Gallic acid • Sulfadimoxine • Dedifferentiation • Chondrocytes • Phenotype maintenances

Abstract

Background: The phenotype of chondrocyte is easy to be lost when expanded in vitro by a process defined "dedifferentiation". Traditional growth factors such as transforming growth factor (TGF-β1) are effective in preventing of dedifferentiation, but high costs and loss of activity limited their use. It is of significance to find substitutes which can reduce dedifferentiation and preserve chondrocytes phenotype to ensure sufficient differentiated cells for further study. Methods: We synthesized new type of sulfonamido-based gallates named ZXHA-C and investigated its effect on primary articular chondrocytes of rats. After preliminary screening by cytotoxicity test, ZXHA-C of 1.06 × 10^{-6}, 1.06 × 10^{-7} and 1.06 × 10^{-8}M were chosen for further studies. Cell proliferation, morphology, viability, GAG synthesis and cartilage specific gene expression were detected. Also the effects of ZXHA-C on Wnt/β-catenin signaling pathway were investigated. Results: ZXHA-C could significantly promote chondrocytes growth. And it could enhance ECM synthesis by up-regulating expression levels of cartilage specific markers like aggrecan, collagen II and Sox9. Expression of collagen I which marked chondrocytes dedifferentiation was also significantly down-regulated after treated by ZXHA-C. Further exploration of the molecular mechanism indicated that ZXHA-C activated the Wnt/β-catenin signal pathway in chondrocytes, as evidenced by up-regulated gene expression of β-catenin, Wnt-4, cyclin D1 and Frizzled-2 and decreased glycogen synthase kinase 3β (GSK-3β). Among the various concentrations, ZXHA-C of 1.06 × 10^{-7} M showed the best performance, which was close to positive control (group with TGF-β1). Conclusion: ZXHA-C might be potential a novel agent for the maintenances of chondrocytes phenotype.

Introduction

Articular cartilage has limited regenerative capacity after injury. Approaches based on chondrocytes implantation are useful tools for cartilage regeneration [1, 2]. Since only a small amount of cartilage can be harvested at the donor site, isolated chondrocytes should be expanded in vitro to obtain sufficient cells for clinical application [3, 4]. However, chondrocytes have a tendency to dedifferentiate as a result of the cytoskeleton modification when cultured in monolayer [5, 6]. Dedifferentiated chondrocytes were characterized as a decrease of the production of type II collagen, which may lead to the formation of an inferior quality engineered cartilage when implanted in the cartilage defect [7]. To retain the phenotype and accelerate the proliferation of chondrocytes cultured in vitro, lots of growth activity and rapid degradation of growth factors limited their application in clinic. Therefore, to find low-cost and stable agents to substitute growth factors is of significance.

Most anti-oxidant and anti-inflammatory agents have the ability to enhance chondrocyte proliferation and matrix secretion besides of their protective effects on osteoarthritis (OA) [8, 9], application of which may retain the phenotype and accelerate the proliferation of chondrocytes. Gallic acid (GA) and its derivatives are a group of polyphenol compounds that with strong anti-oxidant effect, and have been known to impact several pharmacological and biochemical pathways [10]. It was reported that alyophilized extract of wine which contains large amounts of phenolic components have the protective effects in cartilage alteration [11]. However, bioactivity of GA was compromised because it is much more hydrophilic than its esters, resulting in much weaker anti-oxidant effect than its esters in cell systems [10]. It was reported that GA suppressed the proliferation of cells [12]. This may be attributed to its inhibition of Wnt/β-catenin signaling pathway [13] which plays a key role in the processes of cell proliferation [14].

