SOME REMARKS ON LOG SURFACES

HAI HaDONG LIU

ABSTRACT. Fujino and Tanaka established the minimal model theory for \( \mathbb{Q} \)-factorial log surfaces in characteristic 0 and \( p \), respectively. We prove that every intermediate surface has only log terminal singularities if we run the minimal model program starting with a pair consisting of a smooth surface and a boundary \( \mathbb{R} \)-divisor. We further show that such a property does not hold if the initial surface is singular.

1. INTRODUCTION

We work over an algebraically closed field of arbitrary characteristic throughout this paper. We will also follow the language and notational conventions of the book [KM98] unless stated otherwise.

Let \((X, \Delta)\) be a log surface. Remember that a pair \((X, \Delta)\) is called log surface if \( X \) is a normal algebraic surface and \( \Delta \) is a boundary \( \mathbb{R} \)-divisor on \( X \) such that \( K_X + \Delta \) is \( \mathbb{R} \)-Cartier. To complete Fujita’s results [Fjt84] on the semi-ampleness of semi-positive parts of Zariski decompositions of log canonical divisors and the finite generation of log canonical rings for smooth projective log surfaces, Fujino [Fjn10] developed the log minimal model program for projective log surfaces in characteristic 0. It is generalized to characteristic \( p > 0 \) by Tanaka in his paper [Tnk12]. One of their main results is the following:

**Theorem 1.1** ([Fjn10] Theorem 3.3), [Tnk12] Theorem 1.1]. Let \((X, \Delta)\) be a log surface which is not necessarily log canonical, and let \( \pi : X \to S \) be a projective morphism onto an algebraic variety \( S \). Assume that \( X \) is \( \mathbb{Q} \)-factorial. Then we can run the log minimal model program over \( S \) with respect to \( K_X + \Delta \) and get a sequence of at most \( \rho(X/S) - 1 \) contractions

\[(X, \Delta) = (X_0, \Delta_0) \to (X_1, \Delta_1) \to \cdots \to (X_k, \Delta_k) = (X^*, \Delta^*)\]

over \( S \) such that one of the following holds:

**Key words and phrases.** \( \varepsilon \)-log terminal, minimal model program on log surfaces.
(1) (Minimal model) $K_{X^*} + \Delta^*$ is nef over $S$. In this case, $(X^*, \Delta^*)$ is called a minimal model of $(X, \Delta)$.

(2) (Mori fiber space) There is a morphism $g : X^* \to C$ over $S$ such that $-(K_{X^*} + \Delta^*)$ is $g$-ample, $\dim C < 2$, and $\rho(X^*/C) = 1$. We sometimes call $g : (X^*, \Delta^*) \to C$ a Mori fiber space.

Note that $X_i$ is $\mathbb{Q}$-factorial for every $i$. Furthermore, if $K_X + \Delta$ is big, then on the minimal model $(X^*, \Delta^*)$, $K_{X^*} + \Delta^*$ is nef and big over $S$.

First, we try to clarify that, given such a log surface $(X, \Delta)$ where $X$ is smooth, what every intermediate surface $X_i$ would look like after running this log minimal model program. Note that the final log surface $(X^*, \Delta^*)$ could be a minimal model or a Mori fiber space $g : (X^*, \Delta^*) \to C$. The following theorem is our main result in this paper to achieve this aim.

**Theorem 1.2** (Theorem 3.1). Notations are as in Theorem 1.1. If $X$ is smooth and the coefficients of $\Delta$ are $\leq 1 - \varepsilon$, then $X_i$ is $\varepsilon$-log terminal for every $i$. In particular, $X^*$ is $\varepsilon$-log terminal.

Next, a natural question is that, given a log surface $(X, \Delta)$ where $X$ is not smooth, what every intermediate surface $X_i$ would look like after running log minimal model program.

**Proposition 1.3.** In Theorem 1.1, $X_i$ is not always log canonical even if $X$ is log canonical.

Moreover, we have:

**Proposition 1.4.** In Theorem 1.1, $X_i$ is not always log canonical even if $X$ is $\varepsilon$-log canonical and the coefficients of $\Delta$ are $\leq 1 - \varepsilon$ for some $0 < \varepsilon < 1$.

