More often than not, models of flavor symmetry rely on the use of nonrenormalizable operators (in the guise of flavons) to accomplish the phenomenologically successful tribimaximal mixing of neutrinos. We show instead how a simple renormalizable two-parameter neutrino mass model of tribimaximal mixing can be constructed with the non-Abelian discrete symmetry $T_7$ and the gauging of $B-L$. This is also achieved without the addition of auxiliary symmetries and particles present in almost all other proposals. Most importantly, it is verifiable at the Large Hadron Collider.

In 2001, the non-Abelian discrete symmetry $A_4$ was shown for the first time [1] to allow for the seemingly incompatible pattern that charged-lepton masses are all very different and yet a symmetry exists to predict the neutrino mixing matrix without knowing the individual neutrino masses. In 2004, it was shown for the first time [2] that $A_4$ could also predict neutrino tribimaximal mixing with $\sin^2 2\theta_{\text{atm}} = 1$ and $\tan^2 \theta_{\text{sol}} = 1/2$. Since early 2005, when the solar angle in neutrino oscillations was revised by SNO [3] to $\tan^2 \theta_{\text{sol}} = 0.45 \pm 0.05$, this idea became widely accepted and the use of non-Abelian discrete symmetries [4] for understanding flavor has appeared in very many publications [3]. The two earliest papers [3, 4] after the SNO revision in 2005 both used $A_4$ and suggested two different two-parameter neutrino mass matrices, whereas the original proposal [2] of 2004 had three parameters.

If the $3 \times 3$ Majorana neutrino mass matrix $M_\nu$ is rotated by the Cabibbo-Wolfenstein unitary matrix [5, 6]

$$U = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix},$$

where $\omega = \exp(2\pi i/3) = -1/2 + i\sqrt{3}/2$, then the tribimaximal form was shown [2] to be

$$U M_\nu U^T = \begin{pmatrix} a + 2b & 0 & 0 \\ 0 & a - b & d \\ 0 & d & a - b \end{pmatrix}.$$  \hspace{1cm} (2)

The two examples mentioned above are then [2] $b = 0$ and [6]

$$U M_\nu U^T = \begin{pmatrix} a - d^2/a & 0 & 0 \\ 0 & a & d \\ 0 & d & a \end{pmatrix}. \hspace{1cm} (3)$$

However, these forms are only obtained at the expense of additional auxiliary symmetries and particles, and with the use of nonrenormalizable operators [6].

On the other hand, it has been shown recently [10] that $A_4$ alone is sufficient to obtain $b = 0$, if the alternative $A_4$ lepton assignments of Ref. [11] are used instead of the original proposal of Ref. [1] and that neutrinos become massive through Higgs triplets [12] in a renormalizable model. Here we show how Eq. (3) may be obtained by the canonical seesaw mechanism for neutrino mass, using the non-Abelian discrete symmetry $T_7$ [13] and gauging $B-L$ [14], without the addition of auxiliary symmetries and particles or the use of nonrenormalizable operators.

Most importantly, our proposal is verifiable at the Large Hadron Collider (LHC). The predicted $Z'$ gauge boson will decay into scalars which support the $T_7$ symmetry. Their subsequent decays into charged leptons will then reveal the predicted $T_7$ flavor structure used in obtaining neutrino tribimaximal mixing.

Since there are three families, non-Abelian discrete symmetries with irreducible three-dimensional representations are of special interest. The smallest group with a real $3$ representation is $A_4$ which has 12 elements. The smallest group with a complex $3$ representation is $T_7$ which has 21 elements. The group $\Delta(27)$ [15] is slightly bigger (27 elements) and also has a complex $3$ representation. They are all subgroups of $SU(3)$. The various irreducible representations of the three groups are

$$A_4 : \mathbf{1}_3 (i = 1, 2, 3), \mathbf{3} :$$  \hspace{1cm} (4)

$$T_7 : \mathbf{1}_7 (i = 1, 2, 3), \mathbf{3}, \mathbf{3}.$$  \hspace{1cm} (5)

$$\Delta(27) : \mathbf{1}_9 (i = 1, 2, 3, 4, 5, 6, 7, 8, 9), \mathbf{3}, \mathbf{\bar{3}}.$$  \hspace{1cm} (6)

