Abstract

As an extension of our previous work in the seesaw mechanism, we analyze the influence of $U_{e3}$ on the properties (masses and mixing) of the RH Majorana neutrinos in three flavors. The quasidegenerate light neutrinos case is also considered. Assuming the hierarchical Dirac neutrino masses, we find the heavy Majorana neutrino mass spectrum is either hierarchical or partial degenerate if $\theta_{23}$ is large. We show that degenerate RH Majorana masses correspond to maximal RH mixing angle while hierarchical ones correspond to the RH mixing angles which scale linearly with the mass ratios of the Dirac neutrino masses. An interesting analogue with the behavior of the matter-

I. INTRODUCTION

By adding the heavy right-handed (RH) neutrinos $\nu_R$, the seesaw mechanism provides a very natural and attractive explanation of the smallness of the neutrino masses compared to the masses of the charged fermions. In the seesaw mechanism the mass matrix of the left-handed (LH) neutrino has the following form:

$$ m_\nu = m_D M^{-1} m_D^T, $$

(1)

where $m_D$ is the Dirac mass matrix and $M$ is the Majorana mass matrix for the right-handed neutrino components. According to some kind of quark-lepton analogy suggested in Grand Unified Theories (GUTs), the structure of the Dirac mass matrix $m_D$ are similar to that in the quark sector. However, the scale of the RH Majorana neutrino masses is not precisely known. In various theoretical model, $\nu_R$ can be the unification scale ($\sim 10^{16}$ GeV) or the intermediate scale ($\sim 10^9 - 10^{13}$ GeV). To understand possible unification of particles and interactions, it is crucial to know if this scale associated with some new physics and at what energy it eventually happens.

The seesaw mechanism can give us hints about the neutrino properties in two aspects. The first is fixing $M$ by some ansatz and predicting masses and mixing of the light neutrinos. With the increasing of the data from the low neutrino experiments, it becomes pressing and practical to determine the structure of the RH Majorana neutrinos from the light neutrino masses and mixing implied by experiments.

The knowledge about neutrino masses and mixing comes mainly from three kinds of neutrino oscillation experiments: the solar and atmospheric neutrino deficits, LSND reactor experiments. The observation of the CHOOZ Collaboration implied a small $U_{e3}$

$$ |U_{e3}| = \sin^2 \theta_{13} \leq 0.13 - 0.23 $$

(2)

and so the atmospheric neutrino oscillation $\nu_\mu \leftrightarrow \nu_\tau$ decouples approximately from the solar neutrino oscillation $\nu_e \leftrightarrow \nu_\mu$. Analysis of the atmospheric neutrino deficit observed by the Super-Kamiokande Collaboration yield the mass-squared difference

$$ \Delta m_{23}^2 = 5.9 \times 10^{-3} \text{ eV}^2 $$

(3)

with the almost maximal mixing $\sin^2 2\theta_{23} = 1$. In contrast, there exists two different oscillation mechanism yielding four possible solutions to the solar neutrino problem: "Just-so" mechanism (or VO, i.e. the long wavelength vacuum oscillations) with
\[
(\Delta m_{12}^2, \sin^2 2\theta_{12}) = \left(6.5 \times 10^{-11} \text{ eV}^2, 0.75\right)
\]  
(4)

and the Mikheyev-Smirnov-Wolfenstein (MSW) mechanism \([12]\) (the matter-enhanced oscillation) with

\[
(\Delta m_{12}^2, \sin^2 2\theta_{12}) = \left(1.8 \times 10^{-5} \text{ eV}^2, 0.76\right) \quad \text{(LMA)},
\]

\[
= \left(7.9 \times 10^{-8} \text{ eV}^2, 0.96\right) \quad \text{(LOW)},
\]

\[
= \left(5.4 \times 10^{-6} \text{ eV}^2, 6.0 \times 10^{-3}\right) \quad \text{(SMA)}.
\]

Here LMA (SMA) refers to large (small) mixing angle and LOW stands for low mass or possibility. All the above we take are the best-fit values. For the convenience of late discussion, we present here the regions of the mass-squared differences \(\Delta m_{12}^2\) from Bahcall and \(\Delta m_{23}^2\) obtained from SK:

\[
\Delta m_{12}^2: \quad 4 \times 10^{-12} \sim 6 \times 10^{-9} \text{ eV}^2 \quad \text{(VO)},
\]

\[
6 \times 10^{-6} \sim 3 \times 10^{-4} \text{ eV}^2 \quad \text{(LMA)},
\]

\[
3 \times 10^{-8} \sim 2 \times 10^{-7} \text{ eV}^2 \quad \text{(LOW)},
\]

\[
4 \times 10^{-6} \sim 1 \times 10^{-5} \text{ eV}^2 \quad \text{(SMA)},
\]

\[
\Delta m_{23}^2: \quad 1 \times 10^{-3} \sim 1 \times 10^{-1} \text{ eV}^2 \quad \text{(From SK)}.
\]

