Uniform convergence of local Fréchet regression, with applications to locating extrema and time warping for metric space valued trajectories*†

Yaqing Chen and Hans-Georg Müller

Department of Statistics, University of California, Davis

ABSTRACT

Local Fréchet regression is a nonparametric regression method for metric space valued responses and Euclidean predictors, which can be utilized to obtain estimates of smooth trajectories taking values in general metric spaces from noisy metric space valued random objects. We derive uniform rates of convergence, which so far have eluded theoretical analysis of this method, for both fixed and random target trajectories, where we utilize tools from empirical processes. These results are shown to be widely applicable in metric space valued data analysis. In addition to simulations, we provide two pertinent examples where these results are important: The consistent estimation of the location of properly defined extrema in metric space valued trajectories, which we illustrate with the problem of locating the age of minimum brain connectivity as obtained from fMRI data; Time warping for metric space valued trajectories, illustrated with yearly age-at-death distributions for different countries.

KEY WORDS: Random objects, Metric space valued functional data, Rates of convergence, Smoothing, fMRI, Mortality distributions.

†Data used in preparation of this article were obtained from the Alzheimer’s Disease Neuroimaging Initiative (ADNI) database (adni.loni.usc.edu). As such, the investigators within the ADNI contributed to the design and implementation of ADNI and/or provided data but did not participate in analysis or writing of this report. A complete listing of ADNI investigators can be found at: http://adni.loni.usc.edu/wp-content/uploads/how_to_apply/ADNI_Acknowledgement_List.pdf
1 Introduction

Non-Euclidean data, or random object data taking values in metric spaces, have become increasingly common in modern data analysis and data science while there is a lack of principled and statistically justified methodology. Since such data are metric space valued, they generally do not lie in a vector space, which means that many classical notions of statistics such as the definition of sample or population mean as an average or expected value do not apply anymore and need to be replaced by barycenters or Fréchet means (Fréchet, 1948), the mathematical and statistical properties of which have been studied for various metric spaces. These include finite-dimensional Riemannian manifolds, the space of symmetric positive definite matrices, Kendall’s shape space, or the Wasserstein space of distributions (Bhattacharya and Patrangenaru, 2003, 2005; Dryden et al., 2009; Agueh and Carlier, 2011; Huckemann, 2012; Le Gouic and Loubes, 2017, among others); the last is not a Riemannian manifold (Ambrosio et al., 2004).

Another important topic is to study the relationship of such random objects with other variables, where regression analysis comes into play. Nonparametric (local) regression techniques have been used for a long time for smoothing and interpolation of Euclidean responses. While Nadaraya–Watson type methods have been proposed in the cases where data lie in finite-dimensional Riemannian manifolds (Pelletier, 2006; Davis et al., 2007; Steinke and Hein, 2009; Steinke et al., 2010; Yuan et al., 2012), and also generic metric spaces (Hein, 2009), local Fréchet regression (Petersen and Müller, 2019), can be viewed as a generalization of local linear regression for metric space valued responses. While pointwise asymptotic results for the corresponding estimates have been previously derived, uniform convergence is much more challenging. Here we derive uniform rates of convergence for the local Fréchet regression estimates of the fixed conditional Fréchet mean trajectory using tools from empirical process theory; see Theorem 1. We then extend this result to the case where local Fréchet regression is applied to recover metric space valued random processes from discrete noisy observations; see Theorem 2. While these results may be of interest in their own right, our derivations are motivated by important applications of uniform convergence. These include the estimation of the location of suitably defined extrema in metric space valued functions as well as time warping for metric space valued functional data.

Estimation of modes or maximum locations has been well studied for regression functions in nonparametric regression for real-valued data (e.g., Devroye, 1978; Müller, 1989; Belitser et al., 2012) and densities of probability distributions (e.g., Parzen, 1962; Vieu, 1996; Balabdaoui et al., 2009). For object data in metric spaces, the location of extrema with regard to functionals of interest can be obtained based on the estimation of the complete conditional Fréchet mean trajectory through local Fréchet regression, where the consistency of the derived estimates of the location of an extremum is guaranteed by the uniform convergence of local Fréchet regression under regularity conditions.

For real-valued functional data, a random function has two types of variation: amplitude variation and phase (or time) variation. Confounding the two types of variation may seriously contaminate conventional statistical methods (Kneip and Gasser, 1992). This issue has been addressed by
time warping, also referred to as curve synchronization, registration or alignment. The prototypical method is dynamic time warping (DTW) (Sakoe and Chiba, 1978) and various statistical approaches have been developed over the years for real-valued functional data (Kneip and Gasser, 1992; Gasser and Kneip, 1995; Wang and Gasser, 1997; Ramsay and Li, 1998; Gervini and Gasser, 2004; James, 2007, among others); see Marron et al. (2015) for a recent review. Beyond classical functional data in $L^2$ Hilbert space, time synchronization has been investigated in engineering for non-Euclidean semi-metric spaces, also referred to as dissimilarity spaces (Faragó et al., 1993), where the DTW method and its variants have been adopted with applications including human motion recognition and video classification (Gong and Medioni, 2011; Vu et al., 2012; Trigeorgis et al., 2018, among others). We note that no theoretical results were provided in these works. To our knowledge, no comprehensive studies exist of time warping for samples of metric space valued trajectories that include an investigation of statistical properties or asymptotic behavior.

Statistical methods devised for real-valued functional data, or random elements of a Hilbert space, are usually not applicable to functional data taking values in a metric space (Huckemann, 2015). Even extending functional data analysis methods without time warping to metric space valued trajectories is challenging (Dubey and Müller, 2020), due to the fact that in general metric spaces one cannot rely on an algebraic structure. In this paper, we tackle the even more challenging task to extend pairwise warping for real-valued curves (Tang and Müller, 2008) to metric space valued functional data. Since random processes are usually not fully observed and only discrete and noisy measurements are available, local Fréchet regression needs to be used to obtain complete subject-specific trajectories. The uniform convergence result in Theorem 2 for local Fréchet regression estimates of random processes is crucial to derive the uniform consistency of estimates of the pairwise warping functions, which form the backbone of the proposed warping method; the uniform consistency provides the major justification for this approach.

The remainder of the paper is organized as follows. A key result on the uniform rate of convergence for local Fréchet regression is presented in Section 2, followed by a study of the case where the target of the local Fréchet regression is a random process rather than a fixed trajectory in Section 3. We present two applications, where the estimation of the location of extrema is based on Theorem 2 and presented in Section 4. A second key application is the time synchronization for metric space valued functional data in Section 5, which is based on Theorem 2. The proposed methods are shown to lead to consistent estimation of time warping functions in Theorem 3 and Corollary 3. We then demonstrate the estimation of extrema locations with functional magnetic resonance imaging (fMRI) data from the Alzheimer’s Disease Neuroimaging Initiative (ADNI) database in Section 6.1, where we find the time of minimum brain connectivity, quantified by the Fiedler values of the brain network. The time warping for metric space valued functional data is illustrated with yearly age-at-death distribution data for different countries from the Human Mortality Database in Section 6.2. We also report the results of various simulation studies for the proposed warping method for distribution-valued functional data in Section S.5 in the Supplementary Material.
2 Uniform Rates of Convergence for Local Fréchet Regression

Let \((\mathcal{M}, d_{\mathcal{M}})\) be a totally bounded separable metric space, and \(\mathcal{T} = [0, \tau]\) be a closed interval in \(\mathbb{R}\). This will be assumed throughout the paper. Consider a random pair \((U, V)\) with a joint distribution on the product space \(\mathcal{T} \times \mathcal{M}\), where \(U\) is a real-valued predictor and \(V\) is a metric space valued response. Suppose \(\{(U_j, V_j)\}_{j=1}^m\) are i.i.d. realizations of \((U, V)\). For any \(t \in \mathcal{T}\), the conditional Fréchet mean of \(V\) given \(U = t\) is defined by

\[
\nu(t) = \arg\min_{z \in \mathcal{M}} L(z, t), \quad L(z, t) = \mathbb{E}[d_{\mathcal{M}}^2(V, z) \mid U = t].
\] (1)

We consider local Fréchet means (Petersen and Müller, 2019)

\[
\tilde{\nu}_b(t) = \arg\min_{z \in \mathcal{M}} \tilde{L}_b(z, t), \quad \tilde{L}_b(z, t) = \mathbb{E}[w(U, t, b)d_{\mathcal{M}}^2(V, z)],
\] (2)

where \(w(s, t, b) = K_b(s-t)[\rho_{2,b}(t) - \rho_{1,b}(t)(s-t)]/\sigma_b^2(t), \quad \rho_{l,b}(t) = \mathbb{E}[K_b(U-t)(U-t)^l]\), for \(l = 0, 1, 2\), \(\sigma_b^2(t) = \rho_{0,b}(t)\rho_{2,b}(t) - \rho_{1,b}(t)^2, \quad K_b(\cdot) = K(\cdot/b), \quad K\) is a smoothing kernel, and \(b = b(m) > 0\) is a bandwidth sequence. Local Fréchet regression estimates of \(\nu(t)\) are given by

\[
\tilde{\nu}_m(t) = \arg\min_{z \in \mathcal{M}} \tilde{L}_m(z, t), \quad \tilde{L}_m(z, t) = m^{-1}\sum_{j=1}^m \tilde{w}(U_j, t, b)d_{\mathcal{M}}^2(V_j, z),
\] (3)

where \(\tilde{w}(s, t, b) = K_b(s-t)[\tilde{\rho}_{2,m}(t) - \tilde{\rho}_{1,m}(t)(s-t)]/\tilde{\sigma}_m^2(t), \quad \tilde{\rho}_{l,m}(t) = m^{-1}\sum_{j=1}^m [K_b(U_j-t)(U_j-t)^l]\), \(l = 0, 1, 2\), \(\tilde{\sigma}_m^2(t) = \tilde{\rho}_{0,m}(t)\tilde{\rho}_{2,m}(t) - \tilde{\rho}_{1,m}(t)^2\).

Let \(\mathcal{T}^o = (0, \tau)\) be the interior of \(\mathcal{T}\). We require the following assumptions to obtain uniform rates of convergence over \(t \in \mathcal{T}\) for local Fréchet regression estimators in (3).

(K0) The kernel \(K\) is a probability density function, symmetric around zero and uniformly continuous on \(\mathbb{R}\). Defining \(K_{kl} = \int_{\mathbb{R}} K(x) x^k dx < \infty\), for \(k, l \in \mathbb{N}\), \(K_{14}\) and \(K_{26}\), are finite. The derivative \(K'\) exists and is bounded on the support of \(K\), i.e., \(\sup_{K(x)>0} |K'(x)| < \infty\); additionally, \(\int_{\mathbb{R}} x^2 |K'(x)| \sqrt{|x \log |x||} dx < \infty\).

(R0) The marginal density \(f_U\) of \(U\) and the conditional densities \(f_{U|V}(\cdot, z)\) of \(U\) given \(V = z\) exist and are continuous on \(\mathcal{T}\) and twice continuously differentiable on \(\mathcal{T}^o\), the latter for all \(z \in \mathcal{M}\). The marginal density \(f_U\) is bounded away from zero on \(\mathcal{T}\), \(\inf_{t \in \mathcal{T}} f_U(t) > 0\). The second-order derivative \(f_U''\) is bounded, \(\sup_{t \in \mathcal{T}^o} |f_U''(t)| < \infty\). The second-order partial derivatives \((\partial^2 f_U/V/\partial t^2)(\cdot, z)\) are uniformly bounded, \(\sup_{t \in \mathcal{T}^o, z \in \mathcal{M}} |(\partial^2 f_U/V/\partial t^2)(t, z)| < \infty\). Additionally, for any open set \(E \subset \mathcal{M}\), \(P(V \in E \mid U = t)\) is continuous as a function of \(t\); for any \(t \in \mathcal{T}\), \(L(z, t)\) is equicontinuous, i.e.,

\[
\limsup_{s \to t} \sup_{z \in \mathcal{M}} |L(z, s) - L(z, t)| = 0.
\] (4)
(R1) For all \( t \in \mathcal{T} \), the minimizers \( \nu(t) \), \( \tilde{\nu}_b(t) \) and \( \hat{\nu}_m(t) \) exist and are unique, the last \( P \)-almost surely. In addition, for any \( \epsilon > 0 \),

\[
\inf_{t \in \mathcal{T}} \inf_{d_{\mathcal{M}}(\nu(t), z) > \epsilon} \left( L(z, t) - L(\nu(t), t) \right) > 0,
\]

\[
\liminf_{b \to 0} \inf_{t \in \mathcal{T}} \inf_{d_{\mathcal{M}}(\tilde{\nu}_b(t), z) > \epsilon} \left( \tilde{L}_b(z, t) - \tilde{L}_b(\tilde{\nu}_b(t), t) \right) > 0,
\]

and there exists \( c = c(\epsilon) > 0 \) such that

\[
P \left( \inf_{t \in \mathcal{T}} \inf_{d_{\mathcal{M}}(\tilde{\nu}_m(t), z) > \epsilon} \left( \tilde{L}_m(z, t) - \tilde{L}_m(\hat{\nu}_m(t), t) \right) \geq c \right) \to 1.
\]

(R2) Let \( B_r(\nu(t)) \subset \mathcal{M} \) be a ball of radius \( r \) centered at \( \nu(t) \) and \( N(\epsilon, B_r(\nu(t)), d_{\mathcal{M}}) \) be its covering number using balls of radius \( \epsilon \). Then

\[
\int_0^1 \sup_{t \in \mathcal{T}} \sqrt{1 + \log N(\epsilon r, B_r(\nu(t)), d_{\mathcal{M}})} d\epsilon = O(1), \quad \text{as } r \to 0+.
\]

(R3) There exists \( r_1, r_2 > 0 \), \( c_1, c_2 > 0 \) and \( \beta_1, \beta_2 > 1 \) such that

\[
\inf_{t \in \mathcal{T}} \inf_{d_{\mathcal{M}}(z, \nu(t)) < r_1} \left[ L(z, t) - L(\nu(t), t) - c_1 d_{\mathcal{M}}(z, \nu(t))^\beta_1 \right] \geq 0,
\]

\[
\liminf_{b \to 0} \inf_{t \in \mathcal{T}} \inf_{d_{\mathcal{M}}(z, \tilde{\nu}_b(t)) < r_2} \left[ \tilde{L}_b(z, t) - \tilde{L}_b(\tilde{\nu}_b(t), t) - c_2 d_{\mathcal{M}}(z, \tilde{\nu}_b(t))^\beta_2 \right] \geq 0.
\]

Similar yet weaker assumptions have been made by Petersen and Müller (2019) for pointwise rates of convergence for local Fréchet regression estimators. Assumption (K0) is needed to apply results of Silverman (1978) and Mack and Silverman (1982), and (R0) is a standard distributional assumption for local nonparametric regression. These assumptions guarantee the asymptotic uniform equicontinuity of \( \tilde{L}_b \) and control the behavior of \( (\tilde{L}_b - L) \) around \( \nu(t) \) uniformly over \( t \in \mathcal{T} \), whence we obtain the uniform rate for the bias part \( d_{\mathcal{M}}(\nu(t), \tilde{\nu}_b(t)) \) and the uniform consistency of the stochastic part \( d_{\mathcal{M}}(\tilde{\nu}_b(t), \hat{\nu}_m(t)) \) for the local Fréchet regression estimators. In particular, (4) guarantees the \( d_{\mathcal{M}} \)-continuity of \( \nu(t) \) in conjunction with (R1). Assumption (R1) is commonly used to establish the uniform consistency of M-estimators (van der Vaart and Wellner, 1996). It ensures the uniform convergence of \( \tilde{L}_b(-, t) \) to \( L(-, t) \) and the weak convergence of the empirical process \( \hat{L}_m(\cdot, t) \) to \( \tilde{L}_b(\cdot, t) \), which, in conjunction with the assumption that the metric space \( \mathcal{M} \) is totally bounded, implies the pointwise convergence of the minimizers for any given \( t \in \mathcal{T} \); it also ensures that the (asymptotic) uniform equicontinuity of \( \tilde{L}_b \) and \( \hat{L}_m \) implies the (asymptotic) uniform equicontinuity of \( \tilde{\nu}_b(\cdot) \) and \( \hat{\nu}_m(\cdot) \), whence the uniform convergence of the minimizers follows as the time domain \( \mathcal{T} \) is compact. Assumptions (R2) and (R3) are adapted from empirical process theory to control the differences \( (\hat{L}_m - \tilde{L}_b) \) and \( (\tilde{L}_b - L) \) near the minimizers \( \tilde{\nu}_b(t) \) and \( \nu(t) \), respectively, which is necessary to obtain the convergence rates for the bias and stochastic parts.
In the following, we discuss assumptions (R1)–(R3) in the context of some specific metric spaces.

**Example 1.** Let $\mathcal{M}$ be the set of probability distributions on a closed interval of $\mathbb{R}$ with finite second moments, endowed with the $L^2$-Wasserstein distance $d_W$; specifically, for any two distributions $z_1, z_2 \in \mathcal{M}$,

$$d_W(z_1, z_2) = \left( \int_0^1 (Q_{z_1}(x) - Q_{z_2}(x))^2 \, dx \right)^{1/2} = d_{L^2}(Q_{z_1}, Q_{z_2}),$$

where $Q_z$ is the quantile function for any given distribution $z \in \mathcal{M}$. The Wasserstein space $(\mathcal{M}, d_W)$ satisfies (R1)–(R3) with $\beta_1 = \beta_2 = 2$.

**Example 2.** Let $\mathcal{M}$ be the space of $r$-dimensional correlation matrices, i.e., symmetric, positive semidefinite matrices in $\mathbb{R}^{r \times r}$ with diagonal elements all equal to 1, endowed with the Frobenius metric $d_F$. The space $(\mathcal{M}, d_F)$ satisfies (R1)–(R3) with $\beta_1 = \beta_2 = 2$.

