Minimizers of Dirichlet functionals on the $n$–torus
and the weak KAM Theory

G. Wolansky

Abstract

Given a probability measure $\mu$ on the $n$–torus $\mathbb{T}^n$ and a rotation vector $P \in \mathbb{R}^n$, we ask whether there exists a minimizer to the integral $\int_{\mathbb{T}^n} |\nabla \phi + P|^2 d\mu$. This problem leads, naturally, to a class of elliptic PDE and to an optimal transportation (Monge-Kantorovich) class of problems on the torus. It is also related to higher dimensional Aubry-Mather theory, dealing with invariant sets of periodic Lagrangians, and is known as the "weak-KAM theory".

1 Overview

1.1 Motivation

Consider the functional

$$H_P(u) := \frac{\varepsilon^2}{2} \int_{\mathbb{T}^n} |\nabla u + i\varepsilon^{-1} Pu|^2 dx - G(|u|)$$  \hspace{1cm} (1.1)

where $\mathbb{T}^n := \mathbb{R}^n \mod \mathbb{Z}^n$ is the flat $n-$torus, $P \in \mathbb{R}^n$ a prescribed, constant vector, $u \in W^{1,2}(\mathbb{T}^n; \mathbb{C})$ is normalized via $\int_{\mathbb{T}^n} |u|^2 dx = 1$ and $G$ is convex (possibly non-local) functional of $|u|$. A critical point $u$ of $H_P$ can be considered as a periodic function on $\mathbb{R}^n$. The function

$$u_0(x) = e^{iP \cdot x/\varepsilon} u(x)$$  \hspace{1cm} (1.2)

is considered as a function on $\mathbb{R}^n$ as well.

Examples:

i) $G(|u|) = -\int_{\mathbb{T}^n} \Xi(x)|u|^2 dx$ where $\Xi$ is a smooth potential on $\mathbb{T}^n$. A critical point of (1.1) is an eigenvalues problem of the Schrödinger operator

$$H_P := -\varepsilon^2 (\nabla + iP)^2 + 2\Xi$$
on the torus. The substitution (1.2) leads to a Bloch state

$$-\varepsilon^2 \Delta u_0 + 2\Xi u_0 + Eu_0 = 0 \text{ on } \mathbb{R}^n .$$  \hspace{1cm} (1.3)

ii) Self-focusing nonlinear Schrödinger equation. Here $G(|u|) = \int_{\mathbb{T}^n} |u|^{\sigma}$ where $2 < \sigma < 2(2+n)/n$. An extremum $u$ of $H_P$ with this choice is given by the nonlinear eigenvalue problem for $u_0$ on $\mathbb{R}^n$:

$$\varepsilon^2 \Delta u_0 + \sigma |u_0|^{\sigma-1} u_0 = Eu_0 .$$  \hspace{1cm} (1.4)

iii) The choice

$$G(|u|) := \sup_{V \in C^1(\mathbb{T}^n)} \left( -\int_{\mathbb{T}^n} \frac{1}{2\gamma} |\nabla V|^2 - V(|u|^2 - 1) \right) dx ,$$
leads to the Schrödinger Poisson system (see, e.g. [BM], [AS], [IZL]) for attractive
(gravitational) field. Again, \( u_0 \) solves

\[-\varepsilon^2 \Delta u_0 - Vu_0 = E(P)u_0\]

where \( V \) is a periodic function on \( \mathbb{R}^n \) solving \( \Delta V + \gamma(|u_0|^2 - 1) = 0 \).

In addition to the (rather obvious) spectral asymptotic questions, there are additional
motivations for the study of this problem, as described below.

The short wavelength limit of the reduced wave equation in a periodic lattice is de-
scribed as

\[\Delta u_0 + \varepsilon^{-2}N(x)u_0 = 0\]

where \( N(x) \) is the (\( \varepsilon \) independent) periodic function representing the refraction index
of the lattice and \( \varepsilon \to 0 \) stands for the wavelength. See, e.g. [RW]. Suppose one can
measure the intensity \( |u_0| \) and the direction \( \hat{P} := P / |P| \) of the carrier wavenumber of
an electromagnetic wave \( u_0(x) = e^{iP \cdot x}u(x) \) in this lattice (here, again, \( u \) is periodic).
Then \( N \) can be recovered from

\[N \equiv \frac{1}{2} |\nabla \phi + \hat{P}|^2 \] (1.5)

where \( \phi \) is the minimizer of \( F(\rho, \hat{P}) \) for a normalized \( \rho = |u_0|^2 \) (see (1.6) below).
Alternatively, suppose we need to design a lattice for a prescribed electromagnetic
intensity \( |u_0|^2 \) and wave propagation \( \hat{P} \). Then (1.5) is the solution as well!