In Section 4 we construct some examples to show that Proposition 1.3, 1.4 are true. Furthermore, we show that $X_i$ could not even be MR log canonical if $X$ is not smooth. In fact this shows that Fujino and Tanaka’s minimal model program on log surfaces is more general than Alexeev’s minimal model program which is running mainly on MR log canonical surfaces in [Alex94, Section 10] (see Definition 2.2 for the definition of MR log canonical).

**Acknowledgments.** The author would like to thank professor Fujino for so many inspirational suggestions and comments. The author would like to thank H. Tanaka for his helpful comments too. He would also like to thank Chen Jiang for many discussions on MR log canonical when they were attending in the conference of HDAG held in Utah.
2. Preliminaries

Let $(X, \Delta)$ be a log surface. If $X$ is smooth, then it is $\mathbb{Q}$-factorial. Choose a set $I \subset [0, 1 - \varepsilon]$ where $\varepsilon \in [0, 1]$ is a fixed real number. Assume that the coefficients of $\Delta$ are in $I$. Remember that a set $I$ of real number satisfies the descending chain condition or DCC, if it does not contain any infinite strictly decreasing sequence. Finally, recall that the volume of an $\mathbb{R}$-divisor $D$ on a normal projective variety $X$ of dimension $n$ is defined as

$$\text{vol}(D) = \limsup_{m \to \infty} \frac{h^0(\lfloor mD \rfloor)}{m^n/n!}$$

We recall some kinds of singularities and MR singularities following the same way of Alexeev.

**Definition 2.1** ([Alex94, Definition 1.5]). Let $(X, \Delta)$ be a log surface. Fixed a small non-negative real number $\varepsilon$, it is called:

1. $\varepsilon$-log canonical, if the total discrepancies $\geq -1 + \varepsilon$
2. $\varepsilon$-log terminal, if the total discrepancies $> -1 + \varepsilon$

for every resolution $f : Y \to X$. Simply, we call it $\varepsilon$-lc or $\varepsilon$-lt instead. Note that when $\varepsilon$ is not zero, we can replace $\varepsilon$ by a smaller positive $\varepsilon'$, and assume that $\varepsilon$-log canonical is $\varepsilon'$-log terminal.

**Definition 2.2** ([Alex94, Definition 1.7]). We call a log surface $(X, \Delta)$ MR log canonical, MR $\varepsilon$-log canonical, MR $\varepsilon$-log terminal etc. if we require the previous inequalities in Definition 2.1 to hold not for all resolutions $f : Y \to X$ but only for a distinguished one, the minimal desingularization.

A strange but trivial example of MR log canonical log surface is the following:

**Example 2.3.** Given a log surface $(X, \Delta)$, where $X$ is smooth and $\Delta$ is a boundary. $(X, \Delta)$ is not necessarily log canonical in the usual sense. But $id : X \to X$ is the minimal desingularization, therefore $(X, \Delta)$ is MR log canonical.

3. Main results

Now we go to the proof of Theorem 1.2. Note that $\varepsilon$ in this theorem could be zero:

**Theorem 3.1.** Notations are as in Theorem 1.1. If $X$ is smooth and the coefficients of $\Delta$ are $\leq 1 - \varepsilon$, then $X_i$ is $\varepsilon$-log terminal for every $i$. In particular, $X^*$ is $\varepsilon$-log terminal.
Proof. **Step 1.** Run log minimal model program on $K_X + \Delta$ as in Theorem [Fjn10, Section 3] and [Tnk12, Section 3],

$$(X, \Delta) = (X_0, \Delta_0) \to (X_1, \Delta_1) \to \cdots \to (X_k, \Delta_k) = (X^*, \Delta^*)$$

where $(X^*, \Delta^*)$ is a minimal model or a Mori fiber space. In the following proof, we consider everything over $X_j$ for a fixed $j$. Put $X^* = X_j$ for this fixed $j$. Then take $X^*$ as a base (if needed, shrink $X^*$ to be affine since $\varepsilon$-log terminal or not is a local property) and run $(K_X + \Delta)$-LMMP on the relative morphism $f : X \to X^*$, which ends up again on $X^*$ and $K_X + \Delta$ is nef over $X^*$. Each step we have a relative morphism $X_i \to X^*$ ($i \leq j$) and denote it by $X_i/X^*$. We use $f_i$ and $h_i$ to denote the morphisms $(X_i, \Delta_i)/X^* \to (X^*, \Delta^*)/X^*$ and $(X, \Delta)/X^* \to (X_i, \Delta_i)/X^*$ with that $h_j = f_0 = f$. By [Fjn10, Proposition 3.8] and [Tnk12, Theorem 3.19],

