}) \cong \text{End}(\mathcal{P}^{\theta'}_{p,\mathbb{F}}). \tag{7.6}
\]

Indeed, the restriction of this endomorphism algebra to \( \mathcal{M}_p^{\theta}(v^{(1)}_{\mathbb{F}})^{reg} \) is Azumaya and the restrictions of both \( \mathcal{P}^{\theta}_{p,\mathbb{F}}, \mathcal{P}^{\theta'}_{p,\mathbb{F}} \) are splitting bundles so differ by a twist with a line bundle.

To establish (7.6) we will first verify that \( \text{End}(\hat{\mathcal{P}}^{\theta}_{p,\mathbb{F}}) = \text{End}(\hat{\mathcal{P}}^{\theta'}_{p,\mathbb{F}}) \). By the construction in Sect. 7.2, the left hand side is \( \Gamma(\mathcal{A}^{\theta}_{\mathbb{F}}(v)^{\wedge_0}), \) while the right hand side is \( \Gamma(\mathcal{A}^{\theta'}_{\mathbb{F}}(v)^{\wedge_0}), \) both are isomorphic to \( \mathcal{A}_{\mathbb{F}}(v)^{\wedge_0} \). Now by the formal function theorem, the completions \( \text{End}(\mathcal{P}^{\theta}_{p,\mathbb{F}})^{\wedge_0}, \text{End}(\mathcal{P}^{\theta'}_{p,\mathbb{F}})^{\wedge_0} \) are isomorphic \( \mathbb{F}[[p]] \)-algebras. We want to deduce the isomorphism \( \text{End}(\mathcal{P}^{\theta}_{p,\mathbb{F}})^{\wedge_0} \cong \text{End}(\mathcal{P}^{\theta'}_{p,\mathbb{F}})^{\wedge_0} \) from here. This will follow if we show the following claim

(*) the isomorphism \( \text{End}(\mathcal{P}^{\theta}_{p,\mathbb{F}})^{\wedge_0} \cong \text{End}(\mathcal{P}^{\theta'}_{p,\mathbb{F}})^{\wedge_0} \) can be made \( \mathbb{F}^\times \)-equivariant by twisting the actions on the indecomposable summands of the vector bundles involved by characters of \( \mathbb{F}^\times \).

To show that we first observe that the restrictions of the indecomposable summands of \( \mathcal{P}^{\theta}_{p,\mathbb{F}} \) to \( \rho_{\mathbb{F}}^{-1}(\mathcal{M}_p(v^{(1)}_{\mathbb{F}})^{1,\wedge_0,reg}) \) are still indecomposable. This follows from the fact that the complement to \( \mathcal{M}_p^{\theta}(v^{(1)}_{\mathbb{F}})^{reg} \) has codimension bigger than 2. Also note that any \( \mathbb{F}^\times \)-equivariantly indecomposable bundle is also indecomposable as an ordinary bundle.

Let us show that any two \( \mathbb{F}^\times \)-equivariant structures on an indecomposable summand of the restriction of \( \mathcal{P}^{\theta}_{p,\mathbb{F}} \) to \( \rho_{\mathbb{F}}^{-1}(\mathcal{M}_p(v^{(1)}_{\mathbb{F}})^{1,\wedge_0,reg}) \), up to an isomorphism, differ by a twist with a character. This statement is equivalent to the analogous one for every indecomposable summand, say \( \mathcal{E} \), of \( \mathcal{P}^{\theta}_{p,\mathbb{F}} \). Let us write \( m \) for the maximal ideal in \( \mathbb{F}[\mathcal{M}_p(v^{(1)}_{\mathbb{F}})]^{\wedge_0} \). Then \( \text{Aut}(\mathcal{E}) \) is the preimage of the group of invertible elements in \( \text{End}(\mathcal{E})/(m) \) under the epimorphism \( \text{End}(\mathcal{E}) \twoheadrightarrow \text{End}(\mathcal{E})/(m) \). The algebra \( \text{End}(\mathcal{E})/(m) \) is finite dimensional, so the group \( \text{Aut}(\mathcal{E}) \) is pro-algebraic. An \( \mathbb{F}^\times \)-equivariant structure gives rise to a semi-direct product \( \mathbb{F}^\times \ltimes \text{Aut}(\mathcal{E}), \) where the action of \( \mathbb{F}^\times \) on \( \text{Aut}(\mathcal{E}) \) preserves the pro-algebraic structure. Another equivariant structure defines an embedding \( \mathbb{F}^\times \twoheadrightarrow \mathbb{F}^\times \ltimes \text{Aut}(\mathcal{E}) \) of the form \( t \mapsto (t, \gamma(t)) \). Conjugating by a suitable element of \( \text{Aut}(\mathcal{E}) \) we achieve that \( \gamma(t) \) commutes with \( \mathbb{F}^\times \). However, since \( \mathcal{E} \) is indecomposable, we have \( \gamma(t) \) is a scalar in this case. (*) follows.
Step 2. So now we can assume that
\[ \mathcal{P}_p^\theta F|_\mathcal{M}_{p(v)}^{reg} \cong \mathcal{P}_p^\theta F|_\mathcal{M}_{p(v)}^{reg}, \]
where we consider \( \mathcal{P}_p^\theta F \) as a bundle on \( \mathcal{M}_p^{\theta}(v) \). We claim that the first self-Ext of these isomorphic bundles vanishes. The variety \( \mathcal{M}_p^{\theta}(v) \) is Cohen–Macaulay by (4) of Corollary 2.4. Since \( H^i(\mathcal{M}_p^{\theta}(v)_F, \text{End}(\mathcal{P}_p^\theta F)) = 0 \) for \( i > 0 \), we see that \( \text{End}(\mathcal{P}_p^\theta F) \) is a Cohen–Macaulay \( F[\mathcal{M}_p^{\theta}(v)] \)-module. Therefore, for a subvariety \( Y \subset \mathcal{M}_p^{\theta}(v)_F \) of codimension \( i \), we have \( H^j_Y(\mathcal{M}_p^{\theta}(v)_F, \text{End}(\mathcal{P}_p^\theta F)) = 0 \) for \( j < i \). Since \( \mathcal{M}_p^{\theta}(v)_F \setminus \mathcal{M}_p^{\theta}(v)_{reg} \) has codimension 3, we use a standard exact sequence for the cohomology with support to see that \( H^i(\mathcal{M}_p^{\theta}(v)_F, \text{End}(\mathcal{P}_p^\theta F)) = 0 \) for \( i < 2 \). Therefore, \( H^1(\mathcal{M}_p^{\theta}(v)_{reg} F, \text{End}(\mathcal{P}_p^\theta F)) = 0 \) and we are done.

Step 3. We have a closed subscheme \( \mathcal{M}_p^{\theta}(v)_{reg} F \subset \mathcal{M}_p^{\theta}(v)_{reg} \). Consider its formal neighborhood \( \mathcal{M}_p^{\theta}(v)_{reg, \lambda} F \). There is a natural morphism \( \iota: \mathcal{M}_p^{\theta}(v)_{reg, \lambda} F \to \mathcal{M}_p^{\theta}(v)_{\lambda} F \) of formal schemes. The bundles \( \iota^* \tilde{\mathcal{P}}_p^\theta F, \iota^* \tilde{\mathcal{P}}_p^\theta F' \) are isomorphic by the previous step, because both deform \( \mathcal{P}_p^\theta F|_\mathcal{M}_p^{\theta}(v)_{reg} \) that has no first extensions. The induced homomorphism \( \text{End}(\tilde{\mathcal{P}}_p^\theta F) \to \text{End}(\iota^* \tilde{\mathcal{P}}_p^\theta F) \) is an isomorphism because both algebras are flat over the complete algebra \( S^\lambda \) and modulo the maximal ideal of \( S^\lambda \) this homomorphism coincides with the isomorphism \( \text{End}(\mathcal{P}_p^\theta F) \to \text{End}(\mathcal{P}_p^\theta F|_\mathcal{M}_p^{\theta}(v)_{reg}) \).

By Step 1, \( \iota^* \tilde{\mathcal{P}}_p^\theta F \) is independent of \( \theta \). So \( \text{End}(\tilde{\mathcal{P}}_p^\theta F) \) is \( \mathbb{G}_m \)-equivariantly isomorphic to \( \text{End}(\tilde{\mathcal{P}}_p^\theta F) \). This yields an isomorphism required in this proposition.

Remark 7.7 The argument in the above proof implies that the bundle \( \mathcal{P}_p^\theta F|_\mathcal{M}(v)_p^{reg} \) is independent of \( \theta \) and the first self-extensions vanish.

7.4 Proof of Proposition 7.1

Let us prove Proposition 7.1. For \( \mathcal{P}^\theta \) we take the restriction of \( \mathcal{P}_p^\theta \) to \( \mathcal{M}_p^{\theta}(v) \). This bundle has no higher self-extensions, this has already been mentioned in Sect. 7.3. Because of that \( \text{End}(\mathcal{P}^\theta) = \text{End}(\mathcal{P}_p^\theta)/(p) \). So the algebras \( \text{End}(\mathcal{P}^\theta) \) for different \( \theta \) are \( \mathbb{C}^\times \)-equivariantly identified.

It remains to show that \( \text{End}(\mathcal{P}^\theta) \) has finite homological dimension. This is what we do in the remainder of this section. For this algebra to have finite homological dimension we will need to make special choices of \( \lambda \) and of \( p \).
First of all, let us notice that there is \( \lambda \in \mathbb{Q}^{>0} \) such that the homological dimension of \( A_\lambda(v) \otimes A_\lambda(v)^{opp} \) is finite. Indeed, for any \( \lambda \) there is \( k \in \mathbb{Z} \) such that the abelian localization theorem holds for \( A_{\lambda+k\theta}(v) \otimes A_{\lambda+k\theta}(v)^{opp} \) on \( M^\theta(v) \times M^{-\theta}(v) \). It follows that the homological dimension of \( A_{\lambda+k\theta}(v) \otimes A_{\lambda+k\theta}(v)^{opp} \) is finite and we replace \( \lambda \) with \( \lambda + k\theta \).

We claim that for \( p \gg 0 \), the homological dimension of \( A_\lambda(v)^F \) is finite. This follows from a more general result.

**Lemma 7.8** Let \( S \) be a finite localization of \( \mathbb{Z} \). Let \( A \) be an \( S \)-algebra such that \( A \otimes S A^{op} \) is Noetherian. Suppose that for \( A_C = \mathbb{C} \otimes S A \), the homological dimension of \( A_C \otimes_c A_C^{opp} \) is finite. Then the algebra \( A_F := F \otimes S A \) has finite homological dimension for all \( p \gg 0 \). Moreover, the projective dimension of the regular \( A_F \)-bimodule is finite.

**Proof** For an algebra \( A \) over a field, the homological dimension is finite provided the projective dimension of the regular bimodule \( A \) is.

Let \( F \) be a finitely generated free \( A \)-bimodule, \( M \) a finitely generated \( A \)-bimodule and \( \varphi \) a homomorphism \( F \to M \) such that the homomorphism \( \varphi_C \) is surjective. Because all bimodules involved are finitely generated, \( \varphi_C \) is an epimorphism for a finite localization \( S' \) of \( S \). So, using induction, we reduce to showing that if \( M \) is a finitely generated \( A \)-bimodule such that \( M_{\text{Frac}(S)} \) is a projective \( A_{\text{Frac}(S)} \)-bimodule, then \( M_{S'} \) is a projective \( A_{S'} \)-bimodule for a finite localization \( S' \) of \( S \). Fix an epimorphism \( \varphi : F \to M \) of \( A \)-bimodules. Then \( \varphi_{\text{Frac}(S)} \) admits a left inverse, \( \iota \). Clearly, \( \iota \) is defined over a finite localization \( S' \) of \( S \). It follows that \( M_{S'} \) is projective.

Therefore the projective dimension of the regular \( A_{S'} \)-bimodule is finite. So the projective dimension of \( A_{F_p} \) is finite for \( p \gg 0 \) proving the lemma. \( \square \)

Since the projective dimension of the regular \( A_\lambda(v)^F \)-bimodule is finite, so is the projective dimension of the regular \( A_\lambda(v)^{\mathbb{C}0} \)-bimodule, because \( A_\lambda(v)^{\mathbb{C}0} \) is a flat (left and right) \( A_\lambda(v)^F \)-module. It follows that \( A_\lambda(v)^{\mathbb{C}0} \) has finite homological dimension. In other words, the homological dimension of \( \text{End}(\mathcal{P}_\mathbb{F}^\theta) \) is finite. Because of the contracting \( \mathbb{F}^\times \)-action, the homological dimension of \( \text{End}(\mathcal{P}_\mathbb{F}^\theta) \) is also finite. The same holds for the deformation \( \text{End}(\mathcal{P}_\mathbb{F}^\theta) \) of \( \text{End}(\mathcal{P}_\mathbb{F}^\theta) \) over \( \tilde{S}^{\mathbb{C}q} \) (here \( \mathcal{P}_\mathbb{F}^\theta \) is the specialization of the bundle \( \mathcal{P}_p,\mathbb{F}^\theta \) constructed in the beginning of Sect. 7.3 to the zero parameter). Again, thanks to the contracting action of \( \mathbb{G}_m \), the homological dimension of \( \text{End}(\mathcal{P}_\mathbb{F}^\theta) \) is finite, and we are done.

### 7.5 Proof of Proposition 7.2

In this section we prove Proposition 7.2 using reduction to characteristic \( p \). We start with reducing finite dimensional representations mod \( p \).
7.5.1 Reduction of representations mod \( p \)

Let \( \lambda \in \mathbb{Q}^{Q_0} \) be such that \( A_\lambda(v) \otimes A_{\lambda}(v)^{opp} \) has finite homological dimension. Here we will discuss the reduction of the finite dimensional representations of \( A_\lambda(v) \) modulo \( p \) for \( p \gg 0 \). Let \( \mathbb{F} \) still be an algebraically closed field of characteristic \( p \). Note that by Lemma 7.8, the algebra \( A_\lambda(v)_{\mathbb{F}} \) has finite homological dimension. Let \( S \) have the same meaning as in Lemma 7.4.

Let \( M \in A_\lambda(v)-\text{mod}_{\text{fin}} \). Pick an \( S \)-lattice \( M_S \subset M \). If \( p \) is invertible in \( S \), then \( M_{\mathbb{F}} := \mathbb{F} \otimes_S M_S \) makes sense. It is a standard result that \([M_{\mathbb{F}}] \in K_0(A_\lambda(v)_{\mathbb{F}}-\text{mod}_{\text{fin}})\) depends only on \([M]\) and the map \([M] \mapsto [M_{\mathbb{F}}]\) is linear.

Inside \( A_\lambda(v)_{\mathbb{F}} \) we have a central subalgebra \( \mathbb{F}[\mathcal{M}(v)^{(1)}] \) known as the \( p \)-center, see, e.g., [9]. Consider the category \( A_\lambda(v)_{\mathbb{F}}\)-mod consisting of all finite dimensional \( A_\lambda(v)_{\mathbb{F}}\)-modules supported at \( 0 \in \mathcal{M}(v)^{(1)}_{\mathbb{F}} \).

Here is the main result of this section.

**Proposition 7.9** The following is true provided \( p \gg 0 \):

1. \( M_{\mathbb{F}} \in A_\lambda(v)_{\mathbb{F}}\)-mod_0.
2. If \( M \) is irreducible, then \( M_{\mathbb{F}} \) is irreducible.
3. If \( M^1, M^2 \) are two non-isomorphic finite dimensional irreducible modules, then \( M^1_{\mathbb{F}} \) and \( M^2_{\mathbb{F}} \) are non-isomorphic.

It follows from Proposition 7.9 that we get an injective map \( K_0(A_\lambda(v)-\text{mod}_{\text{fin}}) \hookrightarrow K_0(A_\lambda(v)_{\mathbb{F}}-\text{mod}_0) \). In Sect. 7.5.2 we will see that there is an isomorphism \( K_0(A_\lambda(v)_{\mathbb{F}}-\text{mod}_0) \sim K_0(\text{Coh}_{\mathbb{F}p^{-1}(0)}(\mathcal{M}^\theta(v))) \) intertwining the injective map above with \( \gamma_\lambda^\theta \).

**Proof of Proposition 7.9** Let \( M \in A_\lambda(v)-\text{mod}_{\text{fin}} \) be irreducible and let \( I \) be its annihilator in \( A := A_\lambda(v) \) so that \( A/I = \text{End}_\mathbb{C}(M) \). Then the annihilator of \( M_S \) in \( A_S \) is \( I_S := A_S \cap I \).

We may assume that \( M \) is a free finite rank module over \( S \). Then \( I_S \) and \( A_S/I_S \) are flat over \( S \). Replacing \( S \) with a finite algebraic extension we achieve that that \( A_S/I_S \sim \text{End}_S(M_S) \). For \( p \) sufficiently large, \( \mathbb{F} \) is an \( S \)-algebra. So, for \( I_{\mathbb{F}} := \mathbb{F} \otimes_S I_S \), we have \( A_{\mathbb{F}}/I_{\mathbb{F}} \sim \text{End}_\mathbb{F}(M_{\mathbb{F}}) \). It follows that \( M_{\mathbb{F}} \) is irreducible and \( I_{\mathbb{F}} \) is the annihilator of \( M_{\mathbb{F}} \) in \( A_{\mathbb{F}} \). (2) is proved.

Let \( M^1, M^2 \) be two non-isomorphic simples. Let \( I \) be the intersection of their annihilators in \( A \). Then we can form the ideals \( I_S \subset A_S \) and \( I_{\mathbb{F}} \subset A_{\mathbb{F}} \) similarly to the above. We will get \( A_{\mathbb{F}}/I_{\mathbb{F}} \sim \text{End}_\mathbb{F}(M^1_{\mathbb{F}}) \oplus \text{End}_\mathbb{F}(M^2_{\mathbb{F}}) \). This implies (3).

Finally, let us prove (1). Note that \( \dim \mathbb{F}[\mathcal{M}(v)^{(1)}_{\mathbb{F}}]/(I_{\mathbb{F}} \cap \mathbb{F}[\mathcal{M}(v)^{(1)}_{\mathbb{F}}]) \leq (\dim M)^2 \) so is bounded with respect to \( p \). On the other hand, it is easy to see that \( I_{\mathbb{F}} \cap \mathbb{F}[\mathcal{M}(v)^{(1)}_{\mathbb{F}}] \) is a Poisson ideal in \( \mathbb{F}[\mathcal{M}(v)^{(1)}_{\mathbb{F}}] \). Since the codimension is bounded with respect to \( p \), we see that the subvariety of \( \mathcal{M}(v)^{(1)}_{\mathbb{F}} \) defined
by this ideal is the union of points that are symplectic leaves. Since we have a contracting \( \mathbb{F}^\times \)-action on \( \mathcal{M}(v)^{(1)} \) we see that the subvariety is actually \{0\}. This finishes the proof of (1). \( \square \)

7.5.2 Isomorphism \( K_0(A_{\lambda}(v)_\mathbb{F} \text{-mod}_0) \sim K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \)

Note that \( R\Gamma(A_{\lambda}^\theta(v)_\mathbb{F}) = A_{\lambda}(v)_\mathbb{F} \). By the construction, the algebra \( A_{\lambda}(v)_\mathbb{F} \) has finite homological dimension. By [12, Section 2.2], the functor \( R\Gamma \) gives an equivalence \( D^b(A_{\lambda}^\theta(v)_\mathbb{F} \text{-mod}) \sim D^b(A_{\lambda}(v)_\mathbb{F} \text{-mod}) \). Consider the subcategory \( D^b_0(A_{\lambda}^\theta(v)_\mathbb{F} \text{-mod}) \subset D^b(A_{\lambda}(v)_\mathbb{F} \text{-mod}) \) of all complexes whose homology are finite dimensional with generalized \( p \)-character 0 and similarly defined subcategory \( D^b_{(\rho(1))^{-1}(0)}(A_{\lambda}^\theta(v)_\mathbb{F} \text{-mod}) \subset D^b(A_{\lambda}(v)_\mathbb{F} \text{-mod}) \). The equivalence \( R\Gamma \) restricts to \( D^b_{(\rho(1))^{-1}(0)}(A_{\lambda}^\theta(v)_\mathbb{F} \text{-mod}) \sim D^b_0(A_{\lambda}(v)_\mathbb{F} \text{-mod}) \).

Since \( A_{\lambda}^\theta(v)_\mathbb{F} \) splits on \( \mathcal{M}^\theta(v)^{\wedge_0} \), we further get an equivalence

\[
\mathcal{F}: D^b_{(\rho(1))^{-1}(0)}(\text{Coh}(\mathcal{M}^\theta(v)^{(1)}_\mathbb{F})) \sim D^b_0(A_{\lambda}(v)_\mathbb{F} \text{-mod})
\]

given by \( N \mapsto R\Gamma(\mathcal{P}^\theta_\mathbb{F} \otimes N) \). So we get an isomorphism

\[
[\mathcal{F}]: K_0(A_{\lambda}(v)_\mathbb{F} \text{-mod}_0) \sim K_0(\text{Coh}_{(\rho(1))^{-1}(0)}(\mathcal{M}^\theta(v)^{(1)}_\mathbb{F}))
\]

The Frobenius push-forward for \( \mathcal{M}^\theta(v)_\mathbb{F} \) induces the isomorphism

\[
[Fr_*]: K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v)_\mathbb{F})) \sim K_0(\text{Coh}_{(\rho(1))^{-1}(0)}(\mathcal{M}^\theta(v)^{(1)}_\mathbb{F}))
\]

(recall that all \( K_0 \)'s we consider are over \( \mathbb{C} \), the map \( [Fr_*] \) is not invertible over \( \mathbb{Z} \)). But \( K_0(\text{Coh}_{(\rho(1))^{-1}(0)}(\mathcal{M}^\theta(v)_\mathbb{F})) \) is naturally identified with \( K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v)_\mathbb{F})) \) since \( p \gg 0 \).

We get an isomorphism \( K_0(A_{\lambda}(v)_\mathbb{F} \text{-mod}_0) \sim K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v)_\mathbb{F})) \) given by \( [Fr_*]^{-1} \circ [\mathcal{F}]^{-1} \) to be denoted by \( \iota \). Set \( \iota' = [\mathcal{P}^\theta] \). Our \( K_0 \) is a \( \mathbb{C} \)-vector space, so the multiplication by \( [\mathcal{P}^\theta] \) (the class of a vector bundle) is an invertible transformation.

7.5.3 Completion of proof

It remains to prove the following lemma.