### 1.2 The Effective Hamiltonian

Note that, in cases i-iii, I referred to critical points of \( H_\varepsilon^P \). If one looks at minimizers
of this functional, or even critical points of finite (\( \varepsilon \)-independent) Morse index, then
one may expect singular limits as \( \varepsilon \to 0 \). However, there is a formal way to obtain
nonsingular limits of these equations as \( \varepsilon \to 0 \) as follows:
Substitute the WKB anzatz (see [K]) \( u_\varepsilon := \sqrt{\rho} e^{i\phi/\varepsilon} \) in (1.1), where \( \phi \in C^1(\mathbb{T}^n) \) and \( \rho \in C^1(\mathbb{T}^n) \) is non-negative function satisfying \( \int_{\mathbb{T}^n} \rho = 1 \). Then

\[
\lim_{\varepsilon \to 0} H^\varepsilon_P(u_\varepsilon) = \frac{1}{2} \int_{\mathbb{T}^n} |\nabla \phi + P|^2 \rho(x) dx - G(|\rho|^{1/2}).
\]

Now, define

\[
F(\rho, P) := \frac{1}{2} \inf_{\phi \in C^1(\mathbb{T}^n)} \int_{\mathbb{T}^n} |\nabla \phi + P|^2 \rho(x) dx
\]

and

\[
H_G(\rho, P) := F(\rho, P) - G(|\rho|^{1/2}).
\]

Note that \( F \) is concave as a function of \( \rho \) for fixed \( P \in \mathbb{R}^n \). Then we can (at least formally) look for the maximizer of \( H_G(\cdot, P) \) over the set of densities \( \rho \in L^1(\mathbb{T}^n; \mathbb{R}^+) \). It is the asymptotic energy spectrum \( H \) associated with \( H^\varepsilon_P \):

\[
\hat{H}_G(P) := \sup_{\rho} \left\{ H_G(\rho, P) \mid \rho \in L^1(\mathbb{T}^n; \mathbb{R}^+) , \int_{\mathbb{T}^n} \rho = 1 \right\}
\]

The pair \((\phi, \rho)\) which realizes the minimum (res. maximum) of \( F \) (res. \( \hat{H}_G(\cdot, P) \)) corresponds to an asymptotic critical point of \( H^\varepsilon_P \) and verifies the Euler-Lagrange equations:

\[
\nabla \cdot [\rho (\nabla \phi + P)] = 0,
\]

\[
\frac{1}{2} |\nabla \phi + P|^2 - G_\rho = E
\]

on \( \mathbb{T}^n \), where \( G_\rho \) is the Fréchet derivative of \( \rho \to G(|\rho|^{1/2}) \) and \( E \) is a Lagrange multiplier corresponding to the constraint \( \int_{\mathbb{T}^n} \rho = 1 \).

Of particular interest is the linear case (1.3). Here (1.7, 1.8) are reduced into

\[
H_\Xi(\rho, P) := F(\rho, P) + \int_{\mathbb{T}^n} \Xi \rho.
\]

\[
\hat{H}_\Xi(P) := \sup_{\rho} \left\{ H_\Xi(\rho, P) \mid \rho \geq 0 , \int_{\mathbb{T}^n} \rho = 1 \right\}
\]

and (1.10) takes the form of the Hamilton-Jacobi equation on the torus:

\[
\frac{1}{2} |\nabla \phi + P|^2 + \Xi = E
\]
which is independent of $\rho$ and so is decoupled from (1.9).

Suppose now there exists a maximizer $\rho_0$ of (1.12). Multiply (1.13) by $\rho_0$ and integrate over $\mathbb{T}^n$ to obtain

$$E = F(\rho_0, P) + \int_{\mathbb{T}^n} \Xi \rho_0 := \hat{H}_\Xi(P) \ .$$

(1.14)

In particular, the Lagrange multiplier $E$ is identical to the asymptotic energy spectrum $\hat{H}_\Xi(P)$. An important point to be noted, at this stage, is that the asymptotic spectrum is in the oscillatory domain of the periodic Schrödinger equation, that is $\hat{H}_\Xi(P) \geq \max_{\mathbb{T}^n} \Xi$ necessarily holds for any $P \in \mathbb{R}^n$, and $\hat{H}_\Xi(P) > \max_{\mathbb{T}^n} \Xi$ if $|P|$ is sufficiently large (see Proposition 4.1).

