How parents can affect excessive spending of time on screen-based activities
How parents can affect excessive spending of time on screen-based activities

Abstract

Background The aim of this study is to explore the association between family-related factors and excessive time spent on screen-based activities among school-aged children.

Methods A cross-sectional survey using the methodology of the Health Behaviour in School-aged Children study was performed in 2013, with data collected from Slovak (n = 258) and Czech (n = 406) 11- and 15-year-old children. The effects of age, gender, availability of a TV or computer in the bedroom, parental rules on time spent watching TV or working on a computer, parental rules on the content of TV programmes and computer work and watching TV together with parents on excessive time spent with screen-based activities were explored using logistic regression models.

Results Two-thirds of respondents watch TV or play computer games at least two hours a day. Older children have a 1.80-times higher chance of excessive TV watching (CI: 1.30-2.51) and a 3.91-times higher chance of excessive computer use (CI: 2.82-5.43) in comparison with younger children. More than half of children have a TV (53%) and a computer (73%) available in their bedroom, which increases the chance of excessive TV watching by 1.59 times (CI: 1.17-2.16) and of computer use by 2.25 times (CI: 1.59-3.20). More than half of parents rarely or never apply rules on the length of TV watching (64%) or time spent on computer work (56%), and their children have a 1.76-times higher chance of excessive TV watching (CI: 1.26-2.46) and a 1.50-times greater chance of excessive computer use (CI: 1.07-2.08). A quarter of children reported that they are used to watching TV together.
with their parents every day, and these have a 1.84-times higher chance of excessive TV watching (1.25-2.70).

**Conclusions** Reducing time spent watching TV by applying parental rules or a parental role model might help prevent excessive time spent on screen-based activities.

**Background**

New information and communication technologies have become an important part of adolescents’ everyday lives. More and more children use them not only as a supporting component in education, but also as a form of entertainment and use of leisure time. Research suggests that children are spending too much of their free time on screen-based activities, including playing PC games, using the Internet or watching TV (Biddle et al., 2009). According to findings of the international HBSC study, around 60% of 11- and 15-year-old adolescents watch television for two or more hours on weekdays, and the prevalence increases with age (Currie et al., 2012). Furthermore, results of the EU Kids Online II survey (Livingstone et al., 2011) indicate that 9- to 16-year-old children use the Internet almost an hour and a half every day, and this increases steeply with age. It is worth mentioning that one of the most important online activities is playing games, which was reported by 83% of European children in the EU Kids Online II survey (Livingstone et al., 2011).

One of the factors also contributing to an increased amount of time spent using media might be the availability of specific electronic devices, such as a TV or computer, in the bedroom (Livingstone & Helsper, 2010; Wethington et al., 2013). Research suggests that around half of 12- to 15-year-old adolescents have a TV in their bedroom (Velde et al., 2011), and these children, especially younger children, spend approximately 20-30 minutes more time in front of the TV per day than those without a TV in their bedroom (van Zutphen et al., 2007).

The family is the primary social environment that influences the behaviour of children and adolescents. The presence of parental rules focused on limiting screen time appeared to be one of the key factors that influence the amount of time spent on screen-based behaviour in youth (Veitch et al., 2013). Data shows that children whose parents report low restrictions on sedentary activities were most likely to watch TV even more than four hours per day. Moreover, a permissive parenting style is associated with increasing risk of such excessive TV viewing among younger adolescents (Jago et al., 2011). Similar results for playing on a computer have been found in other studies. Adolescents who exceeded the recommended screen time, had no parental screen-viewing rules (Cillero & Jago, 2010) or who lacked parental restriction on Internet use were more likely to report an increased amount of time spent online (Helsper et al., 2013). On the other hand, studies are not consistent about the link between parental rules regarding time spent on screen-based activities and the number of hours children use computers. For instance, Sook-Jung & Young-Gil (2007) found no effect of various parental restrictions (e.g. time limits, website restriction) on children’s online activities, including playing games; however, time spent with online activities was not considered. Therefore,
more research is needed to understand the role of parents in moderating children’s screen-based activities.