For Examples 1–2, we note that since the Wasserstein space and the space of correlation matrices are Hadamard spaces (the former as per Kloeckner, 2010), there exists a unique minimizer of $L_p(t)$, for any $t \in \mathcal{T}$ (Sturm, 2003). Examples 1–2 follow from similar arguments as those in the proofs of Propositions 1–2 of Petersen and Müller (2019); we omit the details.

We then obtain uniform rates of convergence over $t \in \mathcal{T}$ for local Fréchet regression estimators as follows. Proofs and auxiliary results are in the Supplementary Material.

**Theorem 1.** Under (K0), (R0)–(R3) and if $b \to 0$, $mb^2(-\log b)^{-1} \to \infty$, as $m \to \infty$, for any $\varepsilon > 0$, it holds for $\nu(t)$, $\tilde{\nu}_b(t)$, and $\tilde{\nu}_m(t)$ as per (1)–(3), respectively, that

$$\sup_{t \in \mathcal{T}} d_{\mathcal{M}}(\nu(t), \tilde{\nu}_b(t)) = O\left(b^{2/3} \right),$$

$$\sup_{t \in \mathcal{T}} d_{\mathcal{M}}(\tilde{\nu}_b(t), \tilde{\nu}_m(t)) = O_P\left(\max\left\{\left(\frac{mb^2}{1/\log b}\right)^{-1}, \left(\frac{mb^2}{1/\log b}\right)^{-1}\right\}\right).$$

Furthermore, with $b \sim m^{-(\beta_1-1)/(2\beta_1+4\beta_2-6+2\varepsilon)}$, it holds that

$$\sup_{t \in \mathcal{T}} d_{\mathcal{M}}(\nu(t), \tilde{\nu}_m(t)) = O_P\left(m^{-1/(\beta_1+2\beta_2-3+\varepsilon)}\right).$$

Theorem 1 is a novel and relevant result for local Fréchet regression in its own right; we expect it to be a useful and widely applicable tool for the study of metric space valued data. We note that although $\mathcal{T}$ is a closed interval, boundary effects do not pose a problem, similar to the situation for local polynomial regression with real-valued responses (e.g., Fan and Gijbels, 1996). For the bias part in (5), we obtain the same rate as for pointwise results. For the stochastic part, the proof is substantially more involved. When $\beta_1 = \beta_2 = 2$ as in Examples 1–2, the uniform convergence rate is found to be arbitrarily close to $O_P(m^{-1/3})$. 

3 Recovering Metric-space Valued Random Processes from Discrete Noisy Measurements

We consider a metric space valued random process $Y: \mathcal{T} \rightarrow \mathcal{M}$ that is assumed to be $d_{\mathcal{M}}$-continuous over $\mathcal{T}$. In practice, the process $Y$ is usually not fully observed; instead one observes noisy measurements at discrete time points. Since a metric space in general is not a vector space and hence does not afford additive operations, it is not obvious how to express the deviation of noisy observations from the underlying process $Y$. To address this issue, we introduce a random perturbation map $P: \mathcal{M} \rightarrow \mathcal{M}$ such that

$$z' = \arg\min_{z \in \mathcal{M}} \mathbb{E}\left[d_{\mathcal{M}}^2(P(z'), z)\right], \quad \text{for all } z' \in \mathcal{M}.$$  

(8)

Consider a random pair $(T, Z)$ following a joint distribution on $\mathcal{T} \times \mathcal{M}$, where $T$ is the time of observation and $Z$ is a noisy observation of the process $Y$ at a random time $T$, given by

$$Z = P(Y(T)).$$  

(9)

Then the conditional Fréchet mean of the observed object $Z$ given the process $Y$ and time $T$ is the process evaluated at that time, i.e.,

$$Y(T) = \arg\min_{z \in \mathcal{M}} \mathbb{E}\left[d_{\mathcal{M}}^2(Z, z) \mid Y, T\right].$$  

(10)

Furthermore, we assume

(P1) The time of observation $T$ and the random perturbation map $P$ are independent of the random process $Y$.

The analogue of assumption (P1) in Euclidean regression is the standard assumption of independence between additive noise and underlying process.

Suppose that available noisy observations of the process $Y$ are $\{(T_j, Z_j)\}_{j=1}^m$, where $Z_j = P_j(Y(T_j))$, and $\{(T_j, P_j)\}_{j=1}^m$ are independent realizations of $(T, P)$. Hence, $\{(T_j, Z_j)\}_{j=1}^m$ are conditionally independent realizations of $(T, Z)$ given the process $Y$. Local Fréchet regression can be utilized to estimate the process trajectories $Y$ via (3), with trajectory estimates

$$\hat{Y}(t) = \arg\min_{z \in \mathcal{M}} \frac{1}{m} \sum_{j=1}^m \hat{v}(T_j, t, b)d_{\mathcal{M}}^2(Z_j, z), \quad \text{for all } t \in \mathcal{T}.$$  

(11)

Here, $\hat{v}(s, t, b) = K_b(s - t)[\hat{g}_2(t) - \hat{g}_1(t)]/\hat{c}_2^2(t)$, $b = b(m) > 0$ is a bandwidth sequence, $\hat{g}_l(t) = m^{-1}\sum_{j=1}^m K_b(t_j - t)(t_j - t)^l$, $l = 0, 1, 2$, and $\hat{c}_m^2(t) = \hat{g}_0(t)\hat{g}_2(t) - \hat{g}_1(t)^2$, $K_b(\cdot) = K(\cdot/b)/b$; $K$ is a kernel function.

We note that while $\hat{v}_m$ in (3) is a local Fréchet regression estimate of the fixed trajectory $\nu$ as per (1), the target of the local Fréchet regression implemented as per (11) is the random process $Y$. 

We next extend the results in Section 2 for local Fréchet regression with fixed targets to the case of such random targets, and obtain the uniform convergence rates for \( \hat{Y} \) over \( \mathcal{T} \).

Let \((\Omega, \mathcal{F}, P)\) be the probability space on which the observed data \((T_j, Z_j)\) are defined, where \(\Omega\) is the sample space, \(\mathcal{F}\) is the \(\sigma\)-algebra of events, and \(P : \mathcal{F} \to [0, 1]\) is the probability measure. As the random mechanisms that generate the data as per (P1) are independent, the probability space \((\Omega, \mathcal{F}, P)\) is a product space of two probability spaces, \((\Omega_1, \mathcal{F}_1, P_{\Omega_1})\), where the metric space valued process \(Y\) is defined, and \((\Omega_2, \mathcal{F}_2, P_{\Omega_2})\), where the observed times \(T_j\) and the random perturbation map \(P_j\) associated with the noisy observations \(Z_j\) are defined. Fixing an element \(\omega_1 \in \Omega_1\) corresponds to a realization of the metric space valued process \(Y\). Given a fixed \(\omega_1 \in \Omega_1\), the observed pairs \(\{(T_j, Z_j)\}_{j=1}^m\) are independent in \((\Omega_2, \mathcal{F}_2, P_{\Omega_2})\) and \(T\) and \(T_j\) do not depend on \(\omega_1\). We use \(Y_{\omega_1}, Z_{\omega_1}, Z_{\omega_1,j}, T\), and \(T_j\) to represent the corresponding quantities given \(\omega_1 \in \Omega_1\) in what follows, and also \(E_{\Omega_2}\) for the expectation (integral) with respect to \(P_{\Omega_2}\). For any fixed \(\omega_1 \in \Omega_1\), \(\{(T_j, Z_{\omega_1,j})\}_{j=1}^m\) are i.i.d. realizations of \((T, Z_{\omega_1})\). For any \(t \in \mathcal{T}\), as per (10),

\[
Y_{\omega_1}(t) = \arg\inf_{z \in \mathcal{M}} M_{\omega_1}(z, t), \quad M_{\omega_1}(z, t) = E_{\Omega_2}[d^2_M(Z_{\omega_1}, z) | T = t]. \tag{12}
\]

The localized Fréchet mean (Petersen and Müller, 2019) is

\[
\tilde{Y}_{\omega_1, b}(t) = \arg\inf_{z \in \mathcal{M}} \tilde{M}_{\omega_1, b}(z, t), \quad \tilde{M}_{\omega_1, b}(z, t) = E_{\Omega_2}[v(T, t, b) d^2_M(Z_{\omega_1}, z)]. \tag{13}
\]

Here, \(v(s, t, b) = K_b(s - t)[q_{2,b}(t) - q_{1,b}(t)(s - t)]/\varsigma_b^2(t)\), where \(q_{l,b}(t) = E_{\Omega_2}[K_b(T - t)(T - t)^l]\), for \(l = 0, 1, 2\), and \(\varsigma_b^2(t) = q_{0,b}(t)q_{2,b}(t) - q_{1,b}(t)^2\). The local Fréchet regression estimates \(\hat{Y}(t)\) in (11) can be expressed as

\[
\hat{Y}_{\omega_1, m}(t) = \arg\inf_{z \in \mathcal{M}} \hat{M}_{\omega_1, m}(z, t), \quad \hat{M}_{\omega_1, m}(z, t) = m^{-1} \sum_{j=1}^m \hat{g}(T_j, t, b) d^2_M(Z_{\omega_1,j}, z). \tag{14}
\]

Let \(\mathcal{T} = (0, \tau)\) be the interior of the time domain \(\mathcal{T}\). Considering an arbitrarily fixed \(\omega_1 \in \Omega_1\), for local Fréchet regression as described in (12)–(14), assumptions (R0)–(R3) can be adapted to obtain uniform rates of convergence of local Fréchet regression estimates \(\hat{Y}_{\omega_1, m}(t)\) over \(t \in \mathcal{T}\). To obtain uniform rates of convergence of the local Fréchet regression estimate \(\hat{Y}\) of the random process \(Y\) over \(\mathcal{T}\), we need to deal with different \(\omega_1 \in \Omega_1\) simultaneously, for which we require the following stronger variants of assumptions (R0)–(R3).

(U0) The marginal density \(f_T\) of \(T\) and the conditional densities \(f_{T|Z_{\omega_1}}(\cdot, z)\) of \(T\) given \(Z_{\omega_1} = z\) exist and are continuous on \(\mathcal{T}\) and twice continuously differentiable on \(\mathcal{T}^c\), the latter for all \(z \in \mathcal{M}\) and \(\omega_1 \in \Omega_1\). The marginal density \(f_T\) is bounded away from zero on \(\mathcal{T}\), \(\inf_{t \in \mathcal{T}} f_T(t) > 0\). The second-order derivative \(f''_T\) is bounded, \(\sup_{t \in \mathcal{T}} |f''_T(t)| < \infty\). The second-order partial derivatives \((\partial^2 f_{T|Z_{\omega_1}}/\partial t^2)(\cdot, z)\) are uniformly bounded, \(\sup_{\omega_1 \in \Omega_1, t \in \mathcal{T}^c, z \in \mathcal{M}} |(\partial^2 f_{T|Z_{\omega_1}}/\partial t^2)(t, z)| < \infty\). Additionally, for any open set \(E \subset \mathcal{M}\), \(P_{\Omega_2}(Z_{\omega_1} \in E \mid T = t)\) is continuous as a function of \(t\).
for all $\omega_1 \in \Omega_1$.

(U1) For all $\omega_1 \in \Omega_1$ and $t \in \mathcal{T}$, the minimizers $Y_{\omega_1}(t)$, $\widetilde{Y}_{\omega_1,b}(t)$ and $\widehat{Y}_{\omega_1,m}(t)$ exist and are unique, the last $P_{\Omega_2}$-almost surely. Additionally, for any $\epsilon > 0$,

$$
\inf_{\omega_1 \in \Omega_1, t \in \mathcal{T}} \inf_{d_M(Y_{\omega_1}(t), z) > \epsilon} \left( M_{\omega_1}(z, t) - M_{\omega_1}(Y_{\omega_1}(t), t) \right) > 0,
$$

$$
\liminf_{b \to 0} \inf_{\omega_1 \in \Omega_1, t \in \mathcal{T}} \inf_{d_M(\widetilde{Y}_{\omega_1,b}(t), z) > \epsilon} \left( \widetilde{M}_{\omega_1,b}(z, t) - \widetilde{M}_{\omega_1,b}(\widetilde{Y}_{\omega_1,b}(t), t) \right) > 0.
$$

(U2) Let $B_r(Y_{\omega_1}(t)) \subset \mathcal{M}$ be a ball of radius $r$ centered at $Y_{\omega_1}(t)$ and $N(\epsilon, B_r(Y_{\omega_1}(t)), d_M)$ be its covering number using balls of radius $\epsilon$. Then

$$
\sup_{r > 0} \sup_{\omega_1 \in \Omega_1} \int_0^1 \sup_{t \in \mathcal{T}} \sqrt{1 + \log N(r\epsilon, B_r(Y_{\omega_1}(t)), d_M)} d\epsilon < \infty.
$$

(U3) There exist $c_1, c_2 > 0$, and $\beta_1, \beta_2 > 1$ such that for any $r_1, r_2 > 0$,

$$
\inf_{\omega_1 \in \Omega_1, t \in \mathcal{T}} \inf_{d_M(z, Y_{\omega_1}(t)) < r_1} \left[ M_{\omega_1}(z, t) - M_{\omega_1}(Y_{\omega_1}(t), t) - c_1 d_M(z, Y_{\omega_1}(t))^{\beta_1} \right] \geq 0,
$$

$$
\liminf_{b \to 0} \inf_{\omega_1 \in \Omega_1, t \in \mathcal{T}} \inf_{d_M(z, \widetilde{Y}_{\omega_1,b}(t)) < r_2} \left[ \widetilde{M}_{\omega_1,b}(z, t) - \widetilde{M}_{\omega_1,b}(\widetilde{Y}_{\omega_1,b}(t), t) - c_2 d_M(z, \widetilde{Y}_{\omega_1,b}(t))^{\beta_2} \right] \geq 0.
$$

We note that the assumption of equicontinuity of $L$ as per (4) to guarantee the $d_M$-continuity of $\nu$ is not needed in this case, since the process $Y$ is assumed to be $d_M$-continuous. We then obtain the uniform convergence rates for $\widehat{Y}$ over $\mathcal{T}$ as follows.

**Theorem 2.** Under (P1), (K0), and (U0)–(U3), for any $\epsilon > 0$,

$$
\sup_{t \in \mathcal{T}} d_M\left( Y(t), \widehat{Y}(t) \right) = O\left( b^{2/(\beta_1-1)} \right);
$$

$$
\sup_{t \in \mathcal{T}} d_M\left( \widehat{Y}(t), \widehat{Y}(t) \right) = O_P\left( \max\left\{ (mb^2)^{-1/[2(\beta_2-1)+\epsilon]}, (mb^2(-\log b)^{-1/[2(\beta_2-1)]}) \right\} \right).
$$

Furthermore, if $b \sim m^{-1/(\beta_1-1)/(2\beta_1+4\beta_2-6+2\epsilon)}$,

$$
\sup_{t \in \mathcal{T}} d_M\left( Y(t), \widehat{Y}(t) \right) = O_P\left( m^{-1/(\beta_1+2\beta_2-3+\epsilon)} \right).
$$

We note that Examples 1 and 2 indeed satisfy (U1)–(U3) with $\beta_1 = \beta_2 = 2$, where the uniform convergence rate in (16) can be arbitrarily close to $O_P(m^{-1/3})$. We also note that the uniform convergence results for local Fréchet regression with fixed and random targets in Theorems 1 and
4 Estimation of the Location of Extrema

In this section, we consider the problem of estimating the locations of extrema (maxima and/or minima) of the conditional Fréchet mean trajectory \( \nu(t) \) as per (1) with regard to some functional of interest. Without loss of generality, we focus on the case of extrema that are minima. Consider a functional \( \Gamma: \mathcal{M} \to \mathbb{R} \) that quantifies a property of interest of the objects situated in metric space \( \mathcal{M} \), whence the corresponding property of the conditional Fréchet mean \( \nu(t) \) of \( V \) given \( U = t \) as per (1) is

\[
\Lambda(t) = \Gamma(\nu(t)), \quad \text{for all } t \in \mathcal{T}.
\]

Our goal is to find the location where \( \Lambda(\cdot) \) is minimized,

\[
t_{\min} = \arg\min_{t \in \mathcal{T}} \Lambda(t). \quad (17)
\]

An estimate of the minimizer \( t_{\min} \) of \( \Lambda(\cdot) \) is given by replacing \( \nu(t) \) with its local Fréchet regression estimate, i.e.,

\[
\hat{t}_{\min} = \arg\min_{t \in \mathcal{T}} \hat{\Lambda}(t), \quad \text{with } \hat{\Lambda}(t) = \Gamma(\hat{\nu}_m(t)). \quad (18)
\]

In addition, we assume

(D1) There exists \( C_1 > 0 \) and \( \alpha_1 > 1 \) such that for all \( z_1, z_2 \in \mathcal{M}, |\Gamma(z_1) - \Gamma(z_2)| \leq C_1 d_\mathcal{M}(z_1, z_2)^{\alpha_1}. \)

(D2) The minimizer \( t_{\min} \) exists and is unique. Additionally, for any \( \epsilon > 0 \), \( \inf_{|t - t_{\min}| > \epsilon} [\Lambda(t) - \Lambda(t_{\min})] > 0. \)

(D3) There exists \( r, C_2 > 0 \) and \( \alpha_2 > 1 \) such that \( \inf_{|t - t_{\min}| < r} [\Lambda(t) - \Lambda(t_{\min}) - C_2 |t - t_{\min}|^{\alpha_2}] \geq 0. \)

Assumptions (D1) and (D2) guarantee the consistency of the minimizer estimate \( \hat{t}_{\min} \), and hence can be used to obtain the corresponding convergence rate in conjunction with (D3). An example scenario where (D1) holds with \( \alpha_1 = 1 \) will be given in Section 6.1. For (D2) and (D3), a sufficient condition is, for instance, that \( \Lambda(\cdot) \) is twice continuously differentiable on \( \mathcal{T} \) with unique minimizer \( t_{\min} \) and \( \Lambda''(t_{\min}) > 0 \); specifically, \( \alpha_2 = 2 \) in (D3).