As an alternative, to couple some lipophilic compounds may improve the bioactivity of GA and broaden its application. Several derivatives of GA showed excellent biological properties. GA-based indanone derivatives exhibited no toxicity to human erythrocytes even at higher concentrations [15]. Epigallocatechin-3-gallate (EGCG), a derivative of GA, enhances aggrecan and type II collagen synthesis and ameliorates IL-1β-mediated suppression of TGF-β1 synthesis in human chondrocytes [16]. Recently, Nuti et al. reported a series of new N-isoproxy-arylsulfonamide hydroxamate inhibitors which contain several phenyl and sulfonamide group were proved to be effective in inhibiting in vivo cartilage degradation [17]. This implied that incorporate sulfonamides to GA may enhance the bioactivity and therefore accelerate the growth of chondrocytes. In this study, we synthesized sulfonamido-based gallate - ZXHA-C and investigated its chondroprotective effect by detecting the cell proliferation, cell viability, DNA and GAG content and expression of cartilage specific markers. A positive control (TGF-β1) comparison of ZXHA-C was also performed.

Materials and Methods

Synthesis of ZXHA-C

Electrospray ionization mass spectrum (ESI-MS) was recorded on a Shimadzu LC-MS 2010A. 1Hand 13C NMR spectra were obtained from a Bruker Advance II 300 at 400 and 125 MHz, respectively.

Acetic acid 2, 3-diacetoxy-5-{4-(5, 6-dimethoxy-pyrimidin-4-ylsulamoyl)-phenylcarbamoyl}-phenylester (ZXHA-C) was prepared from GA and sulfadimoxine. The synthetic route is presented in Fig. 1 in detail. GA and acetyl oxide in the oil bath (120°C) reflux reacted for 6-10h. Reaction products with SOCl2 in oil bath (80°C) reflux reacted for 5h, then rotary evaporation SOCl2. With sulfadimoxin (1:1), THF, pyridine, ice bath for 12h. After reactions, appropriate distilled water was added to the mixture, and then the raw product precipitated was separated by vacuum filtration. The raw product was recrystallized in a
THF-methanol solvent system. The purity of ZXHA-C is greater than 95% detected by TLC (in three different development system only one spot appeared) and HPLC analysis.

**Positive control**

Human transforming growth factor (TGF-β1, PEPROTECH, USA) was used as the positive control, and its purity is greater than 98% that detected by SDS-PAGE gel and HPLC analyses.

**Articular cartilage cells culture**

Joint hyaline cartilage was isolated from newborn Sprague-Dawley (SD) rats by enzymatic digestion with 0.25% trypsin (Solarbio, China) for 30 min and then with 2 mg/mL collagenase type II (Gibco, USA) in Minimum Essential Medium Alpha (α-MEM, Gibco, USA) for 3 h. After centrifugation (1000 rpm, 5 min), cells were re-suspended in a basal culture medium of α-MEM containing 10% Fetal Bovine Serum (FBS, Gibco, USA) and 1% antibiotics (penicillin 100 U/mL, streptomycin 100 U/mL). The culture medium was changed every 2 days. Culture conditions in an incubator (Thermo Fisher Scientific, UK) at 5% CO2 37°C humidified atmosphere. Cells were passaged when the confluence reached to 80–90%. Chondrocytes of passage one were used for further studies. This study was approved by the Institutional Ethical Committee of Guangxi Medical University (approval no. 20131221) and was conducted in accordance with the guidelines of US for laboratory animal use and care.

**ZXHA-C treatment**

ZXHA-C was dissolved in sodium hydroxide solution (NaOH, Sigma, USA) of 0.1 mg/mL as stock solution and stored at 4°C. The stock solution of ZXHA-C was then added to the cell cultures medium to provide various concentrations. Culture medium containing various concentrations of ZXHA-C was replaced every 3 days. Also a negative control that with only fresh culture media and a positive control with 15 ng/mL TGF-β1 were carried out.

