Abstract

Background: Laminitis, an inflammation of the claw laminae, is one of the major causes of bovine lameness, which can lead to enormous economic losses and animal welfare problems in dairy farms. Angelica polysaccharide (AP) is proved to possess anti-inflammatory properties. But the role of AP on inflammatory response of the claw dermal cells has not been reported. The aim of this study was to investigate the anti-inflammatory effects of AP on lipopolysaccharide (LPS)-induced primary claw dermal cells of dairy cow and clarify the potential mechanisms. In the current research, the primary claw dermal cells were exposed to gradient concentrations of AP (10, 50, 100 µg/mL) in the presence of 10 µg/mL LPS. The levels of cytokines and nitric oxide (NO) were detected with ELISA and Griess colorimetric method. The mRNA expressions of TLR4, MyD88 and chemokines were measured with qPCR. The activation of NF-κB and MAPK signaling pathways was detected with western blotting.

Results: The results indicated that AP reduced the production of inflammatory mediators (TNF-α, IL-1β, IL-6 and NO), downregulated the mRNA expression of TLR4, MyD88 and some pro-inflammatory chemokines (CCL2, CCL20, CXCL2, CXCL8, CXCL10), and suppressed the NF-κB and MAPK signaling pathways evidenced by inhibition of the phosphorylation of IκBα, p65 and ERK, JNK, p38.

Conclusions: Our results demonstrated that AP may exert its anti-inflammatory effects on claw dermal cells of dairy cow by regulating the NF-κB and MAPK signaling pathways.

Background

Lameness is one of the most important and intractable diseases in dairy farms worldwide, which can lead to economic losses and animal welfare problems [1, 2]. Laminitis, a diffuse aseptic inflammation of corium, is reported to be a crucial reason for lameness [3]. Laminitis can lead to other claw diseases, such as sole hemorrhage, sole ulcer, and white line disease, and is also responsible for milk yield reduction, reproduction disorders and weight loss [4, 5].

Nutrition disorder is one of the main causes of laminitis [6]. A large intake of high-energy feed can lead to the excessive proliferation of rumen microorganisms and lactic acid production, followed with the release of histamine and endotoxins into peripheral blood, resulting in the blood vessels network damage in claw [7]. Endotoxins, also called lipopolysaccharide (LPS), could activate the inflammatory response in claw lamellar tissue, increase the permeability of the capillary wall, lead to the microcirculation disorder of the claw, and ultimately contribute to the appearance of laminitis [8].

The preventive and therapeutic strategies for laminitis are concentrated on diet management. Gluconeogenic precursors and rumen modifiers like Monensin, Lasalocid were added to alleviate the severity of laminitis [6, 9]. However, there are growing concerns about food safety and drug resistance. On the other hand, medicinal plants, due to their low drug resistance and multi-target therapeutic properties, have become a potential source for feed supplement or alternative drugs for various diseases [10].
Angelica sinensis is a traditional Chinese herbal medicine that has long been used for nourishing, replenishing blood and relieving pain [11]. Modern pharmacological studies have demonstrated that angelica sinensis and its extracts possess multiple beneficial properties such as anti-inflammation, antioxidation, antitumor, neuroprotection [12-14], and has a potential effect for rumen fermentation improvement [15]. Angelica polysaccharide (AP), a β-d-pyranoid polysaccharide, is the major bioactive component of Angelica sinensis [16]. Accumulating evidences have confirmed the anti-inflammatory effect of AP. For example, AP mitigated the inflammatory injury induced by LPS in PC-12 cell line [17] and neuronal cell line HT22 [18]. Another study also proved that AP alleviated the LPS-induced inflammatory injury of human keratinocytes HaCaT cells [19]. Hence, we hypothesized that AP might have some protective effects on bovine laminitis, but the related literature is limited.

The aim of this study was to investigate the potential protective effects of AP on LPS-induced inflammatory claw dermal cells in vitro, and provide theoretical basis for the application of AP on bovine laminitis in the future.

