Abstract

Neural network language and translation models have recently shown their great potentials in improving the performance of phrase-based machine translation. At the same time, word representations using different word factors have been translation quality and are part of many state-of-the-art machine translation systems. In this work, we combined these two ideas by investigating the combination of both techniques. By representing words in neural network language models using different factors, we were able to improve the models themselves as well as their impact on the overall machine translation performance. This is especially helpful for morphologically rich languages due to their large vocabulary size. Furthermore, it is easy to add additional knowledge, such as source side information, to the model.

In this work, we improved the translation quality of a state-of-the-art phrase-based machine translation system by 0.7 BLEU points. We performed experiments on three language pairs for the news translation task of the WMT 2016 evaluation.

1 Introduction

Recently, neural network models are deployed extensively for better translation quality of statistical machine translation (Le et al., 2011; Devlin et al., 2014). For the language model as well as for the translation model, neural network-based models showed improvements when used during decoding as well as when used in re-scoring.
section, we will describe the experiments on the WMT 2016 data. Finally, we will end the paper with a conclusion of the work.

2 Related Work

Additional information about words, encoded as word factors, e.g. the lemma of word, POS tags, etc., is employed in state-of-the-art phrase-based systems. (Koehn and Hoang, 2007) decomposes the translation of factored representations to smaller mapping steps, which are modelled by translation probabilities from input factor to output factor or by generating probabilities of additional output factors from existing output factors. Then those pre-computed probabilities are jointly combined in the decoding process as a standard translation feature scores. In addition, language models using these word factors have shown to be very helpful to improve the translation quality. In particular, the aligned-words, POS or word classes are used in the framework of modern language models (Mediani et al., 2011; Wuebker et al., 2013).

Recently, neural network language models have been considered to perform better than standard n-gram language models (Schwenk, 2007; Le et al., 2011). Especially the neural language models constructed in recurrent architectures have shown a great performance by allowing them to take a longer context into account (Mikolov et al., 2010; Sundermeyer et al., 2013).

In this work, we used the torch7 implementation of an RNN-based language model (Léonard et al., 2015). First, the words were mapped to their word embeddings. We used an input embedding size of 100. Afterwards, we used two LSTM-based layers. The first has the size of the word embeddings and for the second we used a hidden size of 200. Finally, the word probabilities were calculated using a softmax layer.

The models were trained using stochastic gradient descent. The weights were updated using mini-batches with a batch size of 128. We used a maximum epoch size of 1 million examples and selected the model with the lowest perplexity on the development data.

3 Recurrent Neural Network-based Language Models

In contrast to feed forward neural network-based language models, recurrent neural network-based language models are able to store arbitrary long word sequences. Thereby, they are able to directly model $P(w|h)$ and no approximations by limiting the history size are necessary. Recently, several authors showed that RNN-based language models could perform very well in phrase-based machine translation. (Mikolov et al., 2010; Sundermeyer et al., 2013)

In this work, we used the torch7 implementation of an RNN-based language model (Léonard et al., 2015). First, the words were mapped to their word embeddings. We used an input embedding size of 100. Afterwards, we used two LSTM-based layers. The first has the size of the word embeddings and for the second we used a hidden size of 200. Finally, the word probabilities were calculated using a softmax layer.

The models were trained using stochastic gradient descent. The weights were updated using mini-batches with a batch size of 128. We used a maximum epoch size of 1 million examples and selected the model with the lowest perplexity on the development data.

4 Factored Language Model

When using factored representation of words, words are no longer represented as indices in the neural network. Instead, they are represented a tuples of indices $w = (f_1, \ldots, f_D)$, where $D$ is the number of different factors used to describe the word. These factors can be the word itself, as well as the POS, automatic learned classes (Och, 1999) or other information about the word. Furthermore, we can use different types of factors for the input and the output of the neural network.

Our work exhibits several essential differences from theirs. Firstly, we leverage not only the target morphological information but also word factors from both source and target sides in our models. Furthermore, we could use as many types of word factors as we can provide. Thus, we are able to make the most of the information encoded in those factors for more accurate prediction.

\footnote{http://torch.ch/}
4.1 Input Representation

In a first step, we obtained a factored representation for the input of the neural network. In the experiments, we represented a word by its surface form, POS-tags and automatic word class, but the framework can be used for any number of word factors. Although there are factored approaches for $n$-gram based language models (Bilmes and Kirchhoff, 2003), most $n$-gram language models only use one factor. In contrast, in neural network based language models, it is very easy to add additional information as word factors. We can learn different embeddings for each factor and represent the word by concatenating the embeddings of several factors. As shown in the bottom of Figure 1, we first project the different factors to the continuous factor embeddings. Afterwards, we concatenate these embeddings into a word embedding.