$$K_{X_i} + \Delta_i = f_i^*(K_{X^*} + \Delta^*) + E_i$$

where $E_i$ are all effective over $X^*$ for every $0 \leq i < j$. In particular, $h_i(K_X + \Delta) = K_{X_i} + \Delta_i$, $h_i(\Delta) = \Delta_i$. Furthermore, every curve in $\text{Exc}(f) = \text{Supp}(E_0)$ is a smooth rational curve by [Fjn10, Proposition 3.8] and [Tnk12, Theorem 3.19].

**Step 2.** Now we may assume that there is no $(-1)$-curve in $\text{Exc}(f)$. Indeed, if there is some $(-1)$-curve, say $C$, in $\text{Exc}(f)$, then by Castelnuovo’s theorem, contracting this $(-1)$-curve in $X/X^*$ leads to a new smooth surface $X'/X^*$. Therefore we can run another $(K_{X^*} + \Delta)$-LMMP over $X^*$ until reaching to a final log surface $(\tilde{X}, \tilde{\Delta})/X^*$, where $\Delta'$ is the image of $\Delta$. Every assumption of $(X, \Delta)$ is obviously keeping if we replace $(X, \Delta)$ by $(X', \Delta')$ except that we need to prove $(\tilde{X}, \tilde{\Delta}) \cong (X^*, \Delta^*)$. We have three morphisms over $X^*$: $\pi : X \to X'$, $g : X' \to \tilde{X}$ and $\rho : \tilde{X} \to X^*$ such that

$$K_X + \Delta = \pi^*(K_{X'} + \Delta') + aC$$

$$K_{X'} + \Delta' = g^*(K_{\tilde{X}} + \tilde{\Delta}) + E_0$$

$$K_{\tilde{X}} + \tilde{\Delta} = \rho^*(K_{X^*} + \Delta^*) + D$$

where $\pi : X \to X'$ is the Castelnuovo’s contraction, $\rho$ is not necessarily the identity and $K_{\tilde{X}} + \tilde{\Delta}$ is nef over $X^*$. Then by negativity lemma (see [KM98, Lemma 3.39 and Lemma 3.40]), we have that $-D \geq 0$, since $K_{\tilde{X}} + \tilde{\Delta} - D \sim_{\rho} 0$ and $D$ is $\rho$-exceptional. Remember that $K_X + \Delta = f^*(K_{X^*} + \Delta^*) + E_0$, $f^* = \pi^*g^*\rho^*$. That is, $E_0 \sim_f \pi^*g^*D + \pi^*E_0 + aC$. By negativity lemma again, $D > 0$ since $E_0$ is effective and both sides have the same support. Therefore we get a contradiction unless $\rho$ is
an identity. That is, $(\tilde{X}, \tilde{\Delta}) \cong (X^\dagger, \Delta^\dagger)$. Then, by contracting $(-1)$-curves finitely many times, we may assume that \( \text{Exc}(f) \) contains no $(-1)$-curve from now on.

**Step 3.** Assume that $C_i$ is the contracted curve in step $i$ of the log minimal model program, then $(K_{X_i} + \Delta_i) \cdot C_i < 0$. Therefore

\[
(K_X + \Delta) \cdot h_i^*(C_i) = (K_{X_i} + \Delta_i) \cdot C_i < 0
\]

Note that $(h_i^*(C_i))^2 = (C_i)^2 < 0$ by the negativity lemma. Then $K_X \cdot h_i^*(C_i) \geq 0$ since $h_i^*(C_i)$ is effective and its support contains no $(-1)$-curve. Indeed, if $K_X \cdot h_i^*(C_i) < 0$, there must be a curve, say, $E$, in $\text{Supp} h_i^*(C_i)$ such that $K_X \cdot E < 0$. But $E^2 < 0$ since $E$ is in $\text{Exc}(f)$. Thus it is a $(-1)$-curve which contradicts our assumption. Therefore \( \Delta \cdot h_i^*(C_i) < 0 \). Then

\[
\Delta_i \cdot C_i = h_i^*(\Delta) \cdot C_i = \Delta \cdot h_i^*(C_i) < 0
\]

That is, $C_i$ is in $\text{Supp} \Delta_i$, and its strict transform is in $\text{Supp} \Delta$. Therefore all those curves in $\text{Exc}(f)$ must be such a strict transform of $C_i$ under the assumption of the above step.