Methods

Materials

Dulbecco’s Modified Eagle Medium (DMEM), fetal bovine serum (FBS) and 1×Insulin-Transferrin-Selenium (ITS) were obtained from Gibco (Grand Island, NY). LPS (Escherichia coli O55: B5) was purchased from Sigma (St. Louis, USA). Angelica polysaccharide (≥90% purity), cell counting kit-8 (CCK-8), RIPA cell lysis buffer, BCA protein assay kit, and NBT/BCIP chromogen kit were acquired from Solarbio (Beijing, China). ELISA kits of tumor necrosis factor-α (TNF-α), interleukin (IL)-1β and IL-6 for dairy cow were purchased from DG Biotech Co. Ltd. (Beijing, China). Nitric oxide (NO) kit was purchased from Nanjing Jiancheng Bioengineering Institute (Nanjing, China). The primary antibodies against phosphor-JNK, phosphor-ERK, phosphor-p38, JNK, ERK, and p38 were obtained from Cell Signaling Technology (Danvers, MA, USA). Antibodies for phosphor-IκBα, phosphor-p65 NF-κB, IκBα, p65 NF-κB and β-actin were obtained from Bioss (Woburn, MA, USA). The HRP-conjugated secondary antibody was purchased from ZSGB-Bio (Beijing, China). Ultrapure RNA extraction kit and HiFiScript cDNA Synthesis Kit were purchased from CWBIO (Beijing, China). 2×Fast Super EvaGreen® qPCR Mastermix was acquired from US Everbright Inc. (CA, USA). All other chemicals were of reagent grade.

Cell culture and treatment

Claw dermal cells of dairy cow were isolated using the tissue adherent culture method as previously described [26]. Claw lamellar tissues were collected at a local abattoir from adult dairy cows without any visual disease. The tissues were aseptically cut off and put into sterile saline solution with antibiotics (200 units/mL of Penicillin, 200 μg/mL of Streptomycin), and then transported on ice to the laboratory within 2 h. The acquired tissues were washed with sterile phosphate buffered saline (PBS) for 3 times, trimmed into small pieces and soaked in 0.25% trypsin solution at 4°C for 18-24 h. After rinsing with PBS, the epidermis and dermis were separated. The dermis pieces were seeded onto 6-well plates coated with
rat tail collagen, cultured in DMEM, supplemented with 15% FBS, 1×ITS, 0.025 M HEPES, 200 units/mL of Penicillin, 200 µg/mL of Streptomycin, and maintained in 5% CO₂ incubator at 37°C. Medium was replaced every 2-3 days. Tissue pieces were removed when cells were about 50% confluence. Upon 80-90% confluence, cells were detached with 0.25% trypsin-EDTA solution and seeded into 25 cm² flasks.

The claw dermal cells were exposed to different concentrations of AP (1-100 µg/mL) with or without the stimulation of 10 µg/mL LPS for different times based on different experimental conditions.

**Cell viability assay**

Cell viability was measured using the Cell Counting Kit-8 (CCK-8). Claw dermal cells were seeded into 96-well plates at a density of 1×10⁵ cells/ well and cultured until 80-90% confluency. The cells were treated with different concentrations of AP (1-100 µg/mL) for 24 h and 48 h. Then 10 µL CCK-8 was added into each well. The cells were incubated at 37°C for 1 h. The absorbance at 450 nm was measured by a microplate reader (Bio-Rad, CA, USA).

**Cytokine measurement**

The levels of TNF-α, IL-1β and IL-6 in supernatants were detected using commercial ELISA kits, according to the manufacturer's guidelines. The OD value at a wavelength of 450 nm was measured. The NO concentration in cell supernatant was measured using Griess colorimetric method, following the manufacturer's protocol. Absorbance was measured at 550 nm. Draw a standard curve with the standard solution concentrations as the horizontal axis and the measured OD value as the vertical axis, then calculate the concentrations of cytokines on the basis of standard curve.

**Quantitative real-time PCR analysis**

Total RNA was extracted from dermal cells using Ultrapure RNA extraction kit following the manufacturer’s protocol. The concentration and purity (OD260/OD280 absorption ratio >1.8) of total RNA were evaluated by a NanoDrop 2000 spectrophotometer (Thermo Scientific, Ottawa, ON, Canada). Subsequently, the total RNA was reverse transcribed into cDNA with the use of HiFiscript cDNA Synthesis Kit according to the manufacturer's instructions. Quantitative real-time PCR was performed using 2× Fast Super EvaGreen® qPCR Mastermix on a LightCycler96 Real-Time PCR system (Roche, Basel, Switzerland). Primer sequences are listed in Table 1. The following cycling conditions were performed: 95°C for 300 s, 40 cycles of 95°C for 5 s, 56°C for 30 s and 72°C for 15 s. The relative expression of target genes was normalized relative to the level of the control (GAPDH) and calculated using the 2⁻ΔΔCt method [48].

