Abstract
Expander graphs in general, and Ramanujan graphs in particular, have been of great interest in the last three decades with many applications in computer science, combinatorics and even pure mathematics. In these notes we describe various efforts made in recent years to generalize these notions from graphs to higher dimensional simplicial complexes.

0 Introduction

Expander graphs are highly connected finite sparse graphs. These graphs play a fundamental role in computer science and combinatorics (cf. [Lub94, HLW06], and the references within) and in recent years even found numerous applications in pure mathematics ([Lub12]). Among these graphs, Ramanujan graphs stand out as optimal expanders (at least from the spectral point of view). The theory of expanders and Ramanujan graphs has led to a very fruitful interaction between mathematics and computer science (and between mathematicians and computer scientists). In the early days, deep mathematics (e.g. Kazhdan property (T) and Ramanujan conjecture) has been used to construct expanders and Ramanujan graphs. But recently, the theory of computer science pays its debt to mathematics and expanders start to appear more and more also within pure mathematics.

The fruitfulness of this theory calls for a generalization to high dimensional theory. Here the theory is much less developed. The goal of these notes is to describe some of these efforts and to call the attention of the mathematical and computer science communities to this challenge. We strongly believe that a beautiful and useful theory is waiting for us to be explored.

Most of the notes will be dedicated to the story of Ramanujan complexes. These generalizations of Ramanujan graphs, which has been developed in [CSZ03, L04, LSV05a, LSV05b, Sar07] became possible by the significant development of the theory of automorphic forms in positive characteristic and especially the work of L. Lafforgue [Laf02]. In §1, we will describe the classical theory of Ramanujan graphs, in a way which will pave the way for a smooth presentation in §2, of the much more complicated theory of Ramanujan complexes.

The situation with high dimensional expanders is more chaotic. Here it is not even agreed what should be the “right” definition. Several generalizations of the concept of expander graph have been suggested, which are not equivalent. It is not clear at this point which one is more useful. Each has its own charm and part of the active research on this subject is to understand the relationships between the various definitions.

We describe these activities briefly in §3. It can be expected (and, in fact, I hope!) that these notes will not be up to date by the time they will appear in press.

Acknowledgement. The author is indebted to Konstantin Golubev, Gil Kalai, Tali Kaufman, Roy Meshulam and Uli Wagner for many discussions regarding the material of these notes. I am especially grateful to Ori Parzanchevski, whose help and advice in preparing these notes have improved them significantly.
This work was supported by ERC, ISF and NSF. Some of this work was carried out while the author visited Microsoft Research laboratory in Cambridge, Ma. We are grateful for the warm hospitality and support. We are also grateful for the Mathematical Society of Japan for the invitation to deliver the Takagi lectures, the hospitality and the valuable remarks we received from the audience.

1 Ramanujan Graphs

In this chapter we will survey Ramanujan graphs, which are optimal expanding graphs from a spectral point of view. The material is quite well known by now and has been described in various places ([LPS88][Sar90][Lab94][Val97]). We present it here in a way which will pave the way for the high dimensional generalization - the Ramanujan complexes - which will come in the next chapter.

1.1 Eigenvalues and expanders

Let $X = (V,E)$ be a finite connected $k$-regular graph, $k \geq 3$, with a set $V$ of $n$ vertices, and adjacency matrix $A = A_X$, i.e. $A$ is an $n \times n$ matrix indexed by the vertices of $X$ and $A_{ij}$ is equal to the number of edges between $i$ and $j$ (which is either 0 or 1 if $X$ is a simple graph).

**Definition 1.1.1.** The graph $X$ is called Ramanujan if for every eigenvalue $\lambda$ of the symmetric matrix $A$, either $\lambda = \pm k$ (“the trivial eigenvalues”) or $|\lambda| \leq 2\sqrt{k-1}$.

Recall that $k$ is always an eigenvalue of $A$ (with the constant vector/function as an eigenfunction) while $-k$ is an eigenvalue of $A$ iff $X$ is bi-partite, i.e. the vertices of $X$ can be divided into two disjoint sets $Y$ and $Z$ and every edge $e$ in $E$, has one endpoint in $Y$ and one in $Z$. In this case, the eigenfunction is 1 on $Y$ and $-1$ on $Z$.

Ramanujan graphs have been defined and constructed in [LPS88] (see also [Mar88] and see [Sar90][Lab94][Val97] for more comprehensive treatment). The importance of the number $2\sqrt{k-1}$ comes from Alon-Boppana Theorem which asserts that for any fixed $k$, no better bound can be obtained on the non-trivial eigenvalues of an infinite sequence of finite $k$-regular graphs.

**Theorem 1.1.2** (Alon-Boppana (cf. [LPS88][Nil91])). For a finite connected $k$-regular graph $X$, denote

$$
\mu_1 (X) = \max \{ |\lambda| \mid \lambda \text{ an eigenvalue of } A \text{ and } \lambda \neq k \} \\
\mu_0 (X) = \max \{ |\lambda| \mid \lambda \text{ an eigenvalue of } A \text{ and } \lambda \neq k \} \\
\mu (X) = \max \{ |\lambda| \mid \lambda \text{ an eigenvalue of } A \text{ and } \lambda \neq \pm k \}.
$$

If $\{X_i\}_{i=1}^\infty$ is a sequence of such graphs with $|X_i| \to \infty$, then

$$
\lim \inf_{i \to \infty} \mu (X_i) \geq 2\sqrt{k-1}.
$$
The hidden reason for the number $2\sqrt{k-1}$ is: All the finite connected $k$-regular graphs are covered by the $k$-regular tree, $T = T_k$. Let $A_T$ be the adjacency operator of $T$, i.e., for every function $f$ on the vertices of $T$ and for every vertex $x$ of it,

$$A_T(f)(x) = \sum_{y \sim x} f(y)$$

namely, $A_T$ sums $f$ over the neighbors of $x$. Then $A_T$ defines a self-adjoint operator $L^2(T) \to L^2(T)$.

**Proposition 1.1.3** ([Kes59]). The spectrum of $A_T$ is $[-2\sqrt{k-1}, 2\sqrt{k-1}]$.

Of course, $k$ is not an eigenvalue of $A_T$ as the constant function is not in $L^2$. It is even not in the spectrum (unless $k = 2$, in which case $T_k$ is a Cayley graph of the amenable group $\mathbb{Z}$, but this is a different story). But, $k$ is necessarily an eigenvalue for all the adjacency operators induced on the finite quotients $\Gamma \backslash T$ where $\Gamma$ is a discrete cocompact subgroup of $\text{Aut}(T)$. Similarly, $-k$ is an eigenvalue of the finite quotient $\Gamma \backslash T$ if it is bi-partite (which happens if $\Gamma = \pi_1(\Gamma \backslash T)$ preserves the two-coloring of the vertices of $T$). Now, Ramanujan graphs are the “ideal objects” having their non-trivial spectrum as good as the “ideal object” $T$.

There is another way to characterize Ramanujan graphs. These are the graphs which satisfy the “Riemann hypothesis”, i.e. all the poles of the Ihara zeta function associated with the graph lie on the line $\Re(s) = \frac{1}{2}$. See [Lub94, §4.5] and especially the works of Ihara [Iha66], Sunada [Sun88] and Hashimoto [Has89].

The work of Ihara showed the close connection between number theoretic questions and the combinatorics of some associated graphs. While it was Satake [Sat66] who showed how the classical Ramanujan conjecture can be expressed in a representation theoretic way. These works have paved the way to the explicit constructions of Ramanujan graphs to be presented in §1.2 and §1.3.

Ramanujan graphs have found numerous applications in combinatorics, computer science and pure mathematics. We will not describe these but rather refer the interested readers to the thousands references appearing in google scholar when one looks for Ramanujan graphs.

We should mention however their main application and original motivation: expanders.

**Definition 1.1.4.** For $X$ a $k$-regular graph on $n$ vertices, denote:

$$h(X) = \min_{0 < |A| < |V|} \frac{n \cdot |E(A, V \backslash A)|}{|A||V \backslash A|}$$

where $E(A, V \backslash A)$ is the set of edges from $A$ to its complement. We call $h(X)$ the Cheeger constant of $X$.

**Remark 1.1.5.** In most references, the Cheeger constant is defined as

$$\overline{h}(X) = \min_{0 < |A| \leq |V|/2} \frac{|E(A, V \backslash A)|}{|A|}.$$
Clearly $h(X) \leq h(X) \leq 2h(X)$. For our later purpose, it will be more convenient to work with $h(X)$.

**Definition 1.1.6.** The graph $X$ is called $\varepsilon$-expander (for $0 < \varepsilon \in \mathbb{R}$) if $h(X) \geq \varepsilon$.

Expander graphs are of great importance in computer science. Ramanujan graphs give outstanding expanders due to the following result:

**Theorem 1.1.7** ([Tan84, Dod84, AM85, Alo86]). For $X$ as above,

$$\frac{h^2(X)}{8k} \leq k - \mu_0(X) \leq h(X).$$

In particular, Ramanujan $k$-regular graphs are $\varepsilon$-expanders with $\varepsilon = k - 2\sqrt{k - 1}$ (or if one prefers the more standard notation $h(X) \geq \frac{h}{2} - \sqrt{k - 1}$).

A very useful result in many applications is the following Expander Mixing Lemma:

**Proposition 1.1.8.** For $X = (V, E)$ as above and for every two subsets $A$ and $B$ of $V$,

$$\left| E(A, B) - \frac{k|A||B|}{|V|} \right| \leq \mu_0(X) \sqrt{|A||B|}.$$

Note that $\frac{k|A||B|}{|V|}$ is the expected number of edges between $A$ and $B$ if $X$ would be a “random $k$-regular graph”. So, if $\mu_0(X)$ is small, e.g. if $X$ is Ramanujan, it mimics various properties of random graphs. This is one of the characteristics which make them so useful.

There is no easy method to construct Ramanujan graphs. Let us better be more precise here: There are many ways to get for a fixed $k$ finitely many $k$-regular Ramanujan graphs (see [Lub94, Chapter 8]), but there is essentially only one known way to get, for a fixed $k$, infinitely many $k$-regular Ramanujan graphs.

The current state of the art is, that for every $k \in \mathbb{N}$ of the form $k = p^\alpha + 1$ where $p, \alpha \in \mathbb{N}$ and $p$ prime, there are infinitely many $k$-regular Ramanujan graphs but for all other $k$’s this is still open:

**Open Problem 1.1.9.** Given $k$ which is not of the form $p^\alpha + 1$, are there infinitely many $k$-regular Ramanujan graphs?

We stress that this problem is open for every single $k$ like that (e.g. $k = 7$) and it is not known if such graphs exist, let alone an explicit construction.

In the next subsection we will describe the Bruhat-Tits tree and present the basic theory that will enable us in the following subsection to get explicit constructions of Ramanujan graphs.
1.2 Bruhat-Tits trees and representation theory of PGL$_2$

Let $F$ be a local field (e.g. $F = \mathbb{Q}_p$ the field of $p$-adic numbers, or a finite extension of it, or $F = \mathbb{F}_q((t))$ the field of Laurent power series over the finite field $\mathbb{F}_q$) with ring of integers $\mathcal{O}$ (e.g. $\mathcal{O} = \mathbb{Z}_p$ or $\mathcal{O} = \mathbb{F}_q[[t]]$), maximal ideal $m = \pi \mathcal{O}$ where $\pi$ is a fixed uniformizer, i.e., an element of $\mathcal{O}$ with valuation $\nu(\pi) = 1$ (e.g. $\pi = p$ or $\pi = t$, respectively), so $k = \mathcal{O}/m$ is a finite field of order $q$. Let $G = \text{PGL}_2(F)$ and $K = \text{PGL}_2(\mathcal{O})$, a maximal compact subgroup of $G$.

The quotient space $G/K$ is a discrete set which can be identified as the set of vertices of the regular tree of degree $q + 1$ in the following way:

Let $V = F^2$ be the two dimensional vector space over $F$. An $\mathcal{O}$-submodule $L$ of $V$ is called an $\mathcal{O}$-lattice if it is finitely generated as an $\mathcal{O}$-module and spans $V$ over $F$. Every such $L$ is of the form $L = \mathcal{O} \alpha + \mathcal{O} \beta$ where $\{\alpha, \beta\}$ is some basis of $V$ over $F$. The standard lattice is the one with $\{\alpha, \beta\} = \{e_1, e_2\}$, where $\{e_1, e_2\}$ is the standard basis of $V$.