Applying Theorem 1, we obtain the following result of the minimum location estimate \( \hat{t}_{\min} \) based on local Fréchet regression.

**Corollary 1.** Under \((K0), (R0)-(R3), \) and \((D1)-(D3), \) for any \( \epsilon > 0 \) and for \( b \sim m^{-(\beta_1-1)/(2\beta_1+4\beta_2-6+2\epsilon)}, \)

it holds for the estimate \( \hat{t}_{\min} \) in (18) of the minimizer \( t_{\min} \) in (17) that

\[
|\hat{t}_{\min} - t_{\min}| = O_P \left( m^{-\alpha_1/[\alpha_2(\beta_1+2\beta_2-3+\epsilon)]} \right). \quad (19)
\]
We will illustrate this approach with an application to the study of brain connectivity utilizing fMRI data in Section 6.1. More generally, for an aggregation statistic determined by a functional \( \Gamma^* \) such that \( |\Gamma^*(\hat{\nu}_m) - \Gamma^*(\nu)| \leq C^*_\alpha \sup_{t \in T} d_M(\hat{\nu}_m(t), \nu(t))^{\alpha^*_\alpha} \), for some \( C^*_\alpha > 0 \) and \( \alpha^*_\alpha > 1 \), where \( \Gamma^*(\nu), \Gamma^*(\hat{\nu}_m) \in \mathbb{R} \), analogous rates of convergence as in (19) can be obtained for \( |\Gamma^*(\hat{\nu}_m) - \Gamma^*(\nu)| \).

Examples where such results are useful include the estimation of zero crossings or more general level crossings and the estimation of intervals where \( \Gamma^*(\nu) \) exceeds a certain level.

5 Time Warping for Metric-space Valued Functional Data

5.1 Global Warping

We consider the time warping problem for metric space valued random trajectories. With \( T = [0, \tau] \) being the time domain, consider a set of warping functions \( \mathcal{W} = \{ g : T \rightarrow T \mid g(0) = 0, g(\tau) = \tau, g \) is continuous and strictly increasing on \( T \} \). Note that for each function \( g \in \mathcal{W}, g(\cdot)/\tau \) is a strictly increasing cdf on \( T \). Suppose \( \mu : T \rightarrow \mathcal{M} \) is a fixed metric space valued trajectory, and \( h \in \mathcal{W} \) is a random (global) warping function such that \( \mathbb{E}[h(t)] = t \), for all \( t \in T \). We consider the following model for the metric space valued random process \( Y : T \rightarrow \mathcal{M} \) in Section 3,

\[
Y(t) = \mu(h^{-1}(t)), \quad \text{for all } t \in T. \tag{20}
\]

where \( \mu \) is referred to as the mean trajectory, and the stochastic fluctuations of the random warping function \( h \) around the identity function id determines the phase variation of the process \( Y \). Considering a random pair \((T, Z)\) consisting of time of observation \( T \) and process \( Z \) which is observed with a perturbation that is determined by the map \( \mathcal{P} \) satisfying (8), suppose \( \{(h_i, Y_i, T_i, \mathcal{P}_i, Z_i)\}_{i=1}^n \) is a set of \( n \) independent realizations of the quintuple \((h, Y, T, \mathcal{P}, Z)\), where as per (20), the metric space valued processes \( Y_i \) are

\[
Y_i(t) = \mu(h_i^{-1}(t)), \quad \text{for all } t \in T, \tag{21}
\]

and the observed objects are \( Z_i = \mathcal{P}_i(Y_i(T_i)) \), as per (9).

Furthermore, we make the following assumptions regarding the fixed mean trajectory \( \mu \) and random warping function \( h \in \mathcal{W} \).

(W1) The trajectory \( \mu \) is \( d_M \)-continuous, i.e., \( \lim_{\Delta \rightarrow 0} d_M(\mu(t + \Delta), \mu(t)) = 0 \), for any \( t \in T \).

(W2) Defining a bivariate function \( d_\mu : T^2 \rightarrow \mathbb{R} \) as \( d_\mu(s, t) = d_M(\mu(s), \mu(t)) \), \( d_\mu \) is twice continuously differentiable with \( \inf_{s=t \in T} |(\hat{d}_d/\hat{d}s)(s, t)| > 0 \). For any \( t_1, t_2 \in T \) with \( t_1 < t_2 \),

\[
\int_{t_1}^{t_2} [(\hat{d}_d/\hat{d}s)(s, t)]^2 ds > 0, \quad \text{for all } t \in T.
\]

(W3) The difference quotients of the global warping function \( h \) are bounded from above and below, i.e., there exist constants \( c, C \in (0, +\infty) \) with \( c < C \) and \( cC \leq 1 \) such that \( c \leq (h(s) - h(t))/(s - t) \leq C \), for all \( s, t \in T \) with \( s < t \).
Assumption (W1) implies the $d_M$-continuity of the random process $Y$ in conjunction with the continuity of the warping function $h$; (W2) excludes the possibility that any part of the trajectory $\mu$ could be flat. This is necessary to ensure the uniqueness of the warping functions, and will be used to establish the uniform convergence of the proposed estimates for the pairwise warping functions; see Section 5.4. Assumption (W3) guarantees there are no plateaus or steep increases in the global warping function and its inverse.

5.2 Pairwise Warping

For any $i, i' \in \{1, \ldots, n\}$ such that $i \neq i'$, the random pairwise warping function $g_{i'i} : \mathcal{T} \to \mathcal{T}$ is a temporal transformation from $Y_{i'}$ towards $Y_i$ defined by

$$g_{i'i}(t) = h_{i'}(h_i^{-1}(t)), \quad \text{for all } t \in \mathcal{T}.$$

We note that $g_{i'i} \in \mathcal{W}$. Moreover, we assume that (warping) functions in $\mathcal{W}$ can be parameterized by linear splines (as per Tang and Müller, 2008). Let $t_k = k\tau/(p + 1)$, for $k = 1, \ldots, p$, be $p$ equidistant knots in $\mathcal{T}$, with $t_0 = 0$, and $t_{p+1} = \tau$. For any function $g \in \mathcal{W}$, defining a coefficient vector $\theta_g = [g(t_1), \ldots, g(t_{p+1})]^\top$, the piecewise linear formulation of $g$ can be expressed as

$$g(t) = \theta_g^\top A(t), \quad \text{for all } t \in \mathcal{T},$$

where $A(t) = [A_1(t), \ldots, A_{p+1}(t)]^\top$, $A_k(t) = A_k^{(1)}(t) - A_k^{(2)}(t)$, $A_k^{(1)}(t) = (t - t_{k-1})/(t_k - t_{k-1}) \cdot \mathbf{1}_{[t_{k-1}, t_k)}$, $A_k^{(2)}(t) = (t - t_k)/(t_k - t_{k-1}) \cdot \mathbf{1}_{[t_{k-1}, t_k)}$, for $k = 1, \ldots, p + 1$, and $A_{p+2}^{(2)} = 0$. Due to the definition of the warping function space $\mathcal{W}$, the parameter space $\Theta$ of the splines coefficient vector $\theta_g$ is

$$\Theta = \{\theta \in \mathbb{R}^{p+1} : 0 < \theta_1 < \cdots < \theta_{p+1} = \tau\}. \tag{23}$$

The corresponding family of warping functions is $\mathcal{W} = \mathcal{W}_{LS} = \{g \in \mathcal{W} : g = \theta_g^\top A \text{ with } \theta_g \in \Theta\}$. We assume that the pairwise warping function $g_{i'i}$ can be represented by (22), i.e.,

$$g_{i'i}(\cdot) = \theta_{g_{i'i}}^\top A(\cdot), \quad \text{with } \theta_{g_{i'i}} \in \Theta. \tag{24}$$

5.3 Samples and Estimation

For each $i = 1, \ldots, n$, suppose available observations for the process $Y_i$ are $\{(T_{ij}, Z_{ij})\}_{j=1}^{m_i}$, where $Z_{ij} = \mathcal{P}_{ij}(Y_i(T_{ij}))$, and $\{(T_{ij}, \mathcal{P}_{ij})\}_{j=1}^{m_i}$ are $m_i$ independent realizations of $(T_i, \mathcal{P}_i)$. To estimate the warping functions $h_i$, a first step is to estimate the processes $Y_i$ by local Fréchet regression. Specifically, as per (11), the estimated trajectories are

$$\hat{Y}_i(t) = \arg\min_{z \in \mathcal{M}} \frac{1}{m_i} \sum_{j=1}^{m_i} \hat{v}(T_{ij}, t, b_i) d_M^2(Z_{ij}, z), \quad \text{for all } t \in \mathcal{T}, \tag{25}$$
where \( \hat{v} \) is as defined after (11) and \( b_i = b_i(m_i) > 0 \) are bandwidth sequences.

Our next step is to obtain an estimator for the pairwise warping functions \( g_{i'i} \) as per (24), for any distinct \( i', i \in \{1, \ldots, n\} \). This is equivalent to estimating the corresponding spline coefficients \( \theta_{g_{i'i}} \in \Theta \), which can be obtained by minimizing the integral of the squared distance between \( \hat{Y}_{i'} \) with time shifted toward \( \hat{Y}_i \) over the time domain \( \mathcal{T} \), with a regularization penalty on the magnitude of warping. Specifically, an estimator for \( \theta_{g_{i'i}} \) is

\[
\hat{\theta}_{g_{i'i}} = \arg\min_{\theta \in \Theta} \mathcal{C}_{\hat{Y}, \lambda}(\theta; \hat{Y}_{i'}, \hat{Y}_i),
\]

with

\[
\mathcal{C}_{\hat{Y}, \lambda}(\theta; \hat{Y}_{i'}, \hat{Y}_i) = \int_{\mathcal{T}} \left[ d_{\mathcal{M}}^2\left(\hat{Y}_{i'}(\theta^\top A(t)), \hat{Y}_i(t)\right) + \lambda (\theta^\top A(t) - t)^2 \right] dt,
\]

whence we obtain an estimator \( \hat{g}_{i'i} \) of the pairwise warping functions

\[
\hat{g}_{i'i}(t) = \hat{\theta}_{g_{i'i}}^\top A(t), \quad \text{for all } t \in \mathcal{T}.
\]

By the assumption \( \mathbb{E}[h(t)] = t \), we have \( \mathbb{E}[g_{i'i}(t) \mid h_i] = \mathbb{E}[h_{i'}(h_i^{-1}(t)) \mid h_i] = h_i^{-1}(t) \), for all \( t \in \mathcal{T} \), which justifies estimating the inverse global warping functions \( h_i^{-1} \) by

\[
\hat{h}_i^{-1}(t) = n^{-1} \sum_{i' = 1}^n \hat{g}_{i'i}(t), \quad \text{for all } t \in \mathcal{T}.
\]

Hence, estimators \( \hat{h}_i \) for the global warping functions \( h_i \) can be obtained by inversion, with estimated aligned trajectories given by \( \hat{Y}_i(\hat{h}_i(t)) \), for \( t \in \mathcal{T} \).

### 5.4 Asymptotic Results for Time Warping

In order to obtain the convergence rate for the proposed estimates \( \hat{h}_i \) for the warping functions as per (28) based on discrete and noisy observations \( \{(T_{ij}, Z_{ij})\}_{j=1}^{m_i} \), an initial step is to derive bounds for the difference between the actual metric space valued processes \( Y_i \) and their estimates \( \hat{Y}_i \) as per (25), obtained by local Fréchet regression. Specifically, a uniform rate of convergence over the time domain \( \mathcal{T} \), beyond the pointwise results shown by Petersen and Müller (2019), is needed. Furthermore, the targets of the local Fréchet regression implemented here are random processes \( Y_i \) rather than fixed trajectories as per (1). Thus, Theorem 2, where the targets are random processes, needs to be invoked. Subsequently, we derive the rate of convergence for the estimates for warping functions and time synchronized processes.

For any distinct \( i', i = 1, \ldots, n \), define functions \( \mathcal{C}_\mu(\cdot; h_{i'}, h_i) : \mathbb{R}^{p+1} \rightarrow \mathbb{R} \),

\[
\mathcal{C}_\mu(\theta; h_{i'}, h_i) = \int_{\mathcal{T}} d_{\mathcal{M}}^2\left(\mu(h_{i'}^{-1}[\theta^\top A(t)]), \mu(h_i^{-1}(t))\right) dt, \quad \theta \in \mathbb{R}^{p+1}.
\]

We show in Lemma S.2 in the Supplementary Material that for any distinct \( i, i' = 1, \ldots, n \), the coefficient vector \( \theta_{g_{i'i}} \) corresponding to the pairwise warping functions \( g_{i'i} \) is the unique minimizer
of $\mathcal{C}_\mu(\theta; h_i, h_t)$ under certain constraints.

In order to deal with the estimation of $n$ trajectories simultaneously, we make the following assumption on the bandwidths $b_i$ and numbers of discrete observations per trajectory $m_i$.

(W4) There exist sequences $m = m(n)$ and $b = b(n)$ such that (1) $\inf_{1 \leq i \leq n} b_i \geq m$; (2) $0 < C_1 < \inf_{1 \leq i \leq n} b_i / b \leq \sup_{1 \leq i \leq n} b_i / b < C_2 < \infty$, for some constants $C_1$ and $C_2$; and (3) $m \to \infty$, $b \to 0$, and $mb^2(-\log b)^{-1} \to \infty$, as $n \to \infty$.

We then derive an asymptotic bound for the discrepancy between the two objective functions $\mathcal{C}_\mu$ and $\mathcal{C}_{\hat{Y},\lambda}$, whence we obtain the convergence rates for the estimates of the coefficient vector $\theta_{g_{vi}}$ and the corresponding pairwise warping function in conjunction with Theorem 2 as follows.

**Theorem 3.** Under (P1), (W1)–(W4), (K0), and (U0)–(U3), for any $\varepsilon > 0$, if $b_i \sim m_i^{\frac{1}{2(\beta_1+2\beta_2-3+\varepsilon)}}$ for all $i = 1, \ldots, n$, and if $\lambda \to 0$, as $n \to \infty$, then, for any distinct $i'$ and $i$, it holds for the constrained minimizer $\hat{\theta}_{g_{vi}}$ in (26) that

$$\|\hat{\theta}_{g_{vi}} - \theta_{g_{vi}}\| = O\left(\lambda^{1/2}\right) + O_P\left(m^{-1/[2(\beta_1+2\beta_2-3+\varepsilon)]}\right),$$

(30)

where $m$ is defined in (W4). Furthermore, for the corresponding estimate of the pairwise warping function $\hat{g}_{vi}$ in (27) it holds that

$$\sup_{t \in T} |\hat{g}_{vi}(t) - g_{vi}(t)| = O\left(\lambda^{1/2}\right) + O_P\left(m^{-1/[2(\beta_1+2\beta_2-3+\varepsilon)]}\right).$$

(31)

We next obtain asymptotic results for local Fréchet regression estimates $\hat{Y}_i$ across trajectories $i = 1, \ldots, n$ in Corollary 2, which is used in conjunction with Theorem 3 to obtain the convergence rates for the estimates of the warping functions $\hat{h}_i$, and the aligned trajectories $\hat{Y}_i(\hat{h}_i(\cdot))$ in Corollary 3.

**Corollary 2.** Under (P1), (W1), (W4), (K0), and (U0)–(U3), for any $\varepsilon > 0$, and $\varepsilon' \in (0, 1)$, if $b_i \sim m_i^{\frac{1}{2(\beta_1+2\beta_2-3+\varepsilon)}}$, and $\lim\sup_{n \to \infty} nm_{\beta_2-1/2(\beta_2-1+\varepsilon')} < \infty$, it holds that

$$\sup_{t \in T} d_M\left(Y_i(t), \hat{Y}_i(t)\right) = O_P\left(m^{-(1-\varepsilon')/(\beta_1+2\beta_2-3+\varepsilon)}\right),$$

for all $i = 1, \ldots, n$;

$$\sup_{t \in T} n^{-1} \sum_{i=1}^n d_M\left(Y_i(t), \hat{Y}_i(t)\right)^\alpha = O_P\left(m^{-\alpha(1-\varepsilon')/(\beta_1+2\beta_2-3+\varepsilon)}\right),$$

(33)

for any given $\alpha \in (0, 1]$.

**Corollary 3.** Under (P1), (W1)–(W4), (K0), and (U0)–(U3), for any $\varepsilon > 0$ and $\varepsilon' \in (0, 1)$, if $b_i \sim m_i^{\frac{1}{2(\beta_1+2\beta_2-3+\varepsilon)}}$ for all $i = 1, \ldots, n$, and $\lim\sup_{n \to \infty} nm_{\beta_2-1/2(\beta_2-1+\varepsilon')} < \infty$, and if $\lambda \to 0$, as $n \to \infty$, it holds for the estimated warping functions $\hat{h}_i$ that

$$\sup_{t \in T} |\hat{h}_i(t) - h_i(t)| = O\left(\lambda^{1/2}\right) + O_P\left(m^{-(1-\varepsilon')/[2(\beta_1+2\beta_2-3+\varepsilon)]}\right) + O_P\left(n^{-1/2}\right).$$

(34)
Furthermore, if the mean trajectory $\mu$ is Lipschitz $d_\mathcal{M}$-continuous, i.e., there exists $C_\mu > 0$, such that $d_\mathcal{M}(\mu(t_1), \mu(t_2)) \leq C_\mu |t_1 - t_2|$, for all $t_1, t_2 \in \mathcal{T}$, then it holds for the estimates of the aligned trajectories $\hat{Y}_i(\hat{h}_i(\cdot))$ that

$$
\sup_{t \in \mathcal{T}} d_\mathcal{M}(\hat{Y}_i(\hat{h}_i(t)), Y_i(h_i(t))) = O\left(\lambda^{1/2}\right) + O_P\left(m^{-(1-\varepsilon')/\left[2(\beta_1+2\beta_2-3+\varepsilon)\right]}\right) + O_P\left(n^{-1/2}\right).$$

Defining $\gamma = (1 - \varepsilon')^{-1} - 1$, $\varepsilon' \in (0, 1)$ entails $\gamma > 0$. To discuss some more specific rates, under the assumptions of Corollary 3, the minimum number of observations per trajectory $m$ should be bounded below by a multiple of $n^{2[1-(\gamma+1)^{-1}]^{-1}[1+\varepsilon'(2(\beta_2-1))]}$, which implies that the rates in the second terms on the right hand sides of (34)–(35) are bounded above by a multiple of $n^{-\gamma^{-1}[(\beta_2-1+\varepsilon)/2]/(\beta_2-1)/\gamma(\beta_1+2\beta_2-3)^{-1}}$, where the latter can be arbitrarily close to $n^{-1/\gamma(\beta_1+2\beta_2-3)}$.