**Cytotoxicity test**

The cytotoxicity of ZXHA-C on chondrocytes was performed by the 3-(4, 5)-dimethylthiahiazol-(2-yl)-3, 5-di-phenyltetrazolium-romide (MTT, Gibco, USA) method. Chondrocytes were trypsinized by 0.25% trypsin/EDTA (Solarbio, China) when the cells of first passage reached to 60~70% confluence. After centrifuged, cells were re-suspended with fresh medium and counted by a hemocytometer, then seeded on 96-plates. The final cell number in each well was 5 × 10^5. Concentrations of ZXHA-C ranged from 1.06 × 10^{-10} M~5.45 × 10^{-9} M were treated with chondrocytes. After 3 days of culture, cytotoxicity test was carried out by MTT analysis. Briefly, a solution of MTT in PBS was added into each well with the final concentration of 5 mg/mL then incubated at 37°C for 4 h. After the medium was removed, 200 μL dimethylsulfoxide (DMSO, Sigma) was added, which was used to dissolve MTT formazan formed by metabolically viable cells. The absorbance was detected by a microplate reader (Thermo Fisher Scientific, UK) at 570 nm. All experiments were performed in five times.

**Cell viability assay**

The viability of chondrocytes was determined by fluorescein diacetate (FDA, GenwayBiotech, Inc, USA)/propidium iodide (PI, Sigma, USA) staining at day 2, 4 and 6 respectively. Briefly, the stock solutions
of FDA and PI were added to the cells at a final concentration of 2 µmol/L and 2 µg/L respectively and incubated in the dark for 5 min at 37°C. Images were captured via a laser scanning confocal microscope (Nikon A1, Japan).

**Cell Morphological Analysis**

After being culture alone or with different concentrations of ZXHA-C or TGF-β1 for 2, 4 and 6 days, the cells were washed by PBS for three times and fixed with 95% alcohol for 30 min. Then the cells were washed by PBS again and stained with hematoxylin and eosin kit (HE, JianChengBiotech, China) to observe the morphology of chondrocytes. Images were photographed by an inverted phase contrast microscope (Zeiss Corporation, German).

Samples in all groups were permeabilized using 0.5% Triton X-100 (Sigma Aldrich, USA), with 1% BSA (Santa Cruz Biotechnology Inc, Santa Cruz, CA, USA) as a blocking buffer for 30 min at 37°C. Cells were stained for 30 min at room temperature with rhodamine phalloidin (Invitrogen,USA), following by Hoechst 33258 (Beyotime, USA) for 5 min to visualize nuclei. Imaging was performed using a scanning confocal microscope (Nikon A1, Japan).

**Cell proliferation analysis and Biochemical assay**

After cultured for 2, 4 and 6 days respectively, chondrocytes were washed by PBS, and then digested with 0.25% trypsin /EDTA. Cells were centrifuged and then re-suspended in PBS containing 60 µg/mL protease K (Sigma, USA) for 16 h at 60°C. The DNA content was determined by spectrophotometer using Hoechst 33258 (Sigma, USA) dye at 460 nm with calf thymus DNA as standard and the absorption of Hoechst 33258 dye as the baseline [18]. The total secretion of glycosaminoglycan (GAG) was measured using 1, 9-Dimethylmethylen Blue (DMMB, SIGMA-ALORICH, USA) with chondroitin sulphate (Sigma, USA) as standard at 525 nm. The GAG content was quantified on standard curve and accordingly normalized to the total DNA content. All the experiments were carried out in sextuplicate.

**RNA extraction and qRT-PCR analysis**

The qRT-PCR was to analysis the gene expression of aggrecan, sox9, collagen I, II and X. The primer sequences and genbank accession numbers used for qRT-PCR are summarized in Table 1. Chondrocytes were seeded in 6-well plates and cultured alone or with ZXHA-C at concentrations of 1.06 x 10⁻⁸, 1.06 x 10⁻⁷, 1.06 x 10⁻⁶ M or 15 ng/mL TGF-β1. After 2, 4 and 6 days, total RNA was successively extracted with a Total Isolation RNA kit (Invitrogen Corporation, CA, USA) according to the instructions of manufactures. Reverse transcription of RNA was carried out at 25°C for 5 min, 42°C for 60 min and then 72°C for 5 min using a Reverse Transcription kit (Fermentas Company, USA). The qRT-PCR reactions were performed using a Quantitative PCR Detection System (Eppendorf Corporation, USA) with a Fast Start Universal SYBR Green Master (Mix, Roche Company, Germany) under the condition of 10 min at 95°C, 15 s at 95°C and 1 min at