**Lemma 7.10** We have \( \gamma_{\lambda}^\theta([M]) = \iota'([M_\mathbb{F}]) \).
Proof Note that we still have the degeneration map

$$K_0(A^\theta_\lambda(v)_F \text{-mod}_{\rho^{-1}(0)}) \to K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v)_F)), \ [N] \mapsto [\text{gr} \ N].$$

So we get the map $$\gamma^\theta_{\lambda,F} : K_0(A^\theta_\lambda(v)_F \text{-mod} \text{fin}) \to K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v)_F)).$$ Let us check that $$\gamma^\theta_{\lambda,F}(\mathcal{M}_C) = \gamma^\theta_{\lambda,F}(\mathcal{M}_F).$$

Now take $$L \in \text{Coh}_{(\rho^{-1}(0))(\mathcal{M}^\theta(v)_F^{(1)})}.$$ The corresponding object $$\mathcal{M}_F \in D_0^b(A^\theta_\lambda(v)_F \text{-mod})$$ is $$R\Gamma(P^\theta_F \otimes L).$$ But

$$A^\theta_\lambda(v)_F \otimes^L_{A^\theta_\lambda(v)_F} \mathcal{M}_F = \mathcal{P}^\theta_F \otimes L. \tag{7.7}$$

The class of the right hand side of (7.7) is $$[\mathcal{P}^\theta_F][L].$$ So $$\gamma^\theta_{\lambda,F}(\mathcal{M}_F) = [\mathcal{P}^\theta_F][\text{Fr}_*]^{-1}[N].$$ Since $$[N] = [\mathcal{F}]^{-1}([\mathcal{M}_F])$$ we get the required equality $$[\gamma^\theta_{\lambda,F}](\mathcal{M}_F) = \iota'([\mathcal{M}_F]).$$

8 Proof of the lower bound

In this section we prove (I) from the beginning of Sect. 6 and various related statements.

In Sect. 8.1 we prove Theorem 6.2 relating the wall-crossing functor to a Rickard functor. In Sect. 8.2 we study the K-theory of quiver varieties, in particular, we use results of Sect. 7 to identify the $$K_0$$-groups $$K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v)))$$ for different generic $$\theta$$. We show that the Chern character maps are isomorphisms that intertwine these identifications with the identification of homology explained in Sect. 2.1. In Section 8.3 we prove that the identifications $$K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \sim K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta'(v)))$$ intertwine the maps from $$K_0(A^\theta_\lambda(v) \text{-mod} \text{fin})$$.

This shows, in particular, that $$CC : K_0(A^\theta_\lambda(v) \text{-mod} \text{fin}) \to L_\omega[v]$$ is independent of the choice of $$\theta$$. Finally, in Sect. 8.4 we equip $$\bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v)))$$ with an $$\alpha$$-action and modify the degeneration map

$$\bigoplus_v K_0(A^\theta_\lambda(v) \text{-mod}_{\rho^{-1}(0)}) \to \bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v)))$$

so that it intertwines $$[E_\alpha]$$ with $$e_\alpha$$ and $$[F_\alpha]$$ with $$f_\alpha$$. We deduce Proposition 6.1 (and hence (I)) from here.
8.1 Wall-crossing versus Rickard complexes

In this subsection we prove Theorem 6.2. Our proof follows the scheme of construction of $E_i$, $F_i$: we use reduction in stages to reduce to what essentially is the case of a quiver with a single vertex and no loops.

We will use the notation of Sect. 5.2 and of 2.1.3. Recall that we assume that $\theta_k > 0$ for all $k$ and $\lambda_j \in \mathbb{Z}_{\geq 0}$. In the proof we will need to deal with various functors that we will now describe.

8.1.1 Quotient functors

Consider the quotient functors

$$\pi^i_{\theta_i}(v): D_R\text{-mod}^{G, \lambda} \rightarrow D_{G_r(v_i, \tilde{w}_i)}^{\lambda_i} \otimes D_R\text{-mod}^{G, \tilde{\lambda}},$$

$$\pi^\theta(v): D_{G_r(v_i, \tilde{w}_i)}^{\lambda_i} \otimes D_R\text{-mod}^{G, \tilde{\lambda}} \rightarrow A^\theta_{\lambda}(v)\text{-mod}.$$

so that $\pi^\theta_i(v) = \pi^\theta(v) \circ \pi^i_{\theta_i}(v)$ (below we will omit the subscript).

Recall, 2.5.4, that the functor $\pi^\theta(v)$ extends to a quotient functor $D^b_{G, \lambda}(D_R\text{-mod}) \rightarrow D^b(A^\theta_{\lambda}(v)\text{-mod})$ still denoted by $\pi^\theta(v)$. For completely similar reasons, we get quotient functors

$$\pi^i_{\theta}(v): D^b_{G, \lambda}(D_R\text{-mod}) \rightarrow D^b_{G_r(v_i, \tilde{w}_i)}^{\lambda_i} \otimes D_R\text{-mod},$$

$$\pi^\theta(v): D^b_{G_r(v_i, \tilde{w}_i)}^{\lambda_i} \otimes D_R\text{-mod} \rightarrow A^\theta_{\lambda}(v)\text{-mod}.$$

such that $\pi^\theta(v)$ still decomposes as $\pi^\theta(v) \circ \pi^i_{\theta_i}(v)$. Assuming that $\lambda \in \mathbb{P}^{ISO}$ and $(\lambda, \theta) \in \mathfrak{A}(v)$, the functor $\pi^\theta(v)$ admits a left adjoint functor $L\pi^\theta(v)^!$. Under the same assumptions, $\pi^\theta(v)$ admits a derived left adjoint functor $L\pi^\theta(v)^!$. Further, possibly after replacing $\lambda$ with $\lambda + k\theta$ for $k > 0$ we may assume, in addition, that $\pi^i_{\theta_i}(v)$ admits a derived left adjoint $L\pi^i_{\theta_i}(v)^!$. So we have $L\pi^\theta(v)^! = L\pi^i_{\theta_i}(v)^! \circ L\pi^\theta(v)^!$.

8.1.2 Wall-crossing functors

Recall that $\lambda'$ stands for $s_i \cdot 0^{e_i} v \lambda$. Consider the functor

$$\mathcal{M}_{\lambda_i \rightarrow \lambda'_i}: D^b_{G, \lambda}(A^\theta_{\lambda_i}(v)\text{-mod}) \rightarrow D^b_{G, \lambda}(A^{-\theta_i}_{\lambda_i}(v)\text{-mod})$$

that is the composition of

$$\mathcal{M}_{\lambda_i \rightarrow \lambda'_i}: D^b_{G, \lambda}(A^\theta_{\lambda_i}(v)\text{-mod}) \rightarrow D^b_{G, \lambda}(A^{-\theta_i}_{\lambda_i}(v)\text{-mod})$$

$\mathfrak{g}$ Springer
and the equivalence
\[
D^b_{G, \lambda} (A^{-\theta_i} (v) \text{-mod}) \sim D^b_{G, \lambda'} (A^{-\theta_i} (v) \text{-mod})
\]
(an integral change of the twisted equivariance condition).

We have \((\lambda, \theta) \in \mathfrak{AL}(v)\) by our assumptions. Also \((\lambda_i, \theta_i) \in \mathfrak{AL}(v_i)\) because \(\lambda_i, \theta_i \geq 0\). These two observations imply \((\lambda', s_i \theta) \in \mathfrak{AL}(s_i \bullet v)\) and \((\lambda'_i, \theta_i) \in \mathfrak{AL}(\tilde{w}_i - v_i)\).

**Lemma 8.1**

\[
\mathcal{WC}_{\lambda \to \lambda'} = \pi^\theta (s_i \bullet v) \circ \mathcal{WC}_{\lambda \to \lambda'} \circ L \pi^\theta (v)^!.
\] (8.1)

**Proof** Note that we have the next four functor isomorphisms
\[
\mathcal{WC}_{\lambda \to \lambda'} \cong \pi^{-\theta_i} (v) \circ (C_{\lambda', -\lambda} \otimes \bullet) \circ L \pi^{\theta_i} (v)^!,
\]
\[
\mathcal{WC}_{\lambda \to \lambda'} \cong \pi^{s_i \theta} (v) \circ (C_{\lambda', -\lambda} \otimes \bullet) \circ L \pi^{\theta} (v)^!,
\]
\[
\pi^{s_i \theta} (v) \cong \pi^{s_i \theta} (v) \circ \pi^{-\theta_i} (v),
\]
\[
L \pi^{\theta} (v)^! \cong L \pi^{\theta_i} (v)^! \circ L \pi^\theta (v)^!.
\]
The last two isomorphisms were discussed in Sect. 8.1.1. To prove the second one we use Lemma 2.17 and isomorphisms of functors \(\pi^0_\lambda (v) \cong \pi^\theta (v), \pi^0_\lambda (v) \cong \pi^{s_i \theta} (v)\). The first isomorphism is analogous.

These four equalities imply (8.1). \qed

### 8.1.3 LMN isomorphisms

Tracking the construction of the LMN isomorphisms, see Sects. 2.1.3 and 2.2.4, we see that
\[
s_i* \circ \pi^{s_i \theta} (v) = \pi^\theta (s_i \bullet v) \circ \tilde{s}_i*,
\] (8.2)
where we write \(\tilde{s}_i*\) for the equivalence
\[
D^b_{G, \lambda'} (A^{-\theta_i} (v) \text{-mod}) \sim D^b_{G, \lambda_i} (A^{-\theta_i} (s_i \bullet v) \text{-mod})
\]
that comes from the quantum LMN isomorphism \(A^{-\theta_i} (v) \sim A^{\theta_i} (v)\). Combining (8.1) with (8.2), we get
\[
s_i* \circ \mathcal{WC}_{\lambda \to \lambda'} = \pi^\theta (s_i \bullet v) \circ (\tilde{s}_i* \circ \mathcal{WC}_{\lambda \to \lambda'}) \circ L \pi^\theta (v)^!.
\] (8.3)
8.1.4 Rickard complexes

We consider Rickard complexes that (in a somewhat different framework) were suggested by Chuang and Rouquier [22, Section 6]. We will use the version of [21, Section 8].

Set $k = v_i, N = \tilde{w}_i$. We want to define an object $\Theta$ in the homotopy category of 1-morphisms in $U(\mathfrak{sl}_2)$ (going from the object $N - 2k$ to the object $2k - N$). This will be the complex

$$\Theta^m[-m] \to \Theta^{m-1}[1-m] \to \ldots \to \Theta^1[-1] \to \Theta^0,$$

where $m = \min(k, N - k)$. Here

$$\Theta^i = F^{(N-k-i)}E^{(k-i)},$$

and $[?]$ denotes the grading shift in $U(\mathfrak{sl}_2)$. The differentials in the complex come from adjunctions between $E, F$. We note that what is denoted by $\Theta$ in [21, Section 8] is the cone of $\psi(\Theta)$ (where $\psi$ was introduced in 5.2.2).

Recall that Webster’s functors $E, F$ give rise to an action, say $\alpha$, of the 2-category $U(\mathfrak{sl}_2)$ on the category

$$\bigoplus_{v_i=0} \mathcal{D}^b_{G,\tilde{A}}(D^\lambda_{\text{Gr}(v_i, \tilde{w}_i)} \otimes D_R -\text{mod}).$$

We get an endofunctor $\alpha(\Theta)$ of (8.4). It follows from [21, Theorem 8.1] that it is an equivalence.

8.1.5 Comparison

Now let us compare the wall-crossing functors and the functors coming from Rickard complexes.

**Proposition 8.2** The functor

$$\alpha(\Theta) : \mathcal{D}^b_{G,\tilde{A}}(D^\lambda_{\text{Gr}(v_i, \tilde{w}_i)} \otimes D_R -\text{mod}) \to \mathcal{D}^b_{G,\tilde{A}}(D^\lambda_{\text{Gr}(\tilde{w}_i-v_i, \tilde{w}_i)} \otimes D_R -\text{mod})$$

coincides with $\tilde{s}_i^* \circ \mathcal{W}^i_{\lambda \to \lambda'}$.

**Proof** The statement will be deduced from a result of [21] which provides an isomorphism $I \cong \alpha'(\Theta)$ (where $\alpha'$ is a non-equivariant analog of $\alpha$) between two equivalences

$$I, \alpha'(\Theta) : \mathcal{D}^b(\text{Gr}(k, N) -\text{mod}) \sim \mathcal{D}^b(\text{Gr}(N-k, N) -\text{mod})$$
Consider the homomorphism

\[ \psi' : \mathcal{U}(\mathfrak{s}\mathfrak{l}_2) \to D^b(D\text{Gr}(k,N) \times \text{Gr}(N-k,N) -\text{mod}) \]

that is completely analogous to \( \psi \) considered in Sect. 5.2. The object

\[ \psi'((\Theta_1)) \in D^b(D\text{Gr}(k,N) \times \text{Gr}(N-k,N) -\text{mod}) \]

is shown in [21, Corollary 8.6] to be isomorphic to the complex \( j_* (\mathcal{O}_U)[k(N-k)] \) of \( D \)-modules, where \( j \) is the embedding \( U \to \text{Gr}(k,N) \times \text{Gr}(N-k,N) \). The same is true for the \( \text{GL}_N \)-equivariant derived category.

It remains to show how this statement implies the proposition. Clearly, \( \psi_1((\Theta)) \) is identified with \( \psi((\Theta)) \boxtimes \delta_{R^*}(\mathcal{O}) \), where we used the obvious identification \( (\text{Gr}(v_i, \tilde{w}_i) \times \overline{R}) \times (\text{Gr}(\tilde{w}_i - v_i, \tilde{w}_i) \times \overline{R}) = \text{Gr}(v_i, \tilde{w}_i) \times \text{Gr}(\tilde{w}_i - v_i, \tilde{w}_i) \times \overline{R}^2 \). Here \( \delta_{\overline{R}} : \overline{R} \to \overline{R}^2 \) is the diagonal embedding. Since \( \psi((\Theta)) \cong j_* (\mathcal{O}_U[k(N-k)]) \boxtimes \delta_{\overline{R}^*}(\mathcal{O}) \), to complete the proof it is enough to notice that \( \tilde{s}_i \circ \mathcal{M}_i{\lambda}_\to{\lambda}' \) is given by the convolution with \( j_* (\mathcal{O}_U) \boxtimes \delta_{\overline{R}}(\mathcal{O}) \) (in the \( G \)-equivaraint derived category). This is proved similarly to [4, Theorem 12].

8.1.6 Completion of proof

Let us complete the proof of Theorem 6.2. We have the endofunctor \( \Theta_i \) of \( \bigoplus_v D^b(\mathcal{A}^\theta_\lambda(v) -\text{mod}) \) induced by \( \alpha((\Theta)) \), so that

\[ \Theta_i \circ \pi^\theta(\mathcal{A}) \cong \pi^\theta(s_i \bullet v) \circ \alpha((\Theta)). \]

This implies

\[ \Theta_i = \pi^\theta(s_i \bullet v) \circ \alpha((\Theta)) \circ L \pi^\theta(v)^{\dagger}. \quad (8.5) \]

Thanks to (8.5) and (8.3), we see that Theorem 6.2 follows from Proposition 8.2.

8.2 K-theory and cohomology of quiver varieties

Recall that the homology groups \( H_*(\mathcal{M}^\theta(v)) \) and the cohomology groups \( H^*(\mathcal{M}^\theta(v)) \) are independent of \( \theta \), see 2.1.8. Note that we have Chern character
maps

\[ K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \to H_*(\mathcal{M}^\theta(v)), \quad K_0(\text{Coh}(\mathcal{M}^\theta(v))) \to H^*(\mathcal{M}^\theta(v)) \]

8.2.1 Results of Nakajima

In [58], Nakajima has proved the following results.

**Proposition 8.3** Let \( \theta, \theta' \) be generic stability conditions. Then the Chern character maps

\[ K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \to H_*(\mathcal{M}^\theta(v)), \quad K_0(\text{Coh}(\mathcal{M}^\theta(v))) \to H^*(\mathcal{M}^\theta(v)) \]

are isomorphisms.

This follows from [58, Theorem 7.3.5] and the discussion in the beginning of [58, Section 7.1].

The assignment

\[(M, N) \mapsto \sum_{i=0}^{\infty} (-1)^i \dim \text{Ext}^i(M, N), \quad M \in \text{Coh}(\mathcal{M}^\theta(v)), \quad N \in \text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))\]

descends to a pairing

\[ \langle \cdot, \cdot \rangle : K_0(\text{Coh}(\mathcal{M}^\theta(v))) \times K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \to \mathbb{C}. \quad (8.6) \]

**Proposition 8.4** (Theorem 7.4.1 in [58]) The pairing \( \langle \cdot, \cdot \rangle \) is non-degenerate.

8.2.2 Alternative identifications of \( K_0' \)’s

Note that the results quoted in Sect. 2.1.8 together with Proposition 8.3 give rise to identifications

\[ K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \sim K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^{\theta'}(v))), \quad K_0(\text{Coh}(\mathcal{M}^\theta(v))) \]

\[ \sim K_0(\text{Coh}(\mathcal{M}^{\theta'}(v))). \]

We will call them the *Nakajima isomorphisms*. We will need an alternative description of these identifications.

Recall that we have tilting generators \( \mathcal{P}^? \) on \( \mathcal{M}^? (v) \) (? is \( \theta, \theta' \)) with naturally identified endomorphism algebras, Proposition 7.1. Set \( \tilde{A} := \text{End}(\mathcal{P}^?)^{opp} \).

This algebra has a central subalgebra \( \mathbb{C}[\mathcal{M}(v)] \) so we can consider the category \( \tilde{A} \)-mod\(_0\) of all finite dimensional \( \tilde{A} \)-modules supported at \( 0 \in \mathcal{M}(v) \).

\[ \odot \] Springer
By [12, Section 2.2], the functor $R \text{Hom}(\mathcal{P}^?, \bullet)$ is an equivalence $D^b(\text{Coh}(\mathcal{M}^3(v))) \xrightarrow{\sim} D^b(\tilde{A} \text{-mod})$. This gives an identification $K_0(\text{Coh}(\mathcal{M}^3(v))) \xrightarrow{\sim} K_0(\tilde{A} \text{-mod})$. Moreover, the functor $R \text{Hom}(\mathcal{P}^?, \bullet)$ restricts to an equivalence $D^b_{\rho^{-1}(0)}(\text{Coh}(\mathcal{M}^3(v))) \xrightarrow{\sim} D^b_0(\tilde{A} \text{-mod})$. This gives an identification $K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^3(v))) \xrightarrow{\sim} K_0(\tilde{A} \text{-mod})_0)$. We will use the composite identification $K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^3(v))) \xrightarrow{\sim} K_0(\tilde{A} \text{-mod})_0)$. We will call the resulting isomorphisms $K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^{\theta}(v))) \xrightarrow{\sim} K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^{\theta'}(v)))$ the tilting isomorphisms.

### 8.2.3 Identifications via deformations

We are going to give one more characterization of the tilting isomorphism and use this characterization to show that the tilting isomorphisms are the same as the Nakajima isomorphisms.

Note that $\tilde{A}$ is a graded (with respect to the contracting $\mathbb{C}^\times$-action) algebra of finite homological dimension. Then we have the following classical result.

**Lemma 8.5** Let $\tilde{A}$ be a filtered deformation of $\tilde{A}$. Then the degeneration map $K_0(\tilde{A} \text{-mod}) \rightarrow K_0(\tilde{A} \text{-mod})$, $[M] \mapsto [\text{gr } M]$, is an isomorphism. The inverse sends the class $[\tilde{A}e_i]$ of an indecomposable projective module to the class of its unique deformation.

Now let us consider the graded $\mathbb{C}[p]$-algebra $\tilde{A}_p = \text{End}(\mathcal{P}_p^{\theta})^{opp}$. It is independent of $\theta$ by Proposition 7.6 and its specialization at $0 \in p$ coincides with $\tilde{A}$. Let $\tilde{A}_p$ denote the specialization of $\tilde{A}_p$ to $p \in p$. The grading on $\tilde{A}_p$ gives rise to a filtration on $\tilde{A}_p$ so that $\text{gr } \tilde{A}_p = \tilde{A}$. For $p$ generic, we have an equivalence $R \text{Hom}(\mathcal{P}_p^{\theta}, \bullet) : D^b(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \xrightarrow{\sim} D^b(\tilde{A}_p \text{-mod})$ that is independent of $\theta$ because, by Remark 7.7, $\mathcal{P}_p^{\theta}$ is. We also have the degeneration map $K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \rightarrow K_0(\text{Coh}(\mathcal{M}^{\theta'}(v)))$.

**Lemma 8.6** The following diagram is commutative.
In particular, $K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \to K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod})$.

Proof Note that $\mathcal{P}^\theta = \text{gr} \mathcal{P}_p^\theta$ (here we view $\mathcal{P}_p^\theta$ as a filtered sheaf on $\mathcal{M}^\theta(v)$).

Now pick $M \in \mathbb{C}[\mathcal{M}_p(v)] \text{-mod}$ and equip it with a good filtration so that we can view it as a sheaf on $\mathcal{M}^\theta(v)$ with coherent associated graded. It follows that we have the following equality in $K_0(\tilde{A} \text{-mod})$:

$$\sum_i (-1)^i [\text{Ext}^i(P^\theta, \text{gr} M)] = \sum_i (-1)^i [\text{gr Ext}^i(P^\theta, M)]$$

The left hand side is the image of $[M]$ under $K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \to K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \to K_0(\tilde{A} \text{-mod})$, while the right hand side is the image of $[M]$ under $K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \to K_0(\tilde{A} \text{-mod}) \to K_0(\tilde{A} \text{-mod})$.

This finishes the proof.

Corollary 8.7 The following claims are true:

1. The tilting isomorphism $K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \to K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod})$ is the composition

$$K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \to K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \to K_0(\tilde{A} \text{-mod})$$

2. The Chern character maps intertwine the tilting isomorphism

$$K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \to K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod})$$

and the isomorphism

$$H^*(\mathcal{M}^\theta(v)) \to H^*(\mathcal{M}^\theta(v))$$

from 2.1.8.
Proof (1) is a direct corollary of Lemma 8.6. (2) reduces to checking that the Chern character maps intertwine the degeneration maps $K_0(\mathbb{C}[\mathcal{M}_p(v)] \text{-mod}) \rightarrow K_0(\text{Coh}(\mathcal{M}^\theta(v)))$ and $H^*(\mathcal{M}_p(v)) \rightarrow H^*(\mathcal{M}^\theta(v))$, which is a standard property of the Chern character maps (Chern characters commute with specialization).

\[\Box\]

8.3 $\mathcal{WC}$ vs degeneration to $K_0(\text{Coh})$

According to the previous section we have the identifications $K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^{\theta'}(v)))$ for different generic $\theta, \theta'$.

Let $\lambda$ be such that $A_\lambda(v)$ has finite homological dimension. Then we have the identification

\[\text{[L Loc}_\lambda^\theta]: K_0(A_\lambda(v) \text{-mod}) \rightarrow K_0(A_\lambda(v) \text{-mod}_{\rho^{-1}(0)})\]

and the degeneration map

\[K_0(A_\lambda(v) \text{-mod}_{\rho^{-1}(0)}) \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))).\]

Consider the composed map

\[K_0(A_\lambda(v) \text{-mod}) \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))).\]

**Proposition 8.8** The identification $K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^{\theta'}(v)))$ intertwines the maps from $K_0(A_\lambda(v) \text{-mod})$.