Two $\mathcal{O}$-lattices $L_1$ and $L_2$ are said to be equivalent if there exists $0 \neq \lambda \in F$ such that $L_2 = \lambda L_1$. The group $\text{GL}_2(F)$ acts transitively on the set of $\mathcal{O}$-lattices and its center $Z$, the group of scalar matrices, preserves the equivalent classes. Hence $G = \text{PGL}_2(F)$ acts on these classes, with $K = \text{PGL}_2(\mathcal{O})$ fixing the equivalent class of the standard lattice $x_0 = [L_0]$, $L_0 = \mathcal{O} e_1 + \mathcal{O} e_2$. So, $G/K$ can be identified with the set of equivalent classes of lattices. Two classes $[L_1]$ and $[L_2]$ are said to be adjacent if there exists representatives $L_1' \in [L_1]$ and $L_2' \in [L_2]$ such that $L_1' \subseteq L_2'$ and $L_2'/L_1' \simeq k = \mathcal{O}/m$. This symmetric relation (since $\pi L_2' \subseteq L_1'$ and $L_2'/\pi L_2' \simeq k$) defines a structure of a graph.

**Theorem 1.2.1** (cf. [Ser80, p. 70]). The above graph is a $(q + 1)$-regular tree.

The $q + 1$ neighbors of $[L_0]$ correspond to the $q + 1$ subspaces of co-dimension 1 of the two dimensional space $L_0/\pi L_0 \cong k^2$. We can therefore identify them with $\mathbb{P}^1(k)$, the projective line over $k$.

Let us now shift our attention for a moment to the unitary representation theory of $G$. Let $C = C_c(\mathcal{K}\backslash G/K)$ denote the set of bi-$K$-invariant functions on $G$ with compact support. This is an algebra with respect to convolution:

$$f_1 * f_2(x) = \int_G f_1(xg) f_2(g^{-1}) \, dg.$$ 

The algebra $C$ is commutative (see [Lub94, Chapter 5] and the references therein). If $\mathcal{H}$ is a Hilbert space and $\rho : G \to U(\mathcal{H})$ a unitary representation of $G$, then $\rho$ induces a representation $\overline{\rho}$ of the algebra $C$ by:

$$\overline{\rho}(f) = \int_G f(g) \rho(g) \, dg.$$ 

Let $\mathcal{H}^K$ be the space of $K$-invariant vectors in $\mathcal{H}$. Then $\overline{\rho}(f)(\mathcal{H}^K) \subseteq \mathcal{H}^K$ and so $(\mathcal{H}^K, \overline{\rho})$ is a representation of $C$. A basic claim is that if $\rho$ is irreducible and $\mathcal{H}^K \neq \{0\}$ then $\overline{\rho}$ is irreducible, in fact, as $C$ is commutative Schur’s Lemma

6
implies that \( \dim \mathcal{H}^K = 1 \). So \( \dim \mathcal{H}^K = 0 \) or 1, in the second case we say that \( \rho \) is \( K \)-spherical (or unramified or of class one). We will be interested only in these representations. Such a representation \( \rho \) is uniquely determined by \( \overline{\mathcal{F}} \). Let us understand now what is the algebra \( C \).

Let \( \overline{\delta} \) be the characteristic function of the subset \( K \{ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \} K \) of \( G \). By its definition \( \overline{\delta} \in \mathcal{C} \). In fact, it turns out that \( C \) is generated as an algebra by \( \overline{\delta} \) and hence every \( K \)-spherical irreducible subrepresentation \((\mathcal{H}, \rho)\) of \( G \) is determined by the action of \( \overline{\delta} \) on the one dimensional space \( \mathcal{H}^K \), i.e. by the eigenvalue of this action.

Let us note now that \( C \) also acts on \( L^2(G/K) \) in the following way: If \( f_1 \in C \) and \( f_2 \in L^2(G/K) \) we think of both as functions on \( G \) and we can then look at \( f_2 \ast f_1 \in L^2(G/K) \) (check!)

Spelling out the meaning of that for \( f_1 = \overline{\delta} \), one can see (the reader is strongly encouraged to work out this exercise!):

**Claim 1.2.2.** Let \( f \) be a function defined on the vertices of the tree \( G/K \) and let \( \delta \) be the operator \( \delta : L^2(G/K) \rightarrow L^2(G/K) \) defined by \( \delta(f) = f \ast \overline{\delta} \). Then for every \( x \in G/K \)

\[
\delta(f)(x) = \sum_{y \sim x} f(y).
\]

Namely, \( \delta \) is nothing more then the adjacency operator (whose name in the classical literature is Hecke operator).

Let now \( \Gamma \) be a cocompact discrete subgroup of \( G = \text{PGL}_2(F) \) (for simplicity assume also that \( \Gamma \) is torsion free). Then \( \Gamma \backslash G/K \) is, on one hand a quotient of the \((q+1)\)-regular tree and, on the other hand, a quotient of the compact space \( \Gamma \backslash G \). Hence, this is nothing more than a finite \((q+1)\)-regular graph. Moreover, the discussion above shows that the spectral decomposition of the adjacency matrix of this finite graph (and in particular its eigenvalues) is intimately connected with the spectral decomposition of \( L^2(\Gamma \backslash G) \) as a unitary \( G \)-representation. More precisely, in every irreducible \( K \)-spherical subrepresentation \( \rho \) of \( L^2(\Gamma \backslash G) \), there is a \( K \)-invariant function \( f \), i.e. a function in \( L^2(\Gamma \backslash G/K) \). As explained above the one dimensional space spanned by \( f \) is a representation space \( \mathcal{F} \) for \( C \), which means that \( f \) is an eigenvector for the adjacency operator \( \delta \) of the finite graph \( \Gamma \backslash G/K \). Moreover, every eigenvector \( f \) of \( \delta \) in \( L^2(\Gamma \backslash G/K) \) is obtained like that (we can look at the \( G \)-subspace spanned by \( f \), thinking of it as a \( K \)-invariant function in \( L^2(\Gamma \backslash G) \).

The list of \( K \)-spherical irreducible unitary representations of \( \text{PGL}_2(F) \) is well known (see [Lub94], Theorem 5.4.3] and the references therein). There are representations of two kinds:

(a) The tempered representations - these are the \( K \)-spherical irreducible representations \((\mathcal{H}, \rho)\) with the following property: There exists \( 0 \neq u, v \in \mathcal{H} \) such that \( \phi : G \rightarrow \mathbb{C} \) defined by \( \phi(g) = \langle \rho(g)u, v \rangle \) (the coefficient function of \( \rho \) w.r.t. \( u \) and \( v \)) is in \( L^{2+\varepsilon}(G) \) for every \( \varepsilon > 0 \). The \( K \)-spherical
representations with this property are also called in this case “the principal series” and they are characterized by the property that the associated eigenvalue $\lambda$ of $\delta$ (as a generator of $C$ acting on the one-dimensional space $H^K$) satisfies $|\lambda| \leq 2\sqrt{q}$.

(b) The non-tempered representations - these are the representations for which the above $\lambda$ satisfies $2\sqrt{q} < |\lambda| \leq q + 1$.

The above description explains why and how the representation of $G = \text{PGL}_2(F)$ on $L^2(\Gamma \backslash G)$ is crucial for understanding the combinatorics of the graph $\Gamma \backslash G/K$. In fact we have (see [Lub94, Corollary 5.5.3]):

**Theorem 1.2.3.** Let $\Gamma$ be a cocompact lattice in $G = \text{PGL}_2(F)$. Then $\Gamma \backslash G/K$ is a Ramanujan graph if and only if every irreducible $K$-spherical $G$-subrepresentation of $L^2(\Gamma \backslash G)$ is tempered, with the exception of the trivial representation (which corresponds to $\lambda = q + 1$) and the possible exception of the sign representation (the non-trivial one dimensional representation $sg : G \to \{\pm 1\}$) which corresponds to $\lambda = -(q + 1)$ and which appears in $L^2(\Gamma \backslash G)$ iff $\Gamma \backslash G/K$ is bipartite.

Proving that $\Gamma$’s as in the last theorem indeed exist is a highly nontrivial issue which we discuss in the next section. This will lead to (explicit) constructions of Ramanujan graphs.

**Remark 1.2.4.** In case $\Gamma$ is a non-uniform lattice in $G = \text{PGL}_2(F)$ (which exists only if $\text{char}(F) > 0$) one can develop also a theory of Ramanujan diagrams (cf. [Mor94b]) which is also of interest even for computer science (see [Mor95]).

### 1.3 Explicit constructions

In this section we will quote the deep results which imply that various graphs are Ramanujan and then we will show how to use them to get explicit constructions of such graphs.

Let $k$ be a global field, i.e. $k$ is a finite extension of $\mathbb{Q}$ or of $\mathbb{F}_p(t)$. Let $\mathcal{O}$ be the ring of integers of $k$, $S$ a finite set of valuations of $k$ (containing all the archimedean ones if $\text{char}(k) = 0$) and $\mathcal{O}_S$ the ring of $S$-integers ($= \{x \in k | \nu(x) \geq 0, \forall \nu \notin S\}$). Let $G$ be a $k$-algebraic semisimple group with a fixed embedding $G \hookrightarrow \text{GL}_m$. A general result asserts that

$$\Gamma = G(\mathcal{O}_S) := G(k) \cap \text{GL}_m(\mathcal{O}_S)$$

is a lattice (= discrete subgroup of finite covolume) in $\prod_{\nu \in S} G(k_\nu)$ where $k_\nu$ is the completion of $k$ w.r.t. the valuation $\nu$. In some cases (few of these will be described below) $G(k_\nu)$ is compact for every $\nu \in S$ except of one $\nu_0 \in S$. In such a case the projection of $\Gamma$ to $G(k_{\nu_0})$, which is also denoted by $\Gamma$, is called
an arithmetic lattice in $G_0(k_0)$. The arithmetic lattice $\Gamma$ comes with a system of congruence subgroups defined for every $0 \neq I \triangleleft \mathcal{O}_S$ as:

$$\Gamma (I) = \Gamma \bigcap \ker (\text{GL}_m (\mathcal{O}_S) \to \text{GL}_m (\mathcal{O}_S/I)) .$$

If $G_0(k_0) \simeq \text{PGL}_2(F)$ (or more generally $\text{PGL}_d(F)$ - see Chapter 2) where $F$ is a local field as in §1.2, we get the arithmetic groups we are interested in. We can now state:

**Theorem 1.3.1.** Let $\Gamma (I) \triangleleft \Gamma$ be a congruence subgroup of an arithmetic lattice $\Gamma$ of $G = \text{PGL}_2(F)$ as above. Then every infinite dimensional $K$-spherical irreducible subrepresentation of $L^2(\Gamma (I) \backslash G)$ is tempered.

The only possible finite dimensional $K$-spherical representations are the trivial one and the $sg$ representation. From Theorem 1.2.3 we can now deduce:

**Corollary 1.3.2.** The graph $\Gamma (I) \backslash G/K$ is Ramanujan.

Theorem 1.3.1 is a very deep result whose proof is a corollary of various works by some of the greatest mathematicians of the 20th century. It is based in particular on the solution of the so called “Peterson–Ramanujan conjecture”. (In characteristic 0, in two steps: by Eichler for weight two modular forms which is the relevant case for us, and by Deligne in general. In positive characteristic by Drinfeld). Then one needs to combine it with the Jacquet–Langlands correspondence. The reader is referred to [Lub94] for more and in particular to the Appendix there by J. Rogawski which gives the general picture.

The last result give explicit graphs in the mathematical sense of explicit, but it also paves the way for an explicit construction, in the computer science sense, of Ramanujan graphs. We will present the ones constructed in [LPS88].