Their crucial differences are in the following group multiplications

$$A_4 : 3 \times 3 = \sum_i \mathbf{1}_3 + \mathbf{3} + \mathbf{\bar{3}};$$  \hspace{1cm} (7)

$$T_7 : 3 \times 3 = \mathbf{2} + \mathbf{\bar{2}} + \mathbf{\bar{3}}, \mathbf{3} \times \mathbf{3} = \mathbf{2} + \mathbf{\bar{3}} + \mathbf{\bar{2}};$$  \hspace{1cm} (8)

$$\Delta(27) : \mathbf{3} \times \mathbf{3} = \mathbf{2} + \mathbf{\bar{2}} + \mathbf{\bar{3}}, \mathbf{3} \times \mathbf{\bar{3}} = \mathbf{2} + \mathbf{\bar{2}} + \mathbf{\bar{3}};$$  \hspace{1cm} (9)

We will show that our $T_7$ model assignments cannot be replaced by either those of $A_4$ or $\Delta(27)$. 
The finite group $T_7$ is generated by two noncommuting $3 \times 3$ matrices:

$$a = \begin{pmatrix} \rho & 0 & 0 \\ 0 & \rho^2 & 0 \\ 0 & 0 & \rho^3 \end{pmatrix}, \quad b = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},$$

(10)

where $\rho = \exp(2i\pi/7)$, so that $a^7 = 1$, $b^4 = 1$, and $ab = ba^4$. Let $3 = (x_1, x_2, x_3)$, and $\bar{3} = (\bar{x}_1, \bar{x}_2, \bar{x}_3)$, then their possible multiplications form the following $3$ representations: $(x_3 y_3, x_1 y_1, x_2 y_2)$, $(x_2 y_2, x_3 y_3, x_1 y_1)$, $(x_3 y_3, \bar{x}_3 y_3, \bar{x}_1 y_1, \bar{x}_2 y_2, x_1 y_1, x_2 y_2)$, and the following $\bar{3}$ representations: $(\bar{x}_3 y_3, \bar{x}_1 y_1, \bar{x}_2 y_2, (x_1 y_2, x_2 y_3, x_3 y_1), (x_2 y_3, x_3 y_1, x_1 y_2, x_1 y_1, x_2 y_2))$. The combinations $x_1 y_1 + \omega^{k-1} x_2 y_2 + \omega^{k+2} x_3 y_3$ form the representations $\bar{3}_k$ for $k = 1, 2, 3$ respectively.

Under $T_7$, let $L_i = (\nu, l_i) \sim 3, \bar{3}_i \sim 1, i = 1, 2, 3, \Phi_i = (\phi^+, \phi^0) \sim \bar{3}$, which means that $\tilde{\Phi}_i = (\phi^0, -\phi^-) \sim 3$. The Yukawa couplings $L^j_3 \Phi_i$ generate the charged-lepton mass matrix

$$m_l = \begin{pmatrix} f_{1v_1} & f_{1v_2} & f_{1v_3} \\ f_{1v_2} & \omega^2 f_{2v_2} & \omega f_{3v_3} \\ f_{1v_3} & \omega f_{3v_3} & \omega^2 f_{2v_2} \end{pmatrix} = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega^2 & \omega \\ 1 & \omega & \omega^2 \end{pmatrix} \begin{pmatrix} f_1 & 0 & 0 \\ 0 & f_2 & 0 \\ 0 & 0 & f_3 \end{pmatrix} v_i,$$

(11)

if $v_1 = v_2 = v_3 = v/\sqrt{3}$, as in the original $A_4$ proposal [1].

Let $\nu^c_i \sim \bar{3}$, then the Yukawa couplings $L^i_3 \nu^c_3 \Phi_k$ are allowed, with

$$m_D = f_D \begin{pmatrix} 0 & v_1 & 0 \\ 0 & 0 & v_2 \\ v_3 & 0 & 0 \end{pmatrix} = f_D v \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},$$

(12)

for $v_1 = v_2 = v_3 = v/\sqrt{3}$ which is already assumed for $m_l$. Note that $\Phi$ and $\tilde{\Phi}$ have $B - L = 0$.