Note that Propositions 8.3, 8.8 imply (1) of Proposition 6.3. (2) of Proposition 6.3 follows as well because of the formula

\[\mathcal{WC}_{\theta' \rightarrow \theta} \cong \mathcal{T}_{\lambda',\chi} \circ L \text{ Loc}_\lambda^\theta \circ R \Gamma_{\lambda'}^{\theta'}\]

and the observation that $\mathcal{T}_{\lambda',\chi}$ does not change the characteristic cycle.

The proof of Proposition 8.8 occupies the rest of the section.

8.3.1 Algebras $\tilde{A}_\lambda$

Consider the vector bundle $\mathcal{P}_p^\theta$ on $\mathcal{M}_p^\theta(v)$. It has trivial self-extensions and therefore quantizes to a left $A_\lambda^p(v)$-module to be denoted by $\mathcal{P}_p^\theta$. Set $\tilde{A}_p^\mathfrak{P}(v) := \text{End}(\mathcal{P}_p^\theta)^{opp}$. This is a filtered $\mathbb{C}[\mathfrak{P}]$-algebra with $\text{gr} \tilde{A}_p^\mathfrak{P}(v) = \tilde{A}_p$.

**Lemma 8.9** $\tilde{A}_p^\mathfrak{P}(v)$ does not depend on $\theta$. 
Proof Indeed, \( \mathcal{P}_{\mathfrak{P}}^0 | M_p(v)_{reg} \) is a filtered deformation of \( \mathcal{P}_{\mathfrak{P}}^0 | M_p(v)_{reg} \), unique because the latter bundle has zero 1st self-extensions (see Remark 7.7). By the same remark, \( \mathcal{P}_{\mathfrak{P}}^0 | M_p(v)_{reg} = \mathcal{P}_{\mathfrak{P}}^0 | M_p(v)_{reg} \). So \( \mathcal{P}_{\mathfrak{P}}^0 | M_p(v)_{reg} = \mathcal{P}_{\mathfrak{P}}^0 | M_p(v)_{reg} \). By the same arguments as in Step 1 of Proposition 7.6 and in the proof of Proposition 3.3, we see that \( \text{End}(\mathcal{P}_{\mathfrak{P}}^0) = \text{End}(\mathcal{P}_{\mathfrak{P}}^0 | M_p(v)_{reg}) \). This finishes the proof. \( \square \)

8.3.2 Equivalence \( D^b(\mathcal{A}_\lambda(v) - \text{mod}) \sim D^b(\tilde{\mathcal{A}}_\lambda(v) - \text{mod}) \)

Let \( \mathcal{P}_\lambda^0, \tilde{\mathcal{A}}_\lambda(v) \) be the specializations of \( \mathcal{P}_\lambda^0, \tilde{\mathcal{A}}_\lambda(v) \) at \( \lambda \in \mathfrak{P} \). So we have a functor \( R \text{Hom}(\mathcal{P}_\lambda^0, \bullet) : D^b(\mathcal{A}_\lambda^0(v) - \text{mod}) \to D^b(\tilde{\mathcal{A}}_\lambda(v) - \text{mod}) \). Recall that \( \text{gr} \mathcal{P}_\lambda^0 = \mathcal{P}_\lambda^0 \) and that \( R \text{Hom}(\mathcal{P}_\lambda^0, \bullet) \) is an equivalence. Arguing as in [33, Section 5], we deduce that \( R \text{Hom}(\mathcal{P}_\lambda^0, \bullet) \) is an equivalence. By the construction, the functor \( R \text{Hom}(\mathcal{P}_\lambda^0, \bullet) \) restricts to an equivalence \( D^b_{\rho^{-1}(0)}(\mathcal{A}_\lambda^0(v) - \text{mod}) \to D^b_{fin}(\tilde{\mathcal{A}}_\lambda(v) - \text{mod}) \).

The composition \( R \text{Hom}(\mathcal{P}_\lambda^0, L \text{Loc}_\lambda^0(\bullet)) \) is an equivalence \( D^b(\mathcal{A}_\lambda(v) - \text{mod}) \sim D^b(\tilde{\mathcal{A}}_\lambda(v) - \text{mod}) \) to be denoted by \( \kappa^{(\theta)} \). The equivalence \( \kappa^{(\theta)} \) restricts to \( D^b_{fin}(\mathcal{A}_\lambda(v) - \text{mod}) \sim D^b_{fin}(\tilde{\mathcal{A}}_\lambda(v) - \text{mod}) \). Note that the equivalence \( \kappa^{(\theta)} \) is given by \( R \text{Hom}_\mathcal{A}_\lambda(v)(\mathcal{B}_\lambda^{(\theta)}, \bullet) \), where

\[
\mathcal{B}_\lambda^{(\theta)} := R\Gamma((\mathcal{P}_\lambda^0)^*) \in D^b(\mathcal{A}_\lambda(v) - \tilde{\mathcal{A}}_\lambda(v) - \text{bimod}).
\]

Below we will prove that, for \( M \in \mathcal{A}_\lambda(v) - \text{mod}_{fin} \), the class \( [\kappa^{(\theta)}(M)] \in K_0(\tilde{\mathcal{A}}_\lambda(v) - \text{mod}_{fin}) \) is independent of \( \theta \) and use this independence to prove Proposition 8.8.

8.3.3 Harish–Chandra bimodules

In the proof of the independence below we will need the notions of Harish–Chandra \( \mathcal{A}_\lambda(v) - \tilde{\mathcal{A}}_\lambda(v) \) and \( \mathcal{A}_\mathfrak{P}(v) - \tilde{\mathcal{A}}_\mathfrak{P}(v) \)-bimodules.

Recall that \( \mathbb{C}[[\mathcal{M}(v)]] \) sits as a central subalgebra in \( \tilde{\mathcal{A}}_\lambda(v) \). We say that a \( \mathcal{A}_\lambda(v) - \tilde{\mathcal{A}}_\lambda(v) \)-bimodule \( \mathcal{B} \) is HC if it admits a good filtration, i.e., a bimodule filtration such that \( \text{gr} \mathcal{B} \) is a finitely generated \( \mathbb{C}[[\mathcal{M}(v)]] \)-module (meaning, in particular, that the left action of \( \mathbb{C}[[\mathcal{M}(v)]] \) coincides with the right action). In particular, \( H^j(\mathcal{B}_\lambda^{(\theta)}) \) are HC for all \( j \), compare to 3.1.4.

By [47, Theorem 1.3], the regular \( \mathcal{A}_\lambda(v) \)-bimodule has finite length. Then we argue as in the proof of [47, Theorem 1.2] to show that every HC \( \mathcal{A}_\lambda(v) - \tilde{\mathcal{A}}_\lambda(v) \)-bimodule has finite length.

Now consider \( \mathcal{A}_\mathfrak{P}(v) - \tilde{\mathcal{A}}_\mathfrak{P}(v) \)-bimodules. We filter the algebras \( \mathcal{A}_\mathfrak{P}(v) \), \( \tilde{\mathcal{A}}_\mathfrak{P}(v) \) as in the proof of Lemma 3.5 so that \( \mathbb{C}[\mathfrak{P}] \) is in degree 0. Then we
can define HC bimodules the same way as in the previous paragraph. We can define HC bimodules over \( A_S(v) := S \otimes_{C[\mathfrak{P}]} A_{\mathfrak{P}}(v) \), \( \tilde{A}_S(v) \) for any quotient \( S \) of \( C[\mathfrak{P}] \).

Let us give an example of a HC \( A_{\mathfrak{P}}(v)-\tilde{A}_{\mathfrak{P}}(v)-\)bimodule. Set \( B_{\mathfrak{P}}(\theta) := R\Gamma((P^\theta)^*) \). So we get \( A_{\mathfrak{P}}(v)-\tilde{A}_{\mathfrak{P}}(v)-\)bimodules \( H^j(B_{\mathfrak{P}}(\theta)) \).

**Lemma 8.10** All \( H^j(B_{\mathfrak{P}}(\theta)) \) are HC bimodules.

**Proof** Note that the sheaf \( P^\theta \) acquires a filtration similar to those on \( \tilde{A}_{\mathfrak{P}}(v) \), \( A_{\mathfrak{P}}(v) \) we currently consider. We have \( \text{gr} P^\theta = C[\mathfrak{P}] \otimes P^\theta \). Now we argue as in the proof of [18, Theorem 6.5] (see also Proposition 3.3) and complete the proof of the lemma. \( \square \)

### 8.3.4 \( K_0 \)-class of \( B_{\lambda}(\theta) \) is independent of \( \theta \)

Consider \( B_{\mathfrak{P}}(\theta) \in D^b(A_{\mathfrak{P}}(v)-\tilde{A}_{\mathfrak{P}}(v)-\)bimod), by Lemma 8.10, this is an object with Harish–Chandra cohomology. Note that \( B_{\lambda}(\theta) = C_{\lambda} \otimes L_{C[\mathfrak{P}]} B_{\mathfrak{P}}(\theta) \). We will need the following lemma.

**Lemma 8.11** Let \( A_{\lambda}(v) \) have finite homological dimension. The class of \( B_{\lambda}(\theta) \) in \( K_0(\text{HC}(A_{\lambda}(v)-\tilde{A}_{\lambda}(v))) \) is independent of \( \theta \).

**Proof** First, let us show that

- the \( A_{\mathfrak{P}}(v)-\tilde{A}_{\mathfrak{P}}(v)-\)bimodule \( H^0(B_{\mathfrak{P}}(\theta)) \) is independent of \( \theta \),
- the higher cohomology are torsion over \( \mathfrak{P} \).

The claim about \( H^0 \) follows from the fact that \( P^\theta_{\mathfrak{P}}|_{M_{\mathfrak{P}}(v)_{\text{reg}}} \) is independent of \( \theta \), see the proof of Lemma 8.9. Let us prove that the higher cohomology are torsion. Note that \( H^i(B_{\mathfrak{P}}(\theta)) \) is a finitely generated \( A_{\mathfrak{P}}(v) \)-module. By Lemma 3.5, \( \text{Supp}_{\mathfrak{P}}(H^i(B_{\mathfrak{P}}(\theta))) \) is a constructible subset of \( \mathfrak{P} \). If \( H^i(B_{\mathfrak{P}}(\theta)) \) is not torsion, then \( \text{Supp}_{\mathfrak{P}}(H^i(B_{\mathfrak{P}}(\theta))) \) contains a principal Zariski open subset \( \mathfrak{P}^0 \subset \mathfrak{P} \). We may assume that all \( C[\mathfrak{P}^0] \otimes C[\mathfrak{P}] H^j(B_{\mathfrak{P}}(\theta)) \) are free over \( C[\mathfrak{P}^0] \).

It follows that for \( \lambda \in \mathfrak{P}^0 \), we have \( H^j(B_{\lambda}(\theta)) = H^j(B_{\mathfrak{P}}(\theta)) \). On the other hand, \( H^j(B_{\lambda}(\theta)) = 0 \) for \( j > 0 \) if \( (\lambda, \theta) \in \mathfrak{A}\mathfrak{L}(v) \). By Proposition 4.2, the set of \( \lambda \in \mathfrak{P} \) such that \( (\lambda, \theta) \in \mathfrak{A}\mathfrak{L}(v) \) is Zariski dense. We arrive at a contradiction with \( \mathfrak{P}^0 \subset \text{Supp}_{\mathfrak{P}}(H^i(B_{\mathfrak{P}}(\theta))) \) that finishes the proof of the claim in the previous paragraph.

Now the class \([B_{\lambda}(\theta)]\) equals

\[
\sum_{i=0}^{\infty} (-1)^i [C_{\lambda} \otimes L_{C[\mathfrak{P}]} H^i(B_{\mathfrak{P}}(\theta))].
\]
The summand with \( i = 0 \) is independent of \( \theta \) because \( H^0(B_{\mathbb{P}}) \) is. The other summands are zero because \( H^i(B_{\mathbb{P}}) \) are torsion over \( \mathbb{C}[\mathbb{P}] \). \( \square \)

### 8.3.5 Completion of the proof

**Proof of Proposition 8.8** First of all, note that for any \( B \in D^b_{HC}(A_\lambda(v) - \tilde{A}_\lambda(v) \text{-bimod}) \), the functor \( R \text{Hom}(B, \bullet) \) restricts to \( D^b_{fin}(A_\lambda(v) \text{-mod}) \to D^b_{fin}(\tilde{A}_\lambda(v) \text{-mod}) \). This gives rise to a bilinear map

\[
K_0(HC(A_\lambda(v) - \tilde{A}_\lambda(v))) \otimes K_0(A_\lambda(v) \text{-mod}_{fin}) \to K_0(\tilde{A}_\lambda(v) \text{-mod}_{fin}).
\]

By Lemma 8.11, \([k(\theta)(M)] \in K_0(\tilde{A}_\lambda(v) \text{-mod}_{fin})\) depends only on \([M] \in K_0(A_\lambda(v) \text{-mod}_{fin})\).

Similarly to the proof of Lemma 8.6, we see that the following diagram commutes. The horizontal arrows are the degeneration maps, and the vertical ones come from derived equivalences.

\[
\begin{array}{ccc}
K_0(\tilde{A}_\lambda(v) \text{-mod}_{fin}) & \to & K_0(\tilde{A} \text{-mod_0}) \\
\downarrow & & \downarrow \\
K_0(A_\lambda^0(v) \text{-mod}_{\rho^{-1}(0)}) & \to & K_0(\text{Coh}_{\rho^{-1}(0)}(M^\theta(v)))
\end{array}
\]

So the image of \([L \text{Loc}_\lambda^\theta(M)] \in K_0(\text{Coh}_{\rho^{-1}(0)}(M^\theta(v)))\) is also independent of \( \theta \). This completes the proof. \( \square \)

**Remark 8.12** For similar reasons, \([L \text{Loc}_\lambda^\theta(M)] \in K_0(A_\lambda^0(v) \text{-mod})\) is independent of \( \theta \) for \( M \in A_\lambda(v) \text{-mod} \).

For later applications let us note that we also have a well-defined map

\[
K_0(HC(A_\lambda(v) - \tilde{A}_\lambda(v))) \otimes K_0(A_\lambda(v) \text{-mod}) \to K_0(\tilde{A}_\lambda(v) \text{-mod}).
\]

### 8.4 Actions on \( K_0 \)

In this section we will produce an action of the Lie algebra \( \mathfrak{a} \) on \( \bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(M^\theta(v))) \) and show that, after a suitable modification, degeneration maps \( A_\lambda^0(v) \text{-mod}_{\rho^{-1}(0)} \to K_0(\text{Coh}_{\rho^{-1}(0)}(M^\theta(v))) \) intertwine \([E_\alpha] \) with \( e_\alpha \) and \([F_\alpha] \) with \( f_\alpha \). This will imply Proposition 6.1.

Let us produce an identification \( K_0(A_\lambda^0(v) \text{-mod}) \iso K_0(\text{Coh}(M^\theta(v))) \). Note that the element \([O(\chi)] \) of the algebra \( K_0(\text{Coh}(M^\theta(v))) \) is unipotent.
for any \( \chi \in \mathbb{Z}^Q_0 \): for any variety the operator of multiplication by the class of any line bundle is unipotent. So, as the class in \( K_0[O(\lambda)] \) makes sense for any \( \lambda \in \mathbb{C}^Q_0 \). We identify \( K_0(A^\theta(\lambda_\chi)(v) - \text{mod}) \) with \( K_0(\text{Coh}(\mathcal{M}^\theta(\lambda_\chi)(v))) \) by \([M] \mapsto [O(\theta(v) - \lambda) \otimes \text{gr } M]\). We note that this identification is independent of the choice of the orientation on \( Q \): when we change the orientation we also shift \( \lambda \) by the difference of the \( \varrho \)-vectors and in this sense \( \varrho(v) - \lambda \) is independent of the choice of the filtration. Also the classes of shift functors \( T_{\lambda, \chi} \) from Sect. 5.1.1 are sent to the identity. We modify the degeneration maps \( K_0(A^\theta(\lambda_\chi)(v) - \text{mod})_{\rho^{-1}(0)} \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(\lambda_\chi)(v))) \) in a similar fashion so that our identifications intertwine the natural maps

\[
K_0(A^\theta(\lambda_\chi)(v) - \text{mod})_{\rho^{-1}(0)} \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(\lambda_\chi)(v))) \rightarrow K_0(\text{Coh}(\mathcal{M}^\theta(\lambda_\chi)(v)))^*.
\]

Recall that the algebra \( g(Q) \) acts on \( \bigoplus_v \text{D}^b(A^\theta(\lambda_\chi)(v) - \text{mod}) \) for \( \lambda \in \mathbb{Z}^Q_0 \) and \( \theta_i > 0 \) for all \( i > 0 \), see [63]. Now we define an action of \( g(Q) \) on \( K_0(\text{Coh}(\mathcal{M}^\theta(\lambda_\chi)(v))) \) from the identification \( \bigoplus_v K_0(\text{Coh}(\mathcal{M}^\theta(\lambda_\chi)(v))) \simeq \bigoplus_v K_0(A^\theta(\lambda_\chi)(v) - \text{mod}) \). And then we define a \( g(Q) \)-action on \( \bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(\lambda_\chi)(v))) \). We note that this identification is independent of the choice of filtration. Also the classes of shift functors \( T_{\lambda, \chi} \) from Sect. 5.1.1 are sent to the identity. We modify the degeneration maps \( K_0(A^\theta(\lambda_\chi)(v) - \text{mod})_{\rho^{-1}(0)} \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(\lambda_\chi)(v))) \) in a similar fashion so that our identifications intertwine the natural maps.

Here \( \epsilon \) is the operator that acts by \((-1)^{v_i} \) on the \( v \)-weight space. It is straightforward to check that these operators indeed define a \( g(Q) \)-action.

**Proposition 8.13** There is a choice of Serre generators \( e_\alpha, f_\alpha \in a, \alpha \in \Pi^\theta \), such that the modified degeneration map \( \bigoplus_v K_0(A^\theta(\lambda_\chi)(v) - \text{mod})_{\rho^{-1}(0)} \rightarrow \bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(\lambda_\chi)(v))) \) intertwines \([E_\alpha] \) with \( e_\alpha \) and \([F_\alpha] \) with \( f_\alpha \).

**Proof** First note that \([E_\alpha], [F_\alpha] \) are independent of \( \lambda \), this can be deduced from Remark 5.5 and our identification of \( K_0 \)'s. From Proposition 8.8 and our identifications of \( K_0 \)'s it follows that the wall-crossing functors are the identity on the \( K_0 \) level. By Theorem 6.2, we have \([\Theta_i] = [s_i] \). Note that \([\Theta_i] \) on \( K_0(A^\theta(\lambda_\chi)(v) - \text{mod}) \) equals \( s_i \), where \( s_i \) stands for the action of image of \( \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \in \text{SL}_2(\mathbb{C}) \) on \( \bigoplus_v K_0(A^\theta(\lambda_\chi)(v) - \text{mod}) \). Now, for \( \alpha \in \Pi^\theta \), set \( e_\alpha = \sigma(e_i), f_\alpha = \sigma(f_i) \) if \( \alpha = \sigma \alpha^i \). By the definition of the functors \( E_\alpha, F_\alpha \), we see that \([F_\alpha] = f_\alpha, [E_\alpha] = e_\alpha \) on \( \bigoplus_v K_0(A^\theta(\lambda_\chi)(v) - \text{mod}) \). But we have an isomorphism \( \bigoplus_v K_0(A^\theta(\lambda_\chi)(v) - \text{mod})^* \rightarrow \bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(\lambda_\chi)(v))) \) that intertwines the natural map

\[
K_0(A^\theta(\lambda_\chi)(v) - \text{mod})_{\rho^{-1}(0)} \rightarrow K_0(A^\theta(\lambda_\chi)(v) - \text{mod})^*.
\]
with the modified degeneration map

\[ K_0(A^\theta_\lambda(v) \text{-mod}_{\rho^{-1}(0)}) \rightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))). \]

The isomorphism intertwines \( e_\alpha \) with \( f_\alpha^* \) and \( f_\alpha \) with \( e_\alpha^* \). On the other hand, the map

\[ \bigoplus_v K_0(A^\theta_\lambda(v) \text{-mod}_{\rho^{-1}(0)}) \rightarrow \bigoplus_v K_0(A^\theta_\lambda(v) \text{-mod})^* \]

intertwines \([E_\alpha]\) with \( \epsilon_\alpha[F_\alpha]^* \) and \([F_\alpha]\) with \( \epsilon_\alpha[E_\alpha]^* \), where \( \epsilon_\alpha \) acts by \((-1)^{\nu(h_\alpha)}\) on the \( \nu \)-weight space, because of the adjointness properties of the functors \( E_\alpha, F_\alpha \), see (5.7) for the basic case of adjointness. So it follows that the modified degeneration map \( \bigoplus_v K_0(A^\theta_\lambda(v) \text{-mod}_{\rho^{-1}(0)}) \rightarrow \bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(\mathcal{M}^\theta(v))) \) intertwines \([E_\alpha]\) with \( e_\alpha \) and \([F_\alpha]\) with \( f_\alpha \). This finishes the proof. \( \square \)

**Proof of Proposition 6.1** The equality \([\Theta_i] = [s_i^*]\) from the proof of Proposition 8.13 implies \( CC(\Theta_i) = s_i \). Using this and (2) of Lemma 5.7 we deduce \( CC(E_\alpha) = e_\alpha, CC(F_\alpha) = f_\alpha \) similarly to the proof of Proposition 8.13. \( \square \)

9 Long wall-crossing and dimension of support

In this section we prove Proposition 6.5. A key ingredient is a comparison of the long wall-crossing functor to the homological duality functor. Then we mention some further properties of long wall-crossing bimodules and finish the proof of (2) of Proposition 4.3. Throughout the section we assume that \( Q \) has finite and affine type. By Proposition 4.1, this insures that \( R\Gamma^\theta_\lambda \) is a derived equivalence for all \( \theta \) if and only if \( A_\lambda(v) \) has finite homological dimension.

9.1 Homological duality

Assume that \( A_\lambda(v) \) has finite homological dimension. By homological duality functors we mean the functors

\[ D : D^b(A_\lambda(v) \text{-mod}) \sim D^b(A_\lambda(v)^{\text{opp}} \text{-mod})^{\text{opp}}, \]

\[ D^{-\theta} : D^b(A_{\lambda^{-\theta}}(v) \text{-mod}) \sim D^b(A_{\lambda^{-\theta}}(v)^{\text{opp}} \text{-mod})^{\text{opp}} \]

given by

\[ \text{RHom}_{A_\lambda(v)}(\bullet, A_\lambda(v))[-N], \text{RHom}_{A_{\lambda^{-\theta}}(v)}(\bullet, A_{\lambda^{-\theta}}(v))[-N], \]

\( \square \) Springer
where \( N := \frac{1}{2} \dim \mathcal{M}(v) \). Since \( R\Gamma^{-\theta}_\lambda \) is a derived equivalence mapping \( \mathcal{A}_\lambda^{\theta}(v) \) to \( \mathcal{A}_\lambda(v) \), the following diagram is commutative.

\[
\begin{array}{ccc}
D^b(\mathcal{A}_\lambda^{\theta}(v) \text{-mod}) & \xrightarrow{D^{-\theta}} & D^b(\mathcal{A}_\lambda^{\theta}(v) \text{opp} \text{-mod}) \text{opp} \\
\bigg\downarrow \scriptstyle{R\Gamma^{-\theta}_\lambda} & & \bigg\downarrow \scriptstyle{R\Gamma^{-\theta}_\lambda, \text{opp}} \\
D^b(\mathcal{A}_\lambda(v) \text{-mod}) & \xrightarrow{D} & D^b(\mathcal{A}_\lambda(v) \text{opp} \text{-mod}) \text{opp}
\end{array}
\]

Here \( R\Gamma^{-\theta}_{\lambda, \text{opp}} \) stands for the derived global section functor for right modules.