When $G = \text{PGL}_2(F)$, all the arithmetic lattices in $G$ are obtained via quaternion algebras. Namely, let $D$ be a quaternion algebra defined over $k$ and $G = D^\times/Z$, i.e. the invertible quaternions modulo the central ones. If $D$ splits over $\nu_0 \in S$ (i.e. $D \otimes k_{\nu_0} \simeq M_2(k_{\nu_0})$) while it is ramified over all $\nu \in S \setminus \nu_0$ (i.e. $D \otimes k_{\nu}$ is a division algebra in which case $(D \otimes k_{\nu})^\times/(D \otimes k_{\nu})$ is a compact group) then $G(\mathcal{O}_S)$ gives rise to an arithmetic lattice in $G(k_0) = \text{PGL}_2(k_0)$. Such lattices (and their congruence subgroups) can be used for the construction of arithmetic lattices.

Let us take a very concrete example: Let $D$ be the classical Hamilton quaternion algebra; so $D$ is spanned over $\mathbb{Q}$ by $1,i,j$ and $k$ with $i^2 = j^2 = k^2 = -1$ and $ij = ji = k$. It is well known that it is ramified over $\mathbb{R}$ and over $\mathbb{Q}_p$ while splits over $\mathbb{Q}_p$ for every odd prime $p$, and that $G(\mathbb{R}) = \mathbb{H}^\times/\mathbb{R}^\times \simeq \text{SO}(3)$ while $G(\mathbb{Q}_p) = M_2(\mathbb{Q}_p)^\times/\mathbb{Q}_p^\times \simeq \text{PGL}_2(\mathbb{Q}_p)$. Fix such a prime $p$ and set $S = \{\nu_p, \nu_\infty\}$. Then $\mathcal{O}_S = \mathbb{Z}\left[\frac{1}{p}\right] = \left\{\frac{a}{p^n} \mid a \in \mathbb{Z}, n \in \mathbb{N}\right\}$, and as explained above, $D\left(\mathbb{Z}\left[\frac{1}{p}\right]\right)$ is a discrete subring of $D(\mathbb{R}) \times D(\mathbb{Q}_p)$, while

$$\Gamma = D(\mathbb{Z}\left[\frac{1}{p}\right])^\times/Z \hookrightarrow \text{SO}(3) \times \text{PGL}_2(\mathbb{Q}_p)$$
is a cocompact lattice.

Moreover, Jacobi’s classical theorem tells us that there are \(8(p+1)\) solutions to the equation: \(x_0^2 + x_1^2 + x_2^2 + x_3^2 = p\) with \((x_0, x_1, x_2, x_3) \in \mathbb{Z}^4\). Assume now \(p \equiv 1 \pmod{4}\). In this case, three of the \(x_i\) are even and one is odd. If we agree to take those with \(x_0\) odd and positive we have a set \(\Sigma\) of \(p+1\) solutions which come in pairs \(\alpha_i, \overline{\alpha}_i, \ldots, \alpha_s, \overline{\alpha}_s\) where \(s = \frac{p+1}{2}\) and where we consider \(\alpha\) as an integral quaternion \(\alpha = x_0 + x_1i + x_2j + x_3k\); \(\overline{\alpha} = x_0 - x_1i - x_2j - x_3k\) so \(\|\alpha_i\| = \|\overline{\alpha}_i\| = p\). These \(p+1\) elements give \(p+1\) elements in \(G(\mathbb{Q}_p)\).

Moreover, each \(\alpha_i\) (and \(\overline{\alpha}_i\)) when considered as an element of \(\text{PGL}_2(\mathbb{Q}_p)\) takes the standard \(p\)-adic lattice \(\mathbb{Z}_p \times \mathbb{Z}_p\) (see §1.2) to an immediate neighbor in the tree and \(\overline{\alpha}_i = \alpha^{-1}\).

One can deduce (see [Lub94 Corollary 2.1.11]) that the group \(\Lambda = \langle \alpha_1, \overline{\alpha}_1, \ldots, \alpha_s, \overline{\alpha}_s \rangle\) is a free group on \(s = \frac{p+1}{2}\) generators acting simply transitively on the Bruhat-Tits \((q+1)\)-regular tree \(T\). One can therefore identify this tree with the Cayley graph of \(\Lambda\) with respect to \(\Sigma = \{\alpha_i | i = 1, \ldots, s\}\). As \(\Lambda\) is also a lattice in \(\text{PGL}_2(\mathbb{Q}_p)\), it is of finite index in \(\Gamma\). One can check (using “strong approximation” or directly) that if \(q\) is another prime with \(q \equiv 1 \pmod{4}\) then \(\Gamma(2q) \setminus T = \text{Cay}(\Lambda/\Lambda \cap \Gamma(2q) \Sigma)\).

Spelling out the meaning of this, one gets the following explicit construction of Ramanujan graphs, which are usually referred to as the LPS-graphs.

**Theorem 1.3.3** ([LPS88, see [Lub94 Theorem 7.4.3]]). Let \(p\) and \(q\) be different prime numbers with \(p \equiv q \equiv 1 \pmod{4}\). Fix \(\varepsilon \in \mathbb{F}_q\) satisfying \(\varepsilon^2 = -1\). For each \(\alpha_i = (x_0, x_1, x_2, x_3), i = 1, \ldots, s\) in the set \(\Sigma\) above, take the matrix

\[
\tilde{\alpha}_i = \begin{pmatrix}
x_0 + \varepsilon x_1 & x_2 + \varepsilon x_3 \\
x_2 + \varepsilon x_3 & x_0 - \varepsilon x_1
\end{pmatrix} \in \text{PGL}_2(\mathbb{F}_q)
\]

and \(\tilde{\Sigma} = \{\tilde{\alpha}_i | i = 1, \ldots, s\}\). Let \(H\) be the subgroup of \(\text{PGL}_2(\mathbb{F}_q)\) generated by \(\tilde{\Sigma}\) and \(X^{p,q} = \text{Cay}(H; \tilde{\Sigma})\), the Cayley graph of \(H\) with respect to \(\tilde{\Sigma}\). Then:

(a) \(X^{p,q}\) is a \((p+1)\)-regular Ramanujan graph.

(b) If \(\left(\frac{p}{q}\right) = -1\), i.e. \(p\) is not a quadratic residue modulo \(q\) then \(H = \text{PGL}_2(\mathbb{F}_q)\) and \(X^{p,q}\) is a bi-partite graph, while if \(\left(\frac{p}{q}\right) = 1\), \(H = \text{PSL}_2(\mathbb{F}_q)\) and \(X^{p,q}\) is not.

The main motivation for the construction of Ramanujan graphs has been expanders, but the LPS graphs turned out to have various other remarkable properties like high girth and high chromatic numbers (simultaneously!). See ([LPS88, Lub94, Sar90, Val97]) for more.

In [Mor94a], Morgenstern constructed, for every prime power \(q\), infinitely many \((q+1)\)-regular Ramanujan graphs. This time by finding an arithmetic lattice in \(\text{PGL}_2(\mathbb{F}_q((t)))\) acting simply transitively on the Bruhat-Tits tree. Another such a construction is given (somewhat hidden) in [LSV05a] as a special case of Ramanujan complexes (to be discussed in the next chapter). These last mentioned Ramanujan graphs are also edge transitive and not merely vertex transitive (see [KL12]).
2 Ramanujan complexes

This Chapter is devoted to the high-dimensional version of Ramanujan graphs, the so-called Ramanujan complexes. These are $(d-1)$-dimensional simplicial complexes which are obtained as quotients of the Bruhat-Tits building $B_d$ associated with $\mathrm{PGL}_d(F)$, $F$ a local field, just like the Ramanujan graphs were obtained as quotients of the Bruhat-Tits tree of $\mathrm{PGL}_2(F)$. What enables this, is the work of Lafforgue [La02] which extended to general $d$, the “Ramanujan conjecture” for $\mathrm{GL}_d$ in positive characteristic, proved first by Drinfeld [Dri88] for $d=2$ (the work of Drinfeld was the basis for the Ramanujan graph constructed by Morgenstern [Mor94]). We will start in §2.1 with the basic definitions and results about buildings and will present the associated Hecke operators, generalizing the Hecke operator (=adjacency matrix) which appeared in Chapter 1. We will present the analogue of Alon-Boppana Theorem and define Ramanujan complexes. In §2.2 we will survey shortly the representation theory of $\mathrm{PGL}_d(F)$ and just as in Theorem 1.2.3, we will show that representation theory is relevant for the combinatorics of $\Gamma \backslash B_d$. Then in §2.3 we will present explicit constructions of Ramanujan complexes.

We will follow mainly [LSV05a] and [LSV05b], where the reader can find precise references for the results mentioned here. The reader is also referred to [Bal00, CSZ03, L04, Sar07] for related material.

2.1 Bruhat-Tits buildings and Hecke operators

Let $K$ be any field. The spherical complex $\mathbb{P}^{d-1}(K)$ associated with $K^d$ is the simplicial complex whose vertices are all the non-trivial (i.e. not $\{0\}$ and not $K^d$) subspaces of $K^d$. Two subspaces $W_1$ and $W_2$ are on the same 1-edge if either $W_1 \subseteq W_2$ or $W_2 \subseteq W_1$, and $\{W_0, \ldots, W_r\}$ is an $r$-cell if every pair $W_i, W_j$ form an edge (i.e. $\mathbb{P}^{d-1}(K)$ is a “clique complex”). It can be shown that this happens iff after some reordering $W_0 \subseteq W_1 \subseteq \ldots \subseteq W_r$. When $K = \mathbb{F}_q$, a finite field of order $q$, $\mathbb{P}^1(\mathbb{F}_q)$ is just a set of $q+1$ points, which can be identified with the projective line over $\mathbb{F}_q$. For $d = 3$, $\mathbb{P}^2(K)$ is the $(q+1)$-regular graph with $2(q^2 + q + 1)$ vertices of “points” versus “lines” of the projective plane. In general, $\mathbb{P}^{d-1}(K)$ is a $(d-2)$-dimensional simplicial complex.

We now describe $\mathcal{B} = B_d(F)$, the affine Bruhat-Tits building of type $\widetilde{A}_{d-1}$ associated with $F$. Here $F$ is a local field with $\mathcal{O}$, $\pi$ and $m$ as in §1.2 and $\mathcal{O}/m = \mathbb{F}_q$. An $\mathcal{O}$-lattice in $V = F^d$ is a finitely generated $\mathcal{O}$- submodule $L$ of $V$ such that $L$ contains an $F$-basis of $V$. Two lattices $L_1$ and $L_2$ are equivalent if $L_1 = \lambda L_2$ for some $0 \neq \lambda \in F$. The vertices of $\mathcal{B}$ are the equivalence classes of $\mathcal{O}$-lattices in $V$, and two distinct equivalent classes $[L_1]$ and $[L_2]$ are adjacent in $\mathcal{B}$ if there exist representatives $L_1' \in [L_1]$ and $L_2' \in [L_2]$ s.t. $\pi L_1' \subseteq L_2' \subseteq L_1'$. The $r$-simplices of $\mathcal{B}$ ($r \geq 2$) are the subsets $\{[L_0], \ldots, [L_r]\}$ such that all pairs $[L_i]$ and $[L_j]$ are adjacent. It can be shown that $\{[L_0], \ldots, [L_r]\}$ forms a simplex if and only if there exist representatives $L_i' \in [L_i]$ such that after reordering the indices, $\pi L_r' \subseteq L_0' \subseteq \ldots \subseteq L_r'$. The complex $\mathcal{B}$ is therefore of dimension...
\(d - 1 = \text{rank}_F (PGL_d (F))\). This is a special case of the Bruhat-Tits building associated with a reductive group over \(F\). The next theorem is also a special case which generalizes Theorem 1.2.1.

**Theorem 2.1.1.** The complex \(B_d (F)\) is contractible. The link of each vertex is isomorphic to \(\mathbb{P}^{d-1} (\mathbb{F}_q)\).

The vertices of \(B\) come with a natural coloring (“type”). Let \(\tau : B^0 \to \mathbb{Z}/d\mathbb{Z}\) be defined as follows: Let \(O^d \subseteq V\) be the standard lattice in \(V\). For any lattice \(L\), there exists \(g \in GL (V) = GL_d (F)\) such that \(L = g (O^d)\). Define \(\tau ([L]) = \nu (\det (g)) (\mod d)\) where \(\nu\) is the valuation of \(F\), e.g., for \(F = \mathbb{F}_q ((t))\), \(\nu \left(\sum_{i=-m}^{\infty} a_i t^i\right) = m\) when \(m \in \mathbb{Z}\) and \(a_m \neq 0\).