**Table 1.** Primer sequences used for amplification of qPCR.
Western blot analysis

Total proteins from claw dermal cells were extracted with RIPA cell lysis buffer and quantified by BCA protein assay kit. Total protein (20-50 μg/sample) was separated on 12% SDS-polyacrylamide gel and transferred to nitrocellulose membranes. Nonspecific binding sites of membranes were blocked with 5% non-fat milk for 1 h at room temperature. Membranes were incubated with antibodies specific for JNK, phosphor-JNK, ERK, phosphor-ERK, p38, phosphor-p38, IkBa, phosphor-IkBa, p65 NF-κB phosphor-p65 NF-κB, and β-actin at 4°C overnight, and then incubated with HRP-conjugated secondary antibodies at room temperature for 1 h. Immunoblot signals were visualized with NBT/BCIP chromogen kit. Densitometric values were obtained from 3 separate experiments using ImageJ software (NIH, Bethesda, MD).

Statistical analysis

Data were presented as mean ± standard deviations (SD) of at least three independent experiments. The statistical analyses were performed with GraphPad Prism 5 (GraphPad Software, La Jolla, USA). Significant differences were evaluated by one-way analysis of variance (ANOVA) with Duncan's post hoc test using SPSS 21.0 software (SPSS Inc., Chicago, IL). $P < 0.05$ was considered as statistically significant.

Results

Cytotoxicity of AP on claw dermal cells
As shown in Figure 1, the indicated concentrations of AP treated for 24 h or 48 h had no cytotoxic effects on claw dermal cells. Thus, 1, 5, 10, 50, 100 μg/mL AP could be used for further research.

**Effects of AP on the levels of inflammatory mediators**

It showed in Figure 2 that the levels of TNF-α, IL-1β, IL-6, NO induced by LPS were higher than those in the control group ($P < 0.01$).

Administration of 1μg/mL AP had no difference in TNF-α and IL-6 levels compared with those in the LPS-treated group for 24 h ($P > 0.05$), but could significantly reduce the levels of TNF-α and IL-6 for the treatment of 48 h. The other doses of AP significantly reduced the levels of TNF-α and IL-6 for the indicated times ($P < 0.01$).

With 1, 5 μg/mL AP treatment for 24 h, there was no significant difference of IL-1 level compared with that in the LPS-treated group ($P > 0.05$), while 10, 50, 100 μg/mL AP significantly reduced the IL-1 level ($P < 0.01$). As for 48 h treatment, 1 μg/mL AP reduced the IL-1 level ($P < 0.05$), while the other doses of AP reduced the IL-1 level ($P < 0.01$) significantly.

Treatment with 50, 100 μg/mL AP reduced the NO level ($P < 0.05$) for 24 h, and reduced the NO level ($P < 0.01$) significantly for 48 h. The other dose with the treatment of indicated times had no significant difference compared with those in the LPS-treated group ($P > 0.05$).

**Effects of AP on relative mRNA levels of chemokines**

As shown in Figure 3, the gene expression levels of CCL2, CCL20, CXCL2, CXCL8, CXCL10 were upregulated significantly in response to LPS challenge. AP treatment downregulated significantly the gene expression levels of these chemokines compared with those in LPS-treated group ($P < 0.01$) in a dose dependent manner.

**Effects of AP on relative mRNA levels of TLR4 and MyD88**

As shown in Figure 4, LPS upregulated markedly the mRNA levels of TLR4 and MyD88 compared with those in the control group ($P < 0.01$). All dosages of AP treatment suppressed significantly these gene expression levels on the indicated times ($P < 0.01$).

**Effects of AP on protein expression of NF-κB and MAPKs pathways**

It showed in Figure 5 that LPS increased significantly the protein levels of p-p65, p-IκBα, p-ERK, p-JNK, p-p38 compared with the control group ($P < 0.01$). In comparison with the LPS-treated group, 10, 50, 100 μg/mL AP treated for 48 h reduced the protein levels of p-p65, p-IκBα, p-ERK, p-JNK, p-p38 significantly ($P < 0.01$).

**Discussion**
Laminitis, an inflammation of the claw laminae, is one of the most significant diseases in dairy industry, accounting for 41% cases of bovine lameness [20]. The laminitis-related diseases not only lead to low milk production, but also relate to weight loss and reproductive capacity reduction, resulting in hidden costs of dairy farming [21].

Lipopolysaccharide (LPS), also known as endotoxins, plays a crucial role in the pathologies of laminitis. Elevated LPS concentrations in plasma were detected in both subclinical and chronic laminitis dairy cows [22], as well as in the high-grain diet model of goats [23]. Lipopolysaccharide transported to the peripheral blood could activate the inflammatory response in the lamellar tissue and result in laminar damage [24]. Additionally, LPS with higher concentrations had negative effects on the tissue integrity of hoof explants \textit{in vitro} [25]. In our previous study, an inflammatory model on claw dermal cells with 10 μg/mL LPS had established [26]. Therefore, in this study, LPS was used as a stimulus to establish an inflammatory model of claw dermal cells to explore the possible therapeutic drug for laminitis \textit{in vitro}.