The advantage of using several word factors is that we can use different knowledge sources to represent a word. When a word occurs very rarely, the learned embedding from its surface form might not be helpful. The additional POS information, however, is very helpful. While using POS-based language models in PBMT may lead to losing the information about high frequent words, in this approach we can have access to all information by concatenating the factor embeddings.

4.2 Output Representation

In addition to use different factors in the input of the neural network, we can also use different factors on the output. In phrase-based machine translation, $n$-gram language models based on POS-tags have been shown to be very successful for morphologically rich languages.

Porting this idea to neural network language models, we can not only train a model to predict the original word $f_1$ given the previous words in factor representation $h = (f_{1,1}, \ldots, f_{1,D}), \ldots, (f_{i,1}, \ldots, f_{i,D})$, but also train a model to predict POS-tags (e.g. $f_2$) given the history $h$.

In a first step, we proposed to train individual models for all factors $1, \ldots, D$ generating probabilities $P_1, \ldots, P_D$ for every sentence. Then these probabilities can be used as features for example in re-scoring of the phrase-based MT system.

Considering that it can be helpful to consider all factors of the word in the input, it can be also helpful to jointly train the models for predicting the different output factors. This is motivated by the fact that multi-task learning has shown to be beneficial in several NLP tasks (Collobert et al., 2011). Predicting all output features jointly requires a modification of the output layer of the RNN model. As shown in Figure 1, we replace the single mapping from the LSTM-layer to the softmax layer, by $D$ mappings. Each mapping then learns to project the LSTM-layer output to the factored output probabilities. In the last layer, we use $D$ different softmax units. In a similar way as the conventional network, the error between the output of the network and the reference is calculated during training.

Using this network, we will no longer predict the probability of one word factor $P_{d, d} \in \{1, \ldots, D\}$, but $D$ different probability distributions $P_1, \ldots, P_D$. In order to integrate this model into the machine translation system we explored two different probabilities. First, we used only the joint probability $P = \prod_{d=1}^{D} P_d$ as a feature in the log-linear combination. In addition, we also used the joint probability as well as all individual probabilities $P_d$ as features.

4.3 Bilingual Model

Using the model presented before, it is possible to add additional information to the model as well. One example we explored in this work is to use
the model as a bilingual model (BM). Instead of using only monolingual information by considering the previous target factors as input, we used source factors additionally. Thereby, we can now model the probability of a word given the previous target words and information about the source sentence. So in this case we model the translation probability and no longer the language model probability.

When predicting the target word $w_{i+1}$ with its factors $f_{i+1,1}, \ldots, f_{i+1,D}$, the input to the RNN is the previous target word $w_i = f_{i,1}, \ldots, f_{i,D}$. Using the alignment, we can find the source word $s_{a(i+1)}$, which is aligned to the target word $w_{i+1}$. When we add the features of source word $s_{a(i+1)} = (f_{a(i+1),1}, \ldots, f_{a(i+1),D_s})$ to the ones of the target word $w_i$ and create a new bilingual token

$$b_i = (f_{i+1,1}, \ldots, f_{i+1,D}, f_{a(i+1),1}, \ldots, f_{a(i+1),D_s})$$

we now can predict the target word given the previous target word and the aligned source word.

In the example in Figure 2, we would insert (completed, VVD, 87, ein, ART) to predict (a, DT, 37).

In this case the number of input factors and output factors are no longer the same. In the input, we have $D + D_s$ input factors, while we have only $D$ factors on the output of the network.

5 Experiments

We evaluated the factored RNNLM on three different language pairs of the WMT 2016 News Translation Task. In each language pair, we created an $n$-best list using our phrase-based MT system and used the factored RNNLM as an additional feature in rescoring. It is worth noting that the POS and word class information are already present during decoding of the baseline system by $n$-gram-based language models based on each of these factors. First, we performed a detailed analysis on the English-Romanian task. In addition, we used the model in a German-English and English-German translation system. In all tasks, we used the model in re-scoring of a PBMT system.

5.1 System Description

The baseline system is an in-house implementation of the phrase-based approach. The system used to generate $n$-best lists for the news tasks is trained on all the available training corpora of the WMT 2015 Shared Translation task. The system uses a pre-reordering technique (Rottmann and Vogel, 2007; Niehues and Kolss, 2009; Herrmann et al., 2013) and facilitates several translation and language models. As shown in Table 1, we use two to three word-based language models and one to two cluster-based models using 50, 100 or 1,000 clusters. The clusters were trained as described in (Och, 1999). In addition, we used a POS-based language model in the English-Romanian system and a bilingual language model (Niehues et al., 2011) in English to German and German to English systems. The POS tags for English-Romanian were generated by the tagger described in (Ion et al., 2012) and the ones for German by RFTagger (Schmid and Laws, 2008).

| Features | EN-RO | EN-DE | DE-EN |
|----------|-------|-------|-------|
| wordLM   | 2     | 3     | 3     |
| POSLM    | 1     | 0     | 0     |
| clusterLM| 2     | 1     | 2     |
| BiLM     | 0     | 1     | 1     |
| #features| 22–23 | 20    | 22    |

In addition, we used discriminative word lexica (Niehues and Waibel, 2013) during decoding and source discriminative word lexica in rescoring (Herrman et al., 2015).