The group \(GL_d (F)\) acts transitively on the \(O\)-lattices in \(V\) and its center preserves the equivalence classes. As the action preserves inclusions, \(G = PGL_d (F)\) acts on the building \(B\). It acts transitively on \(B^0\) - the vertices - without preserving their colors, but \(PSL_d (F)\) does preserves them. The stabilizer of the (equivalence class of the) standard lattice is \(K = PGL_d (O)\). Hence \(B^0\) can be identified with \(G/K\). To every directed edge \((x, y) \in B^1\) one can associate the color \(\tau (y) - \tau (x) \in \mathbb{Z}/d\mathbb{Z}\). The color of edges is preserved by \(PGL_d (F)\).

Let us now define \(d - 1\) operators - the Hecke operators - as follows: For \(1 \leq k \leq d - 1\), \(f \in L^2 (B^0)\) and \(x \in B^0\),

\[
(A_k f) (x) = \sum f (y)
\]

where the summation is over the neighbors \(y\) of \(x\) such that \(\tau (y) - \tau (x) = k \in \mathbb{Z}/d\mathbb{Z}\). This really amounts to a sum over the sublattices of \(L\) containing \(\pi L\), whose projection in \(L/\pi L\) is of codimension \(k\) there. Note that \(A_k\) commutes with the action of \(PGL_d (F)\). One can show that these operators are bounded, normal and commute with each other. But in general they are not self-adjoint. In fact, \(A_k^* = A_{d-k}\) so \(A_k + A_{d-k}\) is self-adjoint. Moreover \(\Delta = \sum_{k=1}^{d-1} A_k\) is the adjacency operator of the 1-skeleton of \(B\). For \(d = 2\), we only have \(A_1 = A_1^*\) which is indeed the adjacency operator of the tree. As the operators \(A_k\) commute with each other they can be diagonalized simultaneously. Their common spectrum is therefore a subset \(\Sigma_d\) of \(\mathbb{C}^{d-1}\).

**Theorem 2.1.2.** Let \(S = \{ (z_1, \ldots, z_d) \in \mathbb{C}^d \mid |z_i| = 1 \text{ and } \prod_{i=1}^{d} z_i = 1 \} \) and \(\sigma : (z_1, \ldots, z_d) \mapsto (\lambda_1, \ldots, \lambda_{d-1})\) where \(\lambda_k = q^{\frac{k(d-k)}{2}} \sigma_k (z_1, \ldots, z_d)\). Here \(\sigma_k\) is the \(k\)th elementary symmetric function, i.e. \(\sigma_k (z_1, \ldots, z_d) = \sum_{i_1 < \ldots < i_k} z_{i_1} \cdots z_{i_k}\).

Then \(\sigma (S)\) is equal to \(\Sigma_d\), the simultaneous spectrum of \(A_1, \ldots, A_{d-1}\) acting on \(L^2 (B^0)\).

Note that indeed \(\lambda_k = \overline{\lambda_{d-k}}\) as had to be expected, since \(A_k = A_{d-k}^*\). Also for \(d = 2\),

\[
\Sigma_2 = \sigma (S) = \left\{ q^{\frac{1}{2}} \left( z + \frac{1}{z} \right) \mid z \in \mathbb{C}, |z| = 1 \right\} = [-2\sqrt{q}, 2\sqrt{q}]
\]
which shows that Theorem 2.1.2 is a generalization of Proposition 1.1.3.

Ramanujan \((q + 1)\)-regular graphs were defined as the finite quotients of \(B_2 = T_{q+1}\) whose “non-trivial” eigenvalues are all in \(\Sigma_2\). Similarly we will define Ramanujan complexes as quotients of \(B_d\) whose “non-trivial” eigenvalues are in \(\Sigma_d\). Let us describe first the trivial eigenvalues: Recall that for \(d = 2\) we have two such: \((q + 1)\) and \(-(q + 1)\). They appear in all the finite quotients \(\Gamma \backslash B_2\) when \(\Gamma\) preserves the colors of the vertices (and only \(q + 1\) appears in all the finite quotients).

So, assume \(\Gamma \leq \text{PGL}_d(F)\) is a cocompact lattice preserving the colors of the vertices of \(B^0\). So, \(\tau\) is well defined on \(X = \Gamma \backslash B^0\), for a \(d^\text{th}\) root of unity \(\xi\), define \(f_\xi : X \to \mathbb{C}\) by \(f_\xi(x) = \xi^{\tau(x)}\). Now, \(A_k f_\xi(x)\) sums over the neighbors of \(x\) of color \(\tau(x) + k\) (mod \(d\)) and there are \([\frac{d}{k}]_q\) vertices like that (where \([\frac{d}{k}]_q\) denotes the number of subspaces of codimension \(k\) in \(F_q^d\)). Hence \(A_k f_\xi(x) = [\frac{d}{k}]_q \xi^{\tau(x)+k} = [\frac{d}{k}]_q \xi^k f_\xi(x)\). Thus, for every \(\xi \in \mathbb{C}\) with \(\xi^d = 1\), we get a simultaneous “trivial” eigenvalue \(\left(\begin{array}{c} \frac{d}{k} \end{array}\right)_q \xi^1, \ldots, [\frac{d}{k}]_q \xi^k, \ldots, [\frac{d}{d-1}]_q \xi^{d-1}\). These are the \(d\) trivial eigenvalues. Again, for \(d = 2\), we get \([\frac{2}{1}]_q \cdot 1 = q + 1\) and \([\frac{2}{1}]_q (-1) = -(q + 1)\). We can now define

**Definition 2.1.3.** A Ramanujan complex (of type \(\tilde{A}_{d-1}\)) is a finite quotient \(X = \Gamma \backslash B_d\) satisfying: every simultaneous eigenvalue \((\lambda_1, \ldots, \lambda_k, \ldots, \lambda_{d-1})\) of \((A_1, \ldots, A_k, \ldots, A_{d-1})\) satisfies: either \((\lambda_1, \ldots, \lambda_{d-1})\) is one of the \(d\) trivial eigenvalues (i.e. \((\lambda_1, \ldots, \lambda_{d-1}) = \left(\begin{array}{c} \frac{d}{k} \end{array}\right)_q \xi^k, \ldots, [\frac{d}{d-1}]_q \xi^{d-1}\) for some \(d\)th root of unity \(\xi\) or \((\lambda_1, \ldots, \lambda_{d-1}) \in \Sigma_d\), described in Theorem 2.1.2.

In the case of \(d = 2\), we saw the Alon-Boppana Theorem (Theorem 1.1.2) which shows that the Ramanujan bounds are the strongest one can hope from an infinite family of \((q + 1)\)-regular graphs (for a fixed \(q\)). The following theorem is a strong high dimensional version.

**Theorem 2.1.4 ([Li04, Theorem 4.3]).** Let \(X_1\) be a family of finite quotients of \(B_d\) with unbounded injective radius (recall that the injective radius of a quotient \(\pi : B \to \Gamma \backslash B\) is the maximal \(r\) such that \(\pi\) is an isomorphism when restricted to any ball of radius \(r\) in \(B\)). Then \(\bigcup \text{spec}_{X_i}(A_1, \ldots, A_{d-1}) \supseteq \Sigma_d\).

This shows that the best we can hope for the \(X_i\)’s is to be Ramanujan. Note that \(\text{spec}_{X_i}(A_1, \ldots, A_{d-1})\) is a finite set for every \(i\).

Let us end this section with the following remark:

**Remark 2.1.5.** The trivial eigenvalues of \((A_1, \ldots, A_{d-1})\) are \((\lambda_1, \ldots, \lambda_{d-1}) = \left(\begin{array}{c} \frac{d}{k} \end{array}\right)_q \xi^1, \ldots, [\frac{d}{d-1}]_q \xi^{d-1}\). So for \(A_k\), \(|\lambda_k| = [\frac{d}{k}]_q \approx q^{k(d-k)}\) while the Ramanujan bound gives:

\[
|\lambda_k| \leq q^{\frac{k(d-k)}{2}} |\sigma_k(z_1, \ldots, z_k)| \leq \left(\begin{array}{c} d \end{array}\right)_q \frac{q^{k(d-k)}}{2}
\]

so for \(d\) fixed and \(q\) large, the Ramanujan bound is approximately the square root of the trivial eigenvalue.
In §1.1 we mentioned that Ramanujan graphs can be characterized by the fact that their zeta functions satisfy the Riemann hypothesis. Recently there have been some efforts to associate zeta functions to higher dimensional complexes with the hope to give a similar characterization for Ramanujan complexes of dimension 2. See [DH06, Sto06, KLW10]. It will be nice if this theory could be extended also to higher dimensions.

2.2 Representation theory of PGLd

In this section we will describe some basic results from the representation theory of PGLd(F), F a local field. For a more comprehensive survey see [Car79]. We will give only those results which are needed for our combinatorial application.

The goal is to get a high dimensional generalization of Theorem 1.2.3 i.e., a representation theoretic formulation of Ramanujan complexes.

Let G = PGLd(F) and K = PGLd(O), O the ring of integers of F. An irreducible unitary representation (H, ρ) of G is called K-spherical if the space of K-fixed points H^K is non-zero. In this case dim H^K = 1. Let C = C_c(K\G/K) be the algebra of compactly supported bi-K-invariant functions from G to C, with multiplication defined by convolution

$$f_1 \ast f_2 (x) = \int_G f_1 (xg) f_2 (g^{-1}) \, dg.$$ 

The algebra C is called the Hecke algebra of G. Let \( \pi_k = \text{diag}(\pi, \pi, ..., \pi, 1, 1, ..., 1) \in \text{GL}_d(F) \) with \( \det(\pi_k) = \pi^{d-k} \), where \( \pi \) is the uniformizer of F. Denote by \( \pi_k \) the image of \( \pi_k \) in \( \text{GL}_d(F) \) and let \( A_k \) be the characteristic function of \( K \pi_k K \). Clearly \( \{A_k\}_{k=1}^{d-1} \subseteq C \) (note \( \pi_0 = \pi_d = I_d \)).

Less trivial is the fact that C is commutative and is freely generated as a commutative algebra by \( A_1, ..., A_{d-1} \) (cf. [Mac79 Chap. V]). Every irreducible unitary representation \((\mathcal{H}, \rho)\) of G gives rise to a representation of C on \( \mathcal{H}^K \) and when \( \mathcal{H}^K \neq \{0\} \), this last representation is in fact given by a homomorphism \( w : C \to \mathbb{C}, f \cdot v_0 = w(f) v_0 \) for \( f \in C \). The representation \( \rho \) is uniquely determined by \( w \) (cf. [LSV05a Prop. 2.2]) and \( w \) is determined by the \((d-1)\)-tuple \( (w(A_1), ..., w(A_{d-1})) \in \mathbb{C}^{d-1} \).

Let us put this in a somewhat more known formulation: a more common parametrization of the irreducible spherical representations of GL_d(F) (and hence also of PGL_d(F)) is by their Satake parametrization \( (z_1, ..., z_d) \in (\mathbb{C}^\times)^d / \text{sym}(d) \). This parametrization is related but not the same as the one we discuss here. Let us just mention here that

(a) A representation of GL_d(F) with Satake parameters \((z_1, ..., z_k)\) factors through PGL_d(F) if \( \prod_{i=1}^d z_i = 1 \).

(b) If \((\mathcal{H}, \rho)\) is an irreducible spherical representation of PGL_d(F) with Satake parameters \((z_1, ..., z_d)\) then \( w(A_k) \) in the notation above is given by
Let $\ equivalence\ class,\ which\ corresponds\ to\ K_0$.

Let us spell it out explicitly. May start to guess the connection to Ramanujan complexes. Let us spell it out theory in [Car79]. At this point, especially in light of (b) and (c) the reader

The reader is referred to more information in [LSV05a] and for the general theory in [Car79]. At this point, especially in light of (b) and (c) the reader may start to guess the connection to Ramanujan complexes. Let us spell it out explicitly.