The function $\hat{H}_\Xi = \hat{H}_\Xi(P)$ defined in (1.14) is considered by Evans and Gomes [EG1, EG2] as the Effective Hamiltonian corresponding to

$$h_\Xi(p, x) = |p|^2/2 + \Xi(x) \ .$$

If $\psi(x, P) := \phi(x)$ is a solution of the Hamilton-Jacobi equation (1.13) corresponding to a given $P$, then a canonical change of variables

$$p = \nabla_x \psi + P \ ; \ X = \nabla_P \psi + x$$

reduces the Hamiltonian equation to an integrable system defined by the Hamiltonian $\hat{H}_\Xi$, that is, $P$ is a cyclic variable and hence a constant of motion.

In general, such a solution does not exist for any $P \in \mathbb{R}^n$. However, (1.12) suggests a way to define the effective Hamiltonian $\hat{H}_\Xi$ without the assumption that (1.13) is solvable. We note, at this stage, that (1.12) seems to be the dual of

$$\hat{H}_\Xi(P) = \inf_{\phi \in C^\infty(\mathbb{T}^n)} \sup_{x \in \mathbb{T}^n} h_\Xi(\nabla \phi + P, x)$$

(1.15)

which was suggested by Gomes and Oberman [GO] as a numerical tool for evaluating $\hat{H}_\Xi$. 

7
1.3 Objectives

As we shall see below, the supremum in (1.12) is not attained in $L^1(\mathbb{T}^n)$, in general, but in the set $\mathcal{M}$ of Borel probability measures on $\mathbb{T}^n$. This, together with (1.11), motivates us to extend the domain of $F$ in (1.6) from the set of non-negative densities in $L^1(\mathbb{T}^n)$ to $\mathcal{M}$. Similarly, the functional $H_{\Xi}$ (1.11) is extended to $\mathcal{M}$ as well. Our first object is

I. to define a generalized minimizer $\phi$ of $F$.

The effective Hamiltonian plays a major rule in the weak KAM Theory. See [F, GCJ, Man, Mat1, S] among other references. For the convenience of the reader we review the fundamentals of the weak KAM Theory and Mather measures in section 2. Our second object is

II. to relate the functional $H_{\Xi}$ to the weak KAM theory. In particular, to relate the generalized minimizer $\phi$ of $F$ to the minimal Mather measure.

An excellent reference to the Monge-Kantorovich Theory of optimal transportation is the book of Villani [V]. The relation between M-K theory and the weak KAM theory was suggested in [E] and further elaborated in a series of publications, among which [G, LSG, BB]. Essentially, it relates the minimal (Mather) measures of a given Lagrangian to a measure which minimizes a certain optimal transportation plan. The third object of this paper is

III. to approximate $F$ and $H_{\Xi}$ by an optimal transportation functions $F_T$ and $H_{\Xi,T}$, respectively.

Finally, we use the suggested functionals to establish an alternative to (1.15) for the evaluation of $\hat{H}_{\Xi}(P)$:
IV. Establish a combinatorial search algorithm for evaluation of \( \hat{H}_\Xi(P) \) to any degree of approximation.

2 Lagrangian dynamics on the torus

2.1 The Aubrey-Mather Theory and minimal orbits

Let
\[
L(p, x) := \frac{|p|^2}{2} - \Xi(x),
\]
(2.1)
a Lagrangian function defined on \( \mathbb{R}^n \times \mathbb{R}^n \) where the potential \( \Xi \) which is 1-periodic in all the variables \( x = (x_1, \ldots, x_n) \). For a given orbit \( (x(t), p(t)) \) of the associated Euler-Lagrange equation
\[
\dot{x} = p \quad ; \quad \dot{p} + \nabla_x \Xi = 0,
\]
(2.2)
a rotation vector \( J \in \mathbb{R}^n \) is assigned to this orbit provided the limit
\[
J = \lim_{|t| \to \infty} t^{-1} x(t)
\]
exists. As a trivial example, consider the \( x \)-independent Lagrangian where \( \Xi \equiv 0 \). Since \( p \) is a constant of motion and \( \dot{x} = p \), the rotation vector is defined for each orbit via \( J = p \). For general \( \Xi \) the rotation vector is not defined for any orbit, in general. The object of the classical KAM theory (see, e.g. [GCJ]) is the study of small perturbation of an integrable system, e.g. for Lagrangians of the form (2.1) where the potential \( \Xi \) is small. In particular, it studies families of solutions of such systems which preserve the rotation vector.