| Table 1. Primer sequences used in qRT-PCR experiments |
|-----------------------------------------------|
| **Gene name** | **Forward primer** | **Reverse primer** |
| B-actin         | 5’-CCCATCTATGAGGGGTAGGC-3’ | 5’-TTTAAAGTCAGCACCAGGATTTC-3’ |

60°C. The dissociation curve of each primer pair was analyzed to confirm the primer specificity. Marker gene expression of chondrocytes was analyzed by the 2-ΔΔCT method using β-actin. The experiments were repeated for triplicate and each sample was repeated three times for each gene.

Safranin O staining
Safranin O staining was scored for glycosaminoglycans (GAGs) secretion. The cells were fixed with 95% alcohol for 30 min and then stained with 0.1% safranin O (Sigma, USA) for 10 min. Subsequently, cells were rinsed with water and sealed with neutral gum. Finally, the cells were observed and photographed under an inverted phase contrast microscope equipped with a computer (Zeiss Corporation, German).

Immunohistochemical examination
For immunohistochemical examination, monoclonal antibody to type I collagen (Boster; China), type II collagen (Boster; China) and β-catenin (Boster; China) were used according to the instructions of manufacture. 4% paraformaldehyde-fixed, TritonX-100-permeabilized, 3% H2O2- incubated cells were blocked with normal goat serum for 10 min at room temperature. Cells were incubated with a primary antibody at a dilution of 1:200 for 2 h. Whereafter, second antibody and biotin labeled horseradish peroxidase were added. Subsequently, 3′-diaminobenzidine tetrahydrochloride (DAB) kit (Boster; China) was used according to the instructions with cells counterstained with haematoxylin. Finally, cells were gradually dehydrated and sealed with neutral gum. An inverted phase contrast microscope (Zeiss Corporation, German) was used to evaluate and photograph the cells.

Statistical Analysis
Results were demonstrated as mean ± SD. Statistical significance was determined using one way analysis of variance (ANOVA) followed by Dunnett’s post hoc test. The level of significance was set to P<0.05.

Results
The synthesis routes of GA and sulfadimoxine sodium was shown in Fig. 1. ZXHA-C with the following properties: MS-ESI: m/z : 1H NMR (400 MHz, DMSO) δ 11.10 (s, 1H, -SO2-NH), 10.69 (s, 1H, -CO-NH), 8.11 (s, 1H, Py-H), 7.99-7.92 (dd, J = 8.9 Hz, 4H, Ar-H), 7.81 (s, 2H, Ar-H), 3.88 (s, 3H, -OCH3), 3.69 (s, 3H, -OCH3), 2.33 (s, 6H, -CH3), 2.31 (s, 6H, 2×-CH3).13C-NMR (125 MHz, DMSO) δ 168.05, 166.99, 163.72, 161.67, 150.42, 143.22, 142.78, 137.67, 132.48, 128.67, 127.33, 120.79, 119.82, 60.29, 54.10, 20.35, 19.90.

The cytotoxicity of ZXHA-C on chondrocytes was detected by MTT assay. Articular cartilage cells of SD rats were treated with ZXHA-C of various concentrations (1.06×10^-10 to 5.45×10^-3 M). As shown in Fig. 2A, ZXHA-C ranged from 1.06×10^-10 to 1.06×10^-4 M exhibited nearly no cytotoxicity on chondrocytes. Especially, ZXHA-C from 1.06×10^-8 M to 1.06×10^-6 M promoted cell growth evidently. In contrast, ZXHA-C at the concentrations of 1.06×10^-7 to 5.45×10^-3 M showed an inhibitive effect on chondrocytes growth. Therefore, the concentrations of ZXHA-C ranged from 1.06×10^-6 M to 1.06×10^-4 M were chosen for further investigation. The cytotoxicity of TGF-β1 was showed in Fig. 2B, TGF-β1 at the concentration of 15 ng/mL was promoted chondrocytes growth evidently.