A full system description can be found in (Ha et al., 2016).

The German to English baseline system uses 20 features and the English to German systems uses 22 features.

The English-Romanian system was optimized on the first part of news-dev2016 and the rescoring was optimized on this set and a subset of 2,000
sentences from the SETimes corpus. This part of the corpus was of course excluded for training the model. The system was tested on the second half of news-dev2016.

The English-German and German-English systems were optimized on news-test2014 and also the re-scoring was optimized on this data. We tested the system on news-test2015.

For English to Romanian and English to German we used an \( n \)-best List of 300 entries and for German to English we used an \( n \)-best list with 3,000 entries.

For decoding, for all language directions, the weights of the system were optimized using minimum error rate training (Och, 2003). The weights in the rescoring were optimized using the ListNet algorithm (Cao et al., 2007) as described in (Niehues et al., 2015).

The RNN-based language models for English to Romanian and German to English were trained on the target side of the parallel training data. For English to German, we trained the model and the Europarl corpus and the News commentary corpus.

### 5.2 English - Romanian

In the first experiment on the English to Romanian task, we only used the scores of the RNN language models. The baseline system has a BLEU score (Papineni et al., 2002) of 29.67. Using only the language model instead of the 22 features, of course, leads to a lower performance, but we can see clear difference between the different language models. All systems use a word vocabulary of 5K words and we used four different factors. We used the word surface form, the POS tags and word clusters using 100 and 1,000 classes.

The baseline model using words as input and words as output reaches a BLEU score of 27.88. If we instead represent the input words by factors, we select entries from the \( n \)-best list that generates a BLEU score of 28.46. As done with the \( n \)-gram language models, we can also predict the other factors instead of the words themselves. In all cases, we use all four factors as input factors. As shown in Table 2, all models except for the one with 100 classes perform similarly, reaching up between 28.46 and 28.49. The language model predicting only 100 classes only reaches a BLEU score of 28.23. It suggests that this number of classes is too low to disambiguate the entries in the \( n \)-best list.

| Input  | Prediction | Single |
|--------|------------|--------|
| Word   | Word       | 27.88  |
| All factors | Word     | 28.46  |
| All factors | POS      | 28.48  |
| All factors | 100 Cl.   | 28.23  |
| All factors | 1,000 Cl. | 28.49  |
| All factors | All factors | 28.54 |

If we predict all factors together and use then the joint probability, we can reach the best BLEU score of 28.54 as shown in the last line of the table. This is 0.7 BLEU points better than the initial word based model.

After evaluating the model as the only knowledge source, we also performed experiments using the model in combination with the other models. We evaluated the baseline and the best model in three different configuration in Table 3 using only the joint probability. The three baseline configuration differ in the models used during decoding. Thereby, we are able to generate different \( n \)-best lists and test the models on different conditions.

| Model          | Conf1    | Conf2    | Conf3    |
|----------------|----------|----------|----------|
| Baseline       | 29.86    | 30.00    | 29.75    |
| LM 5K          | 29.79    | 29.84    | 29.73    |
| LM 50K         | 29.64    | 29.84    | 29.83    |
| Factored LM 5K | 29.94    | 30.01    | 30.01    |
| Factored LM 50K| 30.05    | 30.27    | 30.29    |

In Table 3, we tested the word-based and the factored language model using a vocabulary of 5K and 50K words. Features from each model are used in addition to the features of the baseline system. As shown in the table, the word-based RNN language models perform similarly, but both could not improve over the baseline system. One possible reason for this is that we already use several language models in the baseline model and they are partly trained on much larger data. While the RNN models are trained using only the target language model, one word-based language model is trained on the Romanian common crawl corpus. Furthermore, the POS-based and word cluster language models use a 9-gram history and therefore, can already model quite long dependencies.

But if we use a factored language model, we are
able to improve over the baseline system. Using the additional information of the other word factors, we are able to improve the bilingual model in all situations. The model using a surface word vocabulary of 5,000 words can improve by 0.1 to 0.3 BLEU points. The model using a 50K vocabulary can even improve by up to 0.6 BLEU points.