In the eighties, Aubry [A] and Mather [Mat] (see also [Mo]) discovered that Lagrangian flows which induce a monotone, symplectic twist maps on a two dimensional annulus, possess orbits of any given rotation number (in the twist interval), even if the corresponding Lagrangian is not close to an integrable one. The characterization of these orbits is variational: They are minimizers of the Lagrangian action with respect
to any local variation of the orbit. In general, they are embedded in invariant tori of the Lagrangian flow.

There is still another approach to invariant tori of Lagrangian/Hamiltonian systems. An invariant Lagrangian torus can be obtained as a solution of the corresponding Hamilton-Jacobi equation as follows: Suppose there exists, for some $P \in \mathbb{R}^n$, solution $\phi \in C^{1,1}(\mathbb{R}^n)$ which is 1-periodic in each of the coordinates $x_j$ of $x = (x_1, \ldots x_n)$, for

$$\frac{1}{2}\lvert \nabla \phi(x) + P \rvert^2 + \Xi(x) = E, \quad E \in \mathbb{R}. \quad (2.3)$$

Then the graph of the function $(x, P + \nabla \phi(x))$ represents an invariant torus of the Lagrangian flow associated with $L$ [Man]. The projection on $x$ of any orbit in this invariant set is obtained by a solution of the system

$$\dot{x} = P + \nabla \phi(x). \quad (2.4)$$

In the case $n = 2$ the rotation vector $J \in \mathbb{R}^2$ is defined as in (2.3) for any such orbit, given by (2.4).

### 2.2 Weak KAM and minimal invariant measures

For dimension higher than 2, there are counter-examples: There exists a Lagrangian system on the 3 dimensional torus, induced by a metric on this torus, for which there are no minimal geodesics, save for a finite number of rotation vectors [H]. Moreover, it is not known that the limit (2.3) exists for any orbit of (2.4), if $n > 2$. Hence, an extension of Aubry-Mather theory to higher dimensions is not a direct one. If, however, we replace the notion of an orbit by an invariant measure, then it is possible to extend the Aubry-Mather theory to higher dimensions. The relaxation of orbits to invariant measures (and the corresponding minimal orbits to minimal invariant measures) leads to the ”weak KAM Theory”.

Let $\mathcal{M}_L$ be the set of all probability measures on the tangent bundle $\mathbb{T}^n \times \mathbb{R}^n$ which are invariant with respect to the flow induced by the Lagrangian $L$. The rotation vector
\( \alpha : \mathcal{M}_L \to \mathbb{R}^n \) is
\[
\alpha(\nu) := \int_{T^n \times \mathbb{R}^n} p \, d\nu(x, p), \tag{2.5}
\]
and, for any \( \alpha \in \mathbb{R}^n \), the set of all \( \mathcal{M}_L^J \subset \mathcal{M}_L \) corresponds to all \( \nu \in \mathcal{M}_L \) for which \( \alpha(\nu) = J \).

A minimal measure associated with a rotation vector \( \alpha \) is defined by
\[
\nu_J = \arg \min_{\nu \in \mathcal{M}_L^J} \int_{T^n \times \mathbb{R}^n} L \, d\nu \in \mathcal{M}_L^J. \tag{2.6}
\]
Its dual representation is given by minimizing the Lagrangian \( L^P := L(p, x) - P \cdot p \) over the whole set of invariant measures \( \mathcal{M}_L \). The measure \( \nu_P \in \mathcal{M}_L \) is called a Mather measure if
\[
\nu_P = \arg \min_{\nu \in \mathcal{M}_L} \int_{T^n \times \mathbb{R}^n} L^P \, d\nu \in \mathcal{M}_L. \tag{2.7}
\]
These minimal measures are relaxations of minimal invariant orbits of the Aubry-Mather theory. Their properties and the geometry of their supports are the fundamental ingredients of the developing weak KAM theory. For further details, see [Mat1], [Man], [F] or consult [S] for applications and further references.

It should be stressed, however, that the investigation of the functional \( F \) carried in the present paper is not restricted to minimal (Mather) measures. In fact, Mather measures (and their \( T^n \) projections) are defined only for smooth enough Lagrangian systems which allow the existence of dynamics, e.g. \( (2.1) \) where \( \Xi \in C^{1,1}(\mathbb{T}^n) \).