Another neutrino oscillation experiment, LSND, indicates the mass-squared difference

\[
\Delta m_{LSND}^2 \sim 1 \text{ eV}^2
\]

(7)

with the mixing angle \(\sin^2 2\theta_{LSND} \sim 10^{-3} - 10^{-2}\). Four neutrinos are needed to accommodate all the three mass-squared differences. However, the LSND results were not confirmed by the recent KARMEN experiment and we will just set it aside \([13]\).

In the basis that the Dirac mass matrix of charged leptons is diagonal, the seesaw matrix \([2]\), \(S\), can be written as:

\[
S = D_L^T U.
\]

(8)

Here \(D_L\) is just \(U_0\) in Ref. \([5]\) which is the left-handed transformation to diagonalize \(m_D\). We will ignore the CP-violating effect (i.e. all the mixing matrices entered in the seesaw mechanism are real). It is convenient to set \(D_L = I\) and include its influence in the structure of \(U\). In this paper we will consider how a nonzero \(U_{e3}\) will affect the RH neutrino masses.
and mixing as an extension of our previous analysis [5]. There are three reasons for us to devote to this topic: one is that $\theta_{13}^{\nu}$ can be comparable with and can even be far larger than $\theta_{12}^{\nu}$ in the allowed region of the small mixing MSW effect. The other is that $S$ contains the contribution from $D_L^T$. If assuming $m_D$ has the same structure, not only the mass scale but also the mixing matrix, with that in quark sector, one has [3]

\[
D_L = \begin{pmatrix}
1 - \frac{1}{2}\lambda^2 & \lambda & \lambda^4 \\
-\lambda & 1 - \frac{1}{2}\lambda^2 & \lambda^2 \\
\lambda^3 - \lambda^4 & -\lambda^2 & 1 - \frac{1}{2}\lambda^2
\end{pmatrix}
\] (9)

with $\lambda \approx 0.22$. Then $S_{12}$ and $S_{13}$ have the following values:

\[
S_{12} = U_{e2} - \lambda U_{\mu 2} - \frac{1}{2} \lambda^2 U_{e2} + (\lambda^3 - \lambda^4) U_{\tau 2}, \quad (10)
\]

\[
S_{13} = U_{e3} - \lambda U_{\mu 3} - \frac{1}{2} \lambda^2 U_{e3} + (\lambda^3 - \lambda^4) U_{\tau 3}. \quad (11)
\]

Since $\lambda \gg U_{e2} \sim 10^{-2}$ in the SMA region, one can see that $S_{12} \sim S_{13} \sim -\lambda$ even when $\theta_{13}^{\nu} = 0$. The third is that, from Eq. (13) and Eq. (17) (see in Sec. II), the coefficient of $U_{e3}$ in $A$ is the maximal one. Moreover, from Eq. (16) and Eq. (18), the coefficient of $U_{\tau 1}$ in $B$ is also the maximal one. So the scale and structure of the Majorana neutrino may be sensitive, particularly in the SMA region i.e. when $\theta_{12}^{\nu}$ is small, to the value of $U_{e3}$ and $U_{\tau 1}$, that is, to the values of $\theta_{12}^{\nu}$ and $\theta_{13}^{\nu}$.

In section II, the quasidegenerate mass case is briefly discussed. In section III, the hierarchical mass case is studied in two possibilities according to whether $\theta_{12}^{\nu}$ is large or small. Finally, in section V we summary our main results.

II. QUASIDEGENERATE SPECTRUM

In Ref. [5] we have obtained the three eigenvalues of $M$ which can be expressed as

\[
M_1 = F M_1, \quad M_2 = F M_2, \quad M_3 = F M_3,
\] (12)

and the eigenvectors of $M$

\[
V_{ij} = \frac{Y_{ij} + M_jX_{ij}}{(Y_{jj} + M_jX_{jj}) + M_j - \text{Tr}Y} V_{jj} \quad (i, j = 1, 2, 3 \text{ and } i \neq j),
\] (13)
where
\[ F = \left( \frac{m_1^2 m_2^2 m_3^2}{m_1 m_2 m_3} \right)^{\frac{1}{3}}, \]  
(14)
and \( \overrightarrow{M} = e^{-2\eta_3 \lambda_3 - 2\sqrt{3} \eta_8 \lambda_8} \) which satisfy
\[ \overrightarrow{M}_1^{-1} + \overrightarrow{M}_2^{-1} + \overrightarrow{M}_3^{-1} = X_{11} + X_{22} + X_{33} \equiv A, \]  
(15)
\[ \overrightarrow{M}_1 + \overrightarrow{M}_2 + \overrightarrow{M}_3 = Y_{11} + Y_{22} + Y_{33} \equiv B. \]  
(16)