Consider $\lambda = O(n^{-1})$. Then, if $\gamma \in (0, 2(\beta_1 + 2\beta_2 - 3)^{-1}]$, the estimates for the warping functions $h_i$ and mean trajectory $\mu$ as per (34)–(35) converge with a rate of $n^{-1/2}$. Otherwise, if $\gamma > 2(\beta_1 + 2\beta_2 - 3)^{-1}$, the rates in (34)–(35) can be arbitrarily close to $n^{-1/\gamma(\beta_1+2\beta_2-3)}$.

Taking $\beta_1 = \beta_2 = 2$ as in Examples 1–2, the estimates $\hat{h}_i$ and $\hat{Y}_i(\hat{h}_i(\cdot))$ achieve root-$n$ rate, when $\gamma = 2(\beta_1 + 2\beta_2 - 3)^{-1} = 2/3$ and $m \geq n^{5(1+\varepsilon)/2}$. When $\gamma > 2/3$ and $m \geq n^{(2+\varepsilon)/(1+\gamma+1)^{-1}}$, the rate becomes approximately $n^{-1/(3\gamma)}$.

6 Data Illustrations

6.1 Age of Minimum Connectivity in Brain Networks: fMRI Data

Much work has been done in recent years to investigate how normal aging affects functional connectivity in human brains, which reflects spatial integration of brain activity based on resting-state functional magnetic resonance imaging (rs-fMRI) (Ferreira and Busatto, 2013; Dennis, 2014; Zonneveld et al., 2019). Fluctuations in regional brain activity are recorded by blood oxygen-level dependent (BOLD) signals while subjects relax. This leads to voxel-specific time series of activation strength. Patterns of subject-specific functional connectivity are frequently analyzed invoking a spatial parcellation of the brain into a set of predefined regions (Bullmore and Sporns, 2009). Connectivity between pairwise brain regions in the parcellation is then usually quantified by what is referred to in the field as temporal Pearson correlation of the fMRI time series of the correlation strength. Patterns of subject-specific functional connectivity are frequently analyzed invoking local Fréchet regression for the case where the random objects that form the responses are situated in the space of correlation matrices and age is a scalar predictor. Based on the correlation matrices,
networks of connectivity across regions are constructed by standard procedures in neuroimaging (Rubinov and Sporns, 2010); see also Phillips et al. (2015) and Petersen et al. (2016). The resulting networks can then be converted to graph Laplacians, for which the second smallest eigenvalue is known as the Fiedler value, also referred to as algebraic connectivity (Fiedler, 1973). The Fiedler value is a measure of the global connectivity of a graph that indicates how well connected a network is (de Haan et al., 2012; Phillips et al., 2015; Cai et al., 2019). Based on the results obtained from local Fréchet regression, we can then express the Fiedler value as a function of age of a subject and identify the age at which the resting human brain attains the minimum level of connectivity. This is of interest to understand the aging brain and as brain connectivity has been reported to mostly decrease during aging while also increases have been reported (Ferreira and Busatto, 2013).

We investigated the dependence of brain connectivity on age for elderly cognitively normal people using the resting-state fMRI data obtained from the Alzheimer’s Disease Neuroimaging Initiative (ADNI) database (adni.loni.usc.edu). The data used in our analysis consist of fMRI scans from \( m = 402 \) clinically normal elderly subjects at ages ranging from 55.6 to 95.4 years old, where one randomly selected scan is taken for those subjects where multiple scans are available.

Our analysis focused on the inter-regional connectivity of \( r = 10 \) hubs (Buckner et al., 2009, see Table 3). Specifically, we considered spherical seed regions of diameter 8 mm centered at the seed voxels of these hubs. Preprocessing of the BOLD signals was implemented by adopting the standard procedures of head motion correction, slice-timing correction, coregistration, normalization, and spatial smoothing. Subsequently, average signals of voxels within each seed region were extracted, where linear detrending and band-pass filtering are performed to account for signal drift and global cerebral spinal fluid and white matter signals, including only frequencies between 0.01 and 0.1 Hz, respectively. These steps were performed in MATLAB using the Statistical Parametric Mapping (SPM12, www.fil.ion.ucl.ac.uk/spm) and Resting-State fMRI Data Analysis Toolkit V1.8 (REST1.8, http://restfmri.net/forum/?q=rest).

Let \( \{y_{jks}\}_{s=1}^{S} \) be the signal time series of seed region \( k \) of subject \( j \) excluding the first four time points, which were discarded to eliminate nonequilibrium effects of magnetization, for \( k = 1, \ldots, r \), and \( j = 1, \ldots, m \). For subject \( j \), the correlation matrix calculated for analyzing connectivity in fMRI is

\[
R_j = (R_{j,kl})_{1 \leq k, l \leq r}, \quad R_{j,kl} = \frac{\sum_{s=1}^{S}(y_{jks} - \bar{y}_{jk})(y_{jls} - \bar{y}_{jl})}{\left[\sum_{s=1}^{S}(y_{jks} - \bar{y}_{jk})^2 \sum_{s=1}^{S}(y_{jls} - \bar{y}_{jl})^2\right]^{1/2}}. \tag{36}
\]

In the local Fréchet regression, we used age-at-scan as predictor, and the correlation matrices \( R_j \) as response, taken to be elements in the space of correlation matrices of dimension \( r \) equipped with Frobenius metric, \((\mathcal{M}, d_F)\), as in Example 2.

For any correlation matrix \( R \in \mathcal{M} \), the Fiedler value is the second smallest eigenvalue of the corresponding graph Laplacian matrix

\[
L(R) = D(R) - A(R).
\]
Here, $A(R) = (R - I_r)_+$ is the adjacency matrix obtained by applying a threshold and setting the diagonal elements to zero, and $D(R) = \text{diag}\{A(R)1_r\}$ is the (node) degree matrix, where $I_r = \text{diag}\{1_r\}$, $1_r = (1, \ldots, 1)^\top \in \mathbb{R}^r$, and $B_{\pm} = (\max\{B_{kt}, 0\})_{1 \leq k, t \leq r}$, for any $B \in \mathbb{R}^{r \times r}$. Then the Fiedler value corresponding to $R$ is given by a map $\Gamma: \mathcal{M} \to \mathbb{R}$,

$$\Gamma(R) = \lambda_{r-1}(L(R)),$$

that yields the $(r - 1)$th largest, i.e., second smallest eigenvalue of $L(R)$, for any $R \in \mathcal{M}$. Note that $d_F(L(R_1), L(R_2))^2 \leq 3d_F(R_1, R_2)^2$. In view of the Hoffman–Wielandt inequality (Hoffman and Wielandt, 1953), $\Gamma$ satisfies (D1) with $C_1 = \sqrt{3}$ and $\alpha_1 = 1$. Applying local Fréchet regression with bandwidth $b = 13.26$, chosen by leave-one-out cross validation, the Fiedler values for the local Fréchet regression estimates $\hat{\nu}_m(t)$ as per (3) of the conditional mean correlation matrix at age $t$ are

$$\hat{\Lambda}(t) = \Gamma(\hat{\nu}_m(t)) = \lambda_{r-1}(L(\hat{\nu}_m(t))), \quad \text{for } t \in \mathcal{T}. \tag{37}$$

Figure 1 displays the trajectory $\hat{\Lambda}$ of age-varying Fiedler values obtained for the local Fréchet regression estimate of the correlation matrix valued conditional Fréchet mean trajectory according to (37), based on the correlation matrices obtained from fMRI scans as per (36) for $m = 402$ normal subjects in the ADNI data. A convex pattern can be seen around the minimum of $\hat{\Lambda}$, which is attained at 73 years of age. While some studies have found that functional connectivity decreases during normal aging processes before 80 years of age (Ferreira and Busatto, 2013; Mevel et al., 2013), we observe for these data that the decrease is reversed for older ages.

![Figure 1](image-url)

Figure 1: Fiedler values as a function of age, corresponding to the local Fréchet regression estimate of the correlation matrix valued conditional Fréchet mean trajectory as per (37), with the minimum attained at 73 years of age marked by a dashed line.
6.2 Time Warping for Distributional Trajectories: Human Mortality Data

There has been perpetual interest in understanding human longevity. One particular goal is to obtain a general pattern of how the distribution of age-at-death evolves over time. Human mortality data for different countries are available from the Human Mortality Database (http://www.mortality.org/). We consider the calendar time period from 1983 to 2013, for which the mortality data for 28 countries are available throughout. It is known that the mortality distributions generally shift to higher ages during this time interval, which reflects increasing longevity. It is then of interest to ascertain which countries move faster and which move slower towards increased longevity, quantified by the rightward shift of the densities of age-at-death.

To address this question, we apply the proposed time warping method in the metric space of probability distributions with the Wasserstein metric, i.e., the Wasserstein space as per Example 1. In 1983 all countries start out with their warping functions taking values at the initial calendar year 1983, and in 2013 they all assume the value at the ending year 2013, so that the warping effect is considered between these two endpoints. A warping function below the identity function indicates that the country to which it belongs is on an accelerating course towards enhanced longevity, while countries with warping functions above the identity are on a delayed course.

Comparing the estimated warping functions across countries, we found that for males the enhancement in longevity of Japanese from 1983 to 2007 and for Icelanders from 2008 to the 2013 accelerates the fastest among all of the 28 countries between 1987 and 2013, while males have the most delayed increased longevity for Lithuania throughout the period (Figure 2). For females, the movement towards increased longevity is found to be fastest for Japanese women and slowest for

![Figure 2: Estimated warping functions $\hat{h}_i$ as per (28) for the mortality distribution trajectories for females (left) and males (right) for each country in the sample (grey solid curves), where cross-sectional minimum and maximum warping functions are identified and highlighted in different colors. The black dashed lines represent identity functions.](image)
Latvian women. The relative delay in increasing longevity for Lithuania and Latvia, former Soviet republics, is likely due to the aftermath of the breakup of the Soviet Union.

The original and aligned trajectories along with the estimated warping functions for two selected groups of countries are demonstrated in Figures 3 and 4. The former group includes representative countries for which the pattern of the estimated warping functions are similar between females and males, while the latter group consists of representative countries for which the estimated warping functions are mismatched between females and males.

Among the countries shown in Figure 3 with similar warping patterns between males and females, Luxembourg’s warping functions are close to the identity and therefore its longevity increase represents the average increase across all countries, for both males and females. For Japan, both male and female longevity are strongly accelerated compared to the other countries considered, in contrast to the situation for Poland, where the increase in longevity for both males and females is much delayed relative to the average. In addition, countries shown in Figure 4 exhibit an interesting gender heterogeneity. Both France and Israel show average longevity increase patterns for one gender, namely males in France and females in Israel, but not for the other gender, as females in France and males in Israel exhibit accelerated longevity.

Supplementary Material: Theoretical Details

S.1 Proofs of the Uniform Convergence of Local Fréchet Regression with Fixed Targets as in Section 2

Proof of Theorem 1. For any $\varepsilon > 0$, taking $\beta_2' = \beta_2 + \varepsilon/2$, we will first show (6).

We note that under (K0) and (R0), as $b \to 0$, it holds for $l = 0, 1, 2$ that

$$
\rho_{t,b}(t) = \mathbb{E}\left(K_b(U-t)(U-t)^l\right) = b^l \left[ f_U(t)K_{1,l}(t,b) + bf_U'(t)K_{1,l+1}(t,b) + O(b^2) \right],
$$

(S.1)

where $K_{k,l}(t,b) = \int_{(x-t)/b \in \mathcal{T}} K(x)^k x^l dx$, for $k, l \in \mathbb{N}$, and the $O$ terms are all uniform across $t \in \mathcal{T}$. These results are well known (Fan and Gijbels, 1996) and we omit the proofs here.

Let $\vartheta_m = (mb)^{-1/2}(-\log b)^{1/2}$. Under (K0) and (R0), it follows from (S.1) and similar arguments to the proof of Theorem B of Silverman (1978) that

$$
\sup_{t \in \mathcal{T}} |\rho_{0,b}(t)| = O(1), \quad \sup_{t \in \mathcal{T}} |\rho_{1,b}(t)| = O(b), \quad \sup_{t \in \mathcal{T}} |\rho_{2,b}(t)| = O(b^2),
$$

(S.2)

$$
\sup_{t \in \mathcal{T}} |\hat{\vartheta}_{l,m}(t) - \rho_{l,b}(t)| = O_P(\vartheta_m b^l), \quad l = 0, 1, 2, \quad \sup_{t \in \mathcal{T}} \left|\hat{\rho}_{1,m}(t)\right| = O(b) + O_P(\vartheta_m b),
$$

where $\rho_{l,b}(t) = \mathbb{E}[K_b(U-t)|U-t|]$, and $\hat{\vartheta}_{l,m}(t) = m^{-1} \sum_{j=1}^{m} [K_b(U_j-t)|U_j-t|]$, noting that $b^{-t} \hat{\vartheta}_{l,m}(\cdot)$ and $b^{-1} \hat{\rho}_{1,m}(\cdot)$ can all be viewed as kernel density estimators with kernels $K_l(x) = K(x)^l$ and $K^+_l(x) = K(x)|x|$, respectively, as per Silverman (1978), and (S.2) implies $\sup_{t \in \mathcal{T}} \left|\hat{\sigma}_{m}^2(t) - \sigma_b^2(t)\right| = O_P(\vartheta_m b^2)$. Applying Taylor expansion yields

$$
\sup_{t \in \mathcal{T}} \left|\hat{\sigma}_{m}^2(t)\right|^{-1} = O_P(\vartheta_m b^{-2}),
$$

$$
\sup_{t \in \mathcal{T}} \left|\hat{\rho}_{1,m}(t)\right| = O_P(\vartheta_m), \quad \text{and} \quad \sup_{t \in \mathcal{T}} \left|\hat{\vartheta}_{0,m}(t)\right| = O_P(\vartheta_m).
$$

Hence,

$$
\sup_{t \in \mathcal{T}} m^{-1} \sum_{j=1}^{m} \left|\hat{w}(U_j, t, b) - w(U_j, t, b)\right| 
\leq \sup_{t \in \mathcal{T}} \left|\hat{\vartheta}_{0,m}(t)\right| \sup_{t \in \mathcal{T}} \left|\hat{\rho}_{2,m}(t)\right| + \sup_{t \in \mathcal{T}} \left|\hat{\rho}_{1,m}(t)\right| \sup_{t \in \mathcal{T}} \left|\hat{\vartheta}_{1,m}(t)\right| = O_P(\vartheta_m).
$$

(S.3)

For any $R > 0$, define a sequence of events

$$
B_{R,\vartheta} = \left\{ \sup_{t \in \mathcal{T}} m^{-1} \sum_{j=1}^{m} \left|\hat{w}(U_j, t, b) - w(U_j, t, b)\right| \leq R \vartheta \right\}.
$$

(S.4)

Given any $v > 1$, set $a_m = \min\{(mb^2)^{\beta_2/[4(\beta_2-2+v)]}, (mb^2(-\log b)^{-1})^{\beta_2/[4(\beta_2-1)]}\}$; for some $\eta \leq$
\( r_2 \), set \( \tilde{\eta} = \eta^{2/2} \), with \( r_2 \) and \( \beta_2 \) as per (R3). For any \( \ell \in \mathbb{N}_+ \), considering \( m \) large enough such that 
\[ \log_2(\tilde{\eta} a_m) > \ell, \]
\[
P\left( a_m \sup_{t \in \mathcal{T}} d_M(\tilde{\nu}_b(t), \tilde{\nu}_m(t))^{\beta_2/2} > 2^\ell \right) \]
\[ \leq P\left( \sup_{t \in \mathcal{T}} d_M(\tilde{\nu}_b(t), \tilde{\nu}_m(t)) > \eta/2 \right) + P(B_{R,m}^c) \]
\[ + \sum_{k > \ell} P\left( 2^{k-1} \leq a_m \sup_{t \in \mathcal{T}} d_M(\tilde{\nu}_b(t), \tilde{\nu}_m(t))^{\beta_2/2} < 2^k \right) \cap B_{R,m}. \]
\[
(S.5)
\]
Note that (S.3) implies \( \lim_{R \to \infty} \limsup_{m \to \infty} P(B_{R,m}^c) = 0 \). Regarding the first term on the right hand side of (S.5), we will next show that
\[
\sup_{t \in \mathcal{T}} d_M(\tilde{\nu}_b(t), \tilde{\nu}_m(t)) = o_P(1). \]
\[
(S.6)
\]
Given any \( t \in \mathcal{T} \), \( d_M(\tilde{\nu}_b(t), \tilde{\nu}_m(t)) = o_P(1) \) follows from similar arguments to the proof of Lemma 2 in Section S.3 of the Supplementary Material of Petersen and Müller (2019). By Theorems 1.5.4, 1.5.7 and 1.3.6 of van der Vaart and Wellner (1996) and the total boundedness of \( \mathcal{T} \), it suffices to show that for any \( \epsilon > 0 \), as \( \delta \to 0 \),
\[
\limsup_{m \to \infty} P\left( \sup_{s,t \in \mathcal{T}, |s-t| < \delta} |d_M(\tilde{\nu}_b(s), \tilde{\nu}_m(s)) - d_M(\tilde{\nu}_b(t), \tilde{\nu}_m(t))| > 2\epsilon \right) \to 0.
\]
In conjunction with (R1) and the fact that \( |d_M(\tilde{\nu}_b(s), \tilde{\nu}_m(s)) - d_M(\tilde{\nu}_b(t), \tilde{\nu}_m(t))| \leq d_M(\tilde{\nu}_b(s), \tilde{\nu}_b(t)) + d_M(\tilde{\nu}_m(s), \tilde{\nu}_m(t)) \), it suffices to show that
\[
\limsup_{b \to 0} \sup_{s,t \in \mathcal{T}, |s-t| < \delta} \sup_{z \in \mathcal{M}} \left| \hat{L}_b(z,s) - \hat{L}_b(z,t) \right| \to 0, \quad \text{as} \ \delta \to 0, \quad (S.7)
\]
and that for any \( \epsilon > 0 \),
\[
\limsup_{m \to \infty} P\left( \sup_{s,t \in \mathcal{T}, |s-t| < \delta} \sup_{z \in \mathcal{M}} \left| \hat{L}_m(z,s) - \hat{L}_m(z,t) \right| > \epsilon \right) \to 0, \quad \text{as} \ \delta \to 0. \quad (S.8)
\]
Noting that by (K0) and (R0), \( \mathbb{E}[w(U, t, b)] = 1 \) and \( \mathbb{E}[w(U, t, b)(U - t)] = 0 \),

\[
\tilde{L}_b(z, t) = \mathbb{E}[w(U, t, b)L(z, U)] \\
= \mathbb{E}
\left[
    w(U, t, b) \left( L(z, t) + (U - t) \frac{\partial L}{\partial t}(z, t) \right)
\right] \\
+ \mathbb{E}
\left[
    w(U, t, b) \left( L(z, U) - L(z, t) - (U - t) \frac{\partial L}{\partial t}(z, t) \right)
\right] \\
= L(z, t) + \mathbb{E}
\left[
    w(U, t, b) \left( L(z, U) - L(z, t) - (U - t) \frac{\partial L}{\partial t}(z, t) \right)
\right].
\]  