**Step 4.** Next, we need to prove that, for the resolution $f : X \to X^\dagger$ where $K_X = f^*K_{X^\dagger} + \sum a_i F_i$, we have that $a_i > -1 + \varepsilon$. Note that $K_X + \Delta = f^*(K_{X^\dagger} + \Delta^\dagger) + E_0$ where $E_0$ is effective in $\text{Exc}(f)$ and $F_i$ is in $\text{Supp} \Delta$ by the above steps. Furthermore, let $\Delta = \sum \delta_i F_i + \Delta'$ where $\sum F_i$ and $\Delta'$ have no common components. Therefore, $f_* \Delta' = \Delta^\dagger$. Then

\[
K_X + \Delta = f^*K_{X^\dagger} + \sum a_i F_i + \sum \delta_i F_i + \Delta' = f^*K_{X^\dagger} + f^*\Delta^\dagger + E_0
\]

That is,

\[
\sum (a_i + \delta_i) F_i = f^*\Delta^\dagger - \Delta' + E_0
\]

in which both sides are supported in $\text{Exc}(f)$ and the right hand side is effective. Thus comparing both sides, $a_i + \delta_i > 0$. That is, $a_i > -\delta_i \geq -1 + \varepsilon$ since the coefficients of $\Delta$ are $\leq 1 - \varepsilon$.

Finally, we claim that, the resolution $f : X \to X^\dagger$ is a log resolution. That is, the reduced $\sum F_i$ must be a simple normal crossing curve. We can prove this claim by [KM98, Theorem 4.7] and the above steps, which is pointed out by Tanaka. But here we use a different way. Remember that $F_i$ are all smooth extremal rational curves since $X^\dagger$ has rational singularities by [FT12, Theorem 6.2] for any characteristic. Furthermore, the dual graph of $\sum F_i$ must be a tree. This shows that the reduced $\sum F_i$ must be a simple normal crossing curve. We get what we want. \( \square \)
From the above theorem, we know that when $X$ is smooth, those contracting curves in log minimal model program consist of some images of $(-1)$-curves and some components of $\text{Supp}\Delta$. Several direct but important implications of Theorem 3.1 are the following. When $K_X + \Delta$ is big, $K_{X^*} + \Delta^*$ is nef and big on the minimal model. What we have done in the proof of Theorem 3.1 is in fact showing that $f: X' \to X^*$ is exactly the minimal desingularization and $(X^*, \Delta^*)$ is $\text{MR} \, \varepsilon$-log terminal. Then the following corollaries are just simple consequences of [Alex94, Theorem 7.6, Theorem 7.7, Theorem 8.2]. It is another way to see that Fujino and Tanaka’s minimal model program on log surfaces cover Alexeev’s minimal model program stated in [Alex94, Section 10].

**Corollary 3.2.** Let $(X, \Delta)$ be a projective log surface where $X$ is smooth and $K_X + \Delta$ is big. Fixing $\varepsilon > 0$, let $I \subset [0, 1 - \varepsilon]$ be a DCC set and the coefficients of $\Delta$ be in $I$. If there is a positive integer $M$ such that $(K_{X^*} + \Delta^*)^2 \leq M$ where $(X^*, \Delta^*)$ is a minimal model of $(X, \Delta)$, then these $(X^*, \text{Supp}\Delta^*)$ belong to a bounded family.

**Corollary 3.3.** Let $(X, \Delta)$ be a projective log surface where $X$ is smooth and $K_X + \Delta$ is big. Fixing $\varepsilon \geq 0$, let $I \subset [0, 1 - \varepsilon]$ be a DCC set and the coefficients of $\Delta$ be in $I$. Then $(K_{X^*} + \Delta^*)^2$ is a DCC set. In particular the volume $\text{vol}(K_X + \Delta)$ is bounded from below away from 0.