Research suggests that excessive time spent on screen-based activities among adolescents is also associated with the activities of their parents. Some studies show that families are most often engaged with one another during leisure-time activities or eating meals together (Crouter et al., 2004; Offer, 2013). Findings indicate that family TV viewing, as a part of a family’s time spent together, is associated with increased television time, especially among older adolescents (Barradas et al., 2007; Bleakly et al., 2013).

In addition, parents influence the amount of time children spend using media in another way. The mean time children spend on leisure activities is mainly structured by parents and particularly by the extent to which parents share activities with their children (Shannon, 2006). In relation to computer use and playing computer games, a recent literature review suggests that excessive time spent on screen-based activities in children may be an outcome from the lack of unstructured spare time (Blinka, 2014). Concerning TV use, findings indicate that family TV viewing, as a part of a family’s time spent together, is associated with increased television time, especially among older adolescents (Barradas et al., 2007; Bleakly et al., 2013).

Countries like Slovakia or the Czech Republic are of specific interest, particularly due to the current rapid changes in the prevalence and patterns of screen-based activities that might be envisaged. According to a report of the EU Kids Online survey, e.g. in 2006 Slovakia and the Czech Republic were lagging behind other European countries in terms of Internet connectivity at home, but since that time a dramatic change has taken place in this field, which might be related to changes in time spent on screen-based activities as well.

The expansion of electronic devices into many European societies has changed what children do in their leisure time. For instance, it has been shown that the prevalence of extensive time spent on screen-based activities, such as playing games, is increasing in Slovak as well as in Czech children (Helsper et al., 2013; Tyrlik & Sykorova, 2011), which is in turn related to physical and psychological health complaints (Blinka & Smahel, 2010; Nuutinen et al., 2014; Brindova et al., 2015b). A high level of sedentary behaviour was related to sleep problems and musculoskeletal pain (Nuutinen et al., 2014; Costigan et al., 2013). Spending a high number of hours on a computer was related to neck pain (Smith et al., 2008), as well as to recurrent backache and headache (Nuutinen et al., 2014; Torchia et al., 2010). More sedentary time of any type was associated with more psychological complaints, such as depression, or those related to well-being, social support (Costigan et al., 2013) or poorer self-esteem (Tremblay et al., 2011). To understand these associations with spending time in front of screens and to prevent the onset of potential health problems, it is important to consider family-related factors which might play an important role in moderating the extensive time spent on screen-based activities by these children.

The aim of this study is to explore the association between family-related factors (the availability of a TV or computer in the bedroom, parental rules on time spent watching TV or on computer use and the content of such TV watching or computer work, and activities spent together with parents) and excessive time spent on screen-based activities among school-aged children.

Methods

Sample and procedure

This study is based on the international Health Behaviour in School-aged Children (HBSC) study and is consistent with its methodology. The HBSC is an international, school-based study conducted in collaboration with the World Health Organization and focusing on the health and health-related behaviour of 11-, 13- and 15-year-old school children in their social context. More detailed information about the HBSC methodology can be found in a paper by Roberts et al. (2009).

The study was conducted in November 2013 in the Czech Republic and Slovakia and was preceded by a pilot study which included the administration of questionnaires and the use of focus groups in both countries. Based on the data obtained in the pilot study the final set of questions was compiled. We contacted 16 larger and smaller primary schools located in rural as well as in urban areas in the Olomouc region, Czech Republic (7 schools), and the Kosice region, Slovakia (9 schools). The prevalence regarding the explored variables (e.g. family structure, screen-based behaviour, parental rules) in the recruited samples are rather similar to those in other studies covering all regions, so we anticipate that our findings on the associations between family-related factors and adolescent screen-based activities of the adolescent population in the Czech and Slovak republics can be generalized to a wider sample. The schools were randomly chosen to create a representative sample. We succeeded in achieving a 100% response rate on the school level, since all of the contacted schools agreed to participate. Questionnaires were administrated in the 5th and 9th grades by trained research assistants in the absence of a teacher during regular class time.