(S.9)

Defining a function \( \phi : \mathcal{M} \times \mathcal{T} \to \mathbb{R} \) as

\[
\phi(z, t) = \frac{\partial^2 L}{\partial t^2}(z, t), \quad z \in \mathcal{M}, \ t \in \mathcal{T},
\]

(S.10)

it follows from (S.9), (K0), and (R0) that

\[
\sup_{z \in \mathcal{M}, \ t \in \mathcal{T}} \left| \tilde{L}_b(z, t) - L(z, t) \right| \leq \frac{1}{2} b^2 \sup_{t \in \mathcal{T}} \mathbb{E}
\left[
    |w(U, t, b)| \left( \frac{U - t}{b} \right)^2
\right] \sup_{t \in \mathcal{T}, \ z \in \mathcal{M}} |\phi(z, t)|.
\]

Note that \( \sup_{t \in \mathcal{T}} \mathbb{E}[|w(U, t, b)|(U - t)^2b^{-2}] = O(1) \). Furthermore, using similar arguments to the proof of Theorem 3 of Petersen and Müller (2019), we obtain

\[
L(z, t) = \int d^2 \mathcal{M}(z', z) dF_V[t](t, z') = \int d^2 \mathcal{M}(z', z) \frac{f_{U|V}(t, z')}{f_U(t)} dF_V(z'),
\]

(S.11)

where \( F_V \) and \( F_{V|U} \) are the marginal and conditional distribution of \( V \), the latter given \( U \). In conjunction with (K0), (R0), and the dominated convergence theorem, (S.11) implies

\[
\phi(z, t) = \int d^2 \mathcal{M}(z', z) \frac{\partial^2}{\partial t^2} \left[ \frac{f_{U|V}(t, z')}{f_U(t)} \right] dF_V(z'),
\]

(S.12)

whence by (R0) and the boundedness of \( \mathcal{M} \), we obtain \( \sup_{z \in \mathcal{M}, \ t \in \mathcal{T}} |\phi(z, t)| < \infty \). Thus,

\[
\sup_{z \in \mathcal{M}, \ t \in \mathcal{T}} \left| \tilde{L}_b(z, t) - L(z, t) \right| = O(b^2), \quad \text{as} \ b \to 0.
\]

(S.13)

Moreover, by (S.11) and (R0),

\[
\sup_{s, t \in \mathcal{T}, \ |s - t| < \delta \ z \in \mathcal{M}} \left| \tilde{L}_b(z, s) - \tilde{L}_b(z, t) \right| \\
\leq \sup_{s, t \in \mathcal{T}, \ |s - t| < \delta \ z \in \mathcal{M}} \left| L(z, s) - L(z, t) \right| + 2 \sup_{z \in \mathcal{M}, \ t \in \mathcal{T}} \left| \tilde{L}_b(z, t) - L(z, t) \right| \\
= O(\delta) + O(b^2),
\]

(S.14)
whence (S.7) follows. For (S.8), let \( \psi : \mathcal{M} \to \mathbb{R} \) be a function defined as

\[
\psi(z) := \sup_{t \in T} \left| m^{-1} \sum_{j=1}^{m} \left[ w(U_j, t, b) d_{\mathcal{M}}^2(V_j, z) \right] - \mathbb{E} \left[ w(U, t, b) d_{\mathcal{M}}^2(V, z) \right] \right|.
\]

Then

\[
\sup_{z \in \mathcal{M}} \left| \hat{L}_m(z, s) - \hat{L}_m(z, t) \right| \leq 2 \text{diam}(\mathcal{M})^2 \sup_{t \in T} m^{-1} \sum_{j=1}^{m} |\hat{w}(U_j, t, b) - w(U_j, t, b)|
\]

\[
+ \sup_{z \in \mathcal{M}} \left| \hat{L}_b(z, s) - \hat{L}_b(z, t) \right| + 2 \sup_{z \in \mathcal{M}} \psi(z). \tag{S.15}
\]

Regarding \( \psi(z) \), since

\[
m^{-1} \sum_{j=1}^{m} \left[ w(U_j, t, b) d_{\mathcal{M}}^2(V_j, z) \right] - \mathbb{E} \left[ w(U, t, b) d_{\mathcal{M}}^2(V, z) \right]
\]

\[
= \frac{\rho_{2,b}(t)}{\sigma_b^2(t)} \left\{ m^{-1} \sum_{j=1}^{m} \left[ K_b(U_j - t) d_{\mathcal{M}}^2(V_j, z) \right] - \mathbb{E} \left[ K_b(U - t) d_{\mathcal{M}}^2(V, z) \right] \right\}
\]

\[
- \frac{b \rho_{1,b}(t)}{\sigma_b^2(t)} \left\{ m^{-1} \sum_{j=1}^{m} K_b(U_j - t) \left( \frac{U_j - t}{b} \right) d_{\mathcal{M}}^2(V_j, z) \right\}
\]

\[- \mathbb{E} \left[ K_b(U - t) \left( \frac{U - t}{b} \right) d_{\mathcal{M}}^2(V, z) \right] \right\},
\]

under (K0) and (R0), it follows from similar arguments to the proof of Proposition 4 of Mack and Silverman (1982) with kernels \( K_l(x) = K(x)x^l \), for \( l = 0, 1 \), that \( \psi(z) = o_P(1) \), for any given \( z \in \mathcal{M} \). Furthermore, noting that

\[
\sup_{t \in T} m^{-1} \sum_{j=1}^{m} |w(U_j, t, b)| \leq \sup_{t \in T} \left| \hat{\rho}_{0,m}(t) \right| \sup_{t \in T} \left| \frac{\rho_{2,b}(t)}{\sigma_b^2(t)} \right| + \sup_{t \in T} \left| \hat{\rho}_{1,m}^+(t) \right| \sup_{t \in T} \left| \frac{\rho_{1,b}(t)}{\sigma_b^2(t)} \right|,
\]

\[
\sup_{t \in T} \mathbb{E} |w(U, t, b)| \leq \sup_{t \in T} \left| \rho_{0,b}(t) \rho_{2,b}(t) \frac{\sigma_b^2(t)}{\sigma_b^2(t)} \right| + \sup_{t \in T} \left| \rho_{1,b}(t) \rho_{1,b}(t) \frac{\sigma_b^2(t)}{\sigma_b^2(t)} \right|,
\]

by (S.1) and (S.2),

\[
\sup_{t \in T} m^{-1} \sum_{j=1}^{m} |w(U_j, t, b)| = O(1) + O_P(\vartheta_m), \quad \sup_{t \in T} \mathbb{E} |w(U, t, b)| = O(1),
\]

and hence for any \( z_1, z_2 \in \mathcal{M} \),

\[
|\psi(z_1) - \psi(z_2)| \leq 2 \text{diam}(\mathcal{M}) d_{\mathcal{M}}(z_1, z_2) \left( \sup_{t \in T} m^{-1} \sum_{j=1}^{m} |w(U_j, t, b)| + \sup_{t \in T} \mathbb{E} |w(U, t, b)| \right)
\]

\[
= d_{\mathcal{M}}(z_1, z_2) [O(1) + O_P(\vartheta_m)].
\]
In conjunction with the total boundedness of $\mathcal{M}$, $\sup_{z \in \mathcal{M}} \psi(z) = o_P(1)$ follows (Theorems 1.5.4, 1.5.7, and 1.3.6 of van der Vaart and Wellner, 1996). This implies (S.8) in conjunction with (S.15), (S.3) and (S.14). Thus, (S.6) follows.

We move on to the third term on the right hand side of (S.5). For $k \in \mathbb{N}_+$, define sets

$$D_{k,t} = \{ z \in \mathcal{M} : 2^{k-1} \leq a_m d_\mathcal{M}(z, \bar{v}_b(t))^{\beta/2} < 2^k \}. \quad \text{(S.16)}$$

We note that under (R3),

$$\lim\inf_{m \to \infty} \inf_{t \in T} \inf_{z \in D_{k,t}} \left[ \tilde{L}_b(z, t) - \tilde{L}_b(\bar{v}_b(t), t) \right] \geq c_2 2^{2(k-1)} a_m^{-2}.$$

Defining functions $J_t(\cdot) = \tilde{L}_m(\cdot, t) - \tilde{L}_b(\cdot, t)$ on $\mathcal{M}$, applying Markov’s inequality, the third term on the right hand side of (S.5) can be bounded (from above) by

$$\sum_{k > \ell} \sum_{2^k \leq a_m} \left( \sup_{t \in T} \sup_{z \in D_{k,t}} |J_t(z) - J_t(\bar{v}_b(t))| \geq c_2 2^{2(k-1)} a_m^{-2} \right) \cap B_{R,m}$$

$$\leq \sum_{k > \ell} \sum_{2^k \leq a_m} c_2^{-1} 2^{-2(k-1)} a_m^2 \mathbb{E} \left( \mathbb{I}(B_{R,m}) \sup_{t \in T} \sup_{z \in D_{k,t}} |J_t(z) - J_t(\bar{v}_b(t))| \right) \quad \text{(S.17)}$$

where $\mathbb{I}(E)$ is the indicator for an event $E$. For any $z \in \mathcal{M}$, defining

$$J_t^{(1)}(z) = m^{-1} \sum_{j=1}^m \left[ \hat{w}(U_j, t, b) - w(U_j, t, b) \right] d_\mathcal{M}^2(V_j, z),$$

$$J_t^{(2)}(z) = m^{-1} \sum_{j=1}^m \left[ w(U_j, t, b) d_\mathcal{M}^2(V_j, z) \right] - \mathbb{E} \left[ w(U, t, b) d_\mathcal{M}^2(V, z) \right],$$

whence $J_t = J_t^{(1)} + J_t^{(2)}$.

For $J_t^{(1)}$, note that

$$\left| J_t^{(1)}(z) - J_t^{(1)}(\bar{v}_b(t)) \right| \leq 2 \text{diam}(\mathcal{M}) d_\mathcal{M}(z, \bar{v}_b(t)) m^{-1} \sum_{j=1}^m |\hat{w}(U_j, t, b) - w(U_j, t, b)|,$$

for all $z \in \mathcal{M}$ and $t \in T$, and hence given $\delta > 0$, it holds on $B_{R,m}$ that

$$\sup_{t \in T} \sup_{d_\mathcal{M}(z, \bar{v}_b(t)) < \delta} \left| J_t^{(1)}(z) - J_t^{(1)}(\bar{v}_b(t)) \right| \leq 2 \text{diam}(\mathcal{M}) R \delta \vartheta_m. \quad \text{(S.19)}$$

For $J_t^{(2)}$, given any $z \in \mathcal{M}$, $t \in T$ and $\delta > 0$, defining functions $g_{t,z} : T \times \mathcal{M} \to \mathbb{R}$ by

$$g_{t,z}(s, z') = w(s, t, b) \left[ d_\mathcal{M}^2(z', z) - d_\mathcal{M}^2(z', \bar{v}_b(t)) \right], \quad s \in T, z' \in \mathcal{M},$$
and a function class
\[ \mathcal{G}_{b,\delta} = \{ g_{t,z} : d_M(z, \tilde{v}_0(t)) < \delta, \; t \in \mathcal{T} \}. \]

For any \( t_1, t_2 \in \mathcal{T} \) and \( z_l \in B_b(\tilde{v}_0(t_l)) \) for \( l = 1, 2 \),
\[
\left| g_{t_1,z_1}(s, z') - g_{t_2,z_2}(s, z') \right| \\
\leq 2 \text{diam}(\mathcal{M}) \left( d_M(z_1, z_2) + d_M(\tilde{v}_0(t_1), \tilde{v}_0(t_2)) \right) \sup_{t \in \mathcal{T}} |w(s, t, b)| \\
+ 2 \text{diam}(\mathcal{M}) \delta \sup_{s \in \mathcal{T}} |w(s, t_1, b) - w(s, t_2, b)|.
\]

By (S.7) and (R1),
\[
\limsup_{b \to 0} \sup_{s, t \in \mathcal{T}, \; |s - t| < \delta} d_M(\tilde{v}_0(s), \tilde{v}_0(t)) \to 0, \quad \text{as } \delta \to 0. \tag{S.20}
\]

For small \( |t_1 - t_2| \) such that \( d_M(\tilde{v}_0(t_1), \tilde{v}_0(t_2)) < r_2 \), by (R3), it holds that as \( b \to 0 \),
\[
2c_2d_M(\tilde{v}_0(t_1), \tilde{v}_0(t_2))^{\beta_2} \leq 2 \sup_{z \in \mathcal{M}} \left| \tilde{L}_b(z, t_1) - \tilde{L}_b(z, t_2) \right| \\
\leq 2 \text{diam}(\mathcal{M})^2 \sup_{s \in \mathcal{T}} |w(s, t_1, b) - w(s, t_2, b)|.
\]

Noting that \( \sup_{s \in \mathcal{T}} |w(s, t_1, b) - w(s, t_2, b)| = |t_1 - t_2|O(b^{-2}) \) by (K0) and (R0), there exists a constant \( C > 0 \) such that for small \( |t_1 - t_2| \),
\[
\left| g_{t_1,z_1}(s, z') - g_{t_2,z_2}(s, z') \right| \leq C \left( d_M(z_1, z_2) + d_T(t_1, t_2) \right) D_{b,\delta}(s),
\]

where \( d_T : \mathcal{T} \times \mathcal{T} \to [0, +\infty) \) is a metric on \( \mathcal{T} \) defined as
\[
d_T(t_1, t_2) = \max \left\{ b^{-2}|t_1 - t_2|, \; (b^{-2}|t_1 - t_2|)^{1/\beta_2} \right\}, \quad t_1, t_2 \in \mathcal{T},
\]
which can be verified that is indeed a metric, and \( D_{b,\delta} : \mathcal{T} \times \mathcal{M} \to \mathbb{R} \) is a function defined as
\[
D_{b,\delta}(s, z) = \sup_{t \in \mathcal{T}} |w(s, t, b)| + \delta, \quad s \in \mathcal{T}.
\]

An envelope function \( G_{b,\delta} : \mathcal{T} \times \mathcal{M} \to \mathbb{R} \) for the function class \( \mathcal{G}_{b,\delta} \) is
\[
G_{b,\delta}(s, z) = 2 \text{diam}(\mathcal{M}) \delta \sup_{t \in \mathcal{T}} |w(s, t, b)|, \quad s \in \mathcal{T}.
\]