Now add the neutral Higgs singlets $\chi_i \sim 3$ and $\eta_i \sim \bar{3}$, both with $B - L = -2$. Then there are two Yukawa invariants: $\nu^c_i \nu^c_j \chi_k$ and $\nu^c_i \nu^c_j \eta_k$ (which has to be symmetric in $i, j$). Note that $\chi^*_i \sim 3$ is not the same as $\eta_i \sim \bar{3}$ because they have different $B - L$. This means that both $B - L$ and the complexity of the $3$ and $\bar{3}$ representations in $T_7$ are required for this scenario. The heavy Majorana mass matrix for $\nu^c_k$ is then

$$M = h \begin{pmatrix} u_2 & 0 & 0 \\ 0 & u_3 & 0 \\ 0 & 0 & u_1 \end{pmatrix} + h' \begin{pmatrix} 0 & u_3' & u_2' \\ u_3' & 0 & u_1' \\ u_2' & u_1' & 0 \end{pmatrix} = \begin{pmatrix} A & 0 & B \\ 0 & A & 0 \\ B & 0 & A \end{pmatrix},$$

(13)

where $A = hu_1 = hu_2 = hu_3$ and $B = h'u_2$, $u'_1 = u'_3 = 0$ have been assumed, i.e. $\chi_i$ breaks in the (1,1,1) direction, whereas $\eta_i$ breaks in the (0,0,1) direction. This is the $Z_3 - Z_2$ misalignment also used in $A_4$ models.

The seesaw neutrino mass matrix is now

$$m_\nu = -m_D M^{-1} m_D^T = -\frac{f_D^2 v^2}{3A(A^2 - B^2)} \begin{pmatrix} A^2 - B^2 & 0 & 0 \\ 0 & A^2 - AB & 0 \\ 0 & -AB & A^2 \end{pmatrix},$$

(14)

which has only two parameters and is identical to Eq. (3). Detailed numerical analysis of this form was already done in Ref. [7]. Here we achieve the same result without the auxiliary $Z_4 \times Z_3$ symmetry and extra particles assumed there. The key is that $3 \times 3 \times 3$ is an invariant in $T_7$, but not in $(\Delta(27))$, whereas $A_4$ cannot distinguish this from $\bar{3} \times \bar{3} \times \bar{3}$ which yield two other invariants in $T_7$.

To realize the misalignment of $\langle \chi \rangle \sim (1,1,1)$ and $\langle \eta \rangle \sim (0,1,0)$, we need to choose the soft breaking terms in the Higgs potential consistent with these different residual symmetries [16]. However, the quartic terms $\chi_i^* \chi_i \eta^*_j \eta_j$ have several $T_7$ invariants, and most of them will destroy this pattern. To maintain the desired misalignment, this model has to be supersymmetrized.

Consider $\chi \sim 3$ and $\eta \sim \bar{3}$ as superfields with $B - L = -2$. Add $\chi' \sim \bar{3}$ and $\eta' \sim \bar{3}$ with $B - L = 2$. Then the superpotential contains the terms

$$W = f_{ijk} \nu^c_i \nu^c_j \chi_k + f_{ij} \nu^c_i \nu^c_j \eta_k + m_\chi \chi_i' \chi_i' + m_\eta \eta_i' \eta_i',$$

(15)

from which the $F$ terms of the Higgs potential are

$$V_F = |m_\chi |^2 + |m_\eta |^2 + |f_{ijk} \nu^c_i \nu^c_j \chi_k|^2 + |f_{ij} \nu^c_i \nu^c_j \eta_k|^2,$$

(16)

where the $D$ terms from $U(1)_{B-L}$ are

$$V_D = 2g_{B-L}^2 |\chi_i' \chi_i + \eta_i' \eta_i - \chi_i' \eta_i - \eta_i' \chi_i|^2.$$

(17)

With the addition of bilinear soft terms $\chi_i^* \chi_i, \chi_i^* \eta_i, \eta_i^* \chi_i, \eta_i^* \eta_i, H.c.$, $\eta_i^* \eta_i, \eta_i^* \eta_i, \eta_i^* \eta_i, \eta_i^* \eta_i, \eta_i^* \eta_i, \eta_i^* \eta_i, H.c.$, and $(\chi_i + \chi_i + \chi_i) \eta_i^* \eta_i^* + (\chi_i^* + \chi_i^* + \chi_i^*) \eta_i \eta_i + H.c.$, which preserve $U(1)_{B-L}$ as they must, $T_7$ is broken with the desired pattern.