We obtained data from 906 adolescents in the Czech Republic (response rate: 83.20%) and Slovakia (response rate: 74.14%). Non-response was primarily due to illness and parental non-consent regarding the participation of their children. The final sample consisted of 418 Czech (46.1% boys) and 488 Slovak (53.9% boys) primary school pupils, grades five (mean age 10.93, SD=0.62) and nine (mean age 14.90, SD=0.44).
The study was approved by the Ethics Committee of the Faculty of Physical Culture, Palacky University in Olomouc (decision from May 15th 2013) and by the Ethics Committee of the Medical Faculty at P J Safarik University in Kosice (decision from June 18th 2012). The schools selected in the Czech Republic have a general permission granted at the beginning of the school year by all parents. Parents in Slovakia were informed about the study via the school administration and could opt out if they disagreed with it. Participation in the study was fully voluntary and anonymous with no explicit incentives provided for participation in either country.

Measures

Screen-based activities, represented by watching TV and playing computer games, were assessed using two separate items. Watching TV was measured by the question: “About how many hours a day do you usually watch television (including videos) in your free time?” Computer gaming was measured by asking: “About how many hours a day do you play PC-games or TV-games (PlayStation, Xbox, GameCube etc.) in your free time?” All questions had the same nine response categories separately for weekdays and weekends: None at all, About half an hour a day, About 1 hour a day, About 2 hours a day, About 3 hours a day, About 4 hours a day, About 5 hours a day, About 6 hours a day, About 7 or more hours a day (Torsheim et al., 2010).

Using recommendations of the American Academy of Pediatrics (2001), the categories of excessive and non-excessive time spent on screen-based activities were created by dichotomizing responses into two groups: those who spent less than 2 hours per day and those who spent 2 or more hours per day on screen-based activities.

The availability of a TV or computer in the bedroom was assessed using a single item asking adolescents if they have the following things in their bedroom, where they sleep and study: radio/CD player, TV, computer, Internet. Each electronic device had two categories of responses: yes or no. The responses used in the statistical analyses referred to a TV and a computer.

Family structure was measured by asking respondents the following question: “The family, where you live is … (1) a two-parent household, neither is a step-parent (2) one parent is a step-parent, (3) a single-parent household.

Parental rules were items focused on restrictions related to TV or computer use based on previous studies (Veitch et al., 2013; Barradas et al., 2007; Atkin et al., 2013; Springer et al., 2010). To assess the objective of our study, we used separate items related to limitation of the time and content of TV programmes and computer work; adolescents were asked to indicate to what extent selected rules were applied in their family. Respondents were asked to answer the following questions: “My parents limit the time spent with watching TV.”; “My parents limit the content of the programmes I watch in TV.”; “My parents limit the time spent with playing PC games.”; “My parents limit the content of PC work.” Responses were on a 4-point scale: always, mostly, rarely, never and were dichotomized into rarely and never, vs. almost every day and every day.

Family activities were evaluated on a scale adopted from Sweeting et al. (1998) and were assessed using a list of eight activities which some families commonly do together. Participants indicated how often they and their family usually do each of the shared activities together, including watching TV or a video, playing indoor games, eating a meal, going for a walk, going places, visiting friends or relatives, playing sports and talking about things (Loke & Mak, 2013). Responses for frequency were on a 5-point scale: everyday, most days, about once a week, less often and never. Since all these activities – with the exception of watching TV together – are indicators of a latent variable which may be described as “family team spirit”, we used principal component analysis to extract one factor representing this latent variable. All of the above-mentioned variables were entered into this factor with almost the same weight, making it easily interpretable. This factor explains about 50% of the cumulative variance. We constructed a variable representing all shared family activities, but excluding watching TV together with parents; the latter we used as a separate variable. Responses were dichotomized into two categories as follows: (1) watching TV together every day, (2) watching TV together on most days, about once a week, less often and never.

Statistical analyses

Country, gender and age differences in family-related factors as well as screen-based behaviour variables were explored using the chi-square for dichotomous variables and the t-test for independent variables for continuous variables. The association between family-related factors of excessive time spent watching TV and playing computer games was explored using logistic regression models. Firstly, each variable was entered separately into the model adjusted to age and gender (Model 1). When age and gender differences were confirmed in exposure variables, interactions were considered in analytical models. Each interaction was included separately into the model (Model 2). Finally, variables which significantly contributed to the prediction of the outcome measure were included into the model in one step (Model 3).

