BMJ Open

Practice patterns and outcomes associated with early sedation depth in mechanically ventilated patients: a systematic review protocol

Robert J Stephens,1 Matthew R Dettmer,2 Brian W Roberts,3 Susan A Fowler,4 Brian M Fuller5

ABSTRACT

Introduction Mechanical ventilation is a commonly performed intervention in critically ill patients. Frequently, these patients experience deep sedation early in their clinical course. Emerging data suggest that the practice of early deep sedation may negatively impact patient outcomes. The purpose of this review is to assess the world’s literature to describe and determine the impact of early deep sedation on the outcomes of mechanically ventilated patients.

Methods and analysis Randomised controlled trials and non-randomised studies will be eligible for inclusion in this systematic review. With the assistance of a medical librarian, we will comprehensively search MEDLINE, Embase, Scopus, Cochrane Central Register of Controlled Trials, Database of Abstracts of Reviews and Effects, and Cochrane Database of Systematic Reviews for peer-reviewed literature. Grey literature from appropriate professional society conferences, held from 2010 to 2017, will be reviewed manually. Two authors will independently review all search results, and disagreements will be resolved through arbitration by a third author. If appropriate, meta-analysis will be used for quantitative analysis of the data. Heterogeneity between studies will be assessed using the I2 statistic.

Ethics and dissemination The proposed systematic review will not collect data that are associated with individual patients and does not require ethical approval. Results of this study will contribute to the understanding of early sedation, identify future research targets and guide early care in mechanically ventilated patients.

Trial registration number This systematic review has been registered in the international prospective register of systematic reviews (PROSPERO #CRD42017057264).

INTRODUCTION

Mechanical ventilation is a common intervention in critically ill patients.1 There is increasing recognition that the management of non-ventilator-related aspects of care is highly influential on outcome. The management of sedation plays a major role in the care of mechanically ventilated patients.2 While necessary to relieve pain and anxiety and improve tolerance of mechanical ventilation, sedatives have adverse effects on important patient-centred outcomes, such as lengths of stay, delirium and mortality.3 4 Present guidelines recommend that sedatives be titrated to achieve light, as opposed to deep, levels of sedation.2

Despite these recommendations, deep sedation in the intensive care unit (ICU) is common. Specifically, early deep sedation (ie, during the first 48 hours following initiation of mechanical ventilation) occurs in up to 76% of patients.5 6 An emerging body of research suggests that the level of sedation during this early time period is an independent predictor of patient outcomes.7 8 However, the bulk of prior sedation research has not been devoted to this initial early period, often not enrolling patients until after 48 hours of mechanical ventilation.5 While the available evidence supports maintenance of early light sedation, the strength of the association remains unclear.

There have been no systematic reviews on the impact of early sedation on clinical outcomes. An important next step for investigating early sedation practices is to analyse

Strengths and limitations of this study

► This is the first systematic review specifically studying the impact of early sedation depth on patient important outcomes.
► In preparation of this protocol we followed the Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols guidelines, and our study is registered with the international prospective register of systematic reviews (PROSPERO).
► Our robust search strategy will decrease our risk of missing relevant studies.
► Our inclusion of non-randomised trials increases the risk of study bias.
the world literature to ascertain the true impact of early sedation. In this systematic review, we seek to (1) describe the state of global literature focusing on early sedation; and (2) quantify the impact of early sedation depth on patient-centred outcomes. We hypothesise that deep sedation in the 48-hour period following initiation of mechanical ventilation will be associated with increased mortality and longer lengths of stay.

**METHODS AND ANALYSIS**

**Protocol and registration**

This systematic review protocol is prepared in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols (PRISMA-P) statement (see online supplementary material 1). The final results will be reported in accordance with the PRISMA statement and the Meta-analysis of Observational Studies in Epidemiology guidelines. Any deviation from the protocol will be reported with the final results, along with a rationale for protocol deviation. This study will be conducted starting in February 2017 with an intended completion date in May 2017. This systematic review has been registered in the international prospective register of systematic reviews (PROSPERO #CRD42017057264).

**Search for and identification of studies**

An electronic search will include the following databases: MEDLINE, Embase, Scopus, Cochrane Central Register of Controlled Trials, Database of Abstracts of Reviews and Effects, and Cochrane Database of Systematic Reviews. The search terms include the concepts of mechanical ventilation, sedation depth, critical illness and outcome measures (including mortality, delirium, length of stay, tracheostomy, and time ventilated). These strategies were established using a combination of standardised terms and keywords. The fully reproducible search strategy is provided in online supplementary material 2. The search was designed in cooperation with a medical librarian, who performed the electronic search.

The reference lists of the articles selected for inclusion will be manually screened to identify additional studies. To identify potential unpublished data, abstracts from the following meetings (from 2010 to 2017) will be manually searched: Society of Critical Care Medicine, European Society of Intensive Care Medicine, International Symposium on Intensive Care and Emergency Medicine, American Thoracic Society, Society for Academic Emergency Medicine, Pharmacotherapy, American Society of Anaesthesiologists, European Society of Anaesthesiology, International Anesthesia Research Society, Trauma, Critical Care & Acute Care Surgery, American Association for the Surgery of Trauma, and the Eastern Association for the Surgery of Trauma. An online search for details of clinical trials registration (ClinicalTrials.gov) will also be conducted to identify completed, but not yet published, clinical studies. The principal investigators of published and unpublished studies will also be contacted as needed for clarification of potential data for inclusion.