Flavor-changing leptonic interactions through Higgs exchange are present in this model, but they are suppressed by lepton masses, as in the original $A_4$ proposal [1]. The set of three Higgs doublets $\Phi$, transforming as $3$ under $T_7$ is rotated by $U$ of Eq. (1) to form mass eigenstates $\phi_{1,2,3} \sim 1, \omega, \omega^2$ under the residual $Z_3$, where $\phi_0$ is identified with the one Higgs doublet (with $\langle \phi^0 \rangle = v$) of the Standard Model, with Yukawa couplings $v^{-1}[m_{LL} \mu_{LL} \mu_R + m_{LR} \tau_{LL} \tau_R]$, which is of course flavor-conserving. The “flavor-changing” interactions of $\phi_{1,2}$ are then given by

$$\mathcal{L}_{int} = v^{-1}[m_{LL} \mu_{LL} \tau_R + m_{LL} \tau_{LL} \mu_R + m_{LR} \tau_{LL} \tau_R] \phi_1 + v^{-1}[m_{LL} \mu_{LL} \mu_R + m_{LR} \tau_{LL} \tau_R] \phi_2 + H.c.$$

(18)

However, if the neutrino sector is ignored, a lepton flavor trinity ($Z_3$ symmetry) [17] exists here, under which $e, \mu, \tau \sim 1, \omega^2, \omega$, implying thus the decays $\tau^+ \rightarrow
\[ \mu^+ \mu^+ e^- \text{ and } \tau^+ \to e^+ e^+ \mu^- , \text{ but no others. In particular, } \mu \to e \gamma \text{ is forbidden. Using} \]
\[ B(\tau^+ \to \mu^+ \mu^+ e^-) = \frac{m_2^2 m_\mu^2 (m_2^2 + m_\mu^2)^2}{m_1^2 m_\mu^2} B(\tau \to \mu \nu \bar{\nu}), \]

the experimental upper limit of 2.3 \times 10^{-8} yields the bound \[ m_1 m_3 / \sqrt{m_1^2 + m_3^2} > 22 \text{ GeV (174 GeV/} \nu) \]
on the masses of \[ \psi_{1,2}^0 = (\phi_1^0 \pm \phi_2^0) / \sqrt{2}. \]

Since the Higgs singlets \( \chi \) and \( \eta \) which support the neutrino tribimaximal mixing under \( T_\tau \) also transform under \( U(1)_{B-L} \), this model can be tested at the LHC by discovering the \( Z_{B-L} (\equiv Z' \) ) gauge boson. The partial decay rates of \( Z' \) to the usual quarks and leptons are easily calculated. Let \( \Gamma_1 = g_{B,L}^2 m_{Z'} / 12 \pi \), then \( \Gamma_{\text{eff}} = (6)(3)(1/2) \Gamma_0 \), \( \Gamma_i = (3)(-1)^2 \Gamma_0 \), \( \Gamma_\nu = (3)(-1)^2 (1/2) \Gamma_0 \). As \( Z' \to \psi_{1,2} \psi_{1,2}, \) it has the effective partial rate \( \Gamma_{\psi} \approx (2)(2) \sin^4 \theta(1/4) \Gamma_0 \), where \( \sin^2 \theta \) is an effective parameter accounting for the mixing of \( \psi_{1,2}^0 \) to \( \chi \) and \( \eta \) (with the help of a \( B - L = 0 \) singlet \( S_i \sim 3 \)). Using Eq. (18), we find their signature decays to be given by
\[ \psi_{1,2}^0 \to \tau^+ \tau^- , \tau^- \tau^+ , \psi_{1,2}^0 \to \tau^0 \mu^+ , \tau^+ e^- , \]
resulting in \( Z' \) leptonic final states such as \( \tau^- \tau^- \mu^+ e^+ \) for \( Z' \) in addition to \( \tau \) for neutrino tribimaximal mixing to work under \( T_\tau \), the \( U(1)_{B-L} \) gauge symmetry is seen to provide also the means of verifying its predicted interactions. If the singlet neutrinos \( \nu_i^c \) are light enough, they can also be produced by \( Z' \) decay as discussed in Ref. \[ \text{[12]} \]. The mass eigenstates of \( \nu_i \) are given by Eq. (13). Their decays into \( \phi_1^0, \phi_2^0 \), and the subsequent decays of \( \phi_{1,2} \) to leptons (resulting in six leptons in the final state) will then give a complete picture of tribimaximal mixing in this model.