Here \( \lambda_{3,8} \) are diagonal Gell-Mann matrices. The elements of \( X \) and \( Y \) can be expressed as
\[ X_{ij} = \frac{1}{m_i D m_j D} \sum_{k=1}^{3} \overrightarrow{m}_{\nu k} S_{ik} S_{jk}, \]  
(17)
\[ Y_{ij} = \overrightarrow{m}_{iD} \overrightarrow{m}_{jD} \sum_{k=1}^{3} \frac{1}{m_{\nu k}} S_{ik} S_{jk}, \]  
(18)
where \( \overrightarrow{m}_{iD} = e^{-\xi_3 \lambda_3 - \sqrt{3} \xi_8 \lambda_8} \) and \( \overrightarrow{m}_{\nu k} = e^{-2\kappa_3 \lambda_3 - 2\sqrt{3} \kappa_8 \lambda_8}. \)

When \( m_0 = m_1 \approx m_2 \approx m_3 \), we define \( \delta_{12} \) and \( \delta_{13} \) as
\[ m_2 = m_0 (1 + \delta_{12}), \quad m_3 = m_0 (1 + \delta_{13}) \]  
(19)
which satisfy \( \delta_{12} \ll \delta_{13}. \) From the above relations it is easy for one to obtain
\[ M_i \approx \frac{m_i^2 D}{m_0}, \quad i = 1, 2, 3 \]  
(20)
and
\[ \beta_{ij} \approx -\frac{m_i D}{m_j D} \left( H_{ij} (\delta_{12}, \delta_{13}) - g H_{ij} \left( \frac{\delta_{12}}{1 + \delta_{12}}, \frac{\delta_{13}}{1 + \delta_{13}} \right) \right), \quad 1 \leq i < j \leq 3, \]  
(21)
where the function \( H_{ij} \) is defined as
\[ H_{ij} (\delta_{12}, \delta_{13}) = \delta_{12} S_{i2} S_{j2} + \delta_{13} S_{i3} S_{j3} \]  
(22)
and
\[ g = \begin{cases} 
\frac{m_2 D}{m_3 D}, & \text{for } \beta_{12} \text{ and } \beta_{13} \\
\frac{m_2 D}{m_3 D}, & \text{for } \beta_{23} 
\end{cases} \]  
(23)
We can see the RH mixing angles are small. However their scales are sensitive to the inputs of $S_{12}$, $S_{13}$, $\delta_{12}$ and $\delta_{13}$. For example, $\beta_{13} \approx \frac{m_{1D}}{m_{3D}} S_{12} S_{32}$ when $S_{13} = 0$ and $\beta_{13} \rightarrow 0$ when $\frac{S_{13}}{S_{32}} \approx \frac{\delta_{12}}{\delta_{13}}$. Despite this sensitivity, we find

$$\beta_{12} \approx -\frac{m_{1D}}{m_{2D}} \delta_{12} S_{12} S_{22}, \quad \beta_{13} \approx \frac{m_{1D}}{m_{3D}} \delta_{12} S_{12} S_{32}, \quad \beta_{23} \approx \frac{m_{2D}}{m_{3D}} \delta_{13} S_{23} S_{33}$$

when $S_{13} = 0$ and for SMA

$$\beta_{12} \approx -\frac{m_{1D}}{m_{2D}} \delta_{13} S_{13} S_{23}, \quad \beta_{13} \approx \frac{m_{1D}}{m_{3D}} \delta_{13} S_{13} S_{33}, \quad \beta_{23} \approx \frac{m_{2D}}{m_{3D}} \delta_{13} S_{23} S_{33}$$

when $S_{13} \gtrsim S_{12}$.

If assuming $m_0 \sim 1$eV, one has $M_1 = 1.6 \times 10^3$ GeV, $M_2 = 1.8 \times 10^8$ GeV and $M_3 = 1.2 \times 10^{13}$ GeV. Note that $M_{2,3}$ are in the intermediate scale while $M_1$, so suprise, is in the electric-weak scale.

Assuming $D_L = I$, all the corresponding relations can be obtained by replace $S$ with $U$.