Since we are motivated, between other things, by quantum dynamics and wave equation, we must assume much less, e.g the Schrödinger equation \( (1.3) \) is well posed if the potential \( \Xi \) is only continuous.

\(^1\)Note that \( \nu \) is an invariant measure of \( L \) if and only if it is an invariant measure of \( L_P \).
3 An overview of the main results

3.1 List of symbols and definitions

1. $\mathbb{T}^n = \mathbb{R}^n / \mathbb{Z}^n$ the $n$–dimensional flat torus. It is parameterized by $x = (x_1, \ldots, x_n) \mod \mathbb{Z}^n$. The Euclidian distance $\|x - y\|_{\mathbb{T}^n}$ on $\mathbb{T}^n$ is defined as $\min_{z \in \mathbb{Z}^n} |x - y - z|$, where $x, y \in \mathbb{R}^n$ and $| \cdot |$ is the Euclidian norm on $\mathbb{R}^n$.

2. $\mathbb{T}^n \times \mathbb{R}^n$ is the tangent bundle of $\mathbb{T}^n$, that is, $\mathbb{T}^n \times \mathbb{R}^n := \mathbb{R}^n \times \mathbb{T}^n$. A vector in $\mathbb{R}^n$ is denoted by a bold letter, e.g. $\mathbf{v}$. The same symbol will also define a vector field, that is, a section in $\mathbb{T}^n \times \mathbb{R}^n$, e.g $\mathbf{v} = \mathbf{v}(x)$.

3. $\mathcal{M}(D)$ stands for the set of all probability normalized Borel measures $\mu$ on some metric space $D$, subjected to the dual topology of $C(D)$: $|\mu| := \sup_{\phi \in C(D), |\phi|_{\infty} = 1} \int_D \phi d\mu$. We denote $\overline{\mathcal{M}} := \mathcal{M}(\mathbb{T}^n)$ as the set of all such measures on the torus $\mathbb{T}^n$.

4. A Borel map $S : D_1 \to D_2$ induces a map $S_\# : \mathcal{M}(D_1) \to \mathcal{M}(D_2)$, as follows: $S_\# \mu(A) := \mu(S^{-1}(A))$ for any Borel set $A \in D_2$. $S_\# \mu$ is called the push-forward of $\mu \in \mathcal{M}(D_1)$ into $\mathcal{M}(D_2)$.

5. $\pi : \mathbb{T}^n \times \mathbb{R}^n \to \mathbb{T}^n$ is the projection (natural embedding) of $\mathbb{T}^n$ in $\mathbb{T}^n \times \mathbb{R}^n$, namely $\pi(x, p) = x$ for $(x, p) \in \mathbb{T}^n \times \mathbb{R}^n$. In particular, $\pi_\# : \mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n) \to \overline{\mathcal{M}}$ so $\mu = \pi_\# \nu \in \overline{\mathcal{M}}$ is the $\mathbb{T}^n$ marginal of $\nu \in \mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n)$.

6. $\overline{\mathcal{M}}_T := C([0, T], \overline{\mathcal{M}})$. An element $\hat{\mu} \in \overline{\mathcal{M}}_T$ is denoted by $\hat{\mu} := \mu(t)$, $0 \leq t \leq T$. For any $\mu_1, \mu_2 \in \overline{\mathcal{M}}$, the set $\overline{\mathcal{M}}_T(\mu_1, \mu_2) \subset \overline{\mathcal{M}}$ is defined as all $\hat{\mu} \in \overline{\mathcal{M}}_T$ for which $\mu(0) = \mu_1, \mu(T) = \mu_2$. If $\mu_1 = \mu_2 \equiv \mu$ we denote $\overline{\mathcal{M}}_T(\mu) := \overline{\mathcal{M}}_T(\mu, \mu)$.

7. $\overline{\mathcal{M}}^{(2)} := \mathcal{M}(\mathbb{T}^n \times \mathbb{T}^n)$ and $\Pi_i : \mathbb{T}^n \times \mathbb{T}^n \to \mathbb{T}^n$ the projection on the $i$ factor, $i = 1, 2$. For $\mu_1 \in \overline{\mathcal{M}}$, $\mu_2 \in \overline{\mathcal{M}}$ define $\overline{\mathcal{M}}^{(2)}(\mu_1, \mu_2)$ as the set of all $\sigma \in \overline{\mathcal{M}}^{(2)}$ for which $\Pi_{i, \#} \sigma = \mu_i$, $i = 1, 2$. $\overline{\mathcal{M}}^{(2)}(\mu) := \overline{\mathcal{M}}^{(2)}(\mu, \mu)$.