We now study in detail the process \( q \bar{q} \to Z' \to \psi_1 \psi_2 \) (assuming \( m_2 = m_{1/2} \)) with the subsequent decays \( \psi \to \tau^+ e^- \) and \( \phi \to \tau^+ \mu^- \) at the LHC with \( E_{cm} = 14 \text{ TeV} \). We consider only the leptonic decay modes of the \( \tau \), with branching fraction 17.4% to either \( e^- \) or \( \mu^- \). The collider signature of such events is \( e^+ \mu^- e^- \mu^- \) plus missing energy, where \( \ell = e, \mu \). The dominant backgrounds yielding the same signature are the processes (generated by MadEvent/MadGraph [18]):
\[
\begin{align*}
\text{WWZ:} & \quad pp \to W^+ W^- Z, W^\pm \to \ell^\pm \nu, Z \to \ell^\pm \ell^- , \\
\text{ZZ:} & \quad pp \to ZZ, Z \to \ell^+ \ell^-, Z \to \tau^+ \tau^-, \tau^- \to \ell^+ \nu, \\
\text{tt:} & \quad pp \to tt \to b(\to \ell^-) \bar{b}(\to \ell^+) W^+ W^- , W^\pm \to \ell^\pm \nu, \\
\text{Zbb:} & \quad pp \to Zb(\to \ell^-) \bar{b}(\to \ell^+) , Z \to \ell^+ \ell^- ,
\end{align*}
\]
where \( \ell = e, \mu \). Other SM backgrounds, e.g. \( ZZZ \) and \( WWW \), occur at a negligible rate after kinematic cuts, and are not shown here. We require no jet tagging and consider only events with both \( e^+ \) and \( \mu^- \) in the final state. The first two processes are the irreducible background, while the last two are reducible as they only contribute when some tagged particles escape detection, carrying away small transverse momentum (\( p_T \)) or falling out of the detector rapidity coverage.

| Signal and background cross sections (fb) before and after cuts for four (m_{Z'}, m_{\mu\nu}) (GeV) benchmark points: (A) (1000,100), (B) (1500,100), (C) (1000,300), and (D) (1500,300). The "no cut" and "H_T cut" rates are obtained after imposing Eq. (21) and Eq. (22), respectively, whereas the "\( \tau_{i>0} \) cut" rates are obtained after the \( \tau^- \) reconstruction cuts. The bottom row shows the cut acceptance \( \langle A_{cut} \rangle \). |
|---|---|---|---|---|---|---|---|
| (A) | (B) | (C) | (D) | (1,2) | (3,4) |
| \( t\bar{t} \) | WWZ | ZZ | Z | \( B \) |
| no cut | 5.14 | 0.98 | 2.57 | 0.72 | 1.22 | 0.21 | 27.11 | 2.99 |
| basic cut | 1.46 | 0.066 | 1.05 | 0.36 | 0.16 | 0.02 | 0.0052 | 0.024 |
| \( H_T \) cut | 1.41 | 0.065 | 1.04 | 0.36 | 0.08 | 0.006 | 0.0 | 0.0 |
| \( \tau_{i>0} \) cut | 0.69 | 0.032 | 0.52 | 0.18 | 0.015 | 0.002 | 0.0 | 0.0 |
| \( A_{cut} \) | 13.4% | 3.2% | 20% | 25% | 1.2% | 1% | 0.0 | 0.0 |