Let $L_0 = O e_1 + \ldots + O e_d$ be the standard $O$-lattice in $V = F^d$ and $[L_0]$ its equivalence class, which corresponds to $K$ under the identification $G/K = B_0$. Let $\Omega_k$ be the set of neighbors of color $k$ of $[L_0]$. Then $\pi_k^{-1}K \in G/K = B_0$ is one of these neighbors and $K$ (as a subgroup of $G$) acts transitively on $\Omega_k$ so that

\[ K \pi_k^{-1} K = \bigcup y K \text{ where the union is over all } y K \in \Omega_k. \]

Multiplying from the left by an arbitrary $g \in G$, we see that the neighbors of the vertex $g K$ forming an edge of color $k$ with it, are exactly $\{gy K\}_{y K \in \Omega_k}$. It follows that the operator $A_k$ defined in (2.1) in §2.1 can be expressed as follows: Identifying $L^2(B_0) = L^2(G/K)$ with the right $K$-invariant functions in $L^2(G)$, and assuming that $K$ has Haar measure one, for $f \in L^2(B_0)$, and $g K \in B_0$

\[
(A_k f)(g K) = \sum_{y K \in \Omega_k} f(y K) = \sum_{y K \in \Omega_k} \int_{y K} f(g z) d z
\]

\[
= \int_{K \pi_k^{-1} K} f(g z) d z = \int_G f(g z) 1_{K \pi_k K} (z^{-1}) d z = (f * A_k)(g K)
\]

where $A_k$ at the right hand side of equation (2.2) is the characteristic function of $K \pi_k K$, as defined in this section. No confusion should occur here as eq. (2.2) shows that the Hecke operators of (2.1) and the Hecke operators of (2.2) are essentially the same thing! When $C = C_c(K \backslash G/K)$ acts on $L^2(G/K)$, $A_k$ acts as the adjacency operators summing over all the neighbors with edges of color $k$.

We can now use this to deduce the main goal of this subsection (see [LSV05a Prop. 1.5])

**Proposition 2.2.1.** Let $\Gamma$ be a cocompact lattice of $\text{PGL}_d(F)$. Then $\Gamma \backslash B$ is a Ramanujan complex if and only if every irreducible spherical infinite dimensional $G$-subrepresentation of $L^2(\Gamma \backslash \text{PGL}_d(F))$ is tempered.

**Sketch of proof.** Assume every irreducible spherical infinite dimensional subrepresentation of $\mathcal{H} = L^2(\Gamma \backslash \text{PGL}_d(F))$ is tempered. As $\Gamma$ is cocompact, $\mathcal{H}$ is
a direct sum of irreducible representations. Let \( f \in L^2(\Gamma \backslash G/K) \) be a nontrivial simultaneous eigenfunction of the Hecke operators \( A_k \) with \( A_k f = \lambda_k f \). As \( \text{PSL}_d(F) \) has no nontrivial finite dimensional representations, every finite dimensional representation of \( \text{PGL}_d(F) \) factors through \( \text{PSL}_d(F) / \text{PSL}_d(F) \simeq F^* / (F^*)^d \). Since \( F^* \simeq \mathbb{Z} \times O^\times \), we have \( F^* / (F^*)^d \simeq \mathbb{Z} / d\mathbb{Z} \) and since \( f \) is fixed by \( K \), if \( f \) lies in a finite dimensional \( G \)-subspace, it correspond to one of the \( d \) trivial eigenvalue. If \( f \) spans an infinite dimensional \( G \)-space, then it is tempered, its Satake parameters \( (\lambda_1, \ldots, \lambda_d) \) satisfy \( \prod \lambda_i = 1 \) and \( |\lambda_i| = 1 \). The corresponding eigenvalues of \( A_k \) are, as explained in point (b) above, in \( \Sigma_d \) as defined in \( \S 2.1 \).

In the other direction: If \( \mathcal{H}_1 \) is an irreducible spherical finite dimensional subrepresentation of \( L^2(\Gamma \backslash G) \), then its unique (up to scalar) \( K \)-fixed vector \( f \) is a simultaneous eigenvector of all the \( A_k \)'s where \( A_k f = \lambda_k f \). By assumption \( (\lambda_1, \ldots, \lambda_{d-1}) \in \Sigma_d \), from which we deduce that the Satake parameters \( \lambda_i \) all satisfy \( |\lambda_i| = 1 \) and the representation is tempered.

So, once again, as we saw for Ramanujan graphs, the problem of constructing Ramanujan complexes moves from combinatorics to representation theory. In the next subsection, we will describe how deep results in the area of automorphic forms lead to such combinatorial constructions.

### 2.3 Explicit construction of Ramanujan complexes

We will start with a general result which gives a lot of Ramanujan complexes. We then continue to present an explicit construction.

Let us first recall some notations and add a few more: Let \( k \) be a global field of characteristic \( p > 0 \) and \( D \) a division algebra of degree \( d \) over \( k \). Denote by \( G \) the \( k \)-algebraic group \( D^* / k^* \), and fix an embedding of \( G \) into \( \text{GL}_n \) for some \( n \). Let \( T \) be the finite set of valuations of \( k \) for which \( D \) does not split. We assume that for every \( \nu \in T \), \( D_\nu = D \otimes_k k_\nu \) is a division algebra. Let \( \nu_0 \) be a valuation of \( k \) which is not in \( T \) and \( F = k_{\nu_0} \), so that \( G(F) \simeq \text{PGL}_d(F) \), and denote \( S = T \cup \{ \nu_0 \} \). For \( \mathcal{O}_S = \{ x \in k | \forall \nu \in S \} \) the ring of \( S \)-integers in \( k \), \( G(\mathcal{O}_S) := G(k) \cap \text{GL}_n(\mathcal{O}_S) \) embeds diagonally as a discrete subgroup of \( \prod_{\nu \in S} G(k_\nu) \). As \( G(k_\nu) \) is compact for \( \nu \in T \), projecting \( G(\mathcal{O}_S) \) into \( G(k_{\nu_0}) = G(F) \simeq \text{PGL}_d(F) \) gives an embedding of \( G(\mathcal{O}_S) \) as a discrete subgroup in \( \text{PGL}_d(F) \), which we denote by \( \Gamma \). In fact, by a general result on arithmetic subgroups, \( \Gamma \) is a cocompact lattice in \( \text{PGL}_d(F) \). Thus if \( \mathcal{B} = \mathcal{B}_d(F) \) is the Bruhat-Tits building associated with \( \text{PGL}_d(F) \), then \( \Gamma \backslash \mathcal{B} \) is a finite complex. The same is true when we mod \( \mathcal{B} \) by any finite index subgroup of \( \Gamma \). In particular, if \( 0 \neq I \subset \mathcal{O}_S \) is an ideal, then the congruence subgroup \( \Gamma (I) := \ker (G(\mathcal{O}_S) \to G(\mathcal{O}_S/I)) \) is of finite index in \( \Gamma \) and \( \Gamma (I) \backslash \mathcal{B} \) is a finite simplicial complex covered by \( \mathcal{B} \).

**Theorem 2.3.1.** For \( \Gamma \) and \( I \) as above, \( \Gamma (I) \backslash \mathcal{B} \) is a Ramanujan complex.
We now have $S$ are division algebras, while $D$ of the Galois group $\Gamma$ is a division algebra which ramifies at $T$ for every irreducible polynomial $g$ in $F_q(y)$, and the minus degree valuation, $\nu_g(f/y) = \deg g - \deg f$. Let $F_{q^d}$ be the field extension of $F_q$ of degree $d$ and $\phi$ a generator of the Galois group $\text{Gal}(F_{q^d}/F_q) \simeq \mathbb{Z}/d\mathbb{Z}$. Fix a basis $z_0, \ldots, z_{d-1}$ of $F_{q^d}$ over $F_q$ with $z_i = \phi^i(z_0)$. Let $D$ be the $k$-algebra with basis $\{z_i z^j\}_{i,j=0}^{d-1}$ and relations $z_0 = \phi(z_0) z$ and $z^d = 1 + y$. Then $D$ is a division algebra which ramifies at $T = \{v_1 + p, \nu_p^2\}$ and splits at all other completions of $k$ (see [LSV05, Prop. 3.1]). That is, $D_{v_1 + p} = D \otimes_k k_{v_1 + p} = D \otimes_k F_q((1 + y))$ and $D_{\nu_p^2} = D \otimes_k F_q\left(\frac{1}{y}\right)$ are division algebras, while $D_{\nu} \simeq M_d(k_{\nu})$ for $\nu \notin T$. In particular, $G(k_{\nu}) \simeq \text{PGL}_d(k_{\nu})$ for $\nu \notin T$, where we recall that $G$ denotes the $k$-algebraic group $G^k/k^x$.

For $\nu_0$ we take the valuation $\nu_y$, which is given explicitly by $\nu_y(a_m y^m + \ldots + a_n y^n) = m (a_m \neq 0, m \leq n)$. The completion of $k$ at $\nu_0$ is $F = k_{\nu_0} = F_q((y))$, the field of Laurent polynomials over $F_q$. The ring of integer of $F$ is $\mathcal{O} = F_q[[y]]$, and we recall that $\mathcal{B} = \text{PGL}_d(F)/\text{PGL}_d(\mathcal{O})$.

We now have $S = \{v_1, \nu_2, \nu_y\}$, and the ring of $S$-integers in $k$ is $\mathcal{O}_S = F_q\left(\frac{1}{1+y}, y, \frac{1}{x}\right)$. As explained above, embedding $G(k)$ in some $\text{GL}_n(k)$ gives rise to $\Gamma = G(\mathcal{O}_S) = G(k) \cap \text{GL}_n(\mathcal{O}_S)$, which embeds as a cocompact arithmetic lattice in $G(F) \simeq \text{PGL}_d(F)$. 

A word of warning: if $d$ is not a prime then there are ideals in $\mathcal{O}_{\nu_0} = \{x \in k | \nu(x) \geq 0 \forall \nu \neq \nu_0\}$ (so they may disappear in $\mathcal{O}_S$!) which give non-Ramanujan complexes. We refer to [LSV05a] for this delicate point as well as for a proof of Theorem 2.2.1. We will not try to explain the proof, but rather give few hints about it. The Theorem is proved there by going from local to global. By Proposition 2.2.1 above, $\Gamma(I) \setminus \mathcal{B}$ is Ramanujan iff every infinite dimensional irreducible spherical subrepresentation $\rho_0$ of $L^2(\Gamma(I) \setminus \text{PGL}_d(F))$ is tempered. One shows that such $\rho_0$ is a local factor at $\nu_0$ of an automorphic adelic subrepresentation $\rho'$ of $L^2 \left(\mathbb{G}(k) \setminus \mathbb{G}(A)\right)$ where $A$ is the ring of adeles of $k$. By using the Jacquet–Langlands correspondence, one can replace $\rho'$ by a suitable subrepresentation $\rho$ of $L^2 \left(\text{PGL}_d(k) \setminus \text{PGL}_d(A)\right)$. Then one appeals to the work of Lafforgue [Laf02] (for which he got the Fields medal!) which is an extension to general $d$ of the “Ramanujan conjecture” proved by Drinfeld for $d = 2$. This last result says that for various adelic automorphic representations, the local factors are tempered. This can be applied to $\rho$ to deduce that our $\rho_0$ is tempered and hence $\Gamma(I) \setminus \mathcal{B}$ is Ramanujan.

The description of the complexes we gave is pretty abstract but it can be made very explicit in some cases. To this end we will make use (following [LSV05b]) of a remarkable arithmetic lattice $\Gamma$ constructed by Cartwright and Steger [CS98]. This lattice has the following amazing property: It acts simply transitively on the vertices of the building $\mathcal{B}_d$. Such lattices are rare; for example in characteristic zero such lattices exist only for finitely many $d$’s (see [MSG12]). Let us describe their (somewhat technical) construction:

We start with the global field $k = F_q(y)$, whose valuations are $\nu_q$ for every irreducible polynomial $g$ in $F_q[y]$, and the minus degree valuation, $\nu_g(f/y) = \deg g - \deg f$. Let $F_{q^d}$ be the field extension of $F_q$ of degree $d$ and $\phi$ a generator of the Galois group $\text{Gal}(F_{q^d}/F_q) \simeq \mathbb{Z}/d\mathbb{Z}$. Fix a basis $z_0, \ldots, z_{d-1}$ of $F_{q^d}$ over $F_q$ with $z_i = \phi^i(z_0)$. Let $D$ be the $k$-algebra with basis $\{z_i z^j\}_{i,j=0}^{d-1}$ and relations $z_0 = \phi(z_0) z$ and $z^d = 1 + y$. Then $D$ is a division algebra which ramifies at $T = \{v_1, \nu_2\}$ and splits at all other completions of $k$ (see [LSV05, Prop. 3.1]). That is, $D_{v_1} = D \otimes_k k_{v_1} = D \otimes_k F_q((1 + y))$ and $D_{\nu_2} = D \otimes_k F_q\left(\frac{1}{y}\right)$ are division algebras, while $D_{\nu} \simeq M_d(k_{\nu})$ for $\nu \notin T$. In particular, $G(k_{\nu}) \simeq \text{PGL}_d(k_{\nu})$ for $\nu \notin T$, where we recall that $G$ denotes the $k$-algebraic group $G^k/k^x$. 