**Eligibility criteria**

Studies will be eligible regardless of language and will include adult patients receiving invasive positive pressure ventilation. Randomised controlled trials (RCTs), as well as non-randomised studies (prospective and retrospective cohort analyses, cross-sectional studies, before-after trials), will be included. Non-randomised studies will be included for the following reasons: (1) a likelihood that the question of interest may not be investigated strictly with RCTs secondary to a lack of existing randomised trials; (2) to provide an explicit evaluation of strengths and weaknesses of the current literature; (3) to assess evidence of effects (benefit and harm); and (4) to provide evidence for the undertaking of randomised trials. Papers that are reviews, correspondences, editorials and non-human studies will be excluded. Eligibility criteria are listed in table 1.

The intervention will be the sedation provided during the first 48 hours of mechanical ventilation. The comparison will be sedation depth (light sedation vs deep sedation). Eligible studies must report some objective measure of sedation depth, such as the Richmond Agitation-Sedation Scale or the Glasgow Coma Scale. The clinical outcomes will be assessed according to sedation depth. These include mortality, delirium, ventilator-free days, hospital and ICU lengths of stay, and incidence of tracheostomy. The drugs used for early sedation will also be qualitatively reported, as will the study location (ie, ICU, emergency department). If there is a relative paucity of data describing early sedation, we will also qualitatively

| Table 1 Eligibility criteria for inclusion in systematic review |
|---------------------------------|-----------------|-----------------|
| **Inclusion criteria**          | **Exclusion criteria** |
| Population                      | Age ≥ 18 years  |
| Intervention                    | Invasive positive pressure ventilation |
| Reference standard              | None |
| Outcomes                        | Mortality, Hospital length of stay, Intensive care unit length of stay, Time to extubation, Delirium, Incidence of tracheostomy |

**Study design**

Randomised controlled trials, Prospective cohort studies, Retrospective cohort studies, Cross-sectional studies, Before-after trials

Correspondences, Editorials, Non-human studies

---

Stephens RJ, et al. BMJ Open 2017;7:e016437. doi:10.1136/bmjopen-2017-016437
report the sedation provided at trial enrolment for RCTs. Similarly, we will report the depth of sedation at the time of trial enrolment for RCTs.

**Study selection and data abstraction**

Two independent reviewers will screen titles and abstracts of identified studies for eligibility. After this relevance screen, the two reviewers will compare their included studies to determine if disagreement exists. In cases of disagreement, the opinion of a third reviewer will be sought and a consensus will be reached. Full-text articles will then be obtained and these manuscripts will be reviewed for potential inclusion.

The same two reviewers will extract data using standardised forms. The following data on study characteristics will be collected and placed in a table: author, year of publication, study design, number of patients included, characteristics of the patient population, sedation data, study quality, risk of bias and outcomes. We will include pertinent study-specific comments in the table as needed.

**Assessment of study quality**

We will assess quality of randomised clinical trials using the Cochrane Collaboration’s tool for assessing the risk of bias in clinical trials and report a summary assessment for the risk of bias for each studied outcome. For studies of observational design, quality will be assessed with the Newcastle Ottawa Scale, assigning a maximum of nine points. Five or fewer points will indicate a high risk of bias.

**Assessment of publication bias**

A graphical display (funnel plot) of the size of the treatment effect against the precision of the trial will be used to evaluate for potential publication bias.

**Strategy for data synthesis**

We will provide a comprehensive narrative synthesis and qualitative analysis of the data, structured around outcomes related to sedation. After conducting the systematic review, if the data can be pooled, we will use a meta-analytic approach to quantitatively analyse the data. A random-effects model will be used to calculate pooled effect sizes and corresponding 95% CIs between deep and light sedation groups. ORs will be calculated for binary data, such as mortality comparisons. Continuous outcomes will be reported as mean difference, and overall effect estimates will be generated using a Z test and presented as mean differences. A p value of <0.05 will be considered statistically significant.

Heterogeneity between studies will be assessed using the I² statistic, which will be reported as a point estimate with high (I² ≥ 50) and presented as mean differences. A p value of <0.05 will be considered statistically significant.

**ETHICS AND DISSEMINATION**

As this is a systematic review of completed studies, no ethical approval will be required. Results from this systematic review will be submitted for publication in peer-reviewed journals and will be presented at national meetings.

This study will refine the understanding of the impact of early sedation practices and inform healthcare workers providing care to mechanically ventilated patients. We anticipate that this information will improve the postintubation care received by mechanically ventilated patients.

Over the past decade, there has been an increasing recognition that early advanced care has significant impact on patient outcome during critical illness. This concept has been shown to be true with regard to antibiotics in sepsis, lung protective ventilation in respiratory failure and reperfusion therapy in cerebrovascular accident. However, there has not been a similar focus on early sedation care for patients treated with mechanical ventilation.

This systematic review will provide a complete synopsis of the world’s literature examining the impact of early deep sedation on patient outcomes, including mortality and length of stay. We will assess the cohort of studies for study quality, publication bias and heterogeneity, and determine if a meta-analysis is appropriate. We expect to find that deep early sedation is associated with worse mortality, longer lengths of stay and greater ventilation duration. Furthermore, we will identify knowledge gaps in the literature as future research targets.

In conclusion, this systemic review will aim to characterise and quantify the impact of early sedation on patient important outcomes. We hope this study yields additional evidence to guide clinical practice in mechanically ventilated patients, as well as targets for future investigation.