Results

Two-thirds of respondents watched TV or played computer games at least two hours a day (see Table 1). Czech children did not differ from Slovak children (TV/PC: chi square =0.319/1.355, ns/ns); therefore, we did not consider this variable in further models.
Table 1 Descriptive characteristics of the sample

|                          | N (%)                  |

| **Computer use**         |                        |
| less than 2 hours a day  | 340 (40.2)             |
| 2 or more hours a day    | 506 (59.8)             |

Association between family-related factors and excessive time spent watching TV

Children who were 15 years old who had a TV located in their bedroom, whose parents rarely or never applied rules on the length of TV watching and who watched TV together with parents every day had a significantly higher chance of spending excessive time watching TV. Family completeness or applying rules on the content of TV programmes watched do not contribute significantly to the prediction of excessive watching TV (Model 1).

The effect of either or both parental rules and activities shared with parents on the chances of spending excessive time watching TV does not differ between children aged 11 and 15 years old (see Table 2, model 2).
### Table 2: The associations of factors of family context with excessive spending of time watching TV among adolescents

| Family context                          | Model 1 | Model 2 | Model 3 |
|-----------------------------------------|---------|---------|---------|
| Gender                                  |         |         |         |
| boys                                    | 0.81    | 0.82    | 0.82    |
| girls                                   | 1       | 1       | 1       |
| Age (grade)                             |         |         |         |
| 15 years old (9th grade)                | 1.80    | 1.80    | 1.80    |
| 11 years old (5th grade)                | 1       | 1       | 1       |
| Family completeness                     |         |         |         |
| incomplete                              | 1       | 1       | 1       |
| mixed                                   | 1.15    | 1.15    | 1.15    |
| intact                                  | 1       | 1       | 1       |
| TV located in bedroom                   |         |         |         |
| yes                                     | 1.46    | 1.46    | 1.46    |
| no                                      | 1       | 1       | 1       |
| Parents apply rules about time spent watching TV |         |         |         |
| rarely-never                            | 1.84    | 1.84    | 1.84    |
| every day-almost every day              | 1       | 1       | 1       |
| Parents apply rules about content of TV programmes |         |         |         |
| rarely-never                            | 1.40    | 1.40    | 1.40    |
| every day-almost every day              | 1       | 1       | 1       |
| Watching TV together with parents       |         |         |         |
| every day                               | 1.95    | 1.95    | 1.95    |
| most days                              | 1       | 1       | 1       |
| Activities shared with parents          |         |         |         |
| lower score-more frequently shared activities | 0.99    | 0.99    | 0.99    |

**Note:**
- The interaction effect of parental rules about time spent watching TV and age on chance of excessive TV watching was not significant.
- The interaction effect of parental rules about the content of TV programmes and age on chance of excessive TV watching was not significant.
- The interaction effect of activities shared with parents and age on chance of excessive TV watching was not significant.

Discussion

Our results showed that parental rules that restrict the time spent on screen-based activities were associated with a lower probability of excessive computer use. In particular, parental rules that restrict the time spent on computer use were associated with a lower probability of excessive computer use, but parental rules that restrict the content of computer work were not. This result supports previous findings from the existing body of research showing that what parents do regarding children and their media use matters (Cillero & Jago, 2010; Helsper et al., 2013). Although restrictions on the content of computer use are not relevant for the amount of time spent, they may still be relevant for the content of screen-based activities. We did not aim to identify which content gives the highest risk of excessive use (e.g., soap operas, long-lasting PC games). In connection with risk factors, Blinka et al. (2014) showed that playing online games is a risk factor associated with highly excessive Internet use. Given these results, we can conclude that this issue requires further study with more detailed questions than those we used in this study.

In line with prior research (Barradas et al., 2007; Bleakly et al., 2013), we found that Czech and Slovak children who shared watching TV with their parents every day were more likely to report excessive TV watching. An explanation may be that watching TV with parents does not give children another model of how to spend their leisure time; it does not promote adequate structuring of their leisure time. This phenomenon has been described previously in the theoretical literature on the phenomenon of “bedroom culture”. According to the concept, children spend less time in the streets or on playgrounds in favour of staying at home in their media-rich bedrooms, which provide them with a large scale of stimulations (Livingstone & Helsper, 2010).

This study has several strengths but it also has some limitations. An important limitation is the cross-sectional design of this study, which makes it impossible to formulate conclusive statements about the causality of the relationships found.