**Lemma 9.1** The functor \( D^{-\theta} \) gives a contravariant abelian equivalence between the categories of holonomic \( \mathcal{A}_{\lambda}^{-\theta}(v) \)- and \( \mathcal{A}_{\lambda}^{-\theta}(v) \text{opp} \)-modules.

**Proof** The claim boils down to checking that if \( N \) is a holonomic \( \mathcal{A}_{\lambda}^{-\theta}(v) \)-module, then \( \mathcal{E}xt^i(N, \mathcal{A}_{\lambda}^{-\theta}(v)) = 0 \) whenever \( i \neq N \). By the standard commutative algebra, see, e.g., [25, Proposition 18.4], we see that \( \mathcal{E}xt^i(\text{gr } N, \mathcal{O}_{\mathcal{M}^{-\theta}(v)}) \neq 0 \) implies \( i \geq N \). Moreover, if \( i > N \), then the support of \( \mathcal{E}xt^i(\text{gr } N, \mathcal{O}_{\mathcal{M}^{-\theta}(v)}) \) has dimension \( < N \). The space \( \mathcal{E}xt^i(N, \mathcal{A}_{\lambda}^{-\theta}(v)) \) has a natural filtration with \( \text{gr } \mathcal{E}xt^i(N, \mathcal{A}_{\lambda}^{-\theta}(v)) \) being a subquotient of \( \mathcal{E}xt^i(\text{gr } N, \mathcal{O}_{\mathcal{M}^{-\theta}(v)}) \). Since the filtration is separated, we see that \( \mathcal{E}xt^i(N, \mathcal{A}_{\lambda}^{-\theta}(v)) = 0 \) for \( i < N \) and

\[
\dim \text{Supp} \mathcal{E}xt^i(N, \mathcal{A}_{\lambda}^{-\theta}(v)) < N
\]

for \( i > N \). Since the support of any coherent \( \mathcal{A}_{\lambda}^{-\theta}(v) \text{opp} \)-module is coisotropic, see Section 2.4, it cannot have dimension less than \( N \) and we are done. \( \square \)

Now consider the functor \( D \) for the categories of \( \mathcal{A}_\lambda(v) \)-modules.

**Lemma 9.2** Let \( N \) be a simple holonomic \( \mathcal{A}_\lambda(v) \)-module. Then the following claims are true

1. \( H^i(DN) = 0 \) for \( i < N - \dim \text{Supp } N \) or \( i > N \).
2. \( H^i(DN) \) is a nonzero module with support of dimension \( \dim \text{Supp } N \) when \( i = N - \dim \text{Supp } N \).

**Proof** The algebra \( \mathbb{C}[\mathcal{M}(v)] \) is Cohen–Macaulay, see Corollary 2.4. Then [25, Proposition 18.4] implies that, for a finitely generated \( \mathbb{C}[\mathcal{M}(v)] \)-module \( M \), the minimal number \( r \) such that \( \mathcal{E}xt^r(M, \mathbb{C}[\mathcal{M}(v)]) \neq 0 \) equals \( \dim \mathcal{M}(v) - \dim \text{Supp } M \). Moreover, we have

\[
\dim \text{Supp } \mathcal{E}xt^r(M, \mathbb{C}[\mathcal{M}(v)]) = \dim \text{Supp } M,
\]

\( \square \)
dim \text{Supp} \text{Ext}^i(M, \mathbb{C}[\mathcal{M}(v)]) < \dim \text{Supp} M \text{ for } i > r.

The case $i < N - \dim \text{Supp} \mathcal{N}$ is done similarly to the proof of Lemma 9.1 using the facts quoted in the previous paragraph. To deal with the case of $i > N$ we notice that the homological dimension of $A_{\lambda}(v)$ coincides with that of $A_{\lambda}(v)$ because $\Gamma_{\lambda}^\theta$ is an abelian equivalence. The homological dimension of $A_{\lambda}(v)$ does not exceed that of $\text{Coh} \mathcal{M}(v)$ that equals $2N = \dim \mathcal{M}(v)$. This completes the $i > N$ case.

Let us prove (2). As in the proof of Lemma 9.1, we see that $\dim \text{Supp} H^i(D\mathcal{N}) < N - \dim \text{Supp} \mathcal{N}$ for $i > N - \dim \text{Supp} \mathcal{N}$. Since $D^2 = \text{id}$, the inequality $H^i(D\mathcal{N}) \neq 0$ for $i = N - \dim \text{Supp} \mathcal{N}$ follows.

Now we note that we have an isomorphism $A_{\lambda}(v)^{\text{opp}} = A_{\lambda}(v)$ (the equality of quantizations of $A_{\lambda}(v)$). Here $\lambda^* := 2\varrho(v) - \lambda$. This follows, for example, from [42, Proposition 5.4.4]. So in the above constructions, we can replace $A_{\lambda}(v)^{\text{opp}}$ with $A_{\lambda}(v)$ and $A_{\lambda}(v)$ with $A_{\lambda}(v)^{\text{opp}}$.

### 9.2 Proof of Proposition 6.5

Thanks to Proposition 4.2, replacing $\lambda$ with $\lambda + k\theta$ for $k \gg 0$, we may assume that $(\lambda^*, -\theta) \in \mathfrak{A}_L(v)$ (and still $(\lambda, \theta) \in \mathfrak{A}_L(v)$). Now we have the following commutative diagram.

$$
\begin{array}{ccc}
D^b(A_{\lambda}(v)) & \xrightarrow{R\Gamma_{\lambda}^{\theta}} & D^b(A_{\lambda}(v)) \\
\downarrow \cong & & \downarrow \cong \\
D^b(A_{\lambda}(v)) & \xrightarrow{\mathfrak{M}_{\lambda^*}} & D^b(A_{\lambda}(v))
\end{array}
$$

Here we write $D^b(A_{\lambda}(v))$ for $D^b(A_{\lambda}(v) - \text{mod})$, etc.

The functor $R\Gamma_{\lambda^*}^{\theta} \circ \mathfrak{M}_{\lambda^*}^{\theta}$ is an abelian equivalence $A_{\lambda}(v) - \text{mod} \sim A_{\lambda^*}(v) - \text{mod}$. Both functors $R\Gamma_{\lambda^*}^{\theta}$, $D^{\theta}$ are $t$-exact on $D^b_{\text{hol}}$, so the functor $R\Gamma_{\lambda^*}^{\theta} \circ D^{\theta}$ intertwines the standard $t$-structures on $D^b_{\text{hol}}(A_{\lambda}(v))$, $D^b_{\text{hol}}(A_{\lambda^*}(v))$. So we see that the pull-backs of the $t$-structures on $D^b_{\text{hol}}(A_{\lambda^*}(v))$ and on $D^b_{\text{hol}}(A_{\lambda}(v))$ coincide (with the push-forward of the $t$-structure on $D^b_{\text{hol}}(A_{\lambda}(v))$).

Let us prove (1). Thanks to Lemmas 9.1, 9.2, the functor $D$ homologically shifts a simple $M$ by $N - \dim \text{Supp} M$. Part (1) now follows from the coincidence of the $t$-structures on $D^b_{\text{hol}}(A_{\lambda}(v))$ established in the previous paragraph.
Let us prove part (2). The functor $\mathcal{M}_\lambda \rightarrow \lambda^-$ restricts to a derived equivalence

$$D^b_{fin}(A_\lambda(v)\text{-mod}) \sim D^b_{fin}(A_{\lambda^-}(v)\text{-mod}).$$

By Lemma 9.2, for a finite dimensional module $M$, the only nonzero homology of $\mathcal{M}_\lambda \rightarrow \lambda^-$ $M$ is $H_N$. We are done.

**Remark 9.3** Equip $A_\lambda(v)\text{-mod}_{\text{hol}}$ with a filtration by the dimension of support: let $A_\lambda(v)\text{-mod}_{\text{hol}}^{\leq i}$ consist of all modules whose dimension of support does not exceed $i$. The functor $\mathcal{M}_\lambda \rightarrow \lambda^-$ sends an object of $A_\lambda(v)\text{-mod}_{\text{hol}}^{\leq i}$ to a complex whose homology are in $A_{\lambda^-}(v)\text{-mod}_{\text{hol}}^{\leq i}$. The arguments of the proofs of Lemma 9.2 and Proposition 6.5 imply that the functor $H_i(\mathcal{M}_\lambda \rightarrow \lambda^- \bullet)$ gives rise to an equivalence $A_\lambda(v)\text{-mod}_{\text{hol}}^{\leq i}/A_\lambda(v)\text{-mod}_{\text{hol}}^{\leq i-1} \sim A_{\lambda^-}(v)\text{-mod}_{\text{hol}}^{\leq i}/A_{\lambda^-}(v)\text{-mod}_{\text{hol}}^{\leq i-1}$. In particular, $\mathcal{M}_\lambda \rightarrow \lambda^-$ is a perverse equivalence

$$D^b_{\text{hol}}(A_\lambda(v)\text{-mod}) \rightarrow D^b_{\text{hol}}(A_{\lambda^-}(v)\text{-mod})$$

in the sense of Chuang and Rouquier. See Sect. 11.1 below for a precise definition of a perverse equivalence in the case of derived categories (the general case of triangulated categories is completely analogous, see, e.g., [1]). We do not need this result in the rest of the paper so we do not provide details.

### 9.3 Further results

We will need some further results on long wall-crossing functors. Let $\lambda, \lambda^-, \theta$ have the same meaning as above. We will write $A_{\lambda, \lambda^-}^{(-\theta)}$ for $A_{\lambda \rightarrow \lambda^-}(v)$.

**Lemma 9.4** The long wall-crossing $A_{\lambda^-}(v)\cdot A_{\lambda}(v)$-bimodule $A_{\lambda, \lambda^-}^{(-\theta)}$ is simple.

**Proof** The HC $A_{\lambda^-}^{(-\theta)}\cdot A_{\lambda}^{(-\theta)}(v)$ bimodule $A_{\lambda \rightarrow \lambda^-}^{(-\theta)}(v)$ is simple because its rank equals 1. The categories HC$(A_{\lambda^-}^{(-\theta)}\cdot A_{\lambda}^{(-\theta)}(v))$ (see [18, Section 6.1] for the definition of this category) and HC$(A_{\lambda^-}(v)\cdot A_{\lambda}(v))$ of Harish–Chandra bimodules are equivalent, see [18, Corollary 6.6].

**Remark 9.5** We can consider $A_{\lambda \rightarrow \lambda^-}^{(-\theta)}$ as an $A_{\lambda \rightarrow \lambda^-}^{\text{opp}}\cdot A_{\lambda \rightarrow \lambda^-}^{\text{opp}}$-bimodule. It is straightforward to see that it is still a long wall-crossing bimodule.

### 9.4 Corollaries

Now we are ready to prove (2) of Proposition 4.3. To start with, let us prove a stronger version of Proposition 3.14.
Proposition 9.6  For each indecomposable root $\alpha \leq v$, there is a finite subset $\Sigma_{\alpha} \subset \mathbb{C}$ such that the algebra $A_{\lambda}(v)$ is simple whenever $\langle \alpha, \lambda \rangle \notin \Sigma_{\alpha} + \mathbb{Z}$ for all $\alpha \leq v$.

Proof As in the proof of Proposition 3.14, we will first show that, for each root $\alpha \leq v$, there is a finite subset $\Sigma_{\alpha}(v)$ such that the algebra $A_{\lambda}(v)$ have no finite dimensional representations provided $\langle \lambda, \alpha \rangle \notin \Sigma_{\alpha}(v) + \mathbb{Z}$ for all $\alpha \leq v$.

Step 1. Let us construct $\Sigma_{\alpha}(v)$. Pick a Zariski generic point $p \in \ker \alpha$. The variety $M_p(v)$ has a unique minimal symplectic leaf, compare with Step 2 of the proof of Proposition 5.4. It corresponds to a semisimple representation of the form $r_{\alpha}^0$, where $\dim r_1 = \alpha$ and $k$ is maximal such that $(v - k\alpha, 1)$ is a root of the quiver $Q^w$. So we can form the slice algebras $A_{\bar{\lambda}}(\bar{\lambda}), \hat{A}_{\bar{\lambda}}(\hat{\lambda})$, compare to Step 2 of the proof of Proposition 5.4. The set of $(\lambda, \alpha)$ such that the translation bimodules $A_{\bar{\lambda}}(\bar{\lambda}), 1(\hat{\lambda}), \hat{A}_{\bar{\lambda}}(\hat{\lambda}) + 1(\hat{\lambda})$ are not mutually inverse Morita equivalences between $A_{\bar{\lambda}}(\bar{\lambda})$ and $A_{\bar{\lambda}}(\bar{\lambda}) + 1(\hat{\lambda})$ is finite by Proposition 4.5. We take this set for $\Sigma_{\alpha}(v)$.

Step 2. Let $\theta, \theta'$ be two stability conditions from chambers opposite with respect to $\ker \alpha$. Similarly to the proof of Proposition 5.4 we see that $\mathcal{WC}_{\theta \rightarrow \theta'}$ is an abelian equivalence provided $\langle \lambda, \alpha \rangle \notin \Sigma_{\alpha}(v) + \mathbb{Z}$.

Step 3. Now suppose that $\langle \lambda, \alpha \rangle \notin \Sigma_{\alpha}(v)$ for all indecomposable $\alpha \leq v$. By Theorem 5.3, the long wall-crossing functor $\mathcal{WC}_{\theta \rightarrow -\theta}$ decomposes as a composition of short wall-crossing functors and hence is an abelian equivalence. By Theorem 6.5, the algebra $A_{\lambda}(v)$ has no finite dimensional representations if abelian localization holds for $(\lambda, \theta)$. In general, note that if $L$ is a finite dimensional representation of $A_{\lambda}(v)$, then $L \text{ Loc}_{\bar{\lambda}}^\theta(L)$ is a nonzero object supported on $\rho^{-1}(0)$ (indeed, the functor $R\Gamma$ is a left inverse to $L \text{ Loc}$, both functors are considered between bounded from the right derived categories). It follows that for $n \gg 0$, the algebra $A_{\lambda + n\theta}(v)$ has a finite dimensional representation. This gives a contradiction that completes the proof of the claim that $A_{\lambda}(v)$ has no finite dimensions representations provided $\langle \lambda, \alpha \rangle \notin \Sigma_{\alpha}(v) + \mathbb{Z}$ for all indecomposable $\alpha \leq v$.

Step 4. Similarly to the proof of Proposition 3.14, if all proper slice algebras $\hat{A}_{\bar{\lambda}}(\hat{\lambda})$ have no finite dimensional representations, then the algebra $A_{\lambda}(v)$ is simple. Now recall that $r^{-1}(p^{\text{sing}}) \subset p^{\text{sing}}$, see 2.1.6. Using this we get subsets $\Sigma_{\alpha} \subset \mathbb{C}$ for each indecomposable root $\alpha$ such that the proper slice algebras $\hat{A}_{\bar{\lambda}}(\hat{\lambda})$ have no finite dimensional representations when $\langle \lambda, \alpha \rangle \notin \Sigma_{\alpha} + \mathbb{Z}$. So for such $\lambda$, the algebra $A_{\lambda}(v)$ is simple. □

Proof of (2) of Proposition 4.3 Let $\chi$ be inside of the chamber of $\theta$ and such that

$$H^1(M^\theta(v), \mathcal{O}(\chi)) = H^1(M^{-\theta}(v), \mathcal{O}(-\chi)) = 0.$$
If $\langle \lambda, \alpha \rangle \notin \Sigma_\alpha + \mathbb{Z}$ for any indecomposable root $\alpha$, then the algebras $\mathcal{A}_\lambda(v)$, $\mathcal{A}_{\lambda+\chi}(v)$ are simple. Consider the bimodule homomorphisms

$$
\mathcal{A}_{\lambda,\chi}^0(v) \otimes \mathcal{A}_{\lambda+\chi}(v) \rightarrow \mathcal{A}_\lambda(v),
$$

$$
\mathcal{A}_{\lambda,\chi}^0(v) \otimes \mathcal{A}_{\lambda+\chi,\chi}(v) \rightarrow \mathcal{A}_{\lambda+\chi}(v).
$$

It is enough to show that these maps are isomorphisms. Note that the generic rank of $\text{gr} \mathcal{A}_{\lambda,\chi}^0(v)$ on $\mathcal{M}(v)$ is 1. Indeed, we have $\mathcal{A}_{\lambda,\chi}^0(v) = \mathcal{A}_{\lambda,\chi}^{(\theta)}(v)$ by Proposition 4.6. The generic rank of $\text{gr} \mathcal{A}_{\lambda,\chi}^{(\theta)}(v)$ on $\mathcal{M}(v)^{\text{reg}}$ is 1 by the construction. For similar reasons, the generic rank of $\text{gr} \mathcal{A}_{\lambda+\chi,\chi}^0(v)$ equals 1. So the bimodule homomorphisms above become isomorphisms after microlocalizing to $\mathcal{M}(v)^{\text{reg}}$. Since the algebras $\mathcal{A}_\lambda(v)$, $\mathcal{A}_{\lambda+\chi}(v)$ are simple, we deduce that the bimodule homomorphisms are indeed isomorphisms. 

\section{Finite short wall-crossing}

In this section we investigate various questions related to categorification functors $E_\alpha$, $F_\alpha$, the wall-crossing functor through $\ker \alpha$ and connections between them. In Sect. 10.1 we study the category $\mathcal{C}$ introduced in the beginning of Sect. 6.2. In particular, we show that every simple in $\mathcal{C}$ is \textit{regular holonomic} in a suitable sense. We use this to show that Proposition 6.4 implies (II), while (II) and (III) imply Proposition 6.4. In Sect. 10.2 we study singular objects from 6.2.2 and prove Proposition 6.6.

\subsection{Category $\mathcal{C}$}

Recall that $\mathcal{C} \subset \mathcal{A}_\lambda^0(v) \text{-mod}_{\rho^{-1}(0)}$ is the Serre subcategory spanned by the homology of the objects of the form $\mathcal{F}L_0$, where $\mathcal{F}$ is some monomial in the functors $E_\alpha$, $F_\alpha$ and $L_0 \in \mathcal{A}_\lambda^0(\sigma \bullet w)$ for $\sigma \in W(Q)$ such that $\sigma \omega$ is dominant for $\alpha$.

\subsubsection{Regular holonomic modules}

Let us define \textit{regular holonomic} simples in $\mathcal{A}_\lambda^0(v) \text{-mod}_{\rho^{-1}(0)}$. An object in $\mathcal{A}_\lambda^0(v) \text{-mod}$ is called \textit{regular holonomic} if it is obtained from a regular holonomic $(G, \lambda)$-equivariant $D(R)$-module by applying $\pi_\lambda^0(v)$. Actually, we are not interested in all regular holonomic modules. Recall the torus $T = (\mathbb{C}^\times)^{Q_1} \times (\mathbb{C}^\times)^{Q_0}$ from 2.1.3 acting on $R$. We will consider only weakly $T$-equivariant modules.
It is a standard fact that the category of regular holonomic weakly $T$-equivariant $D$-modules stays the same under changing the orientation of $R$ (partial Fourier transforms preserve weakly $T$-equivariant regular holonomic modules [20]) so the notion of a weakly $T$-equivariant regular holonomic $\mathcal{A}_\lambda^\theta(v)$-module is well-defined.

Lemma 10.1 Let $\lambda' = \sigma \cdot v \lambda$. Under the isomorphism $\mathcal{A}_\lambda^\theta(v) \cong \mathcal{A}_{\lambda'}^{\sigma \theta}(\sigma \cdot v)$, a weakly $T$-equivariant regular holonomic module remains weakly $T$-equivariant regular holonomic.

Proof The part concerning the $T$-action follows from the observation, see 2.2.4, that $\sigma_* : \mathcal{A}_\lambda^\theta(v) \text{-mod} \xrightarrow{\sim} \mathcal{A}_{\lambda'}^{\sigma \theta}(\sigma \cdot v) \text{-mod}$ is $T$-equivariant. It is enough to prove the claim that $s_i^* M$ is regular holonomic for a simple reflection $s_i$ provided $M$ is regular holonomic. Recall that in this case the isomorphism $\mathcal{A}_\lambda^\theta(v) \cong \mathcal{A}_{\lambda'}^{\sigma \theta}(\sigma \cdot v)$ is induced by the isomorphism

$$D_R^{\lambda_i} \text{-mod}_{\lambda_i} \otimes D_R \cong D_R^{\lambda_i'} \text{-mod}_{\lambda_i'} \otimes D_R \cong D_R^{\lambda_i} \text{-mod}_{\lambda_i} \otimes D_R \cong D_R^{\lambda_i'} \text{-mod}_{\lambda_i'} \otimes D_R$$

The former reduction is just $D^\lambda_{\text{Gr}(v_i, \tilde{w}_i)} \otimes D_R$ and so there is an intrinsic notion of a regular holonomic module.

We claim that a simple $D^\lambda_{\text{Gr}(v_i, \tilde{w}_i)} \otimes D_R$-module is regular holonomic if and only if it is obtained from a simple regular holonomic $D(R)$-module under the quotient functor

$$D(R) \text{-mod} \xrightarrow{G, \lambda} D^\lambda_{\text{Gr}(v_i, \tilde{w}_i)} \otimes D_R \text{-mod} G, \lambda.$$ 

Indeed, let $L$ be a simple $(\text{GL}(v_i), \lambda_i)$-equivariant $D$-module on $R$ whose support intersects $R^\ominus_{\text{ss}}$. Then $L$ is regular holonomic if and only if the induced twisted $D$-module on the quotient $R/\theta_i \text{GL}(v_i)$ is regular holonomic. This follows from the classification of simple regular holonomic $D$-modules: those are precisely the intermediate extensions of regular holonomic local systems on smooth locally closed subvarieties, see [14, Theorem 7.10.6, 7.12]. Our claim in the beginning of the paragraph is proved.