Denoting the joint distribution of \((U, V)\) by \( \mathcal{F} \), the \( L^2_{\mathcal{F}} \) norm \( \| \cdot \|_{\mathcal{F}} \) is given by \( \| g \|_{\mathcal{F}} = \left[ \mathbb{E}(g(U, V)^2) \right]^{1/2} \), for any function \( g : \mathcal{T} \times \mathcal{M} \to \mathbb{R} \). The envelope function entails \( \| G_{b,\delta} \|_{\mathcal{F}} = O(\delta b^{-1}) \), by (K0) and (R0). Furthermore, by Theorem 2.7.11 of van der Vaart and Wellner (1996), for \( \epsilon > 0 \), the \( \epsilon \| G_{b,\delta} \|_{\mathcal{F}} \)
bracketing number of the function class $\mathcal{G}_{b,\delta}$ can be bounded as

$$
N[I] (\epsilon \|G_{b,\delta}\|_{\mathcal{F}}, \mathcal{G}_{b,\delta}, \| \cdot \|_{\mathcal{F}}) \\
= N[I] \left( 2 \epsilon \|G_{b,\delta}\|_{\mathcal{F}} \frac{\|D_{b,\delta}\|_{\mathcal{F}}}{\|D_{b,\delta}\|_{\mathcal{F}}}, \mathcal{G}_{b,\delta}, \| \cdot \|_{\mathcal{F}} \right) \\
\leq N \left( \frac{\epsilon \|G_{b,\delta}\|_{\mathcal{F}}}{\epsilon \|D_{b,\delta}\|_{\mathcal{F}}}, \{ (t, z) : z \in B_\delta(\tilde{v}_b(t)), t \in T \}, d_{T \times \mathcal{M}} \right) \\
\leq N \left( \frac{\epsilon \|G_{b,\delta}\|_{\mathcal{F}}}{\epsilon \|D_{b,\delta}\|_{\mathcal{F}}}, T, d_T \right) \cdot \sup_{t \in T} N \left( \frac{\epsilon \|G_{b,\delta}\|_{\mathcal{F}}}{\epsilon \|D_{b,\delta}\|_{\mathcal{F}}}, B_\delta(\tilde{v}_b(t)), d_{\mathcal{M}} \right),
$$

where $d_{T \times \mathcal{M}}((t_1, z_1), (t_2, z_2)) = d_T(t_1, t_2) + d_{\mathcal{M}}(z_1, z_2)$, for any $t_1, t_2 \in T$ and $z_1, z_2 \in \mathcal{M}$. Therefore,

$$
N[I] (\epsilon \|G_{b,\delta}\|_{\mathcal{F}}, \mathcal{G}_{b,\delta}, \| \cdot \|_{\mathcal{F}}) \leq C_1 (\epsilon \delta b^2)^{-C_0} \sup_{t \in T} N (C_2 \epsilon \delta, B_\delta(\tilde{v}_b(t)), d_{\mathcal{M}}), \tag{S.21}
$$

where $C_0, C_1, C_2 > 0$ are constants only depending on $\beta_2$, noting that $\|G_{b,\delta}\|_{\mathcal{F}}/\|D_{b,\delta}\|_{\mathcal{F}} \sim \delta$. In conjunction with (5) which will be shown later, for $b$ sufficiently small, there exists a constant $C_3 > C_2$ such that $B_\delta(\tilde{v}_b(t)) \subset B_{C_3 \delta}(\nu(t))$, for any $\delta > 0$ and $t \in T$. Choose $\eta$ in (S.5) such that (R2) holds for all $r \leq C_3 \eta$. Observing that

$$
\int_0^1 \sup_{t \in T} \sqrt{1 + \log N (C_2 \epsilon \delta, B_{C_3 \delta}(\nu(t)), d_{\mathcal{M}})} \, d \epsilon \\
= \frac{C_3}{C_2} \int_0^{C_2/C_3} \sup_{t \in T} \sqrt{1 + \log N (C_3 \epsilon \delta, B_{C_3 \delta}(\nu(t)), d_{\mathcal{M}})} \, d \epsilon \\
\leq \frac{C_3}{C_2} \int_0^1 \sup_{t \in T} \sqrt{1 + \log N (C_3 \epsilon \delta, B_{C_3 \delta}(\nu(t)), d_{\mathcal{M}})} \, d \epsilon,
$$

(S.21) implies for any $\delta \leq \eta$,

$$
\int_0^1 \sqrt{1 + \log N[I] (\epsilon \|G_{b,\delta}\|_{\mathcal{F}}, \mathcal{G}_{b,\delta}, \| \cdot \|_{\mathcal{F}})} \, d \epsilon \\
\leq \int_0^1 \sup_{t \in T} \sqrt{1 + \log N (C_2 \epsilon \delta, B_\delta(\tilde{v}_b(t)), d_{\mathcal{M}})} \, d \epsilon + \int_0^1 \sqrt{-C_0 \log (\epsilon \delta b^2) + \log C_1} \, d \epsilon \\
= O \left( I + \int_0^1 \sqrt{-\log(\delta b) - \log \epsilon} \, d \epsilon \right) = O \left( \sqrt{-\log(\delta b)} \right),
$$

with $I$ being the integral in (R2). By Theorem 2.14.2 of van der Vaart and Wellner (1996),

$$
\mathbb{E} \left( \sup_{t \in T} \sup_{d_{\mathcal{M}}(z, \tilde{v}_b(t)) < \delta} \left| J^{(2)}_t(z) - J^{(2)}_t(\tilde{v}_b(t)) \right| \right) = O \left( \delta^{-1} \sqrt{-\log(\delta b)} \right) \\
= O \left( \delta^{-1} (mb^2)^{-1/2} + \delta (mb^2)^{-1/2} \sqrt{-\log b} \right). \tag{S.22}
$$
Combining (S.19) and (S.22), it holds that
\[
E \left( \mathbb{I} (B_{R,m}) \sup_{t \in T} \sup_{d_M(z, \tilde{\nu}_b(t)) < \delta} \left| J_t(z) - J_t(\tilde{\nu}_b(t)) \right| \right) \leq C (mb^2)^{-1/2} \left( \delta^{2-v} + \delta \sqrt{-\log b} \right), \quad (S.23)
\]
where \( C > 0 \) is a constant depending on \( R \) and the entropy integral in (R2). Note that on \( D_{k,t} \), it holds that \( d_M(z, \tilde{\nu}_b(t)) < (2^k a_m^{-1})^{2/\beta_2} \). Hence, (S.17) can be bounded by
\[
C \sum_{\ell \leq k} \frac{2^{-2(k-1)a_m^2 (mb^2)^{-1/2}}}{2^k} \left[ (2^k a_m^{-1})^{2(2-v)/\beta_2} + (2^k a_m^{-1})^{2/\beta_2} \sqrt{-\log b} \right]
\]
which converges to 0 as \( \ell \to \infty \), since \( \beta_2, v > 1 \). Thus,
\[
\sup_{t \in T} d_M(\tilde{\nu}_b(t), \tilde{\nu}_m(t)) = O_P \left( a_m^{-2/\beta_2} \right),
\]
and (6) follows.

Next, we will show (5). By (S.13) and (R1), \( d_M(\nu(t), \tilde{\nu}_b(t)) = o(1) \), as \( b \to 0 \), for any \( t \in T \). By (4) and the compactness of \( T \), the conditional Fréchet mean trajectory \( \nu \) is \( d_M \)-continuous at any \( t \in T \) and hence uniformly \( d_M \)-continuous on \( T \). In conjunction with (S.20), \( \sup_{t \in T} d_M(\nu(t), \tilde{\nu}_b(t)) = o(1) \) follows. Let \( g_{z,t} : T \to \mathbb{R} \) be a function defined as \( g_{z,t}(s) = L(z, s) - L(\nu(t), s) \), for \( s \in T \). For any \( \delta > 0 \), (S.9) and (S.12), in conjunction with (K0), (R0), and the boundedness of \( M \),
\[
\sup_{t \in T} \sup_{d_M(z, \nu(t)) < \delta} \left| (\tilde{L}_b - L)(z, t) - (\tilde{L}_b - L)(\nu(t), t) \right|
\]
\[
= \sup_{t \in T} \sup_{d_M(z, \nu(t)) < \delta} \left| E \left[ w(U, t, b) \left( g_{z,t}(U) - g_{z,t}(t) - (U - t) g_{z,t}^{t}(t) \right) \right] \right|
\]
\[
\leq \frac{1}{2} \frac{b^2}{\nu} \sum_{t \in T} \left[ w(U, t, b) \right] \left( \frac{U - t}{b} \right)^2 \sup_{d_M(z, \nu(t)) < \delta} \sup_{d_M(z, \nu(t)) < \delta} \left| \phi(z, t) - \phi(\nu(t), t) \right|
\]
\[
= O(b^2 \delta),
\]
with \( \phi(z, t) \) defined as per (S.10). Set \( q_b = b^{-\beta_1/(\beta_1 - 1)} \). Using similar arguments to the proof of (6), there exists a constant \( C > 0 \) such that for small \( b \),
\[
\mathbb{I} \left( q_b \sup_{t \in T} d_M(\nu(t), \tilde{\nu}_b(t)) \right) > 2^k \right) \leq C \sum_{k > \ell} \frac{b^2 (2^k q_b^{-1})^{2/\beta_1}}{2^{2(k-1) q_b^{-2}}} = 4C \sum_{k > \ell} 2^{-2(k-1)/\beta_1},
\]
which converges to 0 as \( \ell \to \infty \), and hence (5) follows.
Lastly, we note that for any $\gamma \in (0, 0.5)$, if $b \sim m^{-\gamma}$, then
\[
\frac{(mb^2(-\log b)^{-1})^{-1/[2(\beta_1-1)]}}{(mb^2)^{-1/[2(\beta_1'-1)]}} \sim \frac{(\log m)^{1/[2(\beta_2-1)]}}{m^{(0.5-\gamma)[(\beta_2-1)^{-1}-(\beta_2'-1)^{-1}]}} \to 0, \quad \text{as } m \to \infty.
\]
With $b \sim m^{-(\beta_1-1)/(2\beta_1+4\beta_2-6)}$, it holds that $b^{2/(\beta_1-1)} \sim (mb^2)^{-1/[2(\beta_2-1)]} \sim m^{-1/(\beta_1+2\beta_2-3)}$, whence (7) follows, which completes the proof.

\section*{S.2 Proofs of the Uniform Convergence of Local Fréchet Regression with Random Targets as in Section 3}

\textbf{Proof of Theorem 2.} Given any fixed $\varepsilon > 0$, define
\[
a_m = \min \left\{ \left( mb^2 \right)^{\beta_2/[4(\beta_2-1+\varepsilon)/2]} \left[ mb_2(-\log b)^{-1} \right]^{\beta_2/[4(\beta_2-1)]} \right\}.
\]
We will show for the bias and stochastic parts respectively that
\[
\sup_{\omega_1 \in \Omega_1} \sup_{t \in T} d_M \left( Y_{\omega_1}(t), \hat{Y}_{\omega_1, b}(t) \right) = O \left( b^{2/(\beta_1-1)} \right), \quad (S.24)
\]
\[
\limsup_{m \to \infty} \sup_{\omega_1 \in \Omega_1} \left( a_m \sup_{t \in T} d_M \left( \hat{Y}_{\omega_1, b}(t), \hat{Y}_{\omega_1, m}(t) \right)^{\beta_2/2} > C \right) \to 0, \quad \text{as } C \to \infty. \quad (S.25)
\]

Observing that
\[
\sup_{t \in T} d_M \left( Y(t), \hat{Y}(t) \right) \leq \sup_{\omega_1 \in \Omega_1} \sup_{t \in T} d_M \left( Y_{\omega_1}(t), \hat{Y}_{\omega_1, b}(t) \right),
\]
\[
\lim_{m \to \infty} P \left( \sup_{t \in T} d_M \left( \hat{Y}(t), \hat{Y}(t) \right) > C a_m^{-2/\beta_2} \right) \leq \limsup_{m \to \infty} \sup_{\omega_1 \in \Omega_1} \left( a_m \sup_{t \in T} d_M \left( \hat{Y}_{\omega_1, b}(t), \hat{Y}_{\omega_1, m}(t) \right)^{\beta_2/2} > C \right),
\]
(15) follows, which implies (16) if $b \sim m^{-(\beta_1-1)/(2\beta_1+4\beta_2-6+2\varepsilon)}$.

For (S.24), we note that for any given $\omega_1 \in \Omega_1$, and $t \in T$, $d_M(Y_{\omega_1}(t), \hat{Y}_{\omega_1,b}(t)) = o(1)$, as $b \to 0$, by Theorem 1. We note that by (K0) and (U0),
\[
\sup_{t \in T} \mathbb{E}_{\Omega_2} \left[ |v(T, t, b)| (T-t)^2 b^{-2} \right] = O(1), \quad \text{as } n \to \infty. \quad (S.26)
\]

Defining
\[
\phi_{\omega_1}(z, t) = \frac{\partial^2 M_{\omega_1}}{\partial t^2}(z, t), \quad (S.27)
\]
it holds following similar arguments to the proof of (S.12) that
\[
\phi_{\omega_1}(z, t) = \int d_M^2(z', z) \frac{\partial^2}{\partial t^2} \left[ \frac{f_{T\mid Z_{\omega_1}}(t, z')}{f_{T}(t)} \right] dF_{Z_{\omega_1}}(z'). \quad (S.28)
\]
In conjunction with (U0) and the boundedness of \( \mathcal{M} \),
\[
\sup_{\omega_1 \in \Omega_1, \, t \in \mathcal{T}, \, z \in \mathcal{M}} |\phi_{\omega_1}(z, t)| < \infty, \tag{S.29}
\]
whence we obtain
\[
\sup_{\omega_1 \in \Omega_1, \, t \in \mathcal{T}} \left| \tilde{M}_{\omega_1,b}(z, t) - M_{\omega_1}(z, t) \right|
\leq \frac{1}{2} b^2 \sup_{t \in \mathcal{T}_2} \left| v(T, t, b) \right| \left( \frac{T - t}{b} \right)^2 \sup_{\omega_1 \in \Omega_1, \, t \in \mathcal{T}, \, z \in \mathcal{M}} |\phi_{\omega_1}(z, t)|
= O(b^2).
\]
This implies \( \sup_{\omega_1 \in \Omega_1, \, t \in \mathcal{T}} d_{\mathcal{M}}(Y_{\omega_1}(t), \tilde{Y}_{\omega_1,b}(t)) = o(1) \) under (U1). Furthermore, by (S.26) and (S.28), there exists a constant \( C > 0 \) such that for \( m \) large enough,
\[
\sup_{\omega_1 \in \Omega_1, \, t \in \mathcal{T}} \sup_{d_{\mathcal{M}}(z, Y_{\omega_1}(t)) < \delta} \left| (\tilde{M}_{\omega_1,b} - M_{\omega_1})(z, t) - (\tilde{M}_{\omega_1,b} - M_{\omega_1})(Y_{\omega_1}(t), t) \right|
\leq \frac{1}{2} b^2 \sup_{t \in \mathcal{T}_2} \left| v(T, t, b) \right| \left( \frac{T - t}{b} \right)^2 \sup_{\omega_1 \in \Omega_1, \, t \in \mathcal{T}, \, d_{\mathcal{M}}(z, Y_{\omega_1}(t)) < \delta} \sup_{t \in \mathcal{T}} |\phi_{\omega_1}(z, t) - \phi_{\omega_1}(Y_{\omega_1}(t), t)|
\leq \frac{1}{2} Cb^2 \delta.
\]
Using similar arguments to the proof of (5), with \( q_b = b^{-\beta_1/(\beta_1 - 1)} \), there exists a constant \( C > 0 \) such that for \( m \),
\[
I \left( \sup_{\omega_1 \in \Omega_1} \sup_{t \in \mathcal{T}} d_{\mathcal{M}} \left( Y_{\omega_1}(t), \tilde{Y}_{\omega_1,b}(t) \right)^{\beta_1/2} > 2^\ell q_b^{-1} \right) \leq C \sum_{k > \ell} b^2 \left( \frac{2^k q_b^{-1}}{2^{2(k-1)} q_b^{-2}} \right)^{2/\beta_1} = 4C \sum_{k > \ell} 2^{-2k(\beta_1 - 1)/\beta_1},
\]
which converges to zero as \( \ell \to \infty \), whence (S.24) follows.

Next, we will show (S.25). Let \( \eta \) be the minimum integer not less than \( \log_2(a_m \text{diam}(\mathcal{M})^{\beta_2/2} + 1) \), and for any \( R > 0 \), define sets
\[
B_{R,m} = \left\{ \sup_{t \in \mathcal{T}} m^{-1} \sum_{j=1}^m |\hat{\nu}(T_j, t, b) - v(T_j, t, b)| \leq R \delta \right\}. \quad \tag{S.31}
\]
For any \( \ell \in \mathbb{N}_+ \), considering \( m \) large enough such that \( \eta > \ell \),
\[
\sup_{\omega_1 \in \Omega_1} \mathbb{P}_{\Omega_2} \left( a_m \sup_{t \in \mathcal{T}} d_{\mathcal{M}} \left( \tilde{Y}_{\omega_1,b}(t), \tilde{Y}_{\omega_1,b}(t) \right)^{\beta_2/2} > 2^\ell \right) \leq \mathbb{P}_{\Omega_2}(B_{R,m}^c) + \sum_{\ell < \eta} \sup_{\omega_1 \in \Omega_1} \mathbb{P}_{\Omega_2} \left( 2^{\ell-1} a_m \sup_{t \in \mathcal{T}} d_{\mathcal{M}} \left( \tilde{Y}_{\omega_1,b}(t), \tilde{Y}_{\omega_1,b}(t) \right)^{\beta_2/2} < 2^\ell \right) \cap B_{R,m} \right), \tag{S.32}
\]
Under (K0) and (U0), it follows from similar arguments to the proof of Theorem B of Silverman
(1978) that there exists $R > 0$ with $P_{\Omega_2}(B_{R,m}) = 0$, for $m$ large enough. Regarding the convergence of the second term on the right hand side of (S.32), using similar arguments to the proof of (6), it holds for $J_{t,\omega_1}^{(2)}(z) = m^{-1} \sum_{j=1}^{m} [v(T_j, t, b) d_M^2(Z_{\omega_1,j} , z)] - \mathbb{E}_{\Omega_2} [v(T, t, b) d_M^2(Z_{\omega_1}, z)]$ that

$$
\mathbb{E} \left( \sup_{t \in T} \sup_{d_M(\varepsilon, \hat{Y}_{t, \omega_1, \theta}(t)) < \delta} \left| J_{t,\omega_1}^{(2)}(z) - J_{t,\omega_1}^{(2)}(\hat{Y}_{t,\omega_1,b}(t)) \right| \right) = O \left( \delta^2 - v(mb^2)^{-1/2} + \delta(mb^2)^{-1/2} \sqrt{-\log b} \right),
$$

where the $O$ term is uniform over $\omega_1 \in \Omega_1$, by (S.24), (U1) and Theorem 2.14.2 of van der Vaart and Wellner (1996). Under (K0) and (U0)–(U3), the second term on the right hand side of (S.32) in the proof of Lemma S.2, and Lemma S.2 shows that the coefficient vector $\theta_{g_{\omega_1}}$ can be bounded by

$$
C \sum_{\ell < k \leq \eta} 2^{-2(k-1)} a_m^2 (mb^2)^{-1/2} \left[ (2^k a_m^{-1})^{2(1-\varepsilon/2)/\beta_2} + (2^k a_m^{-1})^{2/\beta_2} \sqrt{-\log b} \right] 
\leq 4Ca_m^{2(\beta_2-1+\varepsilon/2)/\beta_2}(mb^2)^{-1/2} \sum_{k > \ell} 2^{-2k(\beta_2-1+\varepsilon/2)/\beta_2} 
+ 4Ca_m^{2(\beta_2-1)/\beta_2}(mb^2)^{-1/2} \sqrt{-\log b} \sum_{k > \ell} 2^{-2k(\beta_2-1)/\beta_2} 
\leq 4C \sum_{k > \ell} 2^{-2k(\beta_2-1+\varepsilon/2)/\beta_2} + 4C \sum_{k > \ell} 2^{-2k(\beta_2-1)/\beta_2},
$$

which converges to zero as $\ell \to \infty$, whence (S.25) follows.

\[ \Box \]

### S.3 Proofs of Results in Section 4

**Proof of Corollary 1.** By (17), (18), and (D1),

$$
\Lambda(t_{\min}) - \Lambda(t_{\min}) \leq \Lambda(t_{\min}) - \hat{\Lambda}(t_{\min}) + \hat{\Lambda}(t_{\min}) - \hat{\Lambda}(t_{\min}) 
\leq 2 \sup_{t \in T} |\hat{\Lambda}(t) - \Lambda(t)| \leq 2C_1 \sup_{t \in T} d_M(\hat{\mu}_m(t), \nu(t))^{01}.
$$

This implies $|\hat{t}_{\min} - t_{\min}| = o_P(1)$ in conjunction with (D2) and Theorem 1, whence (19) follows under (D3).

\[ \Box \]

### S.4 Proofs of Results in Section 5

We will first present two auxiliary results (Lemmas S.1 and S.2), where Lemma S.1 will be needed in the proof of Lemma S.2, and Lemma S.2 shows that the coefficient vector $\theta_{g_{\omega_1}}$ is the unique minimizer of $C_{\mu}$ given in (29) under certain constraints, which will be used to derive the rate of convergence for the M-estimator $\hat{\theta}_{g_{\omega_1}}$ of the coefficient vector in Theorem 3.