Our benchmark points are chosen as follows: \( m_{Z'} = 1000 \) (1500) GeV, \( m_{\mu\nu} = 100 \) (300) GeV, \( gb-L = g = e/\sin \theta_W \), and \( \sin^2 \theta = 0.2 \). In our analysis all events are required to pass the following basic acceptance cuts:
\[
\begin{align*}
(1) & \quad p_T, \ell \geq 50 \text{ GeV} , \quad p_T, \ell \geq 20 \text{ GeV} , \quad |\eta| \leq 2.5 , \\
(2) & \quad \Delta R_{ij} \geq 0.4 , \quad \mathcal{E}_T > 30 \text{ GeV} ,
\end{align*}
\]
where \((1,4)\) in the superscript index is the \( p_T \) order of the charged leptons. \( \Delta R_{ij} \) is the separation in the azimuthal angle \( \phi \) - pseudorapidity \( \eta \) plane between \( i \) and \( j \), defined as \( \Delta R_{ij} \equiv \sqrt{(\eta_i - \eta_j)^2 + (\phi_i - \phi_j)^2} \). We also model detector resolution effects by smearing the final-state energy. To further suppress the SM backgrounds, we demand
\[
H_T \equiv \sum_i p_T, i + \mathcal{E}_T > 300 \text{ GeV} ,
\]
where \( i \) denotes the visible particles. Figure (a) shows the normalized \( H_T \) distribution of both signal and background before the \( H_T \) cut. The signal spectrum exhibits an endpoint around the mass of \( Z' \), about 1 TeV, but with a long tail due to the \( Z' \) width and detector smearing effects. Table (b) displays the signal and background cross sections (fb) before and after cuts. The cut acceptance \( \langle A_{cut} \rangle \) increases with \( m_{\mu\nu} \) as heavy scalar decay generates hard leptons and large \( H_T \). For a light \( \psi \) and a heavy \( Z' \) (e.g. the benchmark B), \( A_{cut} \) decreases as the two charged leptons from the light scalar decay are very much parallel and fail the \( \Delta R \) separation cuts.

To reconstruct the scalar \( \psi \), we adopt the collinear approximation that the charged lepton and neutrinos from \( \tau \) decays are parallel due to the large boost of the \( \tau \). Such a condition is satisfied to an excellent degree because the \( \tau \) leptons originate from a heavy scalar decay in the signal event. Denoting by \( \tau_{\ell>0} \) the fraction of the parent \( \tau \) energy which each observable decay particle carries, the
and transverse momentum vectors are related by \[ \vec{E}_T = \frac{1}{x_{\tau_1}} \vec{p}_1 + \frac{1}{x_{\tau_2}} \vec{p}_2. \] (23)

When the decay products are not back-to-back, Eq. (23) gives two conditions for \( x_{\tau} \), with the \( \tau \) momenta as \( \vec{p}_1/x_{\tau_1} \) and \( \vec{p}_2/x_{\tau_2} \), respectively. We further require the calculated \( x_{\tau_2} \) to be positive to remove the unphysical solutions. There are two possible combinations of \( e^+\ell^- \) clusters for reconstructing the scalar \( \psi \) and gauge boson \( Z' \). To choose the correct combination, we require the \( e^+\ell^- \) pairing to be such that \( \Delta R_{e^+\ell^-} \) is minimized. The mass spectra of the reconstructed \( \psi \) and \( Z' \) are plotted in Fig. 1(b) and (c), respectively, which clearly display sharp peaks around \( m_\psi \) and \( m_{Z'} \). In Fig. 1(d), we show the 5\( \sigma \) discovery contours in the plane of \( m_{Z'} \) and \( \sin^2 \theta \) by requiring 8.5 (5) signal events for an integration luminosity of 100 (10) \( \text{fb}^{-1} \) respectively. The regions above those curves are good for discovery.

In the quark sector, if we use \( Q_i = (u, d)_i \sim 3 \) and \( u_i, d_i^c \sim \frac{1}{\sqrt{3}}, i = 1, 2, 3 \) as we assume for the charged leptons, we again obtain arbitrary quark masses, but no mixing. To have realistic mixing angles, the residual \( Z_3 \) symmetry has to be broken.

Non-Abelian discrete symmetries have been successful in explaining the tribimaximal mixing of neutrinos, but not their masses. However, they are very difficult to test experimentally. In this paper, by combining \( T_7 \) and \( U(1)_{\mu-L} \), we show how a simple renormalizable two-parameter neutrino mass model of tribimaximal mixing can be constructed, with verifiable experimental predictions. The key is the possible discovery of \( Z' \) at the \( \text{TeV} \) scale, which then decays into neutral Higgs scalars, whose subsequent exclusive decays into charged leptons have a distinct flavor pattern which may be observable at the LHC.