Now, under the identifications of $D_R^{\lambda_i} \text{-mod}_{\lambda_i} \otimes D_R$ and $D_R^{\lambda_i'} \text{-mod}_{\lambda_i'} \otimes D_R$, the equivalence induced by (10.1) becomes the identity, this follows from the construction of an isomorphism. We deduce that the equivalence induced by the isomorphism $\mathcal{A}_\lambda^\theta(v) \cong \mathcal{A}_{\lambda'}^{\sigma \theta}(\sigma \cdot v)$ maps regular holonomic modules to regular holonomic ones.

Corollary 10.2 The simples in $C$ are weakly $T$-equivariant regular holonomic.
Proof Let us show first that Webster’s functors $E_i, F_i$ preserve the category of direct sums of semisimple weakly $T$-equivariant regular holonomic $A^0_\lambda(v)$-modules with homological shifts. The functors $E_i, F_i$ on $\bigoplus_v D^b(D^{\lambda_i}_{Gr(v_i, \tilde{w}_i)} \otimes D_R^{-\mod G, \lambda})$ have this property by the construction. By the proof of Lemma 10.1, a simple regular holonomic $A^0_\lambda(v)$-module is an image of such a module from $D^{\lambda_i}_{Gr(v_i, \tilde{w}_i)} \otimes D_R^{-\mod G, \lambda}$ and our claim follows.

Lemma 10.1 and the previous paragraph imply that the functors $E_\alpha, F_\alpha$ preserve semisimple complexes of weakly $T$-equivariant regular holonomic modules when $\alpha \in \Pi^\theta$. Note that a unique indecomposable $A^0_\theta(\sigma \circ w)$-module is weakly $T$-equivariant. So it is enough to check that it is regular holonomic. This is definitely true for $\sigma = 1$ (the space $R$ is zero). For arbitrary $\sigma$, the claim again follows from Lemma 10.1. □

10.1.2 Crystal

Consider the full subcategory $C' \subset D^b(A^0_\lambda(v) - \mod_{\rho^{-1}(0)})$ consisting of all objects $M$ such that $M \cong H_*(M)$ and $H_*(M)$ is a semisimple object of $C$. For $L \in \text{Irr}(C)$, we write $d_\alpha(L)$ for the minimal dimension of an irreducible $\mathfrak{sl}_2$-module in $U(\mathfrak{sl}_2)[L]$ (where we consider the action corresponding to the operators $[E_\alpha], [F_\alpha]$).

Lemma 10.3 The functors $E_\alpha, F_\alpha$ for all $\alpha \in \Pi^\theta$ preserve the subcategory $C' \subset D^b(A^0_\lambda(v) - \mod_{\rho^{-1}(0)})$. Furthermore, we have

$$F_\alpha L = \bigoplus_{i=0}^k \tilde{f}_\alpha L[m + 2i] \oplus \bigoplus_{L', d(L') > d(L)} L'[,?]$$

$$E_\alpha L = \bigoplus_{i=0}^\ell \tilde{e}_\alpha L[n + 2i] \oplus \bigoplus_{L'', d(L'') > d(L)} L''[,?]$$

Here $\tilde{f}_\alpha, \tilde{e}_\alpha$ are maps $\text{Irr}(C) \to \text{Irr}(C) \sqcup \{0\}$ forming a crystal for $\mathfrak{sl}_2$, and $k, m, \ell, n$ are some numbers whose precise values are not important for us.

Proof The claim that the functors $E_\alpha, F_\alpha$ preserve the category $C'$ follows from the proof of Corollary 10.2. So we get a categorical $\mathfrak{sl}_2$-action on the additive category $C'$. [61, Theorem 5.8] applies to this action. It follows that the basis $[L], L \in \text{Irr}(C)$, is a dual perfect basis for the $\mathfrak{sl}_2$-action on $\bigoplus_v K_0(A^0_\lambda(v) - \mod_{\rho^{-1}(0)})$ (meaning that the dual basis in $\bigoplus_v K_0(A^0_\lambda(v) - \mod_{\rho^{-1}(0)})^* \subset \text{Irr}(C)$ is perfect in the sense of Berenstein and Kazhdan, see [6, Section 5]). This gives rise to crystal operators $\tilde{e}_\alpha, \tilde{f}_\alpha$ on $\bigcup_v \text{Irr}(A^0_\lambda(v) - \mod_{\rho^{-1}(0)})$ (10.2) follows. □
Corollary 10.4 We have $\text{CC}(K_0(C)) = L_{\omega}^{a}$.

Proof It is clear from the construction of $C$ and Proposition 6.1 that $L_{\omega}^{a} \subset \text{CC}(K_0(C))$. So let us prove the opposite inclusion. Let $v$ be minimal such that $\text{CC}(K_0(C_v)) \supseteq L_{\omega}^{a}[v]$. Then $v$ is dominant (otherwise $\text{CC}(K_0(C_v)) \subset \sum_{\alpha} \text{im } F_{\alpha}$). Pick $L \in \text{Irr}(K_0(C_v))$ with $\text{CC}(L) \notin L_{\omega}^{a}[v]$ and $\alpha \in \Pi^{\theta}$ such that $d_{\alpha}(L)$ is maximal possible over all such $L$ and $\alpha$. Since $L \in C$, we have $d_{\alpha}(L) > 0$. So if $L' \in \text{Irr}(C)$ satisfies $d_{\alpha}(L') > d_{\alpha}(L)$, then $\text{CC}(L') \in L_{\omega}^{a}$. Apply (10.2) for the functor $F_{\alpha}$ and the simple $\tilde{e}_{\alpha}L$. We see that, by Proposition 6.1, $\text{CC}(F_{\alpha}(\tilde{e}_{\alpha}L)) = f_{\alpha}\text{CC}(\tilde{e}_{\alpha}L)$ lies in $L_{\omega}^{a}$. The characteristic cycles of the objects $L'$ from (10.2) are also in $L_{\omega}^{a}$ by the choice of $\alpha$, $L$. So (10.2) implies $\text{CC}(L) \in L_{\omega}^{a}$.

So, indeed, Proposition 6.4 implies (II) (and is equivalent to (II) modulo (III)).

10.2 Singular simples

Recall that singular simples were defined in Sect. 6.2.2. Let us start with an easy alternative characterization of a singular object.

Lemma 10.5 Let $\alpha \in \Pi^{\theta}$ and $L \in \text{Irr}(\mathcal{A}_{\lambda}^{\theta}(v) - \text{mod}_{P^{-1}(0)})$. Then the following are equivalent.

1. $L$ is $\alpha$-singular.
2. $L \notin \text{im } f_{\alpha}$ if $\langle v, \alpha_{i}^{\vee} \rangle \geq 0$ or $L \notin \text{im } \tilde{e}_{\alpha}$ if $\langle v, \alpha_{i}^{\vee} \rangle \leq 0$.

Proof This follows from (10.2).

Proof of Proposition 6.6 The proof is in several steps. Thanks to the construction of the functors $E_{\alpha}$, $F_{\alpha}$, we may assume that $\alpha = \alpha_{i}^{\gamma}$ and $\theta = \theta^{\pm}$. Recall the quotient functor $\pi : \mathcal{A}_{\lambda_{i}}^{\theta_{i}}(v) - \text{mod} \rightarrow \mathcal{A}_{\lambda_{i}}^{\theta_{i}}(v) - \text{mod}$ from 8.1.1. Let $\tilde{L}$ denote the simple in $\mathcal{A}_{\lambda_{i}}^{\theta_{i}}(v) - \text{mod}$ with $\pi(\tilde{L}) = L$. Note that $L$ is $\alpha$-singular if and only if $\tilde{L}$ is singular (for the Webster functors $E_{i}$, $F_{i}$). If $L_{1}$ is such that, say, $f_{\alpha}L_{1} = L$ and $\tilde{L}_{1}$ is the simple in $\mathcal{A}_{\lambda_{i}}^{\theta_{i}}(v) - \text{mod}$ with $\pi(\tilde{L}_{1}) = L_{1}$, then $f_{\tilde{L}_{1}} = \tilde{L}_{1}$ because $\pi$ intertwines $F_{i}$ with $F_{i}$ and $E_{i}$ with $E_{i}$.

Step 1. Let us prove that (2) implies (1). Assume the contrary: $H_{0}(\mathcal{M}_{\theta \rightarrow \theta'} \cdot L) \neq 0$ but $L$ is not $\alpha$-singular. Then $\tilde{L}$ is not singular. On the other hand, $H_{0}(\mathcal{M}_{\theta \rightarrow \theta'} \cdot \tilde{L}) \neq 0$, this follows from 8.1.2. Since $\tilde{L}$ is holonomic, a direct analog of Proposition 6.5 applies. Thanks to that, we see that the singular support of $\Gamma^{\theta_{i}}_{\lambda_{i}}(\tilde{L})$ intersects the open symplectic leaf in the affinization of $T^{*}\text{Gr}(v_{i}, \tilde{w}_{i}) \times T^{*}R$. Equivalently, the singular support of $\tilde{L}$ intersects $\mathbb{O} \times T^{*}R$, where $\mathbb{O}$ is the open $\text{GL}(\tilde{w}_{i})$-orbit in $T^{*}\text{Gr}(v_{i}, \tilde{w}_{i})$. We claim
that this contradicts the condition that \( \tilde{L} \) is not singular. Indeed, in the sake of being definite, assume \( 2v_i \leq \tilde{w}_i \) so that \( \tilde{L} \in \text{im} \hat{f}_i \). From the construction of the functor \( F_i \), the singular support of \( \tilde{L} \) lies in the image of \( Y \times T^*R \) in \( T^*\text{Gr}(v_i, \tilde{w}_i) \), where we write \( Y \) for the conormal bundle to \( \text{Fl}(v_i - 1, v_i; \tilde{w}_i) \subset \text{Gr}(v_i - 1, \tilde{w}_i) \times \text{Gr}(v_i, \tilde{w}_i) \). But the image of \( Y \) does not intersect \( \emptyset \). Contradiction. This finishes the proof of the implication (2) \( \Rightarrow \) (1).

**Step 2.** Let us prove that (1) implies (2). Here we will use Theorem 6.2 that says that \( s_{i*} \circ \mathcal{MC}_{\theta \to \theta'} = \Theta_i \). So (2) is equivalent to \( H_0(\Theta_i L) \neq 0 \). Below, to simplify the notation, we write \( E, F, \Theta \) for \( E_i, F_i, \Theta_i \).

In the proof we will assume that \( 2v_i \leq \tilde{w}_i \), the other case is similar. Recall, see 8.1.4, that \( \Theta L \) is the iterated cone of

\[
F^{(\ell)} L[-m] \to F^{(\ell+1)} E L[1-m] \to \ldots \to F^{(\ell+m)} E^{(m)} L,
\]

where \( m = v_i, \ell = \tilde{w}_i - 2v_i \). Then \( \Theta^2 L \) is the cone of the double complex with the term in the slot \((i - v_i, j - \tilde{w}_i + v_i)\) of the form \( F^{(i)} E^{(\ell-i)} F^{(\ell+j)} E^{(j)} L[i + j - \tilde{w}_i] \). The terms with \( i > 0 \) do not contain \( L \) in their homology because \( L \) is singular. If \( i = 0, j > 0 \), then we can commute \( E^{(\ell)} \) and \( F^{(\ell+j)} \) using the categorical \( \mathfrak{sl}_2 \)-relations, see, e.g., (iii) in [21, Section 2.2]. We get that these terms do not contain \( L \) either. For the same reason, the \((0, 0)\) term splits into a direct sum of \( L \) and some object that does not contain \( L \) in the homology. The summand \( L \) will contribute to \( H_0 \) of the iterated cone of \( \Theta^2 L \). Now recall that \( L \mapsto \Theta L \) is right \( t \)-exact by Theorem 6.2. Since \( H_0(\Theta^2 L) \neq 0 \), we deduce that \( H_0(\Theta L) \neq 0 \). This finishes the proof of the implication (1) \( \Rightarrow \) (2).

**Step 3.** Let us prove the claim about the singular simples in \( H_*(\mathcal{MC}_\theta \to \theta' L) \): only one occurs as a composition factor and it is a quotient of \( H_0 \). This claim is equivalent to an analogous claim for \( H_*(\mathcal{MC}^i_{\theta \to \theta'} \tilde{L}) \). By Step 1, the singular support of \( \tilde{L} \) contains a point that is stable for \( -\theta_i \). Let \( \pi_+, \pi_- \) be the quotient functors from \( D_R \)-mod\( G, \lambda \) to the quotient categories for the stability conditions \( \theta_i, -\theta_i \). Then \( \mathcal{MC}^i_{\theta \to \theta'} = \pi_+ L \pi_-^! \), see (5.3). Let \( \tilde{L} \) be the simple in \( D(R)\)-mod\( G, \lambda \) such that \( \pi_+ (\tilde{L}) = \tilde{L} \). We see that \( \pi_- (\tilde{L}) \) occurs in \( H_0(\mathcal{MC}_{\theta \to \theta'} (\tilde{L})) \) (as a quotient, in fact, because \( \tilde{L} \) is a quotient of \( \pi_-^! (\tilde{L}) \)). Clearly, the multiplicity is 1. The other composition factors of \( H_j(\mathcal{MC}_{\theta \to \theta'} (\tilde{L})) \) are the images of simples in \( \ker \pi_+ \). So the singular supports do not intersect \( \emptyset \times T^*R \). Reversing the argument of Step 1, we see that these simples are shifted by \( \mathcal{MC} \) and hence by \( \Theta \). By Step 2, they cannot be singular. So we get simples \( \tilde{L}' := \pi_- (\tilde{L}) \in \mathcal{A}_{\lambda_j^\theta} (v) \)-mod and the corresponding simple \( L' \in \mathcal{A}_{\lambda_j^\theta} (v) \)-mod \( \rho_{-1}(0) \). Note that \( \tilde{L}' \) singular by the argument above in this step. So \( L' \) is singular.

© Springer
Step 4. It remains to prove that the map $L \mapsto L'$ is a bijection between the sets of $\alpha$-singular objects. By Step 3, $s_{\alpha} \tilde{L}'$ is the only singular simple constituent of $\bigoplus_i H_i(\Theta \tilde{L})$, it is a quotient of $H_0(\Theta \tilde{L})$. The proof of (2) $\Rightarrow$ (1) implies that $\tilde{L}$ is the only singular constituent of $\bigoplus_i H_i(\Theta(s_{\alpha} \tilde{L}))$. This gives rise to a map from the set of $\alpha$-singular simples in $\mathcal{A}_{\lambda}^0(v)$ $\bmod \rho^{-1}(0)$ to the set of singular simples in $\mathcal{A}_{\lambda}^0(v)$ $\bmod \rho^{-1}(0)$ that is the inverse to $L \mapsto L'$.

11 Affine short wall-crossing

Here we consider the situation when $Q$ is an affine quiver, $v = n\delta$, $w = \epsilon_0$, and $\mathcal{A}_{\lambda}(v) = eH_{\kappa,\epsilon}(n)e$. Let us note that $\mu$ is flat. In this section we study the wall-crossing functor through the wall ker $\delta$ proving in particular that the homological shifts of modules under this functor are less than $n$ and that the functor is a perverse equivalence. The proof in a more general situation is obtained in [49, Section 3] (see also [46, Section 6]).

11.1 Results

Let us introduce some conventions and notation.

Pick a generic stability condition $\theta$ in a classical chamber $C'$ that has ker $\delta$ as a wall. Let $C'$ denote the classical chamber sharing the wall ker $\delta$ with $C$.

We consider a parameter $\lambda^\circ$ such that $(\lambda, \theta) \in \mathcal{A}_c(v)$ for any $\lambda \in \lambda^\circ + (C \cap \mathbb{Z}^Q_0)$, such a parameter exists by (2) of Proposition 4.3. The parameter $\lambda^\circ$ is represented in the form $(\kappa, c^\circ)$, where $\kappa = \langle \lambda^\circ, \delta \rangle$ so that $\mathcal{A}_{\lambda^\circ}(v) = eH_{\kappa,\epsilon}(n)e$. We view $c^\circ$ as an element of ker $\delta$ (this includes some renormalization of the usual parameters for the SRA’s). Similarly, choose a parameter $\lambda'^\circ = (\kappa', c'^\circ) \in \lambda^\circ + \mathbb{Z}^Q_0$ such that $(\lambda', \theta') \in \mathcal{A}_c(v)$ for any $\lambda' \in \lambda'^\circ + (C' \cap \mathbb{Z}^Q_0)$. Set $\chi := \lambda'^\circ - \lambda^\circ$. Note that $\kappa' - \kappa = \langle \chi, \delta \rangle \in \mathbb{Z}$.

For $\lambda = (\kappa, c)$, we set $\mathcal{A}_c := \mathcal{A}_{\lambda}(v), \mathcal{A}^c_{+c} := \mathcal{A}_{\lambda+c}(v), B^c := \mathcal{A}_0^{\lambda+c}(v)$. We also consider the universal versions: we write $p_0$ for ker $\delta$ and consider the objects $\mathcal{A}^p_0 := \mathcal{A}_{\lambda+p_0}(v), \mathcal{A}'^{p_0}, B^{p_0} := \mathcal{A}_0^{\lambda+p_0-c}(v)$ so that $\mathcal{A}_c, \mathcal{A}^c_{+c}, B^c$ are the specializations of $\mathcal{A}^p_0, \mathcal{A}'^{p_0}, B^{p_0}$.

Let $m$ denote the denominator of $\kappa$ (we set $m = \infty$ if $\kappa$ is irrational) if $\kappa \notin \mathbb{Z}$. For $\kappa \in \mathbb{Z}$ we assume that $m = \infty$.

We will define chains of ideals $\{0\} = \mathcal{J}_{q+1}^{p_0} \subseteq \mathcal{J}_q^{p_0} \subseteq \ldots \subseteq \mathcal{J}_1^{p_0} \subseteq \mathcal{J}_0^{p_0} = \mathcal{A}^{p_0}, \{0\} = \mathcal{J}_{q+1}^{p_0} \subseteq \mathcal{J}_q^{p_0} \subseteq \ldots \subseteq \mathcal{J}_1^{p_0} \subseteq \mathcal{J}_0^{p_0} = \mathcal{A}'^{p_0},$ where $q = \lfloor n/m \rfloor$, and consider the corresponding specializations $\mathcal{J}_i^c, \mathcal{J}_i^{p_0}$.

One more piece of notation: $d_i := (q - i)(m - 1)$.

Here is our main technical result.
Theorem 11.1  There is a principal open subset $p_0^0 \subset p_0$ such that the HC bimodules

$$
\mathcal{J}_i^{p_0}, A^{p_0}/\mathcal{J}_i^{p_0}, \mathcal{J}_i^{p_0}, A^{p_0}/\mathcal{J}_i^{p_0}, B^{p_0},
$$

$$
\operatorname{Tor}-^A_p (B^{p_0}, A^{p_0}/\mathcal{J}_i^{p_0}), \operatorname{Tor}_j^A (A^{p_0}/\mathcal{J}_i^{p_0}, B^{p_0})
$$

localized to $p_0^0$ are free both as left and as right modules over $\mathbb{C}[p_0^0]$ and moreover, for any $c \in p_0^0$, the following claims are true:

1. $\mathcal{J}_i^{c}\mathcal{J}_j^{c} = \mathcal{J}_{\max(i,j)}^{c}$, $\mathcal{J}_i^{c}\mathcal{J}_j^{c} = \mathcal{J}_{\max(i,j)}^{c}$.
2. For all $i$, $j$, we have $\mathcal{J}_i^{c}\mathcal{J}_j^{c} = \operatorname{Tor}_j^A (B^{c}, A^{c}/\mathcal{J}_i^{c}, B^{c})\mathcal{J}_i^{c} = 0$.
3. We have $\operatorname{Tor}_j^A (B^{c}, A^{c}/\mathcal{J}_i^{c}) = 0$ for $j < d_i$.
4. We have $\mathcal{J}_i^{c}\mathcal{J}_j^{c} = \operatorname{Tor}_j^A (B^{c}, A^{c}/\mathcal{J}_i^{c}) = 0$ for $j > d_i$.
5. Set $B_i^c := \operatorname{Tor}_j^A (B^{c}, A^{c}/\mathcal{J}_i^{c})$. Then $\mathcal{J}_i^{c}B_i^c = B_i^c$.
6. The kernel and the cokernel of the natural homomorphism

$$
B_i^c \otimes A^c \operatorname{Hom}_{A^c}(B_i^c, A^c/\mathcal{J}_i^{c}) \to A^c/\mathcal{J}_i^{c}
$$

are annihilated by $\mathcal{J}_{i-1}^{c}$ on the left and on the right. Similarly, the kernel and the cokernel of the natural homomorphism

$$
\operatorname{Hom}_{A^c}(B_i^c, A^c/\mathcal{J}_i^{c}) \otimes_{A^c} B_i^c \to A^c/\mathcal{J}_i^{c}
$$

are annihilated on the left and on the right by $\mathcal{J}_{i-1}^{c}$.

We remark that under the freeness condition we have imposed on $p_0^0$, the bimodules with superscript $c$ are the specializations of those with superscript $p_0$ provided $c \in p_0^0$. For example, $\operatorname{Tor}_j^A (B^{c}, A^{c}/\mathcal{J}_i^{c}) = \operatorname{Tor}_j^A (B^{p_0}, A^{p_0}/\mathcal{J}_i^{p_0})$. The existence of an open subset satisfying the freeness condition follows from (2) of Corollary 3.6.

The scheme of the proof of Theorem 11.1 is as follows. We first prove the theorem for the algebras $\mathcal{A}_k(n)$, $\mathcal{A}_k'(n)$, where $m = n$, in Sect. 11.3. In this case we just have one proper ideal in either of these two algebras. Then, in Sect. 11.4, we construct the ideals $\mathcal{J}_i^{p_0}, \mathcal{J}_i^{p_0}$ in general. After that we prove (2)–(6) of Theorem 11.1, first, for a Weil generic parameter $c$ and then for a Zariski generic parameter, Sect. 11.5.

Of course, $c^n + (C^n \cap \ker \delta \cap \mathbb{Z}^{Q_0})$ intersects $p_0^0$. We remark that for $c \in [c^n + (C^n \cap \ker \delta \cap \mathbb{Z}^{Q_0})] \cap p_0^0$, thanks to Lemma 5.2, the functor $B^c \otimes_{A^c} \bullet$ is just $\mathcal{W}_C_{\theta \to \theta'}$.

Theorem 11.1 is used to prove that $\mathcal{W}_C_{\theta \to \theta'} : D^b(A_{\lambda^0}(v) \text{-mod}) \to D^b(A_{\lambda_\infty}(v) \text{-mod})$ is a perverse equivalence.
Let us recall the general definition. Let $\mathcal{C}, \mathcal{C}'$ be two abelian categories equipped with filtrations \( \{0\} = \mathcal{C}_{N+1} \subseteq \mathcal{C}_N \subseteq \mathcal{C}_{N-1} \subseteq \cdots \subseteq \mathcal{C}_1 \subseteq \mathcal{C}_0 = \mathcal{C}, \{0\} = \mathcal{C}'_{N+1} \subseteq \mathcal{C}'_N \subseteq \mathcal{C}'_{N-1} \subseteq \cdots \subseteq \mathcal{C}'_1 \subseteq \mathcal{C}'_0 = \mathcal{C}' \) by Serre subcategories. Following Chuang and Rouquier [60, Section 2.6], we say that a derived equivalence $\varphi : D^b(\mathcal{C}) \rightarrow D^b(\mathcal{C}')$ is perverse with respect to the filtrations above if

(i) $\varphi$ restricts to an equivalence $D^b_{\mathcal{C}_i}(\mathcal{C}) \rightarrow D^b_{\mathcal{C}'_i}(\mathcal{C}')$, where we write $D^b_{\mathcal{C}_i}(\mathcal{C})$ for the full subcategory of $D^b(\mathcal{C})$ consisting of all complexes with homology in $\mathcal{C}_i$.