8. $C^1(\mathbb{T}^n)$ is the set of all $C^1$ smooth functions on $\mathbb{T}^n$. 

12
9. Recall the definition of a subgradient of a function $h : B \to \mathbb{R}$ defined on a Banach space $B$: For $b \in B$,

$$\partial_b h := \left\{ b^* \in B^* , h(b') \geq h(b) + \langle b' - b, b^* \rangle \right\} \text{ For any } b' \in B.$$

3.2 $F$ and its generalized minimizers

There is a close relation between the minimal (Mather) measures described in Section 2 and the minimizer of the function $F$ defined in (1.6), where $\rho$ is the density of the $\mathbb{T}^n$ marginal of a minimal measure.

In general, however, there are no smooth densities to the marginals of minimal measures on $\mathbb{T}^n$. Motivated by this, we extend the definition of $F$ to the set $\overline{\mathcal{M}}$ of all probability Borel measures on $\mathbb{T}^n$:

$$F(\mu, P) := \frac{1}{2} \inf_{\phi \in C^1(\mathbb{T}^n)} \int_{\mathbb{T}^n} |\nabla \phi + P|^2 d\mu \quad (3.1)$$

and

$$F^*(\mu, J) := \sup_{P \in \mathbb{R}^n} [P \cdot J - F(\mu, P)] \quad (3.2)$$

its convex dual on $\mathbb{R}^n$.

The first question we address is the existence of minimizers of (3.1) for a general measure $\mu \in \overline{\mathcal{M}}$. Evidently, there is no sense of solutions to the elliptic problem (1.9) for such $\mu$. Our first result, given in Theorem 4.1, indicates the existence and uniqueness of a minimizer in a generalized sense (see Definition 4.2 below). In Theorem 4.2 we discuss the relation between these minimizers and the solutions of the elliptic problem (1.9).

3.3 The Effective Hamiltonian

The second question concerns the maximizers of (1.14), extended to the entire set $\overline{\mathcal{M}}$. Let

$$\tilde{H}_\Xi(P) := \sup_{\mu \in \overline{\mathcal{M}}} \left[ F(\mu, P) + \int_{\mathbb{T}^n} \Xi d\mu \right], \quad (3.3)$$
where $\Xi \in C(T^n)$. Theorem 4.3 relates the generalized minimizers of Theorem 4.1 to the minimal (Mather) measure associated with the Lagrangian (2.1) corresponding to $P$ via (2.7). It claims that, if $\Xi \in C^{1,1}(T^n)$, then the generalized solution of $F(\mu, P)$ corresponding to $\mu$ which maximizes (3.3) is, indeed, a Mather measure associated with the Lagrangian (2.1). In this sense, the weak minimizers of Theorem 4.1 can be considered as generalized Mather measures for Lagrangians with only continuous potentials.

3.4 On the continuity of $F$

The third question addressed is the continuity property of $F$ with respect to $\mu$. It is rather easy to observe that $F$ is convex in $P$ on $\mathbb{R}^n$, and concave in $\mu$ on $\overline{\mathcal{M}}$. These imply that $F$ is continuous on $\mathbb{R}^n$, but only upper-semi-continuous in the natural topology of $\overline{\mathcal{M}}$, which is the weak-* topology induced by $C^*(T^n)$. That is, if $\mu_j \to \mu$ in $C^*(T^n)$, then

$$\lim_{j \to \infty} F(\mu_j, P) \leq F(\mu, P)$$

holds. In general, there is no continuity of $F$ over $\overline{\mathcal{M}}$ with the $C^*$ topology.

Examples:

1. For any atomic measure $\mu = \sum m_i \delta_{x_i} \in \overline{\mathcal{M}}$, we can easily verify that $F(\mu, P) \equiv 0$ for any $P \in \mathbb{R}^n$. In particular, if $\mu_N$ is a sequence of empirical measures: $\mu_N := N^{-1} \sum_{i=1}^N \delta_{x_i}$ satisfying $\mu_N \to \mu \in \overline{\mathcal{M}}$ in $C^*(T^n)$, then the inequality in (3.4) is strict whenever $F(\mu, P) > 0$.