Table 4: English - Romanian Bilingual Models

| Model             | Dev  | Test |
|-------------------|------|------|
| Baseline          | 40.12| 29.75|
| + Factored LM 50K | 40.87| 30.17|
| + Factored BM 5K  | 41.11| 30.44|
| + Factored BM 50K | 41.16| 30.57|

After analyzing the different language models, we also evaluate how we can use the factored representation to include source side information. The results are summarized in Table 4. In these experiments, we used not only the joint probability, but also the four individual probabilities as features. Therefore, we will add five scores for every model, since each model is added to its previous configuration in this experiment.

Exploiting all five probabilities of the language model brought us the similar improvement we achieved using the joint probability from the model. On the test set, the improvements are slightly worse. When adding the model using source side information based on a vocabulary of 5K and 50K words, however, we get additional improvements. Adopting the both bilingual models (BM) along with a factored LM, we improved the BLEU score further leading up to the best score of 30.57 for the test set.

5.3 English - German

In addition to the experiments on English to Romanian, we also evaluated the models on the task of translating English News to German. For the English to German system, we use three factors on the source side and four factors on the target side. In English, we used the surface forms as well as automatic word cluster based on 100 and 1,000 classes. On the target side, we used fine-grained POS-tags generated by the RFTagger (Schmid and Laws, 2008), in addition to the factors for the source side.

The experiments using only the scores of the model are summarized in Table 5. In this experiment, we analyzed a word based- and a factored language models as well as bilingual models. As described in section 4.3, the difference between the language model and the bilingual model is that the latter uses the source side information as additional factor.

Using only the word-based language model we achieved a BLEU score of 20.92. Deploying a factored language model instead, we can improve the BLEU score by 0.7 BLEU points to 21.69. While we achieved a score of 21.33 BLEU points by using a proposed bilingual model, we improved the score up to 21.92 BLEU points by adopting all factors for the bilingual model.

Table 5: English - German Single Score

| Model          | Single |
|----------------|--------|
| LM 5K          | 20.92  |
| Factored LM 5K | 21.69  |
| BM 5K          | 21.33  |
| Factored BM 5K | 21.92  |

In addition to the analysis on the single model, we also evaluated the model’s influence by combining the model with the baseline features. We tested the language model as well as the bilingual model on two different configurations. Adopting the factored language model on top of the baseline features improved the translation quality by around 0.4 BLEU points for both configurations, as shown in Table 6. Although the bilingual model could also improve the translation quality, it could not outperform the factored language model. The combination of the two models, LM and BM, did not lead to further improvements. In summary, the factored language model improved the BLEU score by 0.4 points.

5.4 German - English

Similar experiments were conducted on the German to English translation task. For this language pair, we built models using a vocabulary size of 5,000 words. The models cover word surface forms and two automatic word clusters, which are
based on 100 and 1,000 word classes respectively. First, we will evaluate the performance of the system using only this model in rescoring. The results are summarized in Table 7.

### Table 7: German - English Single Score

| Model       | Single  |
|-------------|---------|
| LM 5K       | 26.11   |
| Factored LM 5K | 26.96   |
| BM 5K       | 26.77   |
| Factored BM 5K | 26.81   |

The word based language model achieves a BLEU score 26.11. Extending the model to include factors improves the BLEU score by 0.8 BLEU points to 26.96. If we use a bilingual model, a word based model achieves a BLEU score of 26.77 and the factored one a BLEU score of 26.81. Although the factored model performed better than the word-based models, in this case the bilingual model cannot outperform the language model.

### Table 8: German - English Language Model

| Model       | Single  |
|-------------|---------|
| Baseline    | 29.33   |
| + Factored BM 5K | 29.51   |
| + Factored LM 5K | 29.66   |

In a last series of experiments, we used the scores combined with the baseline scores. The results are shown in Table 8. In this language pair, we can improve over the baseline system by using both models. The final BLEU score is 0.3 BLEU points better than the initial system.

### 6 Conclusion

In this paper, we presented a new approach to integrate additional word information into a neural network language model. This model is especially promising for morphologically rich languages. Due to their large vocabulary size, additional information such as POS-tags are expected to model rare words effectively.

Representing words using factors has been successfully deployed in many phrase-based machine translation systems. Inspired by this, we represented each word in our neural network language model using factors, facilitating all available information of the word. We showed that using the factored neural network language models can improve the quality of a phrase-based machine translation system, which already uses several factored language models.

In addition, the presented framework allows an easy integration of source side information. By incorporating the alignment information to the source side, we were able to model the translation process. In this model, the source words as well as the target words can be represented by word factors.

Using these techniques, we are able to improve the translation system on three different language pairs of the WMT 2016 evaluation. We performed experiments on the English-Romanian, English-German and German-English translation task. The suggested technique yielded up to 0.7 BLEU points of improvement on all three tasks.

### Acknowledgments

The project leading to this application has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement n° 645452. The research by Thanh-Lê Ha was supported by Ministry of Science, Research and the Arts Baden-Württemberg.