*Proof.* Since $\text{vol}(K_X + \Delta) = \text{vol}(K_{X^*} + \Delta^*) = (K_{X^*} + \Delta^*)^2$ by Theorem 3.1, this corollary is a direct consequence of [Alex94, Theorem 8.2]. □

**Remark 3.4.** Note that in Corollary 3.2 the $\varepsilon$ is smaller, the bounded family of $(X^*, \text{Supp}\Delta^*)$ is bigger. When $\varepsilon$ goes to 0, all those $X^*$ may not be in a bounded family, so not be $(X^*, \text{Supp}\Delta^*)$. See [Lin03, Remark 1.5] for the example showing that $X^*$ could be $\mathbb{Q}$-Fano and not in a bounded family. Note also that Corollary 3.3 is an answer of the question coming from the first version of Di Cerbo’s paper [Dic16, Question 4.3] which has been confirmed by his second version.

4. Examples

By [Alex94, Section 10], we easily see that if the log surface $(X, \Delta)$ is $\text{MR} \, \varepsilon$-log canonical, then so is every $(X_i, \Delta_i)$ in the step of log minimal model program; by Grothendieck spectral sequence, it is also easy to see that if $X$ has only rational singularities, then so has every $X_i$. Now it is natural to generalize Theorem 3.1 and ask that if $X$ is $\varepsilon$-log canonical, is so every $X_i$ or not. But unfortunately we have the following example:
Example 4.1. There is a well known example of log canonical surface. In fact, it is rational but not log terminal. Blowing up at a point of $\mathbb{P}^2$, we get a $(-1)$-curve $E_0$; find three points at $E_0$ and blow up several times (at these three points and some points at the exceptional curves over them), we can easily get a surface $Y$ and four smooth rational curves $E_0, E_1, E_2, E_3$ on it such that $n_0 = -E_0^2 \geq 3$, $n_1 = -E_1^2 = 2$, $n_2 = -E_2^2 = 3$, $n_3 = -E_3^2 = 6$ where by abusing of notations, we still use $E_0$ to denote its strict transform on $Y$. By construction, $E_i \cdot E_0 = 1$, $E_i \cdot E_j = 0$ where $i, j = 1, 2, 3$. Let $E = E_0 + E_1 + E_2 + E_3$, then its dual graph is a triple fork. See also that its intersection matrix is negative definite. Therefore by Artin’s criterion [Art62], we can contract $E$ and finally get a surface $X$ with a singular point. Now we have $f : Y \rightarrow X$ with $K_Y = f^* K_X + \sum a_i E_i$. Using adjunction, we have that:

$$
-2 + n_0 = -a_0 n_0 + a_1 + a_2 + a_3;
0 = -2 + n_1 = a_0 - a_1 n_1 = a_0 - 2a_1;
1 = -2 + n_2 = a_0 - a_2 n_2 = a_0 - 3a_2;
4 = -2 + n_3 = a_0 - a_3 n_3 = a_0 - 6a_3.
$$

Solve these equations we have $a_0 = -1$, $a_1 = -\frac{1}{3}$, $a_2 = -\frac{2}{3}$, $a_3 = -\frac{5}{6}$. These show that the singularity of $X$ is exactly log canonical but not log terminal. Keeping this example in mind, we construct an example as following:

Similar to the above blowing-up method, we can easily construct a surface $Y$ and five smooth rational curves $D, E_0, E_1, E_2, E_3$ on it such that $n = -D^2$ is as big as we want, $n_0 = -E_0^2 \geq 3$, $n_1 = -E_1^2 = 2$, $n_2 = -E_2^2 = 3$, $n_3 = -E_3^2 = 6$ and $E_1 \cdot E_0 = D \cdot E_0 = 1$, $E_i \cdot E_j = D \cdot E_i = 0$ where $i, j = 1, 2, 3$. Let $E = E_0 + E_1 + E_2 + E_3$ and $F = E + D$. Then $E$ is a triple fork and $F$ is a quadruple fork in dual graph. Note that both of the intersection matrices of $E$ and $F$ are negative definite. By contracting $E$ on $Y$ we get a morphism $f$ from $Y$ to a log canonical surface $X$ which is rational but not log terminal as above. Now consider the log surface $(X, D')$ where $D'$ is the image of $D$. $D'$ is still a smooth rational curve by construction since $E \cdot D = 1$. Note that $(K_X + D') \cdot D' < 0$. Indeed, Let $f^* D' = D + \sum c_i E_i$. Then by $E_i \cdot f^* D' = 0$,