(ii) $H_j(\varphi M) = 0$ for $M \in \mathcal{C}_i$ and $j < i$.

(iii) The functor $M \mapsto H_i(\varphi M)$ induces an equivalence $\mathcal{C}_i/\mathcal{C}_{i+1} \sim \mathcal{C}'_i/\mathcal{C}'_{i+1}$. Moreover, $H_j(\varphi M) \in \mathcal{C}'_{j+1}$ for $j > i$ and $M \in \mathcal{C}_i$.

We remark that, thanks to (iii), a perverse equivalence induces a natural bijection between the simple objects in $\mathcal{C}$ and $\mathcal{C}'$. We will write $S \mapsto S'$ for this bijection.

**Theorem 11.2** Set $\mathcal{C} := A_{\lambda^o}(v)\text{-mod}, \mathcal{C}' := A_{\lambda^{o+\psi}}(v)\text{-mod}$. Define $\mathcal{C}_i$ to be the subcategory of all modules in $\mathcal{C}$ annihilated by $J_{q+1-\lfloor j/(m-1) \rfloor}$ (this is a Serre subcategory by (1) of Theorem 11.1) and $\mathcal{C}'_i \subset \mathcal{C}_i$ analogously. Then, perhaps after replacing $\lambda^o$ with $\lambda^o + \psi$ for $\psi \in \mathcal{C} \cap \ker \delta \cap \mathbb{Z}Q_0$, the following holds.

1. $\mathcal{M}_{\theta \rightarrow \theta'}$ is a perverse equivalences with respect to these filtrations.

2. The induced equivalence $\mathcal{C}_j(m-1)/\mathcal{C}_j(m-1)+1 \rightarrow \mathcal{C}'_j(m-1)/\mathcal{C}'_j(m-1)+1$ is given by $B^c_{q+1-j} \otimes_{A^c} \bullet$. Moreover, for a simple $S \in \mathcal{C}_j(m-1) \setminus \mathcal{C}_j(m-1)+1$, the head of $B^c_{q+1-j} \otimes_{A^c} S$ coincides with $S'$.

3. The bijection $S \mapsto S'$ preserves the associated varieties of the annihilators.

**Remark 11.3** A direct analog of Theorem 11.2 holds for all wall-crossing functors through faces of classical chambers. This is proved in a subsequent paper [49], by the second named author. In particular, the short wall-crossing functors through real walls studied in Sect. 10 and the bijection between singular objects $L \mapsto L'$ we considered from Proposition 6.6 is a restriction of the bijection from (3) of generalized Theorem 11.2. Still, Proposition 6.6 cannot be entirely replaced by a generalization of Theorem 11.2 as the former relates the wall-crossing functor to the categorification functors $E_a, F_a$.

### 11.2 HC bimodules for symplectic reflection algebras

Let $V, \Gamma, \mathcal{H}_c$ etc. have the same meaning as in Sect. 2.2.6. In this section we recall some known facts about HC bimodules over the algebras $\mathcal{H}_c$ and $e\mathcal{H}_ce$. The most important cases are $\Gamma = \Gamma_n, \mathcal{S}_n$. 

\[ \text{Springer} \]
Let us recall a description of the symplectic leaves in $V/\Gamma$. The leaves are parameterized by conjugacy classes of stabilizers for the $\Gamma$-action on $V$. Namely, to a stabilizer $\Gamma'$ we assign the image of $\{v \in V|\Gamma_v = \Gamma'\}$ in $V/\Gamma$.

Below we will need a property of restriction functors in the SRA setting. A similar property was obtained in [41, Proposition 3.7.2] for a related, “upgraded”, restriction functor.

Take a symplectic leaf $\mathcal{L} \subset V/\Gamma_n$ and consider the full subcategory $\text{HC}_{\mathcal{L}}(\mathcal{A}_{\mathfrak{p}}(v)) \subset \text{HC}(\mathcal{A}_{\mathfrak{p}}(v))$ consisting of all HC bimodules $\mathcal{M}$ such that $V(\mathcal{M}) \cap \mathcal{M}_0(v) \subset \mathcal{L}$. Similarly, define the subcategory $\text{HC}_{\text{fin}}(\mathcal{A}_{\mathfrak{p}}(\hat{v}))$.

**Proposition 11.4** For $x \in \mathcal{L}$, the functor $\bullet_{\downarrow,x} : \text{HC}_{\mathcal{L}}(\mathcal{A}_{\mathfrak{p}}(v)) \rightarrow \text{HC}_{\text{fin}}(\mathcal{A}_{\mathfrak{p}}(\hat{v}))$ admits a right adjoint $\bullet_{\downarrow,x}^\ast : \text{HC}_{\text{fin}}(\mathcal{A}_{\mathfrak{p}}(\hat{v})) \rightarrow \text{HC}_{\mathcal{L}}(\mathcal{A}_{\mathfrak{p}}(v))$.

**Proof** As in the proof of [41, Proposition 3.7.2], we reduce the proof to showing that $\text{HC}_{\text{fin}}(\mathcal{A}_{\mathfrak{p}}(\hat{v}))$ is finitely generated over $\mathbb{C}[\mathcal{L}]$ and is weakly equivariant under the action of $\mathbb{C}^\times$ on $\mathcal{L}$ is contained in $\mathbb{C}[\mathcal{L}] \subset \mathbb{C}[\mathcal{L}]^{\times}$. This is a special case of [47, Lemma 3.9].

Here is an application of the restriction functors obtained in [41, Section 5]. Consider the case when $\Gamma = \mathcal{S}_n$ and $V = \mathfrak{h} \oplus \mathfrak{h}^*$, where $\mathfrak{h} = \mathbb{C}^{n-1}$ is the reflection representation of $\mathcal{S}_n$. The resulting algebra $\mathcal{H}_k(n)$ is known as the Rational Cherednik algebra of type A, in our previous notation $\mathcal{H}_{\kappa,\varnothing}(n) = D(\mathbb{C}) \otimes \mathcal{H}_k(n), e\mathcal{H}_k(n)e = \mathcal{A}_k(n)$. One can describe all two-sided ideals in $\mathcal{H}_k(n)$, see [41, Section 5.8].

**Proposition 11.5** If $\kappa$ is irrational or $\kappa = \frac{r}{m}$, where $\text{GCD}(r,m) = 1$ and $m > n$, then the algebra $\mathcal{H}_k(n)$ is simple. Otherwise, there are $q := \lfloor n/m \rfloor$ proper ideals that form a chain: $\{0\} = \mathcal{J}_0 \subset \mathcal{J}_1 \subset \cdots \subset \mathcal{J}_q \subset \mathcal{J}_{q+1} = \mathcal{H}_k(n)$. The associated variety of $\mathcal{H}_k/\mathcal{J}_i$ is the closure of the symplectic leaf associated to the parabolic subgroup $\mathcal{S}_m^{q+1-i} \subset \mathcal{S}_n$. Moreover, we have $\mathcal{J}_i \mathcal{J}_j = \mathcal{J}_{\text{max}(i,j)}$.

We will also need the following lemma that is a consequence of Proposition 11.5 and Lemma 3.2. Consider a point $x$ in the symplectic leaf of $(\mathfrak{h} \oplus \mathfrak{h}^*)/\mathcal{S}_n$ corresponding to the parabolic subgroup $\mathcal{S}_m^q \subset \mathcal{S}_n$, where $q = \lfloor n/m \rfloor$.

**Lemma 11.6** The functor $\bullet_{\downarrow,x}$ is faithful.

Let us use the notation from Proposition 11.5. Set $\hat{\mathcal{H}} = \mathcal{H}_k(m)$ and let $\hat{\mathcal{J}}$ be the only proper two-sided ideal in $\hat{\mathcal{H}}$. Let $\hat{\mathcal{J}}_i$ denote the two-sided ideal in $\hat{\mathcal{H}}^{\otimes q}$ that is obtained as the sum of all $q$-fold tensor products of $i$ copies of $\hat{\mathcal{J}}$ and $q - i$ copies of $\hat{\mathcal{H}}$ (in all possible orders).
Lemma 11.7 Let \( J \) be a two-sided ideal in \( \hat{\mathcal{H}} \otimes q \). If \( V(\hat{\mathcal{H}} \otimes q / J) = V(\hat{\mathcal{H}} \otimes q / \hat{J}_i) \), then \( J = \hat{J}_i \).

Proof Let \( x \) be a generic point in an irreducible component in \( V(\hat{\mathcal{H}} \otimes q / \hat{J}_i) \). Recall that these components are labelled by \( i \)-element subsets of \( \{1, \ldots, q\} \). Then \( J_{\hat{J}_i} \) is a proper ideal in \( \hat{\mathcal{H}} \otimes i \). It follows that \( J \) lies in the kernel of the projection of \( \hat{\mathcal{H}} \otimes q \) to the product of \( q - i \) copies of \( \hat{\mathcal{H}} \) and \( i \) copies of \( \hat{\mathcal{H}} / \hat{J}_i \) (in all possible orders). But by Step 3 in the proof of [41, Theorem 5.8.1], the intersection of these kernels is \( \hat{J}_i \). So \( J \subseteq \hat{J}_i \). Moreover, by loc.cit., the kernels are precisely the minimal prime ideals containing \( J \). So \( \hat{J}_i \) is the radical of \( J \). By loc.cit., \( \hat{J}_i^2 = \hat{J}_i \). Therefore \( \hat{J}_i = J \). □

11.3 Type A: case \( \kappa = \frac{r}{n} \)

Here we assume that \( n = m, \kappa = \frac{r}{n} \) with \( \text{GCD}(r, n) = 1 \) and \( \kappa \notin (-1, 0) \).

In this case we have just one proper ideal \( J \subset \mathcal{H} := \mathcal{H}_\kappa(n) \) and the quotient \( \mathcal{H} / J \) is finite dimensional, this is a special case of Proposition 11.5. The algebra \( \bar{A}_\kappa(m) \) is Morita equivalent to \( \mathcal{H} \).

Lemma 11.8 Claims (2)–(6) of Theorem 11.1 hold for the algebras \( \bar{A}_\kappa(m) \).

Proof These claims amount to the following two claims (*) and (**), where (i) implies those claims for \( i = 1 \), while (**) implies them for \( i = 0 \):

(*) We have Tor\( ^{\mathcal{H}}_j(\mathcal{B}, \mathcal{H} / J) = Tor^{\mathcal{H}}_j(\mathcal{H}' / J', \mathcal{B}) = 0 \) if \( j \neq n - 1 \). Furthermore, Tor\( ^{\mathcal{H}}_{n-1}(\mathcal{B}, \mathcal{H} / J) = Tor^{\mathcal{H}}_{n-1}(\mathcal{H}' / J', \mathcal{B}) = \text{Hom}_{\mathbb{C}}(L, L') \), where we write \( L \) (resp., \( L' \)) for the simple finite dimensional \( \mathcal{H} \)-module (resp., \( \mathcal{H}' \)-module).

(**) The kernels and cokernels of the natural homomorphisms

\[
\mathcal{B} \otimes_{\mathcal{H}} \text{Hom}_{\mathcal{H}'}(\mathcal{B}, \mathcal{H}') \to \mathcal{H}', \text{Hom}_{\mathcal{H}}(\mathcal{B}, \mathcal{H}) \otimes_{\mathcal{H}'} \mathcal{B} \to \mathcal{H}
\]

are finite dimensional.

The Tor vanishing statement in (*) is a consequence of (1) of Proposition 6.5 (by Remark 9.5, \( \mathcal{B} \otimes_{\mathcal{H}'}^L \bullet \) is still the wall-crossing functor for the categories of right modules). The category of finite dimensional \( \mathcal{H} \)-modules (resp., of finite dimensional \( \mathcal{H}' \)-modules) is a semisimple category with a single indecomposable object \( L \) (resp., \( L' \)). By (2) of Proposition 6.5, \( \mathcal{B} \otimes_{\mathcal{H}'}^L L = L'[n - 1] \) and \( L' \otimes_{\mathcal{H}'}^L \mathcal{B} = L[n - 1] \). So the equality for the Tor\( _{n-1} \)'s follows from the previous sentence and isomorphisms \( \mathcal{H} / J = \text{Hom}_{\mathbb{C}}(L, L), \mathcal{H}' / J' = \text{Hom}_{\mathbb{C}}(L', L') \).

Let us proceed to (**). Apply the functor \( \bullet \hat{\mathcal{J}},, x \) to the homomorphisms of interest, where \( x \in M_0(v) \) is generic. For the homomorphism

\[
\mathcal{B} \otimes_{\mathcal{H}} \text{Hom}_{\mathcal{H}'}(\mathcal{B}, \mathcal{H}') \to \mathcal{H}'
\]
we get a natural homomorphism
\[ \mathcal{B}_{\dagger, x} \otimes \mathcal{H}_{\dagger, x} \xrightarrow{\text{Hom}_{\mathcal{H}}(\mathcal{B}_{\dagger, x}, \mathcal{H}_{\dagger, x})} \mathcal{H}_{\dagger, x}. \]

But the algebras and bimodules involved are all just \( \mathbb{C} \). So we see that the latter homomorphism is an isomorphism. It follows that the kernel and the cokernel of \( \mathcal{B} \otimes \mathcal{H} \xrightarrow{\text{Hom}_{\mathcal{H}}(\mathcal{B}, \mathcal{H})} \mathcal{H} \) are killed by \( \bullet_{\dagger, x} \). So they have proper associated varieties and hence are finite dimensional. \( \square \)

### 11.4 Chain of ideals

For a partition \( \mu = (\mu_1, \ldots, \mu_k) \) with \( |\mu| \leq n \) set \( \tilde{A}(\mu) = \bigotimes_{i=1}^{k} \tilde{A}_i(\mu_i) \) and define \( \tilde{A}'(\mu) \) similarly. Consider the restriction functors \( \bullet_{\dagger, \mu} : \text{HC}(A^{\mu_0}) \to \text{HC}(\mathbb{C}[p_0] \otimes \tilde{A}(\mu)), \text{HC}(A'^{\mu_0} - A^{\mu_0}) \to \text{HC}(\mathbb{C}[p_0] \otimes \tilde{A}'(\mu) - \mathbb{C}[p_0] \otimes \tilde{A}(\mu)) \) etc. Let \( \bullet_{\dagger, \mu} \) denote the right adjoint functor (defined on bimodules that are finitely generated over \( \mathbb{C} \)) by Proposition 11.4. Recall, Proposition 11.5, that the ideals in the algebra \( \tilde{A}(qm) \) form a chain: \( \tilde{A}(qm) = \tilde{J}_0(qm) \supseteq \tilde{J}_1(qm) \supseteq \cdots \supseteq \tilde{J}_q(qm) \supseteq \tilde{J}_{q+1}(qm) = \{0\} \). We set \( \tilde{J}_i^{p_0} := \tilde{J}_i(qm)_{\dagger, m^q} \). These are precisely the ideals appearing before Lemma 11.7.

We set \( \mathcal{J}_i^{p_0} \) to be the kernel of the natural map
\[ A^{\mu_0} \to (\mathbb{C}[p_0] \otimes [\tilde{A}(m)/\tilde{J}_1(m)]^0_{q+1-i})^{\dagger, (m^q+1-i)}, \]
and define \( \mathcal{J}_i^{p_0} \) similarly.

**Remark 11.9** Note that, by the definition of \( \mathcal{J}_i^{p_0} \) the following is true. If \( \mathcal{J} \subset A^{\mu_0} \) is such that \( \mathcal{J}_{\dagger, (m^q+1-i)} \) is in the kernel of \( \mathbb{C}[p_0] \otimes \tilde{A}(m^q+1-i) \to \mathbb{C}[p_0] \otimes [\tilde{A}(m)/\tilde{J}_1(m)]^{0}_{q+1-i}, \) then \( \mathcal{J} \subset \mathcal{J}_i^{p_0} \).

We are going to establish some properties of these ideals. First, let us describe properties that hold for all parameters \( c \).

**Lemma 11.10** The following is true.

1. \( (\mathcal{J}_i^{c})_{\dagger, (m^q+1-i)} \) coincides with the maximal ideal of \( \tilde{A}(m^{q+1-i}) \).
2. \( V(A^{c}/\mathcal{J}_i^{c}) \) coincides with \( \overline{L}_{(m^q+1-i)}, \) where the latter is the closure of the symplectic leaf corresponding to the subgroup \( \mathbb{S}_m^{q+1-i} \subset \Gamma_n. \)
3. \( (\mathcal{J}_i^{c})_{\dagger, (mq)} = \tilde{J}_i(m^q) \). Moreover, \( (\mathcal{J}_i^{c})_{\dagger, (mq)} = \tilde{J}_i(m^q). \)
4. \( \mathcal{J}_q^{p_0} \subset \mathcal{J}_{q+1}^{p_0} \subset \cdots \subset \mathcal{J}_1^{p_0}. \)

Similar claims hold for \( \mathcal{J}_i^{c}, \mathcal{J}_i^{p_0}. \)
Proof The ideal \((\mathcal{J}_i^c)_{\bar{i},(m^q+1-i)} \subset \bar{\mathcal{A}}(m^q+1-i)\) is contained in the maximal ideal as the latter is the kernel of \(\bar{\mathcal{A}}(m^q+1-i) \rightarrow (\bar{\mathcal{A}}(m)/\bar{\mathcal{J}}(m))^{\otimes (q+1-i)}\). The inclusion \(V(\mathcal{A}^c/\mathcal{J}_i^c) \subset \bar{\mathcal{L}}_{(m^q+1-i)}\) follows from Proposition 11.4. By Lemma 3.9, \(V(\bar{\mathcal{A}}^{\otimes q+1-i}/\mathcal{J}_i^c)\) is a point. The equality in (a) follows from Lemma 11.7. In its turn, the equality in (a) implies the equality in (b).

(b) implies that \(V(\bar{\mathcal{A}}(m^q)/(\mathcal{J}_i^c)_{\bar{i},(m^q)}) = V(\bar{\mathcal{A}}(m^q)/\bar{\mathcal{J}}(m^q))\). Lemma 11.7 yields \((\mathcal{J}_i^c)_{\bar{i},(m^q)} = \bar{\mathcal{J}}(m^q)\). The equality \((\mathcal{J}_i^c)_{\bar{i},(q)} = \bar{\mathcal{J}}(q)\) is proved similarly using Proposition 11.5.

Let us prove (d). We remark that \((\mathcal{J}_i^c)_{\bar{i},(m^q+2-i)}\) is a proper ideal because its associated variety (computed using Lemma 3.9) is proper. Hence \((\mathcal{J}_i^c)_{\bar{i},(m^q+2-i)}\) is contained in the maximal ideal of \(\bar{\mathcal{A}}(m^q+2-i)\). It follows that \((\mathcal{J}_i^{p_0})_{\bar{i},(m^q+2-i)}\) lies in the kernel of the epimorphism \(\mathbb{C}[p_0] \otimes \bar{\mathcal{A}}(m^q+2-i) \rightarrow \mathbb{C}[p_0] \otimes (\bar{\mathcal{A}}(m)/\bar{\mathcal{J}}(m))^{\otimes (q+2-i)}\). The inclusion \(\mathcal{J}_i^{p_0} \subset \mathcal{J}_i^{p_0+1}\) follows from Remark 11.9.

Now let us analyze what happens when \(c\) is Weil generic.

**Lemma 11.11** Let \(c\) be Weil generic. Then the following is true:

1. The functor \(\bullet_{\bar{i},(m^q)}\) is faithful.
2. The ideals \(\mathcal{J}_i^c, i = 1, \ldots, q\), exhaust all proper ideals in \(\mathcal{A}^c\).
3. \(\mathcal{J}_i^c \mathcal{J}_j^c = \mathcal{J}_{\max(i,j)}^c\).

Proof Let us show that for a Weil generic \(c\), the algebra \(\mathcal{A}^c\) has no finite dimensional representations. Similarly to the proof of Proposition 3.14, we see that otherwise there is a two-sided ideal \(\mathcal{J} \subset \mathcal{A}^{p_0}\) such that \(\mathcal{A}^{p_0}/\mathcal{J}\) is generically flat and finite over \(\mathbb{C}[p_0]\) and \(\text{Supp}_p(\mathcal{A}^{p_0}/\mathcal{J}) = p_0\). So, by Proposition 3.13, for the Poisson ideal \(\text{gr} \mathcal{J} \subset \mathbb{C}[\mathcal{M}_{p_0}(v)]\) we have \(\text{Supp}_p(\mathbb{C}[\mathcal{M}_{p_0}(v)]/\text{gr} \mathcal{J}) = p_0\). It follows that, for every \(p \in p_0\), the variety \(\mathcal{M}_p(v)\) contains a point that is a symplectic leaf. We remark that \(\mathcal{M}_{p_0}(v) = \mathcal{M}_{p_0}(v)\delta^n/\mathfrak{S}_n\) (the power is taken over \(p_0\)), this follows from the description of \(\mathcal{M}_{p_0}(v)\) as the generalized Calogero-Moser space, see [27, Section 11]. For \(p\) generic, \(\mathcal{M}_p(\delta)\) is smooth and symplectic and so the minimal dimension of a symplectic leaf in \(\mathcal{M}_p(v)\) is 2. We arrive at a contradiction that shows that \(\mathcal{A}^c\) has no finite dimensional representations provided \(c\) is Weil generic.

Now we are in position to prove (1). This boils down to checking that the associated variety of any HC \(\mathcal{A}^c\)-bimodule (or HC \(\mathcal{A}^c\)-\(\mathcal{A}^c\)-bimodule, etc.) contains \(\mathcal{L}_{(m^q)}\). First of all, let us show that the associated variety contains \(\mathcal{L}_n\), the symplectic leaf corresponding to \(\mathfrak{S}_n \subset \Gamma_n\). Indeed, the slice algebra \(\bar{\mathcal{A}}_{\hat{\lambda}}(\hat{v})\) for any leaf not containing \(\mathcal{L}_n\) has a tensor factor isomorphic to \(e\mathcal{H}_{\kappa,c}(n')e\) with nonzero \(n' \leq n\). But that algebra has no finite dimensional irreducible representations by the first paragraph of the proof, a contradiction. So we see that the associated variety is contained in \(\mathcal{L}_n\). Hence it is \(\mathcal{L}_\mu\) for some partition \(\mu\). The slice algebra \(\bar{\mathcal{A}}_{\hat{\lambda}}(\hat{v})\) is the product \(\bigotimes_{i=1}^k e\mathcal{H}_{\kappa}(\mu_i)e\).
That the associated variety contains $L^{(m_q)}$ follows from the fact that the algebra $\mathcal{H}_\kappa(n')$ has a finite dimensional irreducible representation if and only if $\kappa$ has denominator precisely $n'$. The proof of faithfulness of $\bullet_{\mathcal{J}}^{(m_q)}$ is now complete.