### III. HIERARCHICAL SPECTRUM

In this case the two heavier neutrino masses can be written as $m_2 \approx \sqrt{\Delta m_{21}^2}$ and $m_3 \approx \sqrt{\Delta m_{31}^2}$. Setting $\theta_{23}^\nu = \frac{\pi}{4}$, the neutrino mixing matrix $U$ have the form

$$U = \begin{pmatrix}
\cos \theta_{12}^\nu \cos \theta_{13}^\nu & \sin \theta_{12}^\nu \cos \theta_{13}^\nu & \sin \theta_{13}^\nu \\
-\frac{\sin \theta_{12}^\nu + \cos \theta_{12}^\nu \sin \theta_{13}^\nu}{\sqrt{2}} & \frac{\cos \theta_{12}^\nu - \sin \theta_{12}^\nu \sin \theta_{13}^\nu}{\sqrt{2}} & \frac{\cos \theta_{13}^\nu}{\sqrt{2}} \\
\frac{\sin \theta_{12}^\nu - \cos \theta_{12}^\nu \sin \theta_{13}^\nu}{\sqrt{2}} & \frac{-\cos \theta_{12}^\nu + \sin \theta_{12}^\nu \sin \theta_{13}^\nu}{\sqrt{2}} & \frac{\cos \theta_{13}^\nu}{\sqrt{2}}
\end{pmatrix}.$$  \hfill (26)

In follows, we first consider the small mixing solution to the solar neutrino problem and then VO, LMA and LOW are embodied in a unitized framework, i.e. the large $\theta_{12}^\nu$.

#### A. small $\theta_{12}^\nu$ (SMA)

We will always assume $\sin^2 2 \theta_{12}^\nu \gtrsim 10^{-3}$ so that it remain in the SMA region. When $\theta_{12}^\nu$ is small there are three possibilities by comparing $\theta_{13}^\nu$ with $\theta_{12}^\nu$. 

---

7
1. $\theta_{12}^\nu \gg \theta_{13}^\nu$

We can know from Ref. [5] that in this case

$$M_1 \approx f_1 \frac{m_{1D}^2}{m_2} \frac{1}{\sin^2 \theta_{12}^\nu}, \quad M_2 \approx 2 \frac{m_{2D}^2}{m_3}, \quad M_3 \approx \frac{1}{2} f_1^{-1} \frac{m_{3D}^2}{m_1} \sin^2 \theta_{12}^\nu$$

(27)

and

$$\beta_{12} \approx -\frac{1}{\sqrt{2}} f_1 \frac{m_{1D}}{m_{2D}} \cot \theta_{12}^\nu, \quad \beta_{13} \approx \sqrt{2} f_1 \frac{m_{1D}}{m_{3D}} \cot \theta_{12}^\nu, \quad \beta_{23} \approx -\frac{m_{2D}}{m_{3D}}$$

(28)

where $f = \frac{r_{21}}{r_{21} + \cot \nu_{12}}$ and $r_{21} = \frac{m_2}{m_1} \gg 1$. The relations are obtained when $\theta_{13}^\nu \to 0$ so that

$$U \approx \begin{pmatrix} \cos \theta_{12}^\nu & \sin \theta_{12}^\nu & 0 \\ -\frac{\sin \theta_{12}^\nu}{\sqrt{2}} & \frac{\cos \theta_{12}^\nu}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{\sin \theta_{13}^\nu}{\sqrt{2}} & -\frac{\cos \theta_{13}^\nu}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix}.$$  

(29)

Note that, unlike what one would expect when no mixing occurs $M_i \propto m_i^{-1}$, $M_i$ have rotate dependence on $m_i^{-1}$ in the sense: $M_i \propto m_i^{-1}$ where we define

$$i_k \equiv (i + k) \bmod 3 \quad i, k = 1, 2, 3.$$  

(30)

As noted in Ref. [5] the RH mixing angles scale linearly with the ratios of the Dirac neutrino masses

$$\beta_{ij} \sim \frac{m_{iD}}{m_{jD}}, \quad 1 \leq i < j \leq 3.$$  

(31)

which is different with the LH quark mixing angles where one obtains $\tan \theta_{\text{quark}} \approx \sqrt{\frac{m_4}{m_3}}$ in two-generation case [14].