The anti-inflammatory effects of AP had been verified in previous studies [27, 28], but the effects on claw dermal cells remain unclear. It is widely accepted that the excessive production of some inflammatory mediators and chemokines are tightly related to the inflammatory injury [29]. TNF-α, IL-1β and IL-6 are typical pro-inflammatory cytokines that play a pivotal role in the pathogenesis of inflammatory response [30]. Previous studies have reported that the IL-1β and IL-6 expression in laminar was implicated in the degree of lamellar injury [31]. The higher levels of TNF-α and IL-6 in plasma were also detected in laminitis cows [32]. In addition, the secretion of these cytokines can affect the synthesis of mediators such as PG, leukotriene, and NO [33]. As an intracellular messenger molecule, NO regulates the various functions of cells and involves in the defense functions of the immune system [34]. Excessive secretion of NO leads to cytotoxicity and mediates the inflammation progress [35]. Chemokines, or chemotactic cytokines, are small heparin-binding proteins that direct the migration and positioning of immune cells, and play a crucial role in the inflammation injury and innate immune system [36, 37]. The CCL2, CCL20, CXCL2, CXCL8, and CXCL10 measured in this experiment are common pro-inflammatory chemokines from the CCL and CXCL subfamily of chemokines, which actively participate in the inflammatory response under some pro-inflammatory stimuli like LPS, IL-1, TNF-α [38]. Together, these pro-inflammatory substances could exhibit cytotoxic effects and accelerate the inflammatory response [39]. The reduction of these inflammatory indicators could serve as a therapy signal for inflammation amelioration.

Our results showed that AP markedly reduced the production of TNF-α, IL-1β, IL-6, and NO, and downregulated the mRNA expression of CCL2, CCL20, CXCL2, CXCL8, CXCL10, indicating that AP alleviated the LPS-induced inflammatory response in claw dermal cells by inhibiting the production of inflammatory mediators and chemokines.

It is widely known that toll-like receptor 4 (TLR4) is the main receptor for LPS stimulation [40]. Once recognized, the LPS complex is capable of initiating a series of cascades via the stimulation of myeloid
differentiation factor 88 (MyD88), including the initiation of NF-κB and MAPK signaling pathways, and ultimately induces inflammatory cytokine and chemokine expression [41].

Nuclear factor-κB (NF-κB) is a transcription factor, which involves in the regulation of multiple cell functions, such as proliferation, apoptosis and inflammation, and plays a crucial role in the regulation of pro-inflammatory genes [42]. The predominant form of NF-κB is heterodimer p50-p65 [43]. In an unstimulated state, NF-κB is located in cytoplasm under a silent state because of the binding with κB inhibitor (κB). Stimulator like LPS could induce the phosphorylation and degradation of IκBα, followed by NF-κB/κB complex dissociation, as well as the NF-κB phosphorylation. Then, the phosphorylated NF-κB translocated into the nucleus and induced the expression of pro-inflammatory mediators [44].

Mitogen-activated protein kinases (MAPKs) are a family of serine/threonine protein kinases, consisting of extracellular signal-regulated kinase 1/2 (ERK1/2), p38, and c-Jun NH2-terminal kinase (JNK) [45]. The MAPK signaling pathway plays an important role in the early stage inflammatory responses and the activation of NF-κB pathway [46]. Previous studies have demonstrated that AP exerted its anti-inflammatory effect through repression of NF-κB and MAPK pathways [18, 47]. Our data showed that AP restrained the initiation of NF-κB and MAPK pathways on claw dermal cells by decreasing the phosphorylation of IκBα, p65 and ERK, JNK, p38, which is consistent with the previous studies.

Conclusions

In conclusion, the present study demonstrated that AP protects the primary claw dermal cells of dairy cow against LPS-induced inflammatory injury by decreasing the pro-inflammatory mediators and chemokines, which may be regulated by NF-κB and MAPK signaling pathways. Altogether, AP might serve as a suitable therapeutic candidate for the management of bovine laminitis, but further confirmations should be done in the future.