2. Let $n = 1$, so $T^n$ is reduced to the circle $S^1$. Suppose $\mu \in \overline{\mathcal{M}}(S^1)$ admits a smooth density $\mu(dx) = \rho(x)dx$. If $\rho > 0$ on $S^1$ then the continuity equation (1.9) reduces to a constant $j = \rho(\phi_x + P)$. This implies

$$F(\mu, P) = \frac{1}{2} \int_{S^1} \rho|\phi_x + P|^2 dx = \frac{j^2}{2} \int_{S^1} \rho^{-1} dx$$

(3.5)
as well as  
\[
\int_{S^1} \rho^{-1}dx = \int_{S^1} j^{-1}(\phi_x + P)dx = \frac{P}{j} \implies j = P \left( \int_{S^1} \rho^{-1}dx \right)^{-1}.
\]
Substitute in (3.5) to obtain  
\[
F(\mu, P) = \frac{|P|^2}{2} \left( \int_{S^1} \rho^{-1}dx \right)^{-1}.
\]
In particular,  
\[
\int_{S^1} \rho^{-1}dx = \infty \iff F(\mu, P) = 0 \text{ for } P \neq 0.
\]
Any sequence  
\[
\mu_j(dx) = \rho_j(x)dx
\]
satisfying  
\[
\int_{S^1} \rho_j^{-1} = \infty \text{ which converges in } C^*(S^1) \text{ to } \mu(dx) = \rho(x)dx
\]
satisfying  
\[
\rho \in C^1(S^1), \rho > 0 \text{ on } S^1,
\]
is an example of strict inequality in (3.4).

### 3.5 Lagrangian mappings

In Theorem 4.4 we show that  
\[ F \]  
can be approximated, as a function on  \( \overline{\mathcal{M}} \), by a weakly continuous function  
\[ F^T(\cdot, P) \]  
which satisfies  
\[ F^T(\mu, P) \to F(\mu, P) \]  
as  \( T \to 0 \), for any  \( \mu \in \overline{\mathcal{M}} \). For this, we represent an extension of  \( F \) to orbits  \( \hat{\mu} : [0, T] \to \overline{\mathcal{M}} \),  
\( \hat{\mu}|_t = \mu(t) \in \overline{\mathcal{M}}, t \in [0, T] \), given by  
\[
F(\hat{\mu}, P, T) := \frac{1}{T} \inf_{\phi \in C^1([T^n \times (0, T)])} \int_0^T \int_{T^n} \left[ \frac{\partial \phi}{\partial t} + \frac{1}{2} |\nabla_{x} \phi + P|^2 \right] d\mu(t) dt,
\]
and set  \( F^T(\mu, P) \) as the supremum of  \( F(\hat{\mu}, P, T) \) over all such orbits satisfying  \( \mu|_0 = \mu_0 \in \overline{\mathcal{M}} \),  
\( \hat{\mu}|_T = \mu(T) = \mu \). It is shown that  
\[ F^T(\mu, P) = |P|^2/2 - D_TP(\mu)/(2T^2) \]
where  \( D_P(\mu) \) is defined by the optimal Monge-Kantorovich transport plant from  \( \mu \) to itself, subjected to the cost function  \( c(x, y) := \|x - y - P\|_{T^n}^2 \), where  \( \| \cdot \|_{T^n} \) is the Euclidean metric on  \( T^n \).

As an example, consider the case  \( \mu = \delta_{x_0} \) for some  \( x_0 \in T^n \). Then  \( D_P(\delta_{x_0}) = |\{P\}|^2 \), where  \( \{ \cdot \} \) stands for the fractional part  \( \{P\} := P \mod Z^n \). So  
\[
F^T(\delta_{x_0}, P) = |P|^2/2 - |\{PT\}|^2/(2T^2).
\]
If  \( T \) is sufficiently small so  \( \{TP\} = TP \) then  \( F^T(\delta_{x_0}, P) = 0 \).
3.6 Combinatorial search for the minimal measure

Our last object is to suggest an alternative to the numerical algorithm for the calculation of the effective Hamiltonian based on (1.15), introduced in [GO]. We take an advantage of the following facts

i) An optimal transportation functional (such as \( F_T(\mu, P) \)) are continuous in the weak topology of \( \overline{\mathcal{M}} \).

ii) The set of empirical measures is dense in the set of all measures \( \overline{\mathcal{M}} \).

iii) On the set of empirical measures of a fixed number of sampling points \( j \), an optimal transportation problem is reduced to a finite combinatorial problem on the set of permutation on \( \{1, \ldots, j\} \) (Birkhoff’s Theorem).

Applying (i-iii) to the result of Theorem 4.4, we obtain a discrete, combinatorial algorithm for evaluating the effective Hamiltonian \( \hat{H}_\Xi(P) \). This is summarized in Theorem 4.6.