Let us proceed to the proof of (2) and (3). By (b) of Lemma 11.10, $V(\mathcal{A}/J_{c}^c) = \tilde{L}_{(m_q+1-i)}$. The functor $\bullet_{\mathcal{J}}^{(qm)}$ is faithful, this follows from the argument in the previous paragraph. So the map $\mathcal{J} \mapsto \mathcal{J}_{\mathcal{J}}^{(qm)}$ embeds the poset of two-sided ideals in $\mathcal{A}$ into that for $\tilde{A}(qm)$. (2) follows from here and Proposition 11.5. To check (3) note that $\bullet_{\mathcal{J}}^{(qm)}$ respects the products of ideals and again use Proposition 11.5.

Now let us transfer some of the properties in Lemma 11.11 to the case when $c$ is only Zariski generic.

**Lemma 11.12** We have $\mathcal{J}_{i}^{c} \mathcal{J}_{j}^{c} = \mathcal{J}_{\text{max}(i,j)}^{c}$ for $c$ in some non-empty Zariski open subset of $p_0$.

**Proof** Consider the quotient $\mathcal{J}^{p_0}_{\text{max}(i,j)}/\mathcal{J}^{p_0}_{i} \mathcal{J}^{p_0}_{j}$. By (3) of Lemma 11.11, its specialization to a Weil generic $c$ is zero. It follows from (2) of Corollary 3.6 that the specialization of this HC bimodule to a Zariski generic $c ∈ p_0$ is zero. This implies our claim. □

**11.5 Proof of Theorem 11.1**

We write $\tilde{B}$ for the wall-crossing $\tilde{A}_{\kappa'}(m) - \tilde{A}_{\kappa}(m)$-bimodule.

Without restrictions on $c$, we know that

$$B_{\mathcal{J}}^{c,(m_q+1-i)} = \tilde{B} \otimes q^{+1-i},$$

$$\text{Tor}^{A_c}_{\mathcal{J}}(\mathcal{B}, \mathcal{A}/\mathcal{J}^{c}_{i}) = \text{Tor}^{\tilde{A}_{\kappa'}(m_q+1-i)} \otimes (\tilde{A}(m)/\mathcal{J}(m)) \otimes q^{+1-i},$$

$$\text{Tor}^{A_c}_{\mathcal{J}}(\mathcal{A}/\mathcal{J}^{c}_{i}, \mathcal{B}) = \text{Tor}^{\tilde{A}_{\kappa'}(m_q+1-i)}((\tilde{A}'(m)/\mathcal{J}'(m)) \otimes q^{+1-i}, \tilde{B} \otimes q^{+1-i}).$$

(11.1)

The first equality is a special case of (3.11). The second and third equalities follows from the first and Lemma 3.10.

**Proof of Theorem 11.1** First, we assume that $c$ is Weil generic. By (b) of Lemma 11.10 combined with (2) of Lemma 11.11, for any HC $A^{c} - A^{c}$ bimodule $\mathcal{X}$ the following are equivalent

- $\mathcal{X}_{\mathcal{J}}^{c,(m_q+1-i)} = 0$,
- $\mathcal{X}_{\mathcal{J}}^{c,(m_q+1-i)} = 0$,
- $\mathcal{J}_{\mathcal{J}}^{c,(m_q+1-i)} = 0$.

Springer
This, combined with (11.1) and Sect. 11.3, yields (4) and (6). Further, the following conditions are equivalent as well:

- \( \dim X_{(m^q+1-i)} < \infty \),
- \( XJ_i^c = 0 \),
- \( J_i^c X = 0 \).

This yields (2).

Let us prove (3) and (5). Suppose that (3) is false. Pick the minimal \( i \) such that there is \( j < d_i \) with \( X := \text{Tor}^A_j(B^c, A^c/J_i^c) \neq 0 \). Next, let \( j \) be minimal for the given \( i \). Since \( X_{(m^q+1-i)} = 0 \), we see that

\[
XJ_{i-1}^c = 0. \tag{11.2}
\]

Consider the derived tensor product

\[
B^c \otimes^L_{A^c} A^c/J_{i-1}^c = (B^c \otimes^L_{A^c} A^c/J_i^c) \otimes^L_{A^c/J_i^c} A^c/J_{i-1}^c. \tag{11.3}
\]

By the choice of \( j \), the \( j \)th homology of the right hand side of (11.3) equals \( X \otimes_{A^c/J_i^c} A^c/J_{i-1}^c = X/J_i^c \). The latter equals \( X \) by (11.2). Since \( j < d_i \) and the left hand side of (11.3) has non-vanishing \( j \)th homology, we get a contradiction with our choice of \( i \). This proves \( X = 0 \).

The equality \( \text{Tor}^A_j(A^c/J_i^c, B) = 0 \) for \( j < d_i \) is proved in the same way (using that \( B \) is a long wall-crossing bimodule also when viewed as an \( A^c,opp_{-}A_i^c,opp_{-} \)-bimodule, Remark 9.5). This completes the proof of (3).

Let us proceed to (5) and prove \( B_i^c J_{i-1}^c = B_i^c \). Assume the converse, then \( B_i^c \otimes A^c/J_{i-1}^c \neq 0 \). Similarly to the proof of \( X = 0 \), this implies that \( \text{Tor}^A_{d_i}(B^c, A^c/J_{i-1}^c) \neq \{0\} \) that contradicts (3). This completes the proof of Theorem 11.1 for a Weil generic \( c \).

Let us prove (2)–(6) for a Zariski generic \( c \). We will do (2), the other claims are similar. Consider the HC \( A^p_{-}A^p_{-} \) bimodule \( J_i^{p0} \text{Tor}^{p0}_j(B^p, A^p_{-}J_i^{p0}) \). Its specialization to a Zariski generic parameter \( c \) coincides with \( J_i^c \text{Tor}^A_j(B^c, A^c/J_i^c) \). So a Weil generic specialization of this bimodule vanishes. Therefore the same is true for a Zariski generic specialization, this is a consequence of (2) of Corollary 3.6.

\[\square\]

11.6 Proof of Theorem 11.2

Let us check (i) in the definition of a perverse equivalence. Recall that \( \mathcal{MC}_{\theta \to \theta'} \) is \( B^c \otimes^L_{A^c} \bullet \) and hence \( \mathcal{MC}_{\theta \to \theta'}^{-1} \) is \( R \text{Hom}_{A^c} (B^c, \bullet) \). For example, let us prove \( \mathcal{MC}_{\theta \to \theta'}^{-1} D^{b} C(C') \subset D^{b} C(C') \). For \( M' \) annihilated by \( J_i^c \), we have

\[
R \text{Hom}_{A^c} (B^c, M') = R \text{Hom}_{A^c/J_i^c} (A^c/J_i^c \otimes^L_{A^c} B^c, M').
\]

Now we use (2)
of Theorem 11.1 which says, in particular, that all homology of $\mathcal{A}^c / \mathcal{J}_i^c \otimes_{\mathcal{A}^c} \mathcal{B}^c$ are annihilated by $\mathcal{J}_i^c$ on the right. This checks (i).

(ii) follows from (3) of Theorem 11.1 and the observation that, for $M$ annihilated by $\mathcal{J}_i^c$ we have $\mathcal{B}^c \otimes_{\mathcal{A}^c} M = (\mathcal{B}^c \otimes_{\mathcal{A}^c} \mathcal{A}^c / \mathcal{J}_i^c) \otimes_{\mathcal{A}^c} \mathcal{J}_i^c M$.

Let us prove (iii). By (6) of Theorem 11.1, the functor $\mathcal{B}_i^c \otimes_{\mathcal{A}^c} \mathcal{J}_i^c \bullet : \mathcal{A}^c / \mathcal{J}_i^c \text{-mod} \to \mathcal{A}^c / \mathcal{J}_i^c \text{-mod}$ induces an equivalence $C_{q+1-i} / C_{q+2-i} \to C_{q+1-i} / C'_{q+2-i}$ (for example, a right inverse is given by tensoring with $\text{Hom}_{\mathcal{A}^c}(\mathcal{B}_i^c, \mathcal{A}^c / \mathcal{J}_i^c)$). (6) also implies that, for $M \in C_{q+1-i}$, we have $\text{Tor}_j(\mathcal{B}_i^c, M) \in C'_{q+2-i}$ for all $j > 0$. Together with (4) of Theorem 11.1 this completes the proof of (iii). This finishes the proof of (1) of Theorem 11.2 and also establishes the first claim in (2).

To complete the proof of (2) we need to check that $\mathcal{J}_{q-i}^c(\mathcal{B}_{q+1-i}^c \otimes_{\mathcal{A}^c} S) = \mathcal{B}_{q+1-i}^c \otimes_{\mathcal{A}^c} \mathcal{S}$. By (5) of Theorem 11.1, the natural homomorphism $\mathcal{J}_{q-i}^c \otimes_{\mathcal{A}^c} \mathcal{B}_{q+1-i}^c \to \mathcal{B}_{q+1-i}^c$ is surjective. It follows that the natural homomorphism $\mathcal{J}_{q-i}^c \otimes_{\mathcal{A}^c} \mathcal{B}_{q+1-i}^c \otimes_{\mathcal{A}^c} S \to \mathcal{B}_{q+1-i}^c \otimes_{\mathcal{A}^c} S$ is surjective as well. This finishes the proof of (2) of Theorem 11.2.

To show (3) – that the associated varieties of the annihilators are preserved – one can argue as follows. Let $\mathcal{I}$ denote the annihilator of $S$. So $\mathcal{B}_{q+1-i}^c \otimes_{\mathcal{A}^c} \mathcal{S}$ is a quotient of $\mathcal{B}_{q+1-i}^c \otimes_{\mathcal{A}^c} \mathcal{A}^c / \mathcal{I}$, a HC bimodule annihilated by $\mathcal{I}$ on the right. From Corollary 3.2 one can now deduce that the associated variety of the annihilator $\mathcal{I}'$ of $S'$ is contained in that of $\mathcal{I}$. On the other hand, $S$ is a submodule of $\text{Hom}_{\mathcal{A}^c}(\mathcal{B}_{q+1-i}^c, S') = \text{Hom}_{\mathcal{A}^c}(\mathcal{B}_{q+1-i}^c / \mathcal{I}' \mathcal{B}_{q+1-i}^c, S')$. So the right annihilator of $\mathcal{B}_{q+1-i}^c / \mathcal{I}' \mathcal{B}_{q+1-i}^c$ is contained in the annihilator of $\text{Hom}_{\mathcal{A}^c}(\mathcal{B}_{q+1-i}^c, S')$. The latter is contained in $\mathcal{I}$. This shows that the associated variety of $\mathcal{I}'$ contains that of $\mathcal{I}$ and completes the proof of (3).

Theorem 11.2 is now proved.

12 Proof of counting result and some conjectures

12.1 Extremal simples

Let us start by proving Proposition 6.9.

Proof of Proposition 6.9 We will need to consider the following three cases separately. Fix $\alpha$. Then the set of $\lambda$ with $\alpha^\lambda = \alpha$ looks as follows: we take the union of a countable discrete collection of affine subspaces in $\mathfrak{P}$ and remove another countable discrete collection of affine subspaces. We say that $\lambda$ is generic with respect to $\alpha$ if $\lambda$ is Weil generic in the closure of a connected component.
The three cases we consider are as follows:

1. \( \lambda \in \mathbb{Q}^{Q_0} \),
2. \( \lambda \) is generic with respect to \( a \).
3. \( \lambda \) is arbitrary with \( a^\lambda = a \).

We will also see that in (2) and (3) the endomorphisms \([E_a], [F_a]\) of \( \bigoplus_v K_0(A^\lambda_\rho(v) \text{-mod}_{\rho^{-1}(0)}) \) give rise to an action of \( a \).

Case 1. Consider the case when \( \lambda \) is rational. In this case, by Proposition 7.2, we see that

\[
\bigoplus_v K_0(A^\lambda_\rho(v) \text{-mod}_{\rho^{-1}(0)}) \hookrightarrow \bigoplus_v K_0(\text{Coh}_{\rho^{-1}(0)}(M^\lambda(v))).
\] (12.1)

By Proposition 8.13, we see that the operators \([E_a], [F_a]\) give rise to an \( a \)-action on \( \bigoplus_v K_0(A^\lambda_\rho(v) \text{-mod}_{\rho^{-1}(0)}) \) and (12.1) is equivariant. So we see that \( K_0(C) = \bigoplus_\sigma U(a)K_0(A^\sigma_\rho(\sigma \bullet w) \text{-mod}) \), where the summation is taken over all \( \sigma \in W(Q) \) such that \( \sigma \omega \) is dominant for \( a \).

Recall, Proposition 8.8, that \([\mathcal{WC}_{\theta \rightarrow \theta'}]\) intertwines the embeddings

\[
K_0(A^\theta_\rho(v) \text{-mod}_{\rho^{-1}(0)}), K_0(A^{\theta'}_\rho(v) \text{-mod}_{\rho^{-1}(0)}) \hookrightarrow K_0(\text{Coh}_{\rho^{-1}(0)}(M^\theta(v))).
\]

It follows that \( \mathcal{WC}_{\theta \rightarrow \theta'} \) maps \( D^C_\rho(A^\theta_\rho(v) \text{-mod}) \) to \( D^C_\rho(A^{\theta'}_\rho(v) \text{-mod}) \), where the subscript \( C \) means that we consider the objects with homology in \( C \).

Now consider the wall-crossing functor \( \mathcal{WC}_{\theta \rightarrow \theta'} \) through ker \( \alpha \). Let \( L \) be extremal in \( A^\theta_\rho(v) \text{-mod}_{\rho^{-1}(0)} \). As we have pointed out in the proof of Lemma 6.8, \( v \) is dominant for \( a \). So all constituents of \( H_u(\mathcal{WC}_{\theta \rightarrow \theta'}L) \) but \( L' \) lie in the image of \( f_\alpha \) and hence, by the minimality assumption on \( v \), in \( C \). We deduce that \( L' \notin C \). So \( L' \) is extremal provided the minimality assumption on \( v \) holds for \( \theta' \) as well. But if \( v \) is not minimal for \( \theta' \), then by switching \( \theta', \theta \) in the argument above in this paragraph, we see that \( v \) is not minimal for \( \theta \) either.

Case 2. Now let \( \Gamma \) be a connected component of the closure of \( \{\lambda|a^\lambda = a\} \). Let \( \lambda_1 \in \mathbb{Q}^{Q_0} \). Pick a Weil generic \( \lambda \in \Gamma \). The algebra \( A_\Gamma(v) \) and the sheaf \( A^\theta_\Gamma(v) \) are defined over \( \mathbb{Q} \). It follows that we have a specialization map \( K_0(A_\rho(v) \text{-mod}_{f_{in}}) \rightarrow K_0(A_{\lambda_1}(v) \text{-mod}_{f_{in}}) \). The functors \( E_\alpha, F_\alpha \) are also defined over the rationals, so the specialization map intertwines \([E_\alpha], [F_\alpha]\). The same is true for the wall-crossing functor \( \mathcal{WC}_{\theta \rightarrow \theta'} \) and hence the specialization map intertwines \([\mathcal{WC}_{\theta \rightarrow \theta'}]\).

We claim that there is \( \lambda_1 \in \mathbb{Q}^{Q_0} \) with \( a^{\lambda_1} = a \) such that the degeneration map \( K_0(A_\rho(v) \text{-mod}_{f_{in}}) \rightarrow K_0(A_{\lambda_1}(v) \text{-mod}_{f_{in}}) \) is an embedding.

Let \( d \) be the maximal dimension of an irreducible finite dimensional \( A_\rho(v) \)-module. Since \( \lambda \) is Weil generic, \( d \) is also the maximal dimension of a finite dimensional irreducible for any other Weil generic parameter. Let \( A_\Gamma \) be the quotient of \( A_\Gamma(v) \) by the ideal generated by the elements.
\[ \sum_{\sigma \in S_{2d}} \text{sgn}(\sigma) a_{\sigma(1)} \ldots a_{\sigma(2d)}. \]

The algebra \( A_\Gamma \) is a finitely generated \( \mathbb{C}[\Gamma] \)-module. This is proved using (2.5) similarly to the proof of [39, Theorem 7.2.1], compare to the proof of [46, Lemma 5.1].

So the module of traces, \( A_\Gamma/[A_\Gamma, A_\Gamma] \) is finitely generated over \( \mathbb{C}[\Gamma] \). Because of this there is a Zariski open subset \( \Gamma^0 \) such that the specializations \( A_{\lambda_2} \) with \( \lambda_2 \in \Gamma^0 \) have the same number of irreducible representations. So we can take any \( \lambda_1 \in \Gamma^0 \cap \mathbb{Q}^{Q^0} \). This shows that the degeneration map \( K_0(A_\lambda(v)_{\text{-mod}_{fin}}) \to K_0(A_{\lambda_1}(v)_{\text{-mod}_{fin}}) \) is an inclusion that sends classes of irreducibles to classes of irreducibles.

Since the degeneration map intertwines the operators \([E_\alpha], [F_\alpha]\), we see that \( K_0(C^\theta_\lambda(v)) \) (the summand corresponding to the dimension \( v \) in the category \( C \) for \((\lambda, \theta)\)) gets mapped onto \( K_0(C^\theta_{\lambda_1}(v)) \) for any \( v \) from a given fixed finite set. It follows that, under the degeneration map the class of an extremal object goes to the class of an extremal object. Since the degeneration map is compatible with wall-crossing functors, we reduce the present case to Case 1. In particular, we get an \( a \)-action on \( \bigoplus_v K_0(A_{\lambda}(v)_{\text{-mod}_{\rho^{-1}(0)}}) \).

**Case 3.** Now consider the general case. Let \( \check{\lambda} \) denote the Weil generic element in the connected component of \( \{\lambda | a\check{\lambda} = a\} \) containing \( \lambda \). We can replace \( \lambda \) with its integral shift and assume that \( \check{\lambda} \) is Zariski generic in the closure of the connected component. We still have the injective degeneration maps \( K_0(A_{\check{\lambda}}(v)_{\text{-mod}_{fin}}) \to K_0(A_{\lambda}(v)_{\text{-mod}_{fin}}) \) intertwining the maps \([E_\alpha], [F_\alpha]\) as well as the maps given by wall-crossing functors. So again \( K_0(C^\theta_{\check{\lambda}}(v)) \) maps bijectively onto \( K_0(C^\theta_{\lambda}(v)) \) for any \( v \) from a given fixed finite set. It follows that \( \bigoplus C^\theta_{\check{\lambda}}(v)_{\text{-mod}} \to D^\theta_{\check{\lambda}}(A_{\check{\lambda}}(v)_{\text{-mod}}) \) to \( D^\theta_{\check{\lambda}}(A_{\check{\lambda}}(v)_{\text{-mod}}) \) for any \( v \) from a fixed finite set. Arguing as in Case 1, we see that \( L \mapsto L' \) sends extremal objects to extremal objects. We also see that the operators \([E_\alpha], [F_\alpha]\) give an action of \( a \) on \( K_0(C) \).

12.2 Absence of extremal simples

In this section we will use Proposition 6.5, Theorem 11.2 and Proposition 6.9 to complete the proof of (II) in the following two cases.

(a) The quiver \( Q \) is of finite type.
(b) \( Q \) is an affine quiver, \( v = n\delta, w = \epsilon_0 \).

**Lemma 12.1** Let \( \theta, \theta' \) be two stability conditions. Suppose that

- \( \theta, \theta' \) are not separated by \( \ker \alpha \), where \( \alpha \leq v \) is an imaginary root with \( \langle \alpha, \lambda \rangle \in \mathbb{Z} \).

\[ \sum_{\sigma \in S_{2d}} \text{sgn}(\sigma) a_{\sigma(1)} \ldots a_{\sigma(2d)}. \]
If $\beta \leq v$ is an imaginary root with $\langle \beta, \lambda \rangle \in \mathbb{Z}$, then $\langle \theta, \beta \rangle > 0$.

Let $M$ be an extremal simple $\mathcal{A}_\lambda^\theta(v)$-module. Then $H_0(\mathcal{M}_{\theta \rightarrow \theta'} M)$ has a quotient that is an extremal simple $\mathcal{A}_\lambda^\theta(v)$-module.

**Proof** Let $\theta_1 = \theta, \theta_2, \ldots, \theta_q = \theta'$ be stability conditions such that $\theta_i$ and $\theta_{i+1}$ are separated by $\ker \alpha_i$, where $\alpha_i$ is a real root with $\langle \alpha_i, \lambda \rangle \in \mathbb{Z}$ and $\alpha_i \leq v$. We assume that $q$ is minimal with this property. It follows from Proposition 6.9 that if $M_i$ is an extremal simple $\mathcal{A}_\lambda^\theta(v)$-module, then the head of $H_0(\mathcal{WC}_{\theta_i \rightarrow \theta_{i+1}} M_i)$ again contains an extremal simple, say $M_{i+1}$. We start with $M_1$ and produce the extremal simples $M_2, \ldots, M_q$. By the construction, $M_q$ is a quotient of $H_0(\mathcal{M}_{\theta_1 \rightarrow \theta_q} M)$.

Now we are ready to prove (II) from the beginning of Sect. 6.

**Proof of (II)** We need to prove that there are no extremal simples in $\mathcal{A}_\lambda^\theta(v)$-$\text{mod}_{\rho^{-1}(0)}$ (in the affine case we assume that $\langle \delta, \theta \rangle > 0$). Assume the contrary.

Lemma 12.1 together with Proposition 6.5 lead to a contradiction in case (a).

Now let us deal with case (b) – the SRA case. Pick an extremal simple $M \in \mathcal{A}_\lambda^\theta(v)$-$\text{mod}_{\rho^{-1}(0)}$. We can pick stability conditions $\theta_1, \ldots, \theta_q$ with the following properties:

(a) $\theta = \theta_j$ for some $j$.
(b) $-\theta_q$ and $\theta_1$ lie in chambers separated by $\ker \delta$ and $\langle \theta_1, \delta \rangle > 0$.
(c) $\theta_i$ and $\theta_{i+1}$ are separated by a single wall defined by a real root.
(d) $q$ is minimal with this property.

Let $M_j := M$ and find extremal simples $M_i \in \mathcal{A}_\lambda^\theta(v)$-$\text{mod}, i = 1, \ldots, q$, (where $\lambda_i \in \lambda + \mathbb{Z}^Q$ is such that $(\lambda_i, \theta_i) \in \mathfrak{A}L(v)$) such that $M_i$ and $M_{i+1}$ are in bijection produced by crossing the wall between $\theta_i$ and $\theta_{i+1}$ (with $M = M_i$ and $M' = M_{i+1}$), see Proposition 6.9.