Cell viability was tested by FDA/PI staining (Fig. 3). The results demonstrated that ZXHA-C exerted potent effect on survival of chondrocytes culture in vitro. The FDA/PI staining indicated that live cells in ZXHA-C groups were more than the ones in the negative control. The results implied that ZXHA-C has a positive effect on cell growth. Among the experimental groups, concentration of 1.06×10^-7 M was superior to others, which showed little difference compared with positive control. Fig. 4 showed the morphology of articular chondrocytes cultured in vitro for 2, 4 and 6 days. The chondrocytes treated by ZXHA-C grew better compared with the negative control in the same period. More cell colonies that represent typical morphology of chondrocytes were found in ZXHA-C groups. Especially at the concentration of 1.06×10^-7 M, ZXHA-C facilitated cell proliferation more than others, that was closed to positive control group. Fig. 5 shows the actin filaments of chondrocytes...
by the rhodamine phalloidin/Hoechst 33258 staining, the result of which was in agreement with the HE analysis. It was shown that cells in ZXHA-C treated groups grew in clumps with much denser ECM than other concentrations.

Cell proliferation of ZXHA-C treated groups, at 2, 4 and 6 days respectively. As shown in Fig. 6A, chondrocytes cultured with ZXHA-C promoted cell growth the most in all the ZXHA-C groups, which was close to TGF-β1 group. The histogram showed the GAG production given as a ratio of GAG.
Fig. 4. Hematoxylin-eosin staining images showing the morphology of chondrocytes cultured in vitro alone (Control) or with ZXHA-C (1.06 × 10^-8 M, 1.06 × 10^-7 M, 1.06 × 10^-6 M) and TGF-β1 (T=15 ng/mL) for 2, 4 and 6 days. Cell seeding density: 2 × 10^5/mL (original magnification x 200, scale bar was 100 μm).

Fig. 5. Phalloidin/Hoechst 33258 staining images showing the morphology of chondrocytes cultured in vitro alone (Control) or with ZXHA-C (1.06 × 10^-8 M, 1.06 × 10^-7 M, 1.06 × 10^-6 M) and TGF-β1 (T=15 ng/mL) for 2, 4 and 6 days. Cell seeding density: 2 × 10^5/mL (original magnification x100, scale bar was 100 μm).

to DNA in culture media with different concentrations of ZXHA-C (Fig. 6B). Quantitatively, GAG production in ZXHA-C-treated groups was significantly enhanced than that in negative control at the same time point. The effect of ZXHA-C is dose-dependent, with 1.06 × 10^-7 M at the peak which approximated to positive control. Qualitative assessment by using safranin-O staining also showed a deeper staining in ZXHA-C groups compared with negative control group (Fig. 7). ZXHA-C at concentration of 1.06×10^-5 M exhibited the most GAG synthesis among the three concentrations, approached to TGF-β1 group.

The effect of ZXHA-C on chondrocytes relative gene expression of collagen I, II, and X, Sox9, aggrecan (a proteoglycan composed of GAGs) after 2, 4 and 6 days culture was detected by realtime-PCR. As shown in Fig. 8, aggrecan, collagen II and Sox9 were notably promoted
M showed the highest collagen II, aggrecan and Sox9 expression, among which some were even higher than positive control. The results indicated that ZXHA-C could up-regulate gene expressions collagen II, aggrecan and Sox9. In contrast, type I collagen was down-regulated by ZXHA-C. The results suggested that ZXHA-C may either delay or prevent the chondrocytes from dedifferentiation, acting the same role as TGF-β1. In addition, collagen X expression was scarcely detectable in all groups, which suggested that cell hypertrophy could not be detected. Among all the groups, ZXHA-C at concentration of 1.06×10^{-7} M showed the best overall performance, as demonstrated by the highest expression of aggrecan and collagen II expression and the lowest collagen I expression. Expression of type I and type II collagen by immunohistochemical staining with and without ZXHA-C-treated culture medium was shown in Fig. 9. Large areas of positive staining for cartilage-specific type II collagen was shown in Fig. 9B, while only very sparse