For $\nu_0$ we take the valuation $\nu_y$, which is given explicitly by $\nu_y(a_m y^m + \ldots + a_n y^n) = m (a_m \neq 0, m \leq n)$. The completion of $k$ at $\nu_0$ is $F = k_{\nu_0} = F_q((y))$, the field of Laurent polynomials over $F_q$. The ring of integer of $F$ is $\mathcal{O} = F_q[[y]]$, and we recall that $\mathcal{B} = \text{PGL}_d(F)/\text{PGL}_d(\mathcal{O})$.

We now have $S = \{v_1, \nu_2, \nu_y\}$, and the ring of $S$-integers in $k$ is $\mathcal{O}_S = F_q\left(\frac{1}{1+y}, y, \frac{1}{x}\right)$. As explained above, embedding $G(k)$ in some $\text{GL}_n(k)$ gives rise to $\Gamma = G(\mathcal{O}_S) = G(k) \cap \text{GL}_n(\mathcal{O}_S)$, which embeds as a cocompact arithmetic lattice in $G(F) \simeq \text{PGL}_d(F)$. 

17
Until now we have followed the general construction described in the beginning of this section. In what follows we describe the Cartwright-Steger group, a subgroup of $G$ which acts simply transitively on $\mathcal{B}_d^\circ$.

The definition of $\Gamma = G(\mathcal{O}_S)$ involves a choice of an embedding of $G(k)$ in $\text{GL}_n(k)$. It turns out that this embedding can be chosen so that $\Gamma$ is simply transitive on the vertices of $\mathcal{B}_d$. 

Now, for $i \geq 1$, $\sum_i$ denotes by $\text{spanned by the } \xi$ subgroup of $I \triangleleft \Lambda$ of this section. In what follows we describe the Cartwright-Steger group, a subgroup of $\Gamma$ which acts simply transitively on $\mathcal{B}_d^\circ$.

The definition of $\Gamma = G(\mathcal{O}_S)$ involves a choice of an embedding of $G(k)$ in $\text{GL}_n(k)$. It turns out that this embedding can be chosen so that $\Gamma$ is simply transitive on the vertices of $\mathcal{B}_d$. 

Now, for $i \geq 1$, $\sum_i$ denotes by $\text{spanned by the } \xi$ subgroup of $I \triangleleft \Lambda$ of this section. In what follows we describe the Cartwright-Steger group, a subgroup of $\Gamma$ which acts simply transitively on $\mathcal{B}_d^\circ$.

Theorem 2.3.2 (CS98, cf. LSV05b Prop. 4.8)). The group $\Lambda$ acts simply transitively on the vertices of $\mathcal{B}_d(F)$.

The set $\Sigma_1 = \{ b_u \mid u \in \mathcal{B}_d^\circ / \mathcal{B}_d \}$ takes the “initial vertex” $x_0$ of the building (i.e. the equivalence class of the standard lattice) to the set of its neighbors $x$ with $\tau(x) = 1$ (i.e. the neighboring vertices of color 1, for which the connecting edge also has color 1). These correspond to the codimension one subspaces of $\mathcal{B}_d^\circ$ and indeed there are $\frac{d^d - 1}{q - 1}$ such (on which the finite group $\mathcal{B}_d^\circ / \mathcal{B}_d$ acts transitively!)

Now, for $i = 2, \ldots, d - 1$, let $\Sigma_i = \{ \gamma \in \Lambda \mid \tau((x_0, \gamma x_0)) = i \}$, i.e., the subset of $\Lambda$ of those elements which takes $x_0$ to a neighbor of color $i$. As $\Lambda$ acts simply transitively $|\Sigma_i| = \frac{d^d}{d^i - 1} q$ where $\frac{d^d}{d^i - 1} q$ is the number of subspaces of $\mathcal{B}_d^\circ$ of codimension $i$. Let $\Sigma = \bigcup_{i=1}^{d-1} \Sigma_i$. One can deduce now that the 1-skeleton of $\mathcal{B}_d$ can be identified with $\text{Cay}(\Lambda; \Sigma)$.

Now for every $0 \neq I \triangleleft \mathcal{O}_S$, we can define $\Lambda(I)$ as $\Lambda(I) = \ker (\Lambda \to G(\mathcal{O}_S/I))$. This defines a complex $\Lambda(I) \setminus \mathcal{B}_d$ which by Theorem 2.3.1 is a Ramanujan complex.

Observe now that the building $\mathcal{B}$ is a clique complex, namely, a set of $i + 1$ vertices forms a simplex if and only if every two vertices in it form a 1-edge. In particular, the full structure of the complex is determined by the 1-skeleton. The same is true for the quotients $\Lambda(I) \setminus \mathcal{B}_d$ (at least for large enough quotients, since the map $\mathcal{B}_d \to \Lambda(I) \setminus \mathcal{B}_d$ is a local isomorphism, moreover the injective radius of $\Lambda(I) \setminus \mathcal{B}_d$ grows logarithmically w.r.t. its size). So, these complexes are the Cayley complexes of the group $\Lambda/\Lambda(I)$ with respect to the set of generators $\Sigma$, or more precisely, their images in $\Lambda/\Lambda(I)$. Recall that a Cayley complex of a group $H$ w.r.t. a symmetric set of generators $\Sigma$ is the simplicial complex for which a subset $\Delta$ of $H$ is a simplex if $a^{-1}b \in \Sigma$ for every $a, b \in \Delta$. This is the clique complex determined by $\text{Cay}(H; \Sigma)$.
To make all this explicit also in the computer science sense, one needs to identify the quotients $\Lambda/\Lambda(I)$. This is carried out using the Strong Approximation Theorem. When $I$ is a prime ideal of $\mathcal{O}_S$, we get that $\mathcal{O}_S/I$ is a finite field of order $q^e$ for some $e$. The group $\Lambda/\Lambda(I)$ is then a subgroup of $\text{PGL}_d(\mathbb{F}_{q^e})$. Various choices of ideals $I$ can be made to make sure that any of the subgroups $H$ between $\text{PSL}_d(\mathbb{F}_{q^e})$ and $\text{PGL}_d(\mathbb{F}_{q^e})$ can occur. Note that the quotient $\text{PGL}_d(\mathbb{F}_{q^e})/\text{PSL}_d(\mathbb{F}_{q^e})$ is a cyclic group of order dividing $d$. The resulting graphs are therefore $t$-partite for some $t \mid d$, just as in case $d = 2$ where we have had bi-partite and non-bipartite. We skip the technical details and give only a corollary (see Theorem 1.1 and Algorithm 9.2 in [LSV05b]).

**Theorem 2.3.3.** Let $q$ be a given prime power, $d \geq 2$ and $e \geq 1$. Assume $q^e \geq 4d^2$. Every subgroup $H$, with $\text{PSL}_d(\mathbb{F}_{q^e}) \leq H \leq \text{PGL}_d(\mathbb{F}_{q^e})$, has an (explicit) set $\Sigma$ of $[\frac{d^2}{d-1}; \frac{d^2-1}{d-1}]_q$ generators, such that the Cayley complex of $H$ w.r.t. $\Sigma$ is a Ramanujan complex covered by $\mathcal{B}_d(F)$ when $F = \mathbb{F}_q((y))$.

We mention in passing that the construction in this subsection is of interest even for $d = 2$ (in spite of the fact that we have already seen other constructions of Ramanujan graphs in the previous chapter) since for $d = 2$, $\mathbb{F}_{q^2}/\mathbb{F}_q$ acts transitively on all the $q + 1$ neighbors of the standard lattice. From this one can deduce that the resulting Ramanujan graphs are edge transitive and not merely vertex transitive, as is always the case for Cayley graphs. This extra symmetry plays a crucial role in an application to the theory of error correcting codes (see [KLT12]).

We hope that the higher Ramanujan complexes will also bear some fruits in combinatorics like their one dimensional counterparts. For first steps in this direction see [LM07] and [KL].

### 3 High dimensional expanders

In Definition 1.1.9 we presented the definition of expanding graphs. In recent years several suggestions have been proposed as to what should be the “right” definition of “expander” for higher dimensional simplicial complexes. In this chapter we will bring some of these as well as few results about the relations between them. This area is still in its primal state, and we can expect more developments. The importance of expanding graphs suggests that studying expanding simplicial complexes will also turn out to be very fruitful.

#### 3.1 Simplicial complexes and cohomology

A finite simplicial complex $X$ is a finite collection of subsets of a set $X^{(0)}$, called the set of vertices of $X$, which is closed under taking subsets. The sets in $X$ are called *simplices* or *faces* and we denote by $X^{(i)}$ the set of simplices of $X$ of dimension $i$, which are the sets of $X$ of size $i + 1$. So $X^{(-1)}$ is comprised of
the empty set, \(X^{(0)}\) - of the vertices, \(X^{(1)}\) - the edges, \(X^{(2)}\) - the triangles, etc. Throughout this discussion we will assume that \(X^{(0)} = \{v_1, \ldots, v_n\}\) is the set of vertices and we fix the order \(v_1 < v_2 < \ldots < v_n\) among the vertices. Now, if \(F \in X^{(i)}\) we write \(F = \{v_{j_0}, \ldots, v_{j_i}\}\) with \(v_{j_0} < v_{j_1} < \ldots < v_{j_i}\). If \(G \in X^{(i-1)}\), we denote the oriented incidence number \([F : G]\) by \((-1)^{i}\) \(F \backslash G = \{v_{j_i}\}\) and 0 if \(G \not\subseteq F\). In particular for every vertex \(v \in X^{(0)}\) and for the unique face \(\emptyset \in X^{(-1)}\), \([v : \emptyset] = 1\).

If \(F\) is a field then \(C^i(X,F)\) is the \(F\)-vector space of the functions from \(X^{(i)}\) to \(F\). This is a vectors space of dimension \(|X^{(i)}|\) over \(F\) where the characteristic functions \(\{\epsilon_F \mid F \in X^{(i)}\}\) serve as a basis.

The coboundary map \(\delta_i : C^i(X,F) \to C^{i+1}(X,F)\) is given by:

\[
(\delta_i f)(F) = \sum_{G \in X^{(i)}} [F : G] f(G)
\]

so if \(f = \epsilon_G\) for some \(G \in X^{(i)}\), \(\delta_i \epsilon_G\) is a sum of all the simplices of dimension \(i + 1\) containing \(G\) with signs \(\pm 1\) according to the relative orientations.

It is well known and easy to prove that \(\delta_i \circ \delta_{i-1} = 0\). Thus \(B^i(X,F) = \ker \delta_i\) - "the space of \(i\)-coboundaries" - is contained in \(Z^i(X,F) = \ker \delta_i\) - the \(i\)-cocycles and the quotient \(H^i(X,F) = Z^i(X,F)/B^i(X,F)\) is the \(i\)-th cohomology group of \(X\) over \(F\).

In a dual way one can look at \(C_1(X,F)\) - the \(F\)-vector space spanned by the simplices of dimension \(i\). Let \(\partial_i : C_i(X,F) \to C_{i-1}(X,F)\) be the boundary map defined on the basis element \(F\) by: \(\partial_i F = \sum_{G \in X^{(i-1)}} [F : G] \cdot G\), i.e. if \(F = \{v_{j_0}, \ldots, v_{j_i}\}\) then \(\partial_i F = \sum_{i=0}^{i} (-1)^i \{v_{j_0}, \ldots, \hat{v}_{j_i}, \ldots, v_{j_i}\}\). Again \(\partial_i \circ \partial_{i+1} = 0\) and so the boundaries \(B_i(X,F) = \ker \partial_i\) and \(H_i(X,F) = Z_i(X,F)/B_i(X,F)\) gives the \(i\)-th homology group of \(X\) over \(F\). As \(F\) is a field, it is not difficult in this case to show that \(H_i(X,F) \simeq H^i(X,F)\).