2. $\theta_{12}^\nu \ll \theta_{13}^\nu$

In this case

$$U \approx \begin{pmatrix} 1 & \sin \theta_{13}^\nu & \sin \theta_{12}^\nu \\ -\frac{\sin \theta_{13}^\nu}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ -\frac{\sin \theta_{12}^\nu}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix}.$$  

(32)

Here $U$ is not a strict orthogonal matrix as required. However it brings no trouble in since only the relative magnitudes of the elements of $U$ are used in our analysis. We have
\[ M_1 \approx \frac{m_{1D}^2}{m_3} \frac{1}{\sin^2 \theta_{13}^{\nu}}, \quad M_2 \approx \frac{2m_{2D}^2}{m_1} \frac{\sin^2 \theta_{13}^{\nu}}{r_{21} \sin^2 \theta_{13}^{\nu} + 1}, \quad M_3 \approx \frac{1}{2} \frac{m_{3D}^2}{m_2} \left( r_{21} \sin^2 \theta_{13}^{\nu} + 1 \right) \] (33)

and

\[ \beta_{12} \approx -\frac{m_{1D}}{m_{2D}} \frac{1}{\sqrt{2} \sin \theta_{13}^{\nu}}, \quad \beta_{13} \approx \frac{\sqrt{2} m_{1D}}{m_{3D}} \sin \theta_{13}^{\nu} \frac{r_{21}}{r_{21} \sin^2 \theta_{13}^{\nu} + 1}, \quad \beta_{23} \approx \frac{m_{2D}}{m_{3D}}. \] (34)

From Eq. (33) one has \( M_i \propto m_i^{-1} \) when \( r_{21} \ll \frac{U_{21}^2}{U_{13}^2} \approx \sin^{-1} \theta_{13}^{\nu} \) and \( M_{1(3)} \propto m_{3(1)}^{-1} \) and \( M_2 \propto m_2^{-1} \) when \( r_{21} \gg \sin^{-1} \theta_{13}^{\nu} \).

3. \( \theta_{12}^{\nu} \sim \theta_{13}^{\nu} \)

For convenient, we set \( U_{\tau 1} = 0 \), that is \( \sin \theta_{13}^{\nu} = \tan \theta_{12}^{\nu} \). So that

\[
U = \begin{pmatrix}
\sqrt{\cos 2 \theta_{12}^{\nu}} & \sqrt{\cos 2 \theta_{12}^{\nu}} \tan \theta_{12}^{\nu} & \tan \theta_{12}^{\nu} \\
-\sqrt{2} \sin \theta_{12}^{\nu} & \cos 2 \theta_{12}^{\nu} & \sqrt{2} \cos \theta_{12}^{\nu} \\
0 & -1 & \sqrt{2} \cos \theta_{12}^{\nu}
\end{pmatrix}.
\] (35)

We find

\[
M_1 \approx \frac{m_{1D}^2}{m_3} \cot^2 \theta_{12}^{\nu},
\] (36a)

\[
M_2 \approx \begin{cases} 
\frac{2m_{2D}^2}{m_1} \sin^2 \theta_{12}^{\nu}, & \text{if } r_{21} < r_{21}^{\text{res}} \\
\frac{1}{2} \frac{m_{2D}^2}{m_2}, & \text{if } r_{21} > r_{21}^{\text{res}}
\end{cases}
\] (36b)

\[
M_3 \approx \begin{cases} 
\frac{1}{2} \frac{m_{2D}^2}{m_2} \sin^2 \theta_{12}^{\nu}, & \text{if } r_{21} < r_{21}^{\text{res}} \\
\frac{2m_{2D}^2}{m_1} \sin^2 \theta_{12}^{\nu}, & \text{if } r_{21} > r_{21}^{\text{res}}
\end{cases}
\] (36c)

where \( r_{21}^{\text{res}} = \frac{1}{4} \frac{m_3^2}{m_{2D}} \csc^2 \theta_{12}^{\nu} \). We have two degenerate masses \( M_2 = M_3 \) when \( r_{21} = r_{21}^{\text{res}} \).

The second RH mixing angle \( \beta_{23} \) is given in

\[
\tan 2 \beta_{23} \approx \frac{1}{2} \frac{m_{2D}^2}{m_{3D}} \csc^2 \theta_{12}^{\nu} \approx \frac{2m_{2D}}{m_{3D}} \frac{1}{1 - r_{21}/r_{21}^{\text{res}}}
\] (37)

or

\[
\sin 2 \beta_{23} \approx -\frac{2m_{2D}/m_{3D}}{\sqrt{(1 - r_{21}/r_{21}^{\text{res}})^2 + 4m_{2D}^2/m_{3D}^2}}.
\] (38)
where $\kappa_3 = \frac{1}{4} \ln \frac{m_3}{m_2}$. The other two RH mixing angles are both small and can be expressed in $\beta_{23}$ as follows

$$\beta_{12} \approx \frac{1}{\sqrt{2} \sin \theta_{12}} \left( -\frac{m_{1D}}{m_{2D}} \cos \beta_{23} + \frac{m_{1D}}{m_{3D}} \sin \beta_{23} \right),$$