![Image](image-url)
Fig. 8. Quantitative comparison of ECM-related gene expression was detected by qRT-PCR. The chondrocytes were cultured alone (Control) or with ZXHA-C (1.06 × 10^{-6} M, 1.06 × 10^{-7} M, 1.06 × 10^{-8} M) and TGF-β1 (T=15 ng/mL) for (A) 2 days, (B) 4 days and (C) 6 days (n=3 for each experiment). The gene expression levels in ZXHA-C media relative to the control group were analysed by the 2^{-ΔΔCT} method using GAPDH as the internal control. The data represent the mean ± SD of three independent culture experiments. Bars with different letters are significantly different from each other at P < 0.05.

and light staining for type I collagen was observed (Fig. 9A) in ZXHA-C-treated groups, also positive control done. It is converse in negative control group. The results confirmed the maintenance of chondrocytic phenotype after treated with ZXHA-C (especially at concentration of 1.06×10^{-7} M), which indicated that ZXHA-C may replace TGF-β1 to effectively inhibit de-differentiation of chondrocytes cultured in vitro.

To determine the effect of ZXHA-C on the Wnt/β-catenin signaling pathway in chondrocytes, we used qRT-PCR to examine the mRNA expression of cyclin D1, β-catenin, Frizzled-2, Wnt-4 and GSK-3β (Fig. 10). Compared to negative control group, ZXHA-C up-regulate the expression of cyclin D1, β-catenin, Frizzled-2, Wnt-4 and decrease the expression of GSK-3β, similarly to the TGF-β1 group. In addition, the immunohischemistry staining of β-catenin indicates that ZXHA-C and TGF-β1 accelerated β-catenin nuclear translocation.
Discussion

The amount of autologous chondrocytes is too limited for the transplantation purpose. And chondrocytes are easy to lose phenotype that may impair the cartilage regeneration. Traditional growth factors were effective in preventing of dedifferentiation of chondrocytes and promoting of cell growth [19, 20]. But they are too expensive and easy to lose activity. Therefore, to find the substitute agent is of significance. It has been reported that derivatives of GA appeared to play an important role in protection of chondrocytes. In this study, ZXHA-C was synthesized by coupling sulfonamide groups with GA and its effects on the chondrocytes growth and phenotype maintenance were investigated. The results indicated that ZXHA-C could accelerate chondrocytes growth, as evidenced by more rapid cell proliferation and GAG production (Fig. 6A). ZXHA-C could obviously promote GAGs deposition in cultured chondrocytes which was shown by biochemical assay (Fig. 6B). As the main component of cartilage matrix, GAG is crucial in maintaining cartilage load-bearing capacity [21]. As consistent with the increase of GAG production, the expression of aggrecan, collagen II and Sox9 were up-regulated by ZXHA-C (Fig. 8). Sox9 was considered as the primary chondrogenic marker that enhanced the production of collagen and aggrecan [22] and acted a key role in chondrogenesis [23]. Especially at the dose of $1.06 \times 10^{-7}$ M, ZXHA-C showed the similar results as TGF-β1 done. The results suggested that ZXHA-C could facilitate chondrocytes growth and stimulate exuberant cartilage matrix secretion through regulating the key activator of the chondrocyte-specific enhancer.
Dedifferentiation occurred when type II collagen and cartilage-specific proteoglycan is lost and replaced by a complex collagen phenotype consisting predominately of type I collagen and a low level of proteoglycan synthesis [24, 25]. Results of PCR, biochemical and immunohistochemical assay all showed down-regulation of collagen type I in ZXHA-C groups, which suggested that ZXHA-C could effectively delay or prevent dedifferentiation of chondrocytes. On the other hand, collagen type X that is specifically associated with hypertrophic process of chondrocytes and precedes the onset of endochondral ossification could not be detected in all the ZXHA-C-treated groups. This implied that hypertrophy of chondrocytes would not be induced by ZXHA-C. It should be noted that similar results were obtained between ZXHA-C at concentration of $1.06 \times 10^{-8}$ M and positive control. Therefore, ZXHA-C has the ability to maintain the phenotype of chondrocytes, as proved by the reduced collagen I messages and the barely evident messages of collagen type X indicate the inhibition of the dedifferentiation and hypertrophy, which may be potential candidate as substitute of TGF-β1.