Using LMN isomorphisms, we can identify $\mathcal{M}^\theta_i(v)$ with $\mathcal{M}^\tilde{\theta}_i(n\delta)$ and $\mathcal{A}_\lambda^\theta(v)$ with $\mathcal{A}_\lambda^\tilde{\theta}_i(n\delta)$ for appropriate $n, \tilde{\theta}_i, \tilde{\lambda}_i$. Note that $\tilde{\theta}_i, \tilde{\theta}_{i+1}$ are still separated by a single wall, for $i = 0$, this wall is $\ker \delta$, and for $i > 0$, this is the wall defined by a real root. Moreover, the weight $v$ defined by $v$ is extremal if and only if $n = 0$. Let $M_0$ be the simple in $\mathcal{A}_\lambda^\tilde{\theta}_0(n\delta)$-$\text{mod} = \mathcal{A}_\lambda^\theta_0(v)$-$\text{mod}$ corresponding to $M_1$ under the bijection in (3) of Theorem 11.2.

Consider the complex $\mathcal{M}_{\tilde{\theta}_0 \rightarrow \tilde{\theta}_q}(M_0)$. By Theorem 5.3,

$$\mathcal{M}_{\tilde{\theta}_0 \rightarrow \tilde{\theta}_q}(M_0) = \mathcal{M}_{\tilde{\theta}_1 \rightarrow \tilde{\theta}_q} \circ \mathcal{M}_{\tilde{\theta}_0 \rightarrow \tilde{\theta}_1}(M_0).$$
By Proposition 6.5, the left hand side has vanishing $H_k$ for $k < n$ because $\Gamma^0\tilde{\theta}_0(M_0)$ is finite dimensional. On the other hand, by Theorem 11.2, we have $H_j(\mathfrak{m}\mathfrak{c}_{\tilde{\theta}_0 \rightarrow \tilde{\theta}_1}(M_0)) \rightarrow M_1$ for some $j < n$ and $H_k(\mathfrak{m}\mathfrak{c}_{\tilde{\theta}_0 \rightarrow \tilde{\theta}_1}(M_0)) = 0$ for $k < j$. From Lemma 12.1, we deduce that $H_j(\mathfrak{m}\mathfrak{c}_{\tilde{\theta}_0 \rightarrow \tilde{\theta}_1}(M_0)) \rightarrow M_1$ for some $j < n$ and $H_k(\mathfrak{m}\mathfrak{c}_{\tilde{\theta}_0 \rightarrow \tilde{\theta}_1}(M_0)) = 0$ for $k < j$. We arrive at a contradiction that completes the proof. \[\square\]

### 12.3 Injectivity of CC

In this section we prove (III): the map $CC : \bigoplus_v K_0(\mathcal{A}_{\lambda}(v)\text{-mod}_{\rho^{-1}(0)}) \rightarrow L_\omega$ is injective.

A key step is as follows.

**Lemma 12.2** The operators $[E_\alpha], [F_\alpha]$ on $\bigoplus_v K_0(\mathcal{A}_{\lambda}(v)\text{-mod}_{\rho^{-1}(0)})$ give an $a$-action.

**Proof** It was shown in the proof of Proposition 6.9 (Sect. 12.1) that the restrictions of $[E_\alpha], [F_\alpha]$ to $K_0(C)$ define an action of $a$. On the other hand (II) proved in the previous section shows that $C = \bigoplus_v \mathcal{A}_{\lambda}(v)\text{-mod}_{\rho^{-1}(0)}$. This finishes the proof. \[\square\]

**Proof of (III)** By Proposition 6.1, the map $CC : \bigoplus_v K_0(\mathcal{A}_{\lambda}(v)\text{-mod}_{\rho^{-1}(0)}) \rightarrow L_\omega$ is $a$-linear. The image coincides with $L_\omega$ by (I) and (II). It follows from the construction of $C$ and (10.2) that the $a$-module $K_0(C)$ is generated by $\bigoplus_\sigma K_0(\mathcal{A}_{\lambda}(\sigma \cdot w)\text{-mod}_{\rho^{-1}(0)})$, where the summation is taken over $\sigma \in W(Q)$ such that $\sigma \omega$ is dominant for $a$. Since $C = \bigoplus_v \mathcal{A}_{\lambda}(v)\text{-mod}_{\rho^{-1}(0)}$, it follows that $CC$ is injective. \[\square\]

This finishes the proof of Theorem 1.2.

**Remark 12.3** Let us deduce the original conjecture of Etingof [26, Conjectures 6.3,6.8], from Conjecture 1.1. According to results of [33, Section 5], we have a derived equivalence $D^b(\mathcal{H}_{K,C}(n)\text{-mod}) \sim D^b(\mathcal{A}_{\lambda}(v)\text{-mod})$ that restricts to $D^b_{f in}(\mathcal{H}_{K,C}(n)\text{-mod}) \sim D^b_{\rho^{-1}(0)}(\mathcal{A}_{\lambda}(v)\text{-mod})$. So the number of finite dimensional irreducible $\mathcal{H}_{K,C}(n)$-modules coincides with the number of irreducible $\mathcal{A}_{\lambda}(v)$-modules supported on $\rho^{-1}(0)$. It is easy to see that the number given by Conjecture 1.1 is the same as conjectured by Etingof.

### 12.4 Conjectures on counting simples with arbitrary support

In the remainder of the section we would like to discuss two counting problems that are more general than the problem studied in this paper.

One can pose a problem of counting $\mathcal{A}_{\lambda}(v)$-irreducibles with given (positive) dimension of support. An obvious difficulty here is that the number of
such modules is infinite. There are, at least, three different approaches to the counting problem: to deal with a filtration by support on $K_0$, to work in characteristic $p \gg 0$ or to restrict to a suitable category of modules in characteristic 0.

### 12.4.1 Category $\mathcal{O}$

An easier special case is when there is a Hamiltonian $\mathbb{C}^\times$-action on $\mathcal{M}^\theta(v)$ with finitely many fixed points. This action deforms to a Hamiltonian action on $\mathcal{A}_\lambda(v)$ and hence on $\mathcal{A}_\lambda(v)$. Let $h \in \mathcal{A}_\lambda(v)$ denote the corresponding hamiltonian so that $[h, \cdot]$ coincides with the derivation of $\mathcal{A}$ induced by the $\mathbb{C}^\times$-action. The algebra $\mathcal{A}_\lambda(v)$ acquires an internal grading by eigenspaces of $\text{ad} h$, $\mathcal{A}_\lambda(v) = \bigoplus_{i \in \mathbb{Z}} \mathcal{A}_\lambda(v)^i$. Then we can consider the category $\mathcal{O}_\lambda(v)$ of $\mathcal{A}_\lambda(v)$-modules consisting of all finitely generated modules with locally nilpotent action of $\bigoplus_{i > 0} \mathcal{A}_\lambda(v)^i$, compare with [17, 19, 33, 40]. The simples in this category are in one-to-one correspondence with the irreducible modules over the algebra $\mathcal{A}_\lambda(v)^+ := \mathcal{A}_\lambda(v)^0 / (\bigoplus_{i > 0} \mathcal{A}_\lambda(v)^{-i} \mathcal{A}_\lambda(v)^i)$. It is not difficult to see that the algebra $\mathcal{A}_\lambda(v)^+$ is finite dimensional, compare to [33, Lemma 3.1.4]. Moreover, for $\lambda$ in some non-empty Zariski open subset of $\mathfrak{P}$, the algebra $\mathcal{A}_\lambda(v)^+$ is naturally identified with $\mathbb{C}[\mathcal{M}^\theta(v)^{\mathbb{C}^\times}]$, see [17, Section 5.1]. So we may assume that the irreducibles in our category $\mathcal{O}$ are parameterized by $\mathcal{M}^\theta(v)^{\mathbb{C}^\times}$. Also to every fixed point $p$ we can assign the corresponding Verma module, $\Delta_p := \mathcal{A}_\lambda(v) \otimes_{\mathcal{A}_\lambda(v)^0} \mathbb{C}_p$. Here $\mathbb{C}_p$ stands for the 1-dimensional $\mathcal{A}_\lambda(v)^0$-module corresponding to $p$, view $\mathbb{C}_p$ as an $\mathcal{A}_\lambda(v)^0$-module via the epimorphism $\mathcal{A}_\lambda(v)^0 \rightarrow \mathcal{A}_\lambda(v)^+$. For $\lambda$ in some Zariski open subset the category $\mathcal{O}$ is highest weight with standard objects $\Delta_p$, see [17, Section 5.2]. We identify $K_0(\mathcal{O}_\lambda(v))$ with $\mathbb{C}[\mathcal{M}^\theta(v)^{\mathbb{C}^\times}]$ by sending the class $[\Delta_p]$ of $\Delta_p$ to the basis vector corresponding to $p$. For example, suppose we consider $\mathcal{M}^\theta(n\delta)$ for a cyclic quiver $Q$ with $\ell$ vertices and $w = \epsilon_0$. Then we get the category $\mathcal{O}_{\Gamma_n}(n)$ for cyclotomic Rational Cherednik algebra $\mathcal{H}_{\Gamma_n}(\mathbb{C}^\times)$, as pointed out by Gordon in [32, Section 5.1], let us denote the fixed point corresponding to $\tau$ by $p(\tau)$. It follows from results of [33, Section 3] that $\Delta_{\tau}$ coincides with $\Delta_{p(\tau)}$.

One can ask the question to compute the number of the irreducibles in $\mathcal{O}_\lambda(v)$ with given dimension of support. In the cyclotomic Cherednik algebra case this problem was solved by Shan and Vasserot in [62]. We will state a conjecture in the case when $X = \mathcal{M}^\theta(v)$ and $Q$ is a cyclic quiver (in this case we do have a Hamiltonian $\mathbb{C}^\times$-action with finitely many fixed points). We remark
that different choices of $\mathbb{C}^\times$ lead to different choices of the categories $\mathcal{O}$, but our answer should not depend on the choice. More precisely, there are derived equivalences relating categories $\mathcal{O}$ for different choices of $\mathbb{C}^\times$, see [48], these equivalences can be seen to preserve the supports.

Set $\mathcal{O}_\lambda := \bigoplus_v \mathcal{O}_\lambda(v)$. We also write $\mathcal{O}_\lambda^w$ if we want to indicate the dependence on $w$.

A description of the $\mathbb{C}^\times$-stable points in $\mathcal{M}^\theta(v)$ follows, for example, from the work of Nakajima [57, Sections 3,7]. Namely, consider a maximal torus $T \subset \prod_{k \in Q_0} \text{GL}(w_k)$. Then the $T$-invariant points on $\mathcal{M}^\theta_{\{w\}} := \bigsqcup_v \mathcal{M}^\theta(v, w)$ are naturally identified with

$$\prod_{k \in Q_0} \mathcal{M}^\theta_{\{\epsilon_k\}}^{w_k}$$

The $\mathbb{C}^\times$-fixed locus in $\mathcal{M}^\theta_{\{w\}}$ is then the union of the fixed points in $\prod_{k \in Q_0} \mathcal{M}^\theta_{\{\epsilon_k\}}^{w_k}$, in each dimension there are finitely many of those. The fixed points in $\mathcal{M}^\theta(v, \epsilon_k)$ are indexed by $\ell$-multipartitions of $n_v$ such that $n_v \delta \in W(Q)\nu$.

Conjecture 12.4 Let $m$ denote the denominator of $\lambda$ (equal to $+\infty$ if $\langle \lambda, \delta \rangle \notin \mathbb{Q}$). The subspace $K_0(F_j \mathcal{O}_\lambda) \subset K_0(\mathcal{O}_\lambda)$ is the sum of the images of the operators $b_{m_j 1} \ldots b_{m_j k}$ with $j_1, \ldots, j_k \in \mathbb{Z}_{>0}$ and $(rm - 1)(j_1 + \ldots + j_k) \geq j$.

Now let us proceed to the general case: when $Q$ is a cyclic quiver with $\ell$ vertices and the framing $w$ is arbitrary. We again want to describe the filtration on $K_0(\mathcal{O}_\lambda^w)$ relative to the affine wall. The description will still be given in terms of some Heisenberg action on $K_0(\mathcal{O}_\lambda^w)$.

Let us specify that action. As we have seen above, $K_0(\mathcal{O}_\lambda^w) = \bigotimes_{k \in Q_0} K_0(\mathcal{O}_{\lambda_k}^{\epsilon_k}) \otimes w_k$. The space $K_0(\mathcal{O}_{\lambda_k}^{\epsilon_k})$ can be thought as an integrable highest weight module $\tilde{L}_{\omega_k}$, where $\omega_k$ is the fundamental weight corresponding to
$k$, for the Lie algebra $\hat{gl}_\ell$ (so that $\tilde{L}_{\omega_k} = L_{\omega_k} \otimes \mathcal{F}$), compare to [26, Section 6]. Inside $\hat{gl}_\ell$ consider the Heisenberg subalgebra corresponding to the center of $\mathfrak{gl}_\ell$. It has a basis $b_j$ with $j \in \mathbb{Z}$.

**Conjecture 12.5** Let $m$ denote the denominator of $\langle \lambda, \delta \rangle$ (equal to $+\infty$ if $\lambda \not\in \mathbb{Q}$). Consider the subcategory $F_j^{\text{aff}} \mathcal{O}_w$ consisting of all modules $M$ with $H_i(\mathcal{W}\mathcal{C} M) = 0$ for $i < j$, where $\mathcal{W}\mathcal{C}$ stands for the short wall-crossing functor through the affine wall. The subspace $K_0(F_j^{\text{aff}} \mathcal{O}_w^w) \subset K_0(\mathcal{O}_w^w)$ is the sum of the images of the operators $b_{m_{j_1}} \ldots b_{m_{j_k}}$ with $j_1, \ldots, j_k \in \mathbb{Z}_{>0}$, and $(\bar{w}m - 1)(j_1 + \ldots + j_k) \geq j$, where $\bar{w} := \sum_{k \in Q_0} w_k$.

Modulo Conjecture 12.5, one can state a conjecture regarding the filtration by dimension of support.

**Conjecture 12.6** The span in $K_0(\mathcal{O}_w^w)$ of the classes of all modules with dimension of support $\leq i$ is the sum of $\alpha$-submodules generated by the singular vectors in $F_j^{\text{aff}} \mathcal{O}_w^w(v)$, where $v$ and $i$ are subject to the following condition:

$$w \cdot v - (v, v)/2 - s(\bar{w}m - 1) \leq i.$$

We expect that Conjecture 12.6 should be an easy corollary of Conjecture 12.5 and techniques developed in Sects. 12.1 and 12.2. We remark that it is compatible with Conjecture 1.1 and also with the main result of [62].

### 12.4.2 Filtration on $K_0$

One can also work with a filtration on $K_0(A_\lambda(v)\text{-mod})$ as in [26, Conjectures 6.1,6.7]. As before, we assume that $A_\lambda(v)$ has finite homological dimension so that $K_0$ of the category of finitely generated $A_\lambda(v)$-modules is naturally identified with the split $K_0$ of the category of projective $A_\lambda(v)$-modules. Let $F_j K_0(A_\lambda(v)\text{-mod})$ stand for the subspace in $K_0(A_\lambda(v)\text{-mod})$ generated by all objects $M$ such that $\text{GK-dim}(A_\lambda(v)/\text{Ann} M) \leq \dim M^0(v) - 2j$. Then one can state a conjecture similar to Conjecture 12.6.

### 12.4.3 Characteristic $p$

Yet another setting where one can state counting conjectures is in characteristic $p \gg 0$. We use the notation of Sect. 7.1. In particular, $\mathbb{F}$ stands for an algebraically closed field of characteristic $p$. To simplify the statement we consider the case of a rational parameter $\lambda$ such that the algebra $A_\lambda(v) \otimes \overline{A_\lambda(v)}^{opp}$ has finite homological dimension.
Set $K_p^0 := K_0(\mathcal{A}_\lambda(v)_{\mathbb{F}}\text{-mod})$ and $K_\infty^0 = K_0(\mathcal{A}_\lambda(v)_{\mathbb{C}}\text{-mod})$ (recall that we consider the $K_0$ groups over $\mathbb{C}$). We have the specialization map $\text{Sp} : K_\infty^0 \to K_p^0$ for every prime $p \gg 0$ and it is an isomorphism.

Consider the category $\mathcal{A}_\lambda(v)_{\mathbb{F}}\text{-mod}_0$ of finitely generated modules with zero generalized $p$-character. Set $K_p^0 := K_0(\mathcal{A}_\lambda(v)_{\mathbb{F}}\text{-mod}_0)$. Similarly to Sect. 8.2, we have an identification $K_p^0 \cong K_0(\text{Coh}_{p^{-1}(0)} \mathcal{M}^\theta(v))$.

We have the Ext pairing $\chi : K_p^0 \times K_p^0 \to \mathbb{C}$, compare to the proof of Proposition 8.4. We have basically seen in Sect. 8.2 that this pairing is non-degenerate.

**Conjecture 12.7**

a) There exist polynomials in one variable $D_i(t) \in \mathbb{Q}[t]$, $i = 1, \ldots, \dim K_p^0$, such that for $p \gg 0$ the dimensions of the irreducible modules equal $D_i(p)$.

b) Let $\mathcal{A}_\lambda(v)\text{-mod}_{\leq d}^0$ be the Serre subcategory generated by irreducible objects $L_i$ such that the corresponding polynomial $D_i$ satisfies: $\deg(D_i) \leq d$. Then the induced filtration on $K^0(\mathcal{A}_\lambda(v)_{\mathbb{F}}\text{-mod}_0)$ is dual to the filtration on $K^0(\mathcal{A}_\lambda(v)_{\mathbb{C}}\text{-mod})$ considered in 12.4.2 with respect to the pairing $\chi$.

Let us speculate on a possible scheme of proof. First, we need an analog of Proposition 6.5 that is not available yet, we believe this is the most important thing missing. Second, we need an analog of Webster’s construction in positive characteristic. The latter is not expected to be difficult. Theorem 11.1 and an analog of Conjecture 12.5 should carry over to positive characteristic without significant modifications. This should be sufficient to prove the counting conjecture.

### 12.5 Infinite homological dimension

In this subsection we will state a conjecture on the number of irreducible finite dimensional $\mathcal{A}_\lambda(v)$-modules in the case when the homological dimension of $\mathcal{A}_\lambda(v)$ is infinite. Similar in spirit conjectures can be stated for categories $\mathcal{O}$ (or their replacements) or in positive characteristic, but we are not going to elaborate on that.

Consider the functor $R\Gamma_{\mathcal{A}_\lambda(v)}^\theta : D^b(\mathcal{A}_\lambda(v)\text{-mod}) \to D^b(\mathcal{A}_\lambda(v)\text{-mod})$. It should be a quotient functor, at least, this is so in the SRA situation thanks to an equivalence $D^b(\mathcal{A}_\lambda(v)\text{-mod}) \cong D^b(\mathcal{H}_{\kappa,c}(n)\text{-mod})$ established in [33, 5.1] (see 5.1.6, in particular). Under this equivalence the functor $R\Gamma_{\mathcal{A}_\lambda(v)}^\theta$ becomes the abelian quotient functor $\mathcal{M} \mapsto e\mathcal{M}$. According to Conjecture 4.8, this quotient is proper if and only if $\lambda$ lies in the finite union of hyperplanes (to be called “singular”), the singular hyperplanes can be (conjecturally) described explicitly when $Q$ is of finite or of affine type, see Sect. 4.3.

So $K_0(\mathcal{A}_\lambda(v)\text{-mod}_{fin})$ becomes a quotient of $K_0(\mathcal{A}_\lambda(v)\text{-mod}_{p^{-1}(0)})$. Our goal is to provide a conjectural description of this quotient. Our conjecture
will consist of two parts. The first (easier) will deal with the case when \( \lambda \) is a Zariski generic point of a singular hyperplane. The second (much harder) will handle the general case.

Let us deal with the Grassmanian case first. So let \( Q \) be a quiver with a single vertex and no arrows. The singular locus is \( \lambda = 1 - w, 2 - w, \ldots, -1 \). Assume, for convenience, that \( \theta > 0 \) and \( 2v \leq w \). Identify \( \mathcal{A}_\lambda^\theta(v) \)-mod with \( \mathcal{A}_0(v) \)-mod. The ideals in the latter form a chain: \( \{0\} = \mathcal{J}_v \subset \mathcal{J}_v \subset \cdots \subset \mathcal{J}_1 \subset \mathcal{J}_0 = \mathcal{A}_0(v) \). The kernel of the functor \( R\Gamma_\lambda^\theta \) can be shown to consist of all modules annihilated by \( \mathcal{J}_i \), where

\[
i = v + 1 - \min(v, -\lambda, w + \lambda) \tag{12.2}\]

(or, more precisely, the complexes with such homology). On the level of the categorical \( \mathfrak{sl}_2 \)-action, those should be precisely the complexes lying in the image of \( F^{v+1-i} \).

Let us return to the general setting.

**Conjecture 12.8**

1. Let \( \alpha \) be a real root and \( \lambda \) be a Zariski generic parameter on a singular hyperplane \( \langle \lambda, \alpha \rangle = s \). Then the complexified \( K_0 \) of the kernel of \( D^b(\mathcal{A}_\lambda^\theta(v) \text{-mod}_{\rho^{-1}(0)}) \to D^b(\mathcal{A}_\lambda(v) \text{-mod}_{\text{fin}}) \) coincides with the image of \( f^i_{\alpha^j} \), where \( i \) is determined from \( s \) and \( v, w \) as in (12.2).

2. Let \( \langle \alpha_j, \cdot \rangle = s_j, j = 1, \ldots, k \), be all singular hyperplanes with real \( \alpha_j \) that contain \( \lambda \). Then \( \ker K_0(D^b(\mathcal{A}_\lambda^\theta(v) \text{-mod}_{\rho^{-1}(0)}) \to D^b(\mathcal{A}_\lambda(v) \text{-mod}_{\text{fin}})) \)

is spanned (as a vector space) by the sum of the images of \( f^{i_j}_{\alpha_j}, j = 1, \ldots, k \), where the numbers \( i_j \) are determined as in (1).

We believe that one should not include the singular hyperplanes defined by imaginary roots. The reason is that there are no finite dimensional irreducibles for a Weil generic \( \lambda \) on a hyperplane defined by an imaginary root. When one deals with modules with higher dimensional support on should modify the conjecture to account for imaginary roots. We are not going to elaborate on that.

**Acknowledgements** We are grateful to Pavel Etingof, Joel Kamnitzer, Hiraku Nakajima, Andrei Okounkov, and Ben Webster for numerous helpful discussions. We also would like to thank Dmitry Korb, Kevin McGerty and Yaochen Wu for remarks on the previous versions of this text. We are also grateful to the referees for their comments that helped us to improve the exposition and fix several gaps in the paper. R.B. was supported by the NSF under Grant DMS-1102434. I.L. was supported by the NSF under Grant DMS-1161584.