**Lemma S.1.** For any $g, g^* \in \mathcal{W}$ such that $d_M(\mu(g(t)), \mu(g^*(t))) = 0$, for all $t \in T$, where $\mu$ satisfies (W1)–(W2), it holds that

$$
g(t) = g^*(t), \quad \text{for all } t \in T.
$$
Proof. Suppose there exists \( x_0 \in (0, \tau) \) such that \( g(x_0) \neq g^*(x_0) \). Without loss of generality, we assume \( g(x_0) < g^*(x_0) \). Let \( t_0 = g(x_0) \). We define a sequence \( \{t_k\}_{k=1}^{\infty} \) iteratively by

\[
t_k = g^*(g^{-1}(t_{k-1})), \quad \text{for } k = 1, 2, \ldots
\]  

(S.33)

Then it can be shown by induction that \( \{t_k\}_{k=1}^{\infty} \) is a strictly increasing sequence, whence there exists \( t^* \in \mathcal{T} \) such that \( t_k \uparrow t^* \) as \( k \to \infty \), since \( \{t_k\}_{k=1}^{\infty} \subset \mathcal{T} = [0, \tau) \). Due to the continuity of \( g \) and \( g^* \), taking \( k \to \infty \) on both sides of (S.33) provides \( t^* = g^*(g^{-1}(t^*)) \). Let \( x^* = g^{-1}(t^*) \), then \( t^* = g(x^*) = g^*(x^*) \). Furthermore, for all \( k = 1, 2, \ldots \),

\[
d_M(\mu(t_k), \mu(t_{k-1})) = d_M(\mu(g^*(g^{-1}(t_{k-1}))), \mu(g^{-1}(t_{k-1}))) = 0, \tag{S.34}
\]

since \( d_M(\mu(g(t)), \mu(g^*(t))) = 0 \), for all \( t \in \mathcal{T} \). By (W2), there exists \( s_0 \in (t_0, t_1) \) such that

\[
d_M(\mu(s_0), \mu(t_0)) = d_M(\mu(s_0), \mu(t_1)) > 0. \tag{S.35}
\]

Similarly, we can iteratively define another sequence \( s_k = g^*(g^{-1}(s_{k-1})) \), for \( k = 1, 2, \ldots \), for which it also holds that \( s_k \uparrow t^* \) as \( k \to \infty \) and \( d_M(\mu(s_k), \mu(s_{k-1})) = 0 \), for all \( k = 1, 2, \ldots \). By (S.34),

\[
d_M(\mu(t_0), \mu(t^*)) = d_M(\mu(t_k), \mu(t^*)) \quad \text{for all } k = 1, 2, \ldots \tag{S.36}
\]

Taking \( k \to \infty \) yields \( d_M(\mu(t_0), \mu(t^*)) = \lim_{k \to \infty} d_M(\mu(t_k), \mu(t^*)) = 0 \), by (W1). Similarly, it can be verified that \( d_M(\mu(s_0), \mu(t^*)) = 0 \), whence we obtain \( d_M(\mu(s_0), \mu(t_0)) = 0 \), which contradicts (S.35).

\[\square\]

Lemma S.2. Suppose (W1)–(W3) hold. For any \( i, i' = 1, \ldots, n \) such that \( i \neq i' \), the coefficient vector \( \theta_{g_{i,i'}} \) corresponding to the pairwise warping function \( g_{i,i'} \) is the unique minimizer of the following constrained optimization problem

\[
\min_{\theta \in \mathbb{R}^{p+1}} \mathcal{C}_\mu(\theta; h_{i'}, h_i),
\]

subject to \( I_0(\theta) = \theta_{p+1} - \tau = 0 \), \( I_k(\theta) = \theta_{k-1} - \theta_k + \xi \leq 0 \), \( k = 1, 2, \ldots, p+1 \),

where \( \mathcal{C}_\mu \) is as per (29), \( \theta = (\theta_1, \ldots, \theta_{p+1})^\top \in \mathbb{R}^{p+1} \), \( \theta_0 = 0 \), and \( \xi \in (0, cC^{-1}\tau/(p+1)) \) is a constant with \( c \) and \( C \) as per (W3).

Proof. Considering the fact that \( \mathcal{C}_\mu(\theta; h_{i'}, h_i) \geq 0 \), for all \( \theta \in \mathbb{R}^{p+1} \), and that \( \mathcal{C}_\mu(\theta_{g_{i,i'}}; h_i, h_{i'}) = 0 \), since \( h_{i'}^{-1}(\theta_{g_{i,i'}}(A)) = h_{i'}^{-1}(h_{i'}(h_i^{-1}(t))) = h_i^{-1}(t), \theta_{g_{i,i'}} \) is a constrained minimizer of the optimization problem in (S.36) in conjunction with (W3); it suffices to show the uniqueness. Suppose \( \theta_* \) is a constrained minimizer of \( \mathcal{C}_\mu(\theta; h_{i'}, h_i) \). The Lagrangian function corresponding to (S.36) is

\[
\mathcal{L}_\mu(\theta; h_{i'}, h_i) = \mathcal{C}_\mu(\theta; h_{i'}, h_i) + \sum_{k=0}^{p+1} \zeta_k I_k(\theta), \quad \text{where } \zeta_0 \in \mathbb{R}, \text{ and } \zeta_k \geq 0 \text{ for } k = 1, \ldots, p+1.
\]

By the Karush–Kuhn–Tucker condition (K Karush, 1939; Kuhn and Tucker, 1951), there exist \( \zeta_k^* \geq 0 \), \( k = 0, 1, \ldots, p+1 \), such that \( \nabla \mathcal{C}_\mu(\theta_*; h_{i'}, h_i) + \sum_{k=0}^{p+1} \zeta_k^* \nabla I_k(\theta_*) = 0 \) and \( \zeta_k^* I_k(\theta_*) = 0 \) for \( k = 1, \ldots, p+1 \).
By (W3), it holds that \( \nabla \mathcal{E}_\mu(\theta_*; h_{i'}, h_i) = 0 \), which, in conjunction with (W2) and (W3), implies

\[
d_M \left( \mu(h_{i'}^{-1}[\theta_*^\top A(t)]), \mu(h_i^{-1}(t)) \right) = 0,
\]

for almost everywhere \( t \in \mathcal{T} \) and hence for all \( t \in \mathcal{T} \) by (W1) and the continuity of \( h_i \) and \( h_{i'} \). Applying Lemma S.1 yields

\[
h_{i'}^{-1}[\theta_*^\top A(t)] = h_i^{-1}(t), \quad \text{for all } t \in \mathcal{T},
\]

and hence

\[
\theta_*^\top A(t) = h_{i'} \circ h_i^{-1}(t) = \theta_{g_{i'}}^\top A(t), \quad \text{for all } t \in \mathcal{T}.
\]

For any \( k = 0, 1, \ldots, p \) and \( t \in [t_k, t_{k+1}) \),

\[
\theta_*^\top A(t) = (\theta_*)_{k+1} \frac{t - t_k}{t_{k+1} - t_k} (\theta_*)_k \frac{t - t_{k+1}}{t_{k+1} - t_k},
\]

\[
\theta_{g_{i'}}^\top A(t) = (\theta_{g_{i'}})_{k+1} \frac{t - t_k}{t_{k+1} - t_k} (\theta_{g_{i'}})_k \frac{t - t_{k+1}}{t_{k+1} - t_k}.
\]

If there exists \( k_0 \in \{0, 1, \ldots, p\} \) such that \( (\theta_{g_{i'}})_{k_0} \neq (\theta_*)_0 \), then \( (\theta_{g_{i'}})_k \neq (\theta_*)_k \) for all \( k = k_0, \ldots, p + 1 \), which is contradictory to \( (\theta_{g_{i'}})_{p+1} = (\theta_*)_{p+1} = \tau \). Thus, \( \theta_* = \theta_{g_{i'}} \).

**Proof of Theorem 3.** For any \( i, i' = 1, \ldots, n \) such that \( i \neq i' \), a Taylor expansion yields

\[
\mathcal{E}_\mu(\theta; h_{i'}, h_i) - \mathcal{E}_\mu(\theta_{g_{i'}}; h_{i'}, h_i)
\]

\[
= \frac{1}{2} \left( \theta - \theta_{g_{i'}} \right)^\top \frac{\partial^2 \mathcal{E}_\mu}{\partial \theta \partial \theta^\top} (\theta_{g_{i'}}; h_{i'}, h_i)(\theta - \theta_{g_{i'}}) + o \left( \| \theta - \theta_{g_{i'}} \|^2 \right)
\]

\[
\geq \frac{1}{2} \int_{\mathcal{T}} \left[ \inf_{s \in \mathcal{T}} \frac{\partial^2 \mathcal{E}_\mu}{\partial s \partial s^\top}(s, t) \right] \left[ (\theta - \theta_{g_{i'}})^\top A(t) \right]^2 dt + o \left( \| \theta - \theta_{g_{i'}} \|^2 \right),
\]

as \( \| \theta - \theta_{g_{i'}} \| \to 0 \), where \( C \) is as per (W3), and \( \inf_{s \in \mathcal{T}} (\partial^2 \mathcal{E}_\mu/\partial s^2)(s, t) = \inf_{s \in \mathcal{T}} 2[(\partial^2 \mathcal{E}_\mu/\partial s)(s, t)]^2 \geq 0 \) by (W2). Noting that \( \int_{\mathcal{T}} A(t) A(t)^\top dt \) is positive definite, there exist \( \delta_0 > 0 \) such that

\[
\mathcal{E}_\mu(\theta; h_{i'}, h_i) - \mathcal{E}_\mu(\theta_{g_{i'}}; h_{i'}, h_i) \geq \frac{1}{4} C^{-2} \left[ \inf_{s \in \mathcal{T}} \frac{\partial^2 \mathcal{E}_\mu}{\partial s \partial s^\top}(s, t) \right] \lambda_{\min}^A \| \theta - \theta_{g_{i'}} \|^2, \quad \text{for all } \theta \in B_{\delta_0}(\theta_{g_{i'}}),
\]

where \( \lambda_{\min}^A > 0 \) is the smallest eigenvalue of \( \int_{\mathcal{T}} A(t) A(t)^\top dt \), and \( B_\delta(\theta_{g_{i'}}) \) is a ball of radius \( \delta \) centered at \( \theta_{g_{i'}} \). Furthermore, by Lemma S.2 and the compactness of the feasible region \( \Theta_\xi := \{ \theta \in \mathbb{R}^{p+1} : \theta_k - \theta_{k-1} \geq \xi, \ k = 1, \ldots, p + 1, \ \theta_{p+1} = \tau \} \subset \Theta \) of the optimization problem in (S.36), it
holds for any $\delta > 0$ that

$$\inf_{\theta \in B(\hat{\theta}_{g;\nu}; \delta)} \mathcal{C}_\mu(\theta; h; \nu) - \mathcal{C}_\mu(\theta_{g;\nu}; h; \nu) > 0.$$  

Observing that $\|\theta - \theta_{g;\nu}\|^2 \leq p\tau^2$, let

$$C_0 = \min \left\{ \frac{1}{4} C^{-2} \inf_{s =\epsilon T} \left. \frac{\partial^2 \mu}{\partial s^2} (s, t) \right|_{\text{min}} \right\} \left( p\tau^2 \right)^{-1} \inf_{\theta \in B(\hat{\theta}_{g;\nu}; \delta)} \left[ \mathcal{C}_\mu(\theta; h; \nu) - \mathcal{C}_\mu(\theta_{g;\nu}; h; \nu) \right],$$

where we note that $C_0 > 0$ and

$$\mathcal{C}_\mu(\theta; h; \nu) - \mathcal{C}_\mu(\theta_{g;\nu}; h; \nu) \geq C_0 \|\theta - \theta_{g;\nu}\|^2, \text{ for all } \theta \in \Theta_\xi.$$  

By (26), $\hat{\theta}_{g;\nu}$ minimizes $\mathcal{C}_{\hat{\theta}_{g;\nu}}(\hat{\nu}; \hat{\nu})$ subject to the constraint $\theta \in \Theta_\xi$ for some $\xi \in (0, cC^{-1} \tau/(p + 1))$, whence we obtain

$$\|\hat{\theta}_{g;\nu} - \theta_{g;\nu}\| \leq C_0^{-1/2} \left[ \mathcal{C}_\mu(\hat{\theta}_{g;\nu}; h; \nu) - \mathcal{C}_\mu(\theta_{g;\nu}; h; \nu) + \mathcal{C}_{\hat{\theta}_{g;\nu}}(\hat{\nu}; \hat{\nu}) \right]^{1/2} \tag{S.37}$$

Furthermore, noting that

$$\mathcal{C}_{\hat{\theta}_{g;\nu}}(\hat{\theta}; \hat{\nu}; \hat{\nu}) - \mathcal{C}_\mu(\theta; h; \nu) \leq \int_T \left| d_M \left( \hat{Y}_{h}(t), \hat{Y}_{\nu}(\theta^T A(t)) \right) - d_M \left( \mu(h^{-1}(t), \nu(\theta^T A(t)) \right) \right| dt + \lambda \int_T (\theta^T A(t) - t)^2 dt \leq 2\text{diam}\left(M\right) \int_T \left| d_M \left( \hat{Y}_{h}(t), \hat{Y}_{\nu}(\theta^T A(t)) \right) - d_M \left( Y_{h}(t), Y_{\nu}(\theta^T A(t)) \right) \right| dt + \frac{\tau^3}{3} \lambda$$

(S.37) can then be bounded as

$$\|\hat{\theta}_{g;\nu} - \theta_{g;\nu}\| \leq \left( \frac{4\text{diam}\left(M\right)}{C_0} \right)^{1/2} \left[ \sup_{t \in T} d_M \left( \hat{Y}_{h}(t), Y_{h}(t) \right)^{1/2} \right] + \left( \frac{2\tau^3}{3C_0} \right)^{1/2} \lambda^{1/2},$$

whence (30) follows by Theorem 2, and hence (31) follows by observing that

$$\sup_{t \in T} |\hat{g}_{g;\nu}(t) - g_{g;\nu}(t)| = \sup_{t \in T} |(\hat{\theta}_{g;\nu} - \theta_{g;\nu})^T A(t)| \leq \|\hat{\theta}_{g;\nu} - \theta_{g;\nu}\|,$$

since $\sup_{t \in T} |A_k(t)| \leq 1$, for all $k = 1, \ldots, p + 1$. □
Proof of Corollary 2. With \( b_i \sim m_i^{-(1-\varepsilon')(\beta_1-1)/(2\beta_1+4\beta_2-6+2\varepsilon)} \), (32) follows from (15) in Theorem 2. We only need to show (33).