(39)

$$\beta_{13} \approx \frac{1}{\sqrt{2} \sin \theta_{12}} \left( -\frac{m_{1D}}{m_{2D}} \cos \beta_{23} + \frac{m_{1D}}{m_{3D}} \sin \beta_{23} \right).$$

(40)

The behaviors of $M_i$, $\eta_3 \left( = \frac{1}{4} \ln \frac{M_3}{M_1} \right)$, $\eta_8 \left( = \frac{1}{12} \ln \frac{M_3^2}{M_1 M_2} \right)$ and $\beta_{ij}$ as functions of $\kappa_3$ are shown in Fig. 1. In Fig. 2 we have plotted $M_2$, $M_3$ and $\sin^2 2\beta_{23}$ near $\kappa_{3 \text{res}}$ where $\kappa_{3 \text{res}}$ is the location of the resonance defined as

$$e^{4\kappa_{3 \text{res}}} \equiv \frac{1}{4} \frac{m_{3D}^2}{m_{2D}^2} \csc^2 \theta_{12}. \quad (41)$$

The behavior of $\sin^2 2\beta_{23}$ as a function of $\kappa_3$ is clearly that of a resonance peaked at $\kappa_3 = \kappa_{3 \text{res}}$, when $\sin^2 2\beta_{23} = 1$. We can define the resonance width $\delta_{\kappa_3}$ as that of $\kappa_3$ around $\kappa_{3 \text{res}}$ for which $\sin^2 2\beta_{23}$ becomes $\frac{1}{2}$ instead of the maximum value, unity. It is given by

$$\delta_{\kappa_3} \approx \frac{m_{2D}}{m_{3D}}. \quad (42)$$

The situation is very like that in the matter-enhanced $\nu_e \leftrightarrow \nu_\mu$ oscillation in the sun while here $r_{21}$ plays a part of the effective potential $V = 2\sqrt{2}G_f N_e E_\nu$. Here $G_f$ is the Fermi constant, $N_e$ is the electron number density of the matter and $E_\nu$ is the neutrino energy. When $\sin^2 2\beta_{23} = 1$ (that is when $\kappa_{3 \text{res}} \approx 4.2$ i.e. $m_1 \approx 1.2 \times 10^{-10}$ eV), substituting the SMA data in Eq. (3) into Eq. (36) we have

$$M_1 \approx 1.4 \times 10^7 \text{ GeV}, \quad M_2 \approx M_3 \approx 5 \times 10^{15} \text{ GeV}. \quad (43)$$

**B. large $\theta_{12}^\nu$**

In this case it is no need to consider the relative magnitude of $\theta_{12}^\nu$ and $\theta_{13}^\nu$ since one always has $U_{\tau 1} \approx \frac{\sin \theta_{12}^\nu}{\sqrt{2}}$. We shall therefore consider this problem in the following two possibilities according to the magnitude of $\theta_{13}^\nu$. 
1. $\theta_{13}^\nu$ is tiny

We find, when
\[ \sin^2 \theta_{13}^\nu \ll \min \left( \frac{m_2^2}{m_3} U_{12}^2, \frac{m_2^2}{m_3} U_{i2}^2 \right) \approx \frac{1}{2} \frac{m_1^2}{m_2^2}, \]
the RH Majorana masses are
\[ M_1 \approx \begin{cases} \frac{m_2^2}{m_2} \sin^2 \theta_{12} & \frac{m_3}{m_2} < \frac{2m_1^2}{m_1^2} \sin^2 \theta_{12}^\nu \\ \frac{2m_2^2}{m_3} & \frac{m_3}{m_2} > \frac{2m_1^2}{m_1^2} \sin^2 \theta_{12}^\nu \end{cases} \]
\[ M_2 \approx \begin{cases} \frac{m_2^2}{m_2} \sin^2 \theta_{12} & \frac{m_3}{m_2} < \frac{2m_1^2}{m_1^2} \sin^2 \theta_{12}^\nu \\ \frac{m_3^2}{m_2} & \frac{m_3}{m_2} > \frac{2m_1^2}{m_1^2} \sin^2 \theta_{12}^\nu \end{cases} \]
\[ M_3 \approx \frac{1}{2} \frac{m_3^2}{m_2} \sin^2 \theta_{12}^\nu \]
and the RH mixing angles
\[ \beta_{13} \approx \sqrt{2} \frac{m_1}{m_3} \cot \theta_{12}^\nu, \quad \beta_{23} \approx -\frac{m_2}{m_3} \]
We also give a numerical result for $\beta_{12}$ together with $M_i$, $\eta_{3,8}$ and the other two mixing angles as functions of $\kappa_8 \left( = \frac{1}{12} \ln \frac{m_3^2}{m_1 m_2} \right)$ in Fig. 3 taking $m_3^2 = 0.1$ eV$^2$ and $\kappa_3 = 2$. We also plotted $M_1$, $M_2$ and $\sin^2 2\beta_{12}$ near $\tau_{32}^{\text{res}} \approx 2 \frac{m_1^2}{m_1 D} \sin^2 \theta_{12}^\nu$ in Fig. 4.