Sometimes, it is convenient to identify \(C_i(X,F)\) and \(C^i(X,F)\) by assigning \(F\) to \(e_F\).

The \(i\)-th laplacian of \(X\) over \(F\) is defined as the linear operator \(\Delta_i : C^i(X,F) \to C^i(X,F)\) given by \(\Delta_i = \partial_{i+1} \delta_i + \delta_{i-1} \partial_i\). The operator \(\partial_{i+1} \delta_i\) is sometimes denoted (for clear reasons!) \(\Delta_{i+1}^{up}\), while \(\Delta_{i-1}^{down}\) in fact, \(\delta_{i+1}\) is the dual of \(\delta_i\) and so the eigenvalues of \(\Delta_{i+1}^{up}\) and \(\Delta_{i-1}^{down}\) differ only by the multiplicity of zero. Note that what is customarily called the laplacian of a graph is actually the upper 0-laplacian:

\[
\Delta_{i}^{up} f(x) = \text{deg}(x) f(x) - \sum_{y \sim x} f(y).
\]

### 3.2 \(\mathbb{F}_2\)-coboundary expansion

It seems that the first definition of higher dimensional expansion was given by Linial-Meshulam [LM06], Meshulam-Wallach [MW09] and Gromov [Gro10] (see also [DK10] [GW12] [SKM12] [NRT12]) as follows
Definition 3.2.1. For a simplicial complex $X$, the $\mathbb{F}_2$-coboundary expansion of $X$ in dimension $i$ is

$$E_i(X) = \min \left\{ \frac{\|\delta_{i-1}f\|}{\|f\|} \middle| f \in C^{i-1}(X, \mathbb{F}_2) \setminus B^{i-1}(X, \mathbb{F}_2) \right\}.$$ 

In other papers this notion is referred to as “cohomological expansion”, “coboundary expansion”, or “combinatorial expansion”. Let us explain the notation here: $\mathbb{F}_2$ is the field of order two, for $f \in C^i$ (and similarly for $\delta f \in C^i$), $\|f\|$ is simply the number of $(i-1)$-simplices $F$ for which $f(F) \neq 0$. Finally, $[f]$ is the coset $f + B^{i-1}(X, \mathbb{F}_2)$ and

$$\|[f]\| = \min \{ ||g|| \mid g \in [f] \} = \min \{ ||f + \delta_{i-2}h|| \mid h \in C^{i-2}(X, \mathbb{F}_2) \}.$$ 

One can see that $\|[f]\|$ is the minimal distance of $f$ from $B^{i-1}(X, \mathbb{F}_2)$ in the Hamming metric, and in particular that $\|[f]\| = 0$ iff $f \in B^{i-1}(X, \mathbb{F}_2)$. Some authors prefer to normalize the expansion as follows:

$$\tilde{E}_i(X) = \min \left\{ \frac{\|\delta_{i-1}f\|/|X^{(i)}|}{\|f\|/|X^{(i-1)}|} \middle| f \in C^{i-1}(X, \mathbb{F}_2) \setminus B^{i-1}(X, \mathbb{F}_2) \right\}.$$ 

Let us explain why this artificially looking definition exactly gives expander graphs in the one dimensional case: If $X$ is a graph then $B^0 = \text{in} \delta_{-1}$ is the one dimensional space containing two functions, the zero function 0 and the constant function 1 on all the vertices of $X$. Now, if $f \in C^0(X, \mathbb{F}_2)$ then $f$ is nothing more than the characteristic function $\chi_A$ of some subset $A \subseteq X^{(0)}$, in which case $[f] = f + B^0(X, \mathbb{F}_2) = \{ \chi_A, \chi_{\overline{A}} \}$ where $\overline{A}$ is the complement of $A$ in $X^{(0)}$. Thus $\|[f]\| = \min \{ |A|, |\overline{A}| \}$. Finally, $\|\delta f\|$ is nothing more than the size of $E(A, \overline{A})$, i.e., the set of edges between $A$ and $\overline{A}$. We can now see that the $\mathbb{F}_2$-coboundary expansion $E_1(X)$ (which is the only relevant dimension in this case) is exactly $\chi(X)$ as in Remark 1.1.2.

Very few results have been proven so far about this concept. Here is one of them (see [MW09, Gro10]):

Proposition 3.2.2. The complete complex $\Delta_{\{n-1\}}$, the simplicial complex on $n$ vertices where every subset is a face, has $\mathbb{F}_2$-coboundary expansion $E_i(\Delta_{\{n-1\}}) \geq \frac{n}{i+1}$, $1 \leq i \leq n-1$. Equivalently, $\tilde{E}_i(\Delta_{\{n-1\}}) \geq 1$ (in fact, it converges to 1 when $n$ grows to $\infty$).

Remark 3.2.3. One should note that $X$ has positive $\mathbb{F}_2$-coboundary expansion in dimension $i$ if and only if $H^{i-1}(X, \mathbb{F}_2) = 0$: If $Z^{i-1}(X, \mathbb{F}_2) = B^{i-1}(X, \mathbb{F}_2)$ then $\delta f \neq 0$ for every $f \in C^{i-1} \setminus B^{i-1}$, while if $f \in Z^{i-1}(X, \mathbb{F}_2) \setminus B^{i-1}(X, \mathbb{F}_2)$ then $\delta f = 0$ and $\|[f]\| \neq 0$. This vanishing of $H^{i-1}(X, \mathbb{F}_2)$ in the graph case, $d = 1$, is the vanishing of $H^0(X, \mathbb{F}_2)$ which exactly means that the graph $X$ is connected. Indeed, it is clear that an $\varepsilon$-expander graph is connected.

Most of the known results on coboundary expansion refer to complexes $X$ of dimension $d$ whose $d-1$ skeleton is complete (i.e. every subset of $X^{(0)}$ of size
$d$ is a face in the complex). See [LM06, MW09, Gro10, DK10, Wag11, GW12] for various results, mainly on random complexes.

As far as we know there is no known family of higher dimensional $Z_2$-coboundary expanders of bounded degree (i.e. where the number of faces is linear in the number of vertices). It is natural to suggest that the Ramanujan complexes of §2 (and even more generally, all finite quotients of higher dimensional Bruhat-Tits buildings of simple groups of rank $\geq 2$ over local fields) are such. But this is not the case in general. For example, let $\Gamma$ be any cocompact lattice in $\text{PGL}_3(F)$ where $F$ is a local field and assume $\Gamma/\Gamma^2$ is non-trivial (i.e. $\Gamma$ has a non-trivial abelian quotient of 2-power order - by [Lub87] every lattice has such a sublattice of finite index) then $H^1(\Gamma\backslash B, F_2) \neq 0$ (since $B$ is the Bruhat-Tits building of $\text{PGL}_3(F)$ is contractible) and so by Remark 3.2.3 the $F_2$-coboundary expansion of $X = \Gamma\backslash B$ in dimension 2 is 0. It might be that the vanishing of the cohomology is the only obstruction.

Another possible way to circumvent this is to use instead the notion of Gromov’s “filling”: The filling of $X$ (in dimension $i$) is

$$\nu_i(X) = \max \left\{ \frac{\|f + Z_{i-1}^{-1}\|}{\|\delta_{i-1}f\|} \mid f \in C_{i-1}(X, F_2) \setminus Z_{i-1}(X, F_2) \right\}.$$ 

When $H^{i-1}(X, F_2)$ vanishes, the filling and the $F_2$-coboundary expansion are related by $\nu_i(X) = \frac{1}{\nu_{i}(X)} = \left[ \min_{f \in C_{i-1}\backslash B_{i-1}} \frac{\|\delta_{i-1}f\|}{\|f + B_{i-1}\|} \right]^{-1}$. When $H^{i-1}(X, F_2)$ does not vanish, $E_i(X)$ is zero (see 3.2.3), but $\nu_i(x)$ is always finite since $\|\delta_{i-1}f\| \neq 0$ for $f \not\in Z_{i-1}$. For example, the Cheeger constant $h$ vanishes for a disconnected graph, while $\frac{1}{\nu_i(X)}$ is the mediant (or “freshman sum”) of the Cheeger constants of the connected components of the graph, and it is always positive. We present the following conjecture:

**Conjecture 3.2.4.** Let $B$ be the Bruhat-Tits building associated with $\text{PGL}_d(F)$, $F$ a local field and $d \geq 3$. There exists a constant $\nu = \nu(d, F)$ such that $\nu_i(X) \leq \nu$ for every finite quotient $X$ of $B$.

Even special cases of this conjecture (e.g. the case $d = 3$ and $q$, the residue field of $F$, large) are of importance in coding theory as shown in [KL].

### 3.3 The Cheeger constant

The Cheeger constant $h(X)$ for a graph $X$ is defined in Definition 1.1.4 above (see also Remark 1.1.5 there). One may argue what should be the right definition of $h(X)$ when $X$ is a higher dimensional simplicial complex. Let us follow here the definition given in [PRT12]:

**Definition 3.3.1.** For a $d$-dimensional simplicial complex $X$, denote

$$h(X) = \min_{X^{(0)} = \bigcup_{i=0}^d A_i} \frac{|X^{(0)}|}{|F(A_0, \ldots, A_d)|} \frac{|F(A_0, \ldots, A_d)|}{|A_0| \cdots |A_d|}.$$ 

22
where the minimum is over all the partitions of \( X^{(0)} \) into nonempty sets \( A_0, \ldots, A_d \) and \( F(A_0, \ldots, A_d) \) denotes the set of \( d \)-dimensional simplices with exactly one vertex in each \( A_i \).

For \( d = 1 \), it coincides with Definition 1.1.3. But, in a way, this definition keeps the spirit of the mixing lemma (Proposition 1.1.8): \( h(X) \) measures the number of "edges" (i.e. \( d \)-faces) "between" (i.e. with a single representative in each of) the \( A_i \). The quantity \( |F(A_0, \ldots, A_d)| \) is "normalized" by multiplying it by \( \prod_{i=0}^{d} |A_i| \). This definition works well when \( X \) has a complete \( (d-1) \)-skeleton (see more in §3.5), but as noted in [PRT12] it gives zero whenever \( X^{(d-1)} \) is not complete (If \( G = \{v_0, \ldots, v_{d-1}\} \notin X^{(d-1)} \) take \( A_i = \{v_i\} \) for \( i = 0, \ldots, d - 1 \) and \( A_d = X^{(0)} \setminus G \)). Then \( F(A_0, \ldots, A_d) = \emptyset \). In [PRT12], the authors call the difference

\[
|F(A_0, \ldots, A_d)| - \frac{|X^{(d)}| |A_0| \cdot \ldots \cdot |A_d|}{n^{d+1}}
\]

(3.1)

the discrepancy of \( A_0, \ldots, A_d \), and they bound this value, and the constant \( h(X) \), in terms of the spectrum of the laplacian. This brings us to our next subject.

### 3.4 Spectral gap

In §1 we saw that the notion of expander can be described by means of the eigenvalues of the adjacency matrix \( A \) of the graph. For a \( k \)-regular graph \( X \), the matrix \( A \) is nothing more than \( A = kI - \Delta_0^{up} \) where \( \Delta_0^{up} \) is the 0-dimensional upper laplacian of \( X \) over \( F = \mathbb{R} \) as defined in §3.1. We can translate Theorem 1.1.7 to deduce that a family of \( k \)-regular graphs \( \{X_i\}_{i \in I} \) is a family of expanders iff there exists \( \varepsilon > 0 \) such that every eigenvalue \( \lambda \) of \( \Delta_0^{up}|_{Z_0(X, \mathbb{R})} = \Delta_0|_{Z_0(X, \mathbb{R})} \) satisfies \( \lambda \geq \varepsilon \) (the last is equality is since \( \Delta_i^{down}|_{Z_i(X, \mathbb{R})} = \delta_{i-1} \delta_i (\ker \delta_i) = 0 \)). Note that \( Z_0(X, \mathbb{R}) = \{f : X^{(0)} \to \mathbb{R} \mid \sum_{x \in X^{(0)}} f(x) = 0 \} \). It is therefore natural to generalize and to define

**Definition 3.4.1.** Let \( X \) be a simplicial complex of dimension \( d \) and \( 0 \leq i \leq d - 1 \). We denote \( \lambda_i(X) = \min \text{Spec} \left( \Delta_i|_{Z_i(X, \mathbb{R})} \right) \) and we say that \( X \) has spectral gap \( \lambda_i(X) \) in dimension \( i \). We write \( \lambda(X) \) for \( \lambda_{d-1}(X) \).