$$
0 = 1 - c_0 n_0 + c_1 + c_2 + c_3;
0 = c_0 - c_1 n_1;
0 = c_0 - c_2 n_2;
0 = c_0 - c_3 n_3.
$$
That is, \( c_0 = \frac{1}{n_0 - 1}, \ c_1 = \frac{c_0}{2}, \ c_2 = \frac{c_0}{3}, \ c_3 = \frac{c_0}{6} \). Then
\[
(K_X + D') \cdot D' = (K_Y + D) \cdot f^*D' = (K_Y + D) \cdot (D + \sum c_iE_i)
\]
\[
= (K_Y + D) \cdot D + \sum c_i(K_Y \cdot E_i) + \sum c_i(D \cdot E_i)
\]
\[
= -2 + c_0(-2 + n_0) + c_1(-2 + 2) + c_2(-2 + 3) + c_3(-2 + 6) + c_0
\]
\[
= -2 + c_0(-2 + n_0) + \frac{c_0}{3} + \frac{2c_0}{3} + c_0 = -2 + 1 + c_0 = c_0 - 1 < 0
\]
since \( c_0 = \frac{1}{n_0 - 1} < 1 \). Now contracting \( D' \) on \( X \) by log minimal model program, we get a log surface \((X^*, 0)\) where \( X^* \) is no longer log canonical since the dual graph of \( F \) is a quadruple fork which is not in the classification of dual graph of log canonical singularities in [KM98, Theorem 4.7]. Furthermore, it is not even MR log canonical by calculating the discrepancy of \( E_0 \). But remember that \( X^* \) still has rational singularities.

**Example 4.2.** We just gave an example for Proposition 1.3 where \( \varepsilon = 0 \). In fact, by a similar construction as above, we can get some examples where \( \varepsilon > 0 \). A sketch of construction is the following. As Example 4.1, we can easily construct a surface \( Y \) and five smooth rational curves \( D, E_0, E_1, E_2, E_3 \) on it with \( n = -D^2, \ n_i = -E_i^2 \) such that \( n = 3, \ n_0 = 5, \ n_1 = n_2 = n_3 = 2 \). Let \( E = E_0 + E_1 + E_2 + E_3 \) and \( F = E + D \). Then \( E \) is a triple fork and \( F \) is a quadruple fork which is not in the classification of dual graph of log canonical singularities. Note that both of the intersection matrices of \( E \) and \( F \) are negative definite. Choose an \( \varepsilon \) such that \( 0 < \varepsilon \leq \frac{1}{19} \). The same calculation as Example 4.1 shows that by contracting \( E \) on \( Y \) we get a morphism \( f \) from \( Y \) to an \( \varepsilon \)-log canonical surface \( X \). Now consider the log surface \((X, bD')\) where \( D' \) is the image of \( D \). Note that \( D' \) is still a smooth rational curve by construction. Choose a proper real number \( b \) such that \( (K_X + bD') \cdot D' < 0 \). By careful calculations as in Example 4.1 we can check that \( (K_X + bD') \cdot D' < 0 \) for \( b > \frac{13}{19} \). Therefore,
\[
(K_X + (1 - \varepsilon)D') \cdot D' < 0 \text{ for } 0 < \varepsilon \leq \frac{1}{19}.
\]
Now contracting \( D' \) on \((X, bD')\) by log minimal model program, we get a log surface \((X^*, 0)\) where \( X^* \) is no longer log canonical. This gives an example to confirm Proposition 1.4.

**Remark 4.3.** The above two examples are based on one of the dual graphs of log canonical singularities in [KM98, Theorem 4.7]. In fact, we can construct similar examples based on the other dual graphs there and get a bunch of similar examples.

It will be interesting to ask the following question:
Question 4.4. In Theorem 1.1 if $X$ is canonical, is $X_i$ log canonical?