2. $\theta_{13}^\nu$ is not so small

We find, when $\theta_{13}^\nu$ is small and satisfies
\[ \sin^2 \theta_{13}^\nu \gtrsim \max \left( \frac{m_2^2}{m_3} U_{12}^2, \frac{m_2^2}{m_3} U_{i2}^2 \right) \approx \frac{m_2}{m_3} \sin^2 \theta_{12}^\nu, \]
the RH Majorana neutrino masses are hierarchical
\[ M_1 \approx f_1 \frac{m_1^2}{m_2}, \quad M_2 \approx f_1 \frac{m_1^2}{m_3} \frac{1}{U_{12}}, \quad M_3 \approx \frac{m_3^2}{m_3} U_{12}, \]
where $f_1 = \left( \frac{U_{e2}}{S_{e2}} + \frac{m_3^2}{m_1 m_2} U_{e3} \frac{m_1 m_3}{m_2} U_{\mu3} \right)$ and all the three RH mixing angles are small
\[ \beta_{12} \approx \frac{U_{e2} U_{\mu2} + \frac{m_3^2}{m_1 m_2} U_{e3} \frac{m_1 m_3}{m_2} U_{\mu3}}{S_{e2}^2 + \frac{m_3^2}{m_1 m_2} S_{e3}^2}, \quad \beta_{13} \approx \frac{m_1 U_{e1}}{m_3 U_{\tau1}}, \quad \beta_{23} \approx \frac{m_2 U_{\mu1}}{m_3 U_{\tau1}}. \]
Here we also have rotate dependence of $M_i$ on $m_i^{-1}$ and the RH mixing angles $\beta_{ij}$ scale linearly with the ratios of the Dirac neutrino masses.
IV. SUMMARY AND DISCUSSION

Separating the solution regions of the solar neutrino problem in two cases according to the value of $\theta_{12}^\nu$, we have derived simple relations between parameters of the RH and LH Majorana neutrino masses and mixing in the context of the seesaw mechanism and quark-lepton symmetry within the framework of three families. Especially, as an extension of our previous work, we have embodied quasidegenerate light neutrino mass case and the influence of nonzero $U_{e3}$ on the properties (masses and mixing) of the RH Majorana neutrinos. The CP-violating effect has not included. We find

1. quasidegenerate neutrino spectrum leads to hierarchical RH Majorana masses and small RH mixing angles which scale linearly with the ratios of the Dirac masses

$$
\beta_{ij} \approx \frac{m_{iD}}{m_{jD}}, \quad 1 \leq i < j \leq 3.
$$

2. For SMA, resonance like behavior of $\sin^2 2\beta_{23}$ is found when $U_{r1} \approx 0$. We find when $m_1 \approx 1.2 \times 10^{-10} \text{ eV}$ one has $\sin^2 2\beta_{23} = 1$, $M_1 \approx 1.4 \times 10^7 \text{ GeV}$ and $M_2 \approx M_3 \approx 5 \times 10^{15} \text{ GeV}$. $M_2$, $M_3$ are near the scale of GUT and $M_3 \approx 5 \times 10^{15} \text{ GeV}$ for a wide range of $r_{21}$, quantitatively, for $r_{21}$ below $r_{21}^{\text{res}}$.

3. The behavior $\sin^2 2\beta_{12}$ as a functions of $\kappa_8$ if $\frac{m_2}{m_1}$ is given) is a resonance peaked at $r_{32} = r_{32}^{\text{res}}$ for large $\theta_{12}^\nu$ case while $\theta_{13}^\nu$ is tiny and one has two lighter degenerate RH Majorana masses at this point. In Ref. [5] we have not discuss this case considering that $m_2$ will far less than the lower bound of the solar neutrino solutions if taking $m_3^2 \sim 10^{-3} \text{ eV}^2$ which is around the best-fit value. However, the degenerate $M_1$ and $M_2$ could be coincident with the experimental results considering that $m_3^2$ can reach to about $10^{-1} \text{ eV}^2$ and then one has $m_2^2 \sim 10^{-11} \text{ eV}^2$ which lies in the region of the vacuum explanation to the solar neutrino anomaly but still far less than the lower bound of the LMA and LOW solutions. For LMA and LOW, one always has $\frac{m_1}{m_2} < 2\frac{m_{2D}}{m_{1D}} \sin^2 \theta_{12}^\nu$ and so