Further study showed that unlike Gα, the novel compound activated the Wnt/β-catenin signaling pathway, which plays a crucial role in the regulation of cell proliferation [26]. In the process of cell growth, β-catenin accumulates in the cytosol followed by the activation of Wnt/β-catenin signaling pathway. After translocates to the nucleus, β-catenin binds to the transcription factors [27] which promote cell cycle progression by regulating the expression of cyclin D1. Wnt signaling is related to the maintenance of chondrocytes by wnt-5a and wnt-5b (non-canonical pathway)by promoting the degradation of beta-catenin [28]. The misexpression of Wnt-5a delays the maturation of chondrocytes and the onsets in bone collar

**Fig. 10.** (A) Quantitative comparison of Wnt/β-catenin signaling pathway-related gene expression was detected by qRT-PCR. The chondrocytes were cultured alone (Control) or with ZXHA-C ($1.06 \times 10^{-8}$ M, $1.06 \times 10^{-7}$ M, $1.06 \times 10^{-6}$ M) and TGF-β1 (T=15 ng/mL). Bars with different letters are significantly different from each other at P < 0.05. (B) Immunohistochemical staining images revealed the presence of β-catenin. Cell seeding density: $2 \times 10^3$/mL (original magnification ×200, scale bar is 100 μm).
formation, while misexpression of Wnt-4 promotes these two processes. Beta-catenin is involved in mediating the positive regulatory effect of Wnt-4 [29] to accelerate chondrocytes maturation and bone formation [30]. Our study showed that ZXHA-C up-regulated the expression of Wnt-4, which may inhibit Wnt5a binding with Fzd2. The combination of Wnt5a and Fzd2 may lead to the up-regulation of Gsk3β to further suppress β-catenin expression [31]. These findings indicated that ZXHA-C activates the Wnt/β-catenin signaling pathway by inhibiting GSK-3β to promote the translocation of non-phosphorylated β-catenin into the nucleus to enhance cyclin D1 expression.

Among the various concentrations of ZXHA-C, it was shown that a range between 1.06 × 10^{-10} M to 1.06 × 10^{-4} M was associated with the enhancement of chondrocytes proliferation (Fig. 2A). Among the chosen concentrations, ZXHA-C at the concentration of 1.06×10^{-7} M could support the greatest cell proliferation and stimulate the most matrix secretion, which is close to the positive control.

Due to inferior pharmacological effects and biological property of GA [32-35], the modification is of significance. As one of the derivatives of GA, Epigallocatechin-3-gallate (EGCG) was reported with the effect of inhibiting the degradation of human cartilage proteoglycan and type II collagen, and selectively inhibited ADAMTS-1, ADAMTS-4, and ADAMTS-5 [36, 37]. It was also found that EGCG ameliorates IL-1β-mediated suppression of TGF-β1 synthesis, and enhance type II collagen and aggrecan core protein synthesis in human articular chondrocytes [16]. In this study, ZXHA-C which is a novel derivative of GA, can also support the chondrocytes growth and maintain the phenotype. This may be associated with its activation of Wnt/β-catenin signaling pathway which was inhibited by GA. The results implied that suitable modification of GA may lead to the improvement of the pharmacological and biological effects.