It is natural to expect that just like in graphs where there is a direct connection between the Cheeger constant and the spectral gap, something like that should happen in the higher dimensional case, but examples presented in [PRT12] show that there exist simplicial complexes with \( \lambda(X) = 0 \) while \( h(X) > 0 \). The mystery has been revealed recently in [PRT12] where it is shown that the right generalization of the Cheeger inequalities is:
Theorem 3.4.2 ([PR T12]). Let $X$ be a finite $d$-dimensional complex with a complete $(d-1)$-skeleton. If $k$ is the maximal degree of a $(d-1)$-cell, then

$$d \left(1 - \frac{d-1}{|X^{(0)}|}\right)^2 \frac{h^2(X) - (d-1)k \leq \lambda(X) \leq h(X)}{8k}.$$ 

The reader may note that this Theorem, when specialized to $d = 1$, gives exactly Theorem 1.1.7.

A similar generalization is obtained in [PR T12] for the expander mixing lemma (Proposition 1.1.8 above). Given any two sets of vertices $A, B \subseteq V$, the mixing lemma for graphs bounds the deviation of $|E(A, B)|$ from its expected value in a random $k$-regular graph, in terms of the spectral invariant $\mu_0$. From the perspective of the simplicial laplacian, $\mu_0$ is the spectral radius of $kI - \Delta|Z_{d-1}(X, \mathbb{R})|$, i.e. the maximal absolute value of its eigenvalues. The following generalization then holds for higher dimensional complexes:

Theorem 3.4.3 ([PR T12]). Let $X$ be a finite $d$-dimensional complex with a complete $(d-1)$-skeleton. Let $k$ be the average degree of a $(d-1)$-cell, and define

$$\mu_0(X) = \max \left\{ |\gamma| : \gamma \in \text{Spec} \left( kI - \Delta_{d-1}|Z_{d-1}(X, \mathbb{R})\right) \right\}.$$ 

Then for every disjoint sets of vertices $A_0, \ldots, A_d$,

$$\left| F(A_0, \ldots, A_d) - \frac{k|A_0| \ldots |A_d|}{|X^{(0)}|} \right| \leq \mu_0(X) \left( |A_0| \ldots |A_d| \right)^{\frac{1}{d+1}}.$$ 

Again, when specializing to $d = 1$ this gives the original expander mixing lemma for graphs, except for the additional assumption that the sets of vertices are disjoint. The reader is referred to [PR T12] for the proofs of Theorems 3.4.2 and 3.4.3. So far, the results are under the assumption of full $(d-1)$-skeleton but a work on the general situation is in progress.

It is natural to suggest some extension of Alon-Boppana theorem (Theorem 1.1.2) to this high dimensional case (see also Theorem 2.1.4). In [PR12] it is shown that the high dimensional analogue of Alon-Boppana indeed holds in several interesting cases (for example, for quotients of an infinite complex with nonzero spectral gap), but that it can also fail. The reader is referred to that interesting work for more details.

The most important work so far on the spectral gap of complexes is the seminal work of Garland [Gar73]. As this work has been described in many places (e.g. [Bor73, Znk90, GW12]) we will not elaborate on it here. We just mention that Garland proved Serre’s conjecture that $H^i(X, \mathbb{R}) = 0$ for every $1 \leq i \leq d - 1$ where $X$ is a finite quotient of the Bruhat-Tits building of a simple group of rank $d \geq 2$ over a local field $\mathbb{F}$. He did this by proving a bound on the spectral
gaps which depends only $d$ and $F$ (the $i$-th cohomology group over $\mathbb{R}$ vanishes iff the corresponding spectral gap $\lambda_i$ is nonzero).

It is still not clear what is the relation between the coboundary expansion and the spectral gap. See [GW12, SKM12] where some complexes are presented with $\lambda_i(X)$ arbitrarily small while $E_i(X)$ is bounded away from zero, and also the other way around.

3.5 The overlap property

An interesting “overlap” property for complexes, which is closely related to expanders, was defined by Gromov [Gro10], and was further studied in [FGL+10, MW11, Kar12]. We need first some notation: Let $X$ be a $d$-dimensional simplicial complex and $\varphi : X^{(0)} \to \mathbb{R}^d$ an injective map. The map $\varphi$ can be extended uniquely to a simplicial mapping $\tilde{\varphi}$ from $X$ (considered now as a topological space in the obvious way) to $\mathbb{R}^d$ (i.e. by extending $\varphi$ affinely to the edges, triangles, etc.) This will be called a geometric extension. The map $\varphi$ can be extended in many different ways to a continuous map $\tilde{\varphi} : X \to \mathbb{R}^d$, such $\tilde{\varphi}$ will be called topological extensions.

**Definition 3.5.1.** Let $X$ be a $d$-dimensional simplicial complex and $0 < \varepsilon \in \mathbb{R}$. We say that $X$ has $\varepsilon$-geometric overlap (resp. $\varepsilon$-topological overlap) if for every injective map $\varphi : X^{(0)} \to \mathbb{R}^d$ and a geometric (resp. topological) extension $\tilde{\varphi} : X \to \mathbb{R}^d$, there exists a point $z \in \mathbb{R}^d$ such that $\tilde{\varphi}^{-1}(z)$ intersects at least $\varepsilon \cdot |X^{(d)}|$ of the $d$-dimensional simplices of $X$.

To digest this definition, let us spell out what does this means for expander graphs: Let $\varphi : X^{(0)} \to \mathbb{R}$ be an injective map and $\tilde{\varphi}$ any continuous extension of it to the graph. Let $z \in \mathbb{R}$ be a point such that $\frac{1}{2} |X^{(0)}|$ of the images of the vertices are above it (and call $L \subseteq X^{(0)}$ this set of vertices) and the rest are below it. Then $\tilde{\varphi}^{-1}(z)$ intersects all the edges of $E(L, \overline{L})$ (= the set of edges going from $L$ to its complement). If $X$ is an $\varepsilon$-expander $k$-regular graph, then $X^{(1)} = \frac{|X^{(0)}|k}{2}$ while $|E(L, \overline{L})| \geq \frac{\varepsilon}{2} |L| \approx \frac{\varepsilon}{2} \frac{|X^{(0)}|}{2} = \frac{\varepsilon}{2k} |X^{(1)}|$. Thus $X$ has the $\frac{\varepsilon}{2k}$-topological overlapping property.

The reader should notice however that this property is not equivalent to expander. In fact, it does not even imply that the graph $X$ is connected. It can be a union of a large expanding graph and a small connected component. Still, this property captures the nature of expansion especially in the higher dimensional case.

It is interesting to mention that while it is trivial to prove that the complete graph is an expander, it is a non-trivial result that the higher dimensional complete complexes have the overlap property. This was proved for the geometric overlap in [BFS] for dim 2 and in [Bar82] for all dimensions. For the topological overlap, this was proved in [Gro10] (see also [MW11, Kar12]).
The main result of [FGL+10] asserts that there even exist simplicial complexes of bounded degree with the geometric overlapping property. They prove it by two methods: probabilistic and constructive. The constructive examples are the Ramanujan complexes which were discussed in length in §2 (but under the assumption that \( q \) is large enough w.r.t. \( d \)). In fact, the proof is there valid for all the finite quotients of \( B = B(\text{PGL}_d(\mathbb{F})) \) and not only to the Ramanujan ones (again assuming \( q > d \)). It is quite likely that the same result holds also for the other Bruhat-Tits buildings of simple groups of rank \( \geq 2 \).

In all these results the following theorem of Pach plays a crucial role:

**Theorem 3.5.2 ([Pac98])**. For every \( d \geq 1 \), there exists \( c_d > 0 \) such that for every \( d + 1 \) disjoint subsets \( P_1, \ldots, P_{d+1} \) of \( n \) points in general position in \( \mathbb{R}^d \), there exists \( z \in \mathbb{R}^d \) and subsets \( Q_i \subseteq P_i \) with \( |Q_i| \geq c_d |P_i| \) such that every \( d \)-dimensional simplex with exactly one vertex in each \( Q_i \), contains \( z \).

Let us show now, following [PRT12] how to deduce the geometric overlap property from Pach’s theorem and the mixing lemma, when we have a “concentration of the spectrum”. Let \( X \) be a \( d \)-dimensional complex on \( n \) vertices, with a complete \((d-1)\) skeleton. For an arbitrary injective map \( \varphi : X^{(0)} \rightarrow \mathbb{R}^d \) we can divide \( \varphi (X^{(0)}) \) to \((d+1)\)-disjoint sets \( P_0, \ldots, P_d \), each of order (approximately) \( \frac{d}{d+1} n \). By Pach’s theorem there is a point \( z \in \mathbb{R}^d \) and subsets \( Q_i \subseteq P_i \) of sizes \( |Q_i| = \frac{c_d n}{d+1} \), such that \( z \) belongs to every \( d \)-simplex formed by representatives from \( Q_0, \ldots, Q_d \). This means that for the geometric extension \( \tilde{\varphi} : X \rightarrow \mathbb{R}^d \), \( \tilde{\varphi}^{-1} (z) \) intersects every simplex in \( F(\varphi^{-1} (Q_0), \ldots, \varphi^{-1} (Q_d)) \). Turning to the mixing lemma (Theorem 3.4.3 above), if the average degree of a \((d-1)\)-cell in \( X \) is \( k \), and \( \text{Spec} \Delta_{d-1} \big|_{Z_{d-1}(X, \mathbb{R})} \subseteq [k-\varepsilon, k+\varepsilon] \), then

\[
|F(\varphi^{-1} (Q_0), \ldots, \varphi^{-1} (Q_d))| \geq \frac{k |Q_0| \ldots |Q_d|}{n} - \varepsilon (|Q_0| \ldots |Q_d|) \frac{d}{d+1} = \left( \frac{c_d n}{d+1} \right)^d \left( \frac{k c_d}{d+1} - \varepsilon \right).
\]

Since this applies to every \( \varphi : X^{(0)} \rightarrow \mathbb{R}^d \), the quotient by \( |X^d| = \frac{k \binom{n}{d}}{d+1} \) gives a lower bound for the geometric expansion of \( X \):

\[
\text{overlap} (X) \geq \frac{c_d n}{d+1} \left( \frac{k c_d}{d+1} - \varepsilon \right) \geq \frac{c_d}{e^{d+1}} \left( c_d - \varepsilon (d+1) \frac{1}{k} \right).
\]

This is used in [PRT12] to establish the overlap property for random complexes in the Linial-Meshulam model [LM00]: It is shown that if the expected degree of a \((d-1)\)-cell grows logarithmically in the number of vertices then the complexes have geometric overlap asymptotically almost surely.

While bounds on the spectrum give some geometric overlap properties, it is much more difficult to get the topological overlap property. The only result known to us is the following Theorem of Gromov (see [MWT11] for a simplified proof; though still highly non-trivial):

26
Theorem 3.5.3. If $X$ has normalized $\mathbb{F}_2$-coboundary expansion $\tilde{E}_i(X) \geq \varepsilon_i$ for all $1 \leq i \leq d$ then $X$ has the $\varepsilon$-topological overlap property for some $\varepsilon = \varepsilon(\varepsilon_1, \ldots, \varepsilon_d, d) > 0$.

Still, we do not know any example of higher dimensional complexes of bounded degree with the $\mathbb{F}_2$-coboundary expansion property. It is tempting to conjecture that the finite quotients $X$ of a fixed high-rank Bruhat-Tits building of dimension $d$, with trivial cohomology over $\mathbb{F}_2$, form such a family. We end with this question which seems fundamental for further progress.