$$
M_1 \approx \frac{m_{1D}^2}{m_1} \frac{1}{\sin^2 \theta_{12}^\nu}, \quad M_2 \approx 2\frac{m_{2D}^2}{m_2} \sin^2 \theta_{12}^\nu, \quad M_3 \approx \frac{1}{2} \frac{m_{3D}^2}{m_1} \sin^2 \theta_{12}^\nu; \quad (51)
$$

$$
\beta_{12} \approx -\frac{1}{\sqrt{2}} \frac{m_{1D}}{m_{2D}} \cot \theta_{12}^\nu, \quad \beta_{13} \approx \sqrt{2} \frac{m_{1D}}{m_{3D}} \cot \theta_{12}^\nu, \quad \beta_{23} \approx -\frac{m_{2D}}{m_{3D}}, \quad (52)
$$
that is, $M_i \propto m_i^{-1}$ and $\beta_{ij} \sim \frac{m_i}{m_j}$ ($1 \leq i < j \leq 3$). For VO, the corresponding RH masses when $r_{32} = r_{32}^{\text{res}}$ are $M_1 \approx M_2 \approx 1.2 \times 10^9$ GeV and $M_3 \approx 1.8 \times 10^{17} r_{21}$ GeV.

4. An interesting analogue of the RH parameters around the resonance with the behavior of the matter-enhanced neutrino conversion is presented.

5. As an accessory consequence, we present a numerical method for calculating the physical parameters in the seesaw mechanism which usually involving extreme large and extreme small quantities simultaneously. In our numerical results, eigenvalues larger than unit and the corresponding eigenvectors of $X$ are directly obtained from $X$. By solving the eigenequation of $Y$, we obtain the inverse of the eigenvalues of $X$ larger than unit and the corresponding eigenvectors. The validness of this method can be verified simply by the condition that the product of the three eigenvalues of $X$ is unit. We find this condition is satisfied well.

The results are dependent on the precise determination of $U_{e3}$. Such a goal is expected to be reached in the neutrino long baseline experiment, registration of the neutrino bursts from the Galactic supernova by existing detectors SK and SNO, and the neutrino factories [15]. In this paper we have not discuss the case when $M_R$ and $m_D$ are complex. We hope return to it in future.

**ACKNOWLEDGMENTS**

The authors would like to express our sincere thanks to Professor T.K. Kuo for pointing out this problem to G. Cheng during his visit at Purdue University from January to April, 2000 and provoke our interesting in it. We are also indebted to him for his warmly help in the research progressing and kindness by giving us his papers being prepared. We are grateful to Dr. Du Taijiao and Dr. Tu Tao for useful discussions. The authors are also grateful to the convenience provided by Chinese High Performance Computing Center at Hefei. G. Cheng is supported in part by the National Science Foundation in China grant no.19875047.

FIGURES

FIG. 1. The behavior of the RH Majorana masses, mass ratios and the RH mixing angles as functions of $\kappa_3$ for the SMA solution to the solar neutrino anomaly when $U_{\tau 1} = 0$. We take $m_2^2 = 5.4 \times 10^{-6}$ eV$^2$, $m_3^2 = 5.9 \times 10^{-3}$ eV$^2$, $\sin^2 2\theta_{12} = 6.0 \times 10^{-3}$, $\theta_{13}^\nu = 0.0$ and $\sin^2 2\theta_{23}^\nu = 1.0$.

FIG. 2. The behavior of $M_2$, $M_3$ and $\sin^2 2\beta_{23}$ near $\kappa_3^{\text{res}}$ for the SMA solution. The values of the parameters are the same as in Fig. 1.

FIG. 3. The behavior of the RH Majorana masses, mass ratios and the RH mixing angles as functions of $\kappa_8$ for the vacuum oscillation solution to the solar neutrino anomaly when $U_{e3} = 0$. We take $m_2^2 = 6.5 \times 10^{-11}$ eV$^2$, $m_3^2 = 0.1$ eV$^2$, $\sin^2 2\theta_{12}^\nu = 0.75$ and $\sin^2 2\theta_{23}^\nu = 1.0$.

FIG. 4. The behavior of $M_1$, $M_2$ and $\sin^2 2\beta_{12}$ near $\kappa_8^{\text{res}}$ for the vacuum oscillation solution when $U_{e3} = 0$. The values of the parameters are the same as in Fig. 3.