Given any fixed \( \varepsilon > 0 \) and \( \varepsilon' \in (0, 1) \), define \( \gamma = \varepsilon'\beta_2/[4(\beta_2 - 1 + \varepsilon/2)] \), and
\[
a_{m_i} = \min \left\{ \left( m_i t_i^2 \right)^{\beta_2/[4(\beta_2 - 1 + \varepsilon/2)]}, \left( m_i t_i^2 \right)^{-(\log b_i)^{-1}\beta_2/[4(\beta_2 - 1)]} \right\}.
\]
We will show that for the bias part,
\[
\sup_{1 \leq i \leq n} \sup_{\omega_1 \in \Omega_1} \sup_T d_M \left( Y_{\omega_1}(t), \tilde{Y}_{\omega_1,b_i}(t) \right) = O \left( \sup_{1 \leq i \leq n} b_i^{2/(\beta_1-1)} \right) = O \left( b_i^{2/(\beta_1-1)} \right), \tag{S.38}
\]
and for the stochastic part,
\[
\limsup_{n \to \infty} \sum_{i=1}^n \sup_{\omega_1 \in \Omega_1} P_{\Omega_2} \left( a_{m_i} m_i^{-\gamma} \sup_T d_M \left( \tilde{Y}_{\omega_1,b_i}(t), \tilde{Y}_{\omega_1,m_i}(t) \right)^{\beta_2/2} > C \right) \to 0, \quad \text{as } C \to \infty. \tag{S.39}
\]
For each \( i = 1, \ldots, n \), and \( t \in T \), define \( \tilde{Y}_i(t) : \Omega_1 \to M \) as \( \tilde{Y}_i(t)(\omega_1) = \tilde{Y}_{\omega_1,b_i}(t) \). Observing that
\[
n^{-1} \sum_{i=1}^n \sup_{t \in T} d_M \left( Y_i(t), \tilde{Y}_i(t) \right) \leq \left( \sup_{1 \leq i \leq n} \sup_{\omega_1 \in \Omega_1} d_M \left( Y_{\omega_1}(t), \tilde{Y}_{\omega_1,b_i}(t) \right) \right)^{\alpha},
\]
\[
\limsup_{n \to \infty} P \left( n^{-1} \sum_{i=1}^n \sup_{t \in T} d_M \left( \tilde{Y}_i(t), \tilde{Y}_i(t) \right)^{\alpha} > C \sup_{1 \leq i \leq n} \left( a_{m_i} m_i^{-\gamma} \right)^{-2\alpha/\beta_2} \right) \leq \limsup_{n \to \infty} \sum_{i=1}^n P_{\Omega_2} \left( a_{m_i} m_i^{-\gamma} \sup_{t \in T} d_M \left( \tilde{Y}_{\omega_1,b_i}(t), \tilde{Y}_{\omega_1,m_i}(t) \right)^{\beta_2/2} > C \right),
\]
(33) follows if \( b_i \sim m_i^{-(1-\varepsilon')(\beta_1-1)/(2\beta_1+4\beta_2-6+2\varepsilon)} \).

For (S.38), we will first show \( \sup_{1 \leq i \leq n} \sup_{\omega_1 \in \Omega_1} \sup_{t \in T} d_M \left( Y_{\omega_1}(t), \tilde{Y}_{\omega_1,b_i}(t) \right) = o(1) \). By the Cauchy criterion for uniform convergence, it suffices to show
\[
\sup_{\omega_1 \in \Omega_1} \sup_{t \in T} \left| \sup_{1 \leq i \leq n} d_M \left( Y_{\omega_1}(t), \tilde{Y}_{\omega_1,b_i}(t) \right) - \sup_{1 \leq i' \leq n} d_M \left( Y_{\omega_1}(t), \tilde{Y}_{\omega_1,b_{i'}}(t) \right) \right| \to 0, \tag{S.40}
\]
as \( n, n' \to \infty \). We note that by (K0), (U0), and (W4),
\[
\sup_{1 \leq i \leq n} \sup_{t \in T} E_{\Omega_2} \left[ |v(T, t, b_i)(T - t)^2 b_i^{-2}| \right] = O(1), \quad \text{as } n \to \infty, \tag{S.41}
\]
whence in conjunction with (S.29) we obtain
\[
\begin{align*}
\sup_{1 \leq i \leq n} \sup_{\omega_1 \in \Theta_1, \, t \in T} \sup_{z \in M} & \left| \widetilde{M}_{\omega_1, b_i} (z, t) - M_{\omega_1} (z, t) \right| \\
\leq & \frac{1}{2} \sup_{1 \leq i \leq n} b_i^2 \sup_{1 \leq i \leq n} \sup_{t \in T} \mathbb{E}_{\Omega_1} \left[ |v(T, t, b_i)| \left( \frac{T - t}{b_i} \right)^2 \right] \sup_{\omega_1 \in \Theta_1, \, t \in T} |\phi_{\omega_1} (z, t)| \\
= & O \left( b(n)^2 \right),
\end{align*}
\]
where \( \phi_{\omega_1} \) is defined as per (S.27). Hence,
\[
\begin{align*}
\sup_{1 \leq i \leq n, \, \omega_1 \in \Theta_1, \, t \in T} \sup_{z \in M} & \left| \widetilde{M}_{\omega_1, b_i} (z, t) - \widetilde{M}_{\omega_1, b_i'} (z, t) \right| \\
\leq & \sup_{1 \leq i \leq n} \sup_{\omega_1 \in \Theta_1, \, t \in T} \sup_{z \in M} \left| \widetilde{M}_{\omega_1, b_i} (z, t) - M_{\omega_1} (z, t) \right| + \sup_{1 \leq i' \leq n'} \sup_{\omega_1 \in \Theta_1, \, t \in T} \sup_{z \in M} \left| \widetilde{M}_{\omega_1, b_i'} (z, t) - M_{\omega_1} (z, t) \right| \\
= & O \left( b(n)^2 \right) + O \left( b(n')^2 \right),
\end{align*}
\]
as \( n, n' \to \infty \). Observing that
\[
\begin{align*}
\sup_{\omega_1 \in \Theta_1, \, t \in T} \sup_{1 \leq i \leq n} & d_M \left( Y_{\omega_1} (t), \tilde{Y}_{\omega_1, b_i} (t) \right) - \sup_{1 \leq i' \leq n'} d_M \left( Y_{\omega_1} (t), \tilde{Y}_{\omega_1, b_i'} (t) \right) \\
\leq & \sup_{\omega_1 \in \Theta_1, \, t \in T} \sup_{1 \leq i \leq n, \, 1 \leq i' \leq n'} d_M \left( Y_{\omega_1} (t), \tilde{Y}_{\omega_1, b_i} (t) \right) - d_M \left( Y_{\omega_1} (t), \tilde{Y}_{\omega_1, b_i'} (t) \right) \\
\leq & \sup_{\omega_1 \in \Theta_1, \, t \in T} \sup_{1 \leq i \leq n, \, 1 \leq i' \leq n'} d_M \left( \tilde{Y}_{\omega_1, b_i} (t), \tilde{Y}_{\omega_1, b_i'} (t) \right),
\end{align*}
\]
(S.40) follows in conjunction with (U1).

Using similar arguments to the proof of (5), with \( q_{b_i} = b_i^{-\beta_1/(\beta_1 - 1)} \), by (S.30), there exists a constant \( C > 0 \) such that for large \( n \),
\[
\mathbb{P} \left( \sup_{1 \leq i \leq n} \sup_{\omega_1 \in \Theta_1, \, t \in T} d_M \left( Y_{\omega_1} (t), \tilde{Y}_{\omega_1, b_i} (t) \right) > 2^\ell \sup_{1 \leq i \leq n} q_{b_i}^{-1} \right)
\leq \sup_{1 \leq i \leq n} \mathbb{P} \left( \sup_{\omega_1 \in \Theta_1, \, t \in T} d_M \left( Y_{\omega_1} (t), \tilde{Y}_{\omega_1, b_i} (t) \right) > 2^\ell \sup_{1 \leq i \leq n} q_{b_i}^{-1} \right)
\leq \sup_{1 \leq i \leq n} \mathbb{P} \left( q_{b_i} \sup_{\omega_1 \in \Theta_1, \, t \in T} d_M \left( Y_{\omega_1} (t), \tilde{Y}_{\omega_1, b_i} (t) \right) > 2^\ell \right)
\leq \sup_{1 \leq i \leq n} C \sum_{k > \ell} \frac{b_i^2 (2^k q_{b_i}^{-1})^{2/\beta_1}}{2^{2(k-1)} q_{b_i}^{-2}} = 4C \sum_{k > \ell} 2^{-2k(\beta_1 - 1)/\beta_1},
\]
which converges to zero as \( \ell \to \infty \), whence (S.38) follows.
Furthermore, by (W4), replacing \(a_m\) with \(a_m, m_i^{-\gamma}\) in the proof of (S.25) yields
\[
\limsup_{n \to \infty} \sum_{i=1}^{n} \sup_{\omega_i \in \Omega_1} P_{\Omega_2} \left( a_m, m_i^{-\gamma} \sup_{t \in T} d_{M} \left( \tilde{Y}_{\omega_1, b_i(t)}, \tilde{Y}_{\omega_1, m_i(t)} \right) \right)^{\beta_2/2} > 2^\ell \]
\[
\leq 4C \sum_{k > \ell} 2^{-2k(\beta_2 - 1 + \epsilon/2)/\beta_2} \limsup_{n \to \infty} \sum_{i=1}^{n} m_i^{-2\gamma(\beta_2 - 1 + \epsilon/2)/\beta_2} + 4C \sum_{k > \ell} 2^{-2k(\beta_2 - 1)/\beta_2} \limsup_{n \to \infty} \sum_{i=1}^{n} m_i^{-2\gamma(\beta_2 - 1)/\beta_2} \leq 4C \sum_{k > \ell} 2^{-2k(\beta_2 - 1 + \epsilon/2)/\beta_2} \limsup_{n \to \infty} nm_i^{-2\gamma(\beta_2 - 1 + \epsilon/2)/\beta_2} + 4C \sum_{k > \ell} 2^{-2k(\beta_2 - 1)/\beta_2} \limsup_{n \to \infty} nm_i^{-2\gamma(\beta_2 - 1)/\beta_2},
\]
which converges to zero as \(\ell \to \infty\), whence (S.39) follows.

**Proof of Corollary 3.** By (28) and Theorem 3,
\[
\sup_{t \in T} \left| \tilde{h}_i^{-1}(t) - h_i^{-1}(t) \right| \leq \frac{1}{n} \sum_{i=1}^{n} \sup_{t \in T} |\tilde{g}_{\nu'}(t) - g_{\nu'}(t)| + \frac{1}{n} \sup_{t \in T} \left| \frac{1}{n} \sum_{i=1}^{n} g_{\nu'}(t) - h_i^{-1}(t) \right|.
\]
By Theorem 2.7.5 of van der Vaart and Wellner (1996),
\[
\sup_{t \in T} \left| \frac{1}{n} \sum_{i=1}^{n} g_{\nu'}(t) - h_i^{-1}(t) \right| = \sup_{t \in T} \left| \frac{1}{n} \sum_{i=1}^{n} h_{\nu'}(t) - t \right| = \sup_{t \in T} \left| \frac{1}{n} \sum_{i=1}^{n} h_{\nu'}(t) - E(h_{\nu'}(t)) \right| = O_P \left( n^{-1/2} \right).
\]
Observing that
\[
\frac{1}{n} \sum_{i=1}^{n} \sup_{t \in T} |\tilde{g}_{\nu'}(t) - g_{\nu'}(t)| \leq \frac{1}{n} \sum_{i=1}^{n} \| \hat{\theta}_{g_{\nu'}} - \theta_{g_{\nu'}} \| \leq \text{const.} \left[ \sup_{t \in T} d_{M}(\tilde{Y}_t(t), Y_t(t))^{1/2} + n^{-1} \sum_{i=1}^{n} \sup_{t \in T} d_{M}(\tilde{Y}_{\nu'}(t), Y_{\nu'}(t))^{1/2} + \lambda^{1/2} \right],
\]
it follows from Corollary 2 that
\[
\sup_{t \in T} \left| \tilde{h}_i^{-1}(t) - h_i^{-1}(t) \right| = O \left( \lambda^{1/2} \right) + O_P \left( m^{-(1-\epsilon')/[2(\beta_1 + 2\beta_2 - 3 + \epsilon)]} \right) + O_P \left( n^{-1/2} \right).
\]
By (W3),
\[
\sup_{t \in T} \left| \tilde{h}_i(t) - h_i(t) \right| = \sup_{t \in T} \left| \tilde{h}_i(\tilde{h}_i^{-1}(t)) - h_i(\tilde{h}_i^{-1}(t)) \right| = \sup_{t \in T} \left| t - h_i(\tilde{h}_i^{-1}(t)) \right| \leq C \sup_{t \in T} \left| \tilde{h}_i^{-1}(t) - h_i^{-1}(h_i(\tilde{h}_i^{-1}(t))) \right| = C \sup_{t \in T} \left| h_i^{-1}(t) - \tilde{h}_i^{-1}(t) \right|,
\]
for any specifically adding perturbations to the trajectory evaluated at for any distribution $z$

We consider a family of perturbation/distortion functions $g$ and $T$ |

\[ \mu \text{ fixed trajectories} \]

the time domain is $T = [0, 1]$, and the metric space $(M, d_W)$ considered is the Wasserstein space of continuous probability measures on $[0, 1]$ with finite second moments endowed with the $L^2$-Wasserstein distance as in Example 1. With sample size $n = 30$, two cases were implemented with fixed trajectories $\mu$ in (21) as follows.

Case 1: $\mu(t) = \text{Beta}(\xi_t, \gamma_t)$, where $\xi_t = 1.1 + 10(t - 0.4)^2$, and $\gamma_t = 2.6 + 1.5 \sin(2\pi t - \pi)$, for $t \in T$.

Case 2: $\mu(t) = N(\xi_t, \gamma_t^2)$ truncated on $[0, 1]$, where $\xi_t = 0.1 + 0.8t$, and $\gamma_t = 0.6 + 0.2 \sin(10\pi t)$, for $t \in T$. Specifically, the corresponding distribution function is

\[ F_{\mu(t)}(x) = \frac{\Phi((x - \xi_t)/\gamma_t) - \Phi(-\xi_t/\gamma_t)}{\Phi((1 - \xi_t)/\gamma_t) - \Phi(-\xi_t/\gamma_t)} 1_{[0,1]}(x) + 1_{(1, +\infty)}(x), \quad x \in \mathbb{R}, \]

where $\Phi$ is the distribution function of a standard Gaussian distribution.

We consider a family of perturbation/distortion functions $\{\mathcal{S}_a : a \in \mathbb{Z}\setminus\{0\}\}$, where $\mathcal{S}_a(x) = x - |a\pi|^{-1} \sin(a\pi x)$, for $x \in \mathbb{R}$. The warping functions $h_i$ were generated through the distortion functions $\mathcal{S}_a$; specifically, $h_i = \mathcal{S}_{a_{i1}} \circ \mathcal{S}_{a_{i2}}$, where $a_{il}$ are independent and identically distributed for $l = 1, 2$ and $i = 1, \ldots, n$, such that

\[ P(a_{il} = -k) = P(a_{il} = k) = P(V_2 = k)/[2(1 - P(V_2 = 0))], \]

for any $k \in \mathbb{N}_+$, with $V_2 \sim \text{Poisson}(2)$. We note that this generation mechanism ensures $h_i \in \mathcal{W}$ and $\mathbb{E}[h_i(t)] = t$, for any $t \in T$. With $\mu$ and $h_i$, the sample trajectories $Y_i$ were computed as per (21).

Set the number of discrete observations per trajectory $m_i = 30$, for all $i = 1, \ldots, n$. We sampled $T_{ij} \sim \text{Uniform}(\mathcal{T})$ independently, for $j = 1, \ldots, m_i$, and $i = 1, \ldots, n$. Given a measurable function $g: \mathbb{R} \to \mathbb{R}$, a push-forward measure $g#z$ is defined as $g#z(E) = z\{x : g(x) \in E\}$, for any distribution $z \in \mathcal{M}$ and set $E \subset \mathbb{R}$. The observed distributions $Z_{ij}$ were generated by adding perturbations to the trajectory evaluated at $T_{ij}$, $Y(T_{ij})$, through push-forward measures; specifically $Z_{ij} = \mathcal{S}_{u_{ij}}#(Y_i(T_{ij}))$, where $u_{ij}$ are independent and identically distributed following
Uniform\{\pm 4\pi, \pm 5\pi, \ldots, \pm 8\pi\}, and are also independent of the observed times \(T_{ij}, j = 1, \ldots, m_i,\) and \(i = 1, \ldots, n.\)

We applied the proposed pairwise warping method to the simulated data with Epanechnikov kernel and bandwidths \(b_i\) chosen by cross-validation in the presmoothing step as per (25), where the local Fréchet regression was implemented using the R package \texttt{frechet} (Chen et al., 2020). We assessed the results through mean integrated squared errors (MISEs) for the estimated time-synchronized trajectories \(\hat{Y}_i(\hat{h}_i(\cdot))\) and the estimated warping functions \(\hat{h}_i\) as per (25) and (28); specifically,

\[
\begin{align*}
\text{TMISE} & = \frac{1}{n} \sum_{i=1}^{n} \int_{\mathcal{T}} d_{\mathcal{M}}^2 \left( \hat{Y}_i(\hat{h}_i(t)), \mu(t) \right) \, dt, \\
\text{WMISE} & = \frac{1}{n} \sum_{i=1}^{n} \int_{\mathcal{T}} \left( \hat{h}_i(t) - h_i(t) \right)^2 \, dt.
\end{align*}
\]  

(S.42)

Figure 5: Summary of TMISE (red) and WMISE (blue) as per (S.42) out of 1000 Monte Carlo runs for Case 1 (top two rows) and Case 2 (bottom two rows).

Since too many knots will result in shape distortion of the estimated warping function (Ramsay
and Li, 1998), 1000 Monte Carlo runs were conducted for $p \in \{2, 3, 4, 9, 19, 99\}$, and $\lambda \in \{0\} \cup \{10^l : l = -1, 0, 1\}$. Results in terms of TMISE and WMISE for Case 1 and Case 2 are summarized in the boxplots in Figure 5, the top two rows show the results for Case 1 and the bottom two rows for Case 2. For both cases, for any given value of the number of knots $p$, the proposed estimators perform almost equally well in terms of TMISE and WMISE with small values (no more than 1) of the penalty parameter $\lambda$, and the performance turns worse as $\lambda$ increases from 1 to 10. Furthermore, across different choices of the number of knots $p$, the estimators achieve the minimum estimation errors with small $p \in \{2, 3, 4\}$. Thus, the simulations indicate that the proposed method is not sensitive to the choice of $p$ and $\lambda$ when $p$ and $\lambda$ are relatively small, which is in agreement with findings in the literature (Ramsay and Li, 1998; Tang and Müller, 2008).