Abbreviations

AP: angelica polysaccharide, CCK-8, Cell counting kit-8; DMEM, Dulbecco’s Modified Eagle Medium; ELISA, Enzyme-linked immunosorbent assay; FBS, Fetal bovine serum; IκBα, κB inhibitor α; IL-1β, Interleukin-1β; ITS: Insulin-Transferrin-Selenium; LPS, lipopolysaccharides; MAPK: Mitogen-activated protein kinases; MyD88, myeloid differentiation factor 88; NF-κB: Nuclear factor-κB; NO: nitric oxide; PBS, Phosphate buffered saline; TNF-α, Tumor necrosis factor-α; TLR4, toll-like receptor 4.

Declarations

Ethics approval and consent to participate

Claw lamellar tissues were collected at a local abattoir from healthy adult dairy cows at Baoding Lianchi slaughter house (Hebei, China) and used with the consent of the slaughter house. All dairy cows were
slaughtered for meat production and no animal was slaughtered specifically for the purpose of tissue collection.

Consent for publication

Not applicable.

Availability of data and materials

The datasets used and/or analysed during the current study are available from the corresponding author on reasonable request.

Competing interests

The authors declare that they have no competing interests.

Funding

This research was supported by Hebei key research and development program (19226611D), Innovation ability training program of Hebei Province for Graduate candidate (CXZZBS2020101), Project of Bureau of Hebei Animal Husbandry and Veterinary Medicine (2013107), Hebei Dairy Cattle Innovation Team of Modern Agro-industry Technology Research System (HBCT2018120406), and Hebei Beef Innovation Team of Modern Agro-industry Technology Research System (HBCT20181130405). The funding body had no role in the design of the study, collection, analysis, and interpretation of data or in the writing of this manuscript.

Authors’ contributions

YZM conceived and designed the study, and critically revised the manuscript. MYT performed most of the experiments, analyzed the results, and drafted the manuscript. KL and RNL assisted in experimental design, data interpretation and manuscript preparation. JLD and DMZ assisted in ELISA, qPCR and WB experiments. All authors read and approved the final manuscript.

Acknowledgments

Figures
Figure 1

Cytotoxic of angelica polysaccharide (AP) on claw dermal cells. Cell viability was measured by cell counting kit-8 (CCK-8) method with the treatment of various concentrations (1, 5, 10, 50, 100 μg/mL) of AP for 24 h or 48 h. The data were presented as mean ± standard deviations (n = 6).
Figure 2

Effects of angelica polysaccharide (AP) on the levels of tumor necrosis factor-α (TNF-α) (A), interleukin-1β (IL-1β) (B), interleukin-6 (IL-6) (C), nitric oxide (NO) (D) in LPS-induced claw dermal cells. Cells were exposed to various concentrations of AP (1, 5, 10, 50, 100 μg/mL) with or without the presence of 10 μg/mL LPS for 24 h and 48 h. The data were presented as mean ± standard deviations (n = 6). *P < 0.05 vs. LPS model group; **P < 0.01 vs. LPS model group. # P < 0.05 vs. control group; ## P < 0.01 vs. control group.
Figure 3

Effects of angelica polysaccharide (AP) on mRNA expression levels of chemokines (CCL2, CCL20, CXCL2, CXCL8, CXCL10) in LPS-induced claw dermal cells. Cells were exposed to various concentrations of AP (10, 50, 100 μg/mL) with or without the presence of 10 μg/mL LPS for 48 h. The data were presented as mean ± standard deviations (n = 6). *P < 0.05 vs. LPS model group; **P < 0.01 vs. LPS model group. # P < 0.05 vs. control group; ## P < 0.01 vs. control group.
Effects of angelica polysaccharide (AP) on mRNA expression levels of toll-like receptor 4 (TLR4) and myeloid differentiation factor 88 (MyD88) in LPS-induced claw dermal cells. Cells were exposed to various concentrations of AP (10, 50, 100 μg/mL) with or without the presence of 10 μg/mL LPS for 48 h. The data were presented as mean ± standard deviations (n = 6). *P < 0.05 vs. LPS model group; **P < 0.01 vs. LPS model group. # P < 0.05 vs. control group; ## P < 0.01 vs. control group.
Figure 5

Effects of angelica polysaccharide (AP) on protein expression of nuclear factor-κB (NF-κB) (A) and mitogen-activated protein kinase (MAPK) (B) signaling pathways in LPS-induced claw dermal cells. Cells were exposed to various concentrations of AP (10, 50, 100 μg/mL) with or without the presence of 10 μg/mL LPS for 48 h. The data were presented as mean ± standard deviations (n = 6). *P < 0.05 vs. LPS model group; **P < 0.01 vs. LPS model group. # P < 0.05 vs. control group; ## P < 0.01 vs. control group.