4 Detailed description of the main results

4.1 Minimizers of the Dirichlet functional over the \( n \)-torus

Let us recall the definition, for \( P \in \mathbb{R}^n \), \( J \in \mathbb{R}^n \) and \( \mu \in \overline{\mathcal{M}} \):

\[
F(\mu, P) := \frac{1}{2} \inf_{\phi \in C^1(\mathbb{T}^n)} \int_{\mathbb{T}^n} |\nabla \phi + P|^2 d\mu ,
\]

\[
F^*(\mu, J) := \sup_{P \in \mathbb{R}^n} \left[ P \cdot J - F(\mu, P) \right]
\]

Let also \( \mathcal{E} \) a function on \( \overline{\mathcal{M}} \times \mathbb{R}^n \times C^1(\mathbb{T}^n) \) defined as:

\[
\mathcal{E}(\mu, J, \phi) := \frac{1}{2} \left\{ J - \int_{\mathbb{T}^n} \nabla \phi d\mu \right\}^2 - \int_{\mathbb{T}^n} |\nabla \phi|^2 d\mu .
\]

Next, we consider the notion of weak solution of (1.9), corresponding to the minimizer of (4.1):
Definition 4.1.:

1. The set $\Lambda \subset \mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n)$ consists of all probability measures $\nu(dx dp)$ for which
   \[\int_{\mathbb{T}^n \times \mathbb{R}^n} p \cdot \nabla \theta(x) d\nu = 0 \quad \forall \theta \in C^1(\mathbb{T}^n) \quad \text{and} \quad \int_{\mathbb{T}^n \times \mathbb{R}^n} |p|^2 d\nu < \infty .\]

2. Given $\mu \in \overline{\mathcal{M}}$, the set $\Lambda_\mu \subset \Lambda$ of liftings of $\mu$ is composed of all $\nu \in \Lambda$ for which $\pi_# \nu = \mu$.

3. For each $J \in \mathbb{R}^n$, the set $\Lambda^J_\mu$ is defined as all $\nu \in \Lambda_\mu$ which satisfies
   \[\int_{\mathbb{T}^n \times \mathbb{R}^n} p d\nu = J .\]

Remark 4.1. The set $\Lambda_\mu$ is never empty. Indeed, $\nu = \delta_p^0 \otimes \mu \in \Lambda_\mu$ for any $\mu \in \overline{\mathcal{M}}$. However, the set $\Lambda^J_\mu$ can be empty. For example, if $F(\mu, P) = 0$ for all $P \in \mathbb{R}^n$ then $\Lambda^J_\mu = \emptyset$ for any $J \neq 0$.

Definition 4.2. For given $P \in \mathbb{R}^n$, $\nu \in \Lambda_\mu$ is a weak solution of $F(\mu, P)$ provided
   \[\int_{\mathbb{T}^n \times \mathbb{R}^n} \left[ \frac{|p|^2}{2} - p \cdot P \right] d\nu \leq \int_{\mathbb{T}^n \times \mathbb{R}^n} \left[ \frac{|p|^2}{2} - p \cdot P \right] d\xi ; \forall \xi \in \Lambda_\mu .\]

The existence and uniqueness of weak solution is described in Theorem 4.1 below.

Theorem 4.1. For any $\mu \in \overline{\mathcal{M}}$ and $P \in \mathbb{R}^n$, there exists a unique weak solution $\nu \in \Lambda_\mu$ of $F(\mu, P)$. Moreover,
   \[F(\mu, P) = -\int_{\mathbb{T}^n \times \mathbb{R}^n} \left[ \frac{|p|^2}{2} - p \cdot P \right] d\nu , \tag{4.4}\]

and
   \[F^*(\mu, J) = \frac{1}{2} \inf_{\nu \in \Lambda_\mu} \int_{\mathbb{T}^n \times \mathbb{R}^n} |p|^2 d\nu , \tag{4.5}\]

where the RHS of (4.5) is attained for the weak solution of $F(\mu, P)$, provided\footnote{The existence of a subgradient of $F$ with respect to $P$, among other results, is stated and proved in Lemma 5.1, section 5.2.} $J \in \partial_P F(\mu, P)$.
If $\mu(dx) = \rho(x)dx$ where $\rho \in C^1(T^n)$ and $\rho > 0$ on $T^n$, then a weak solution $\nu$ of $F(\mu, P)$ takes the form $\nu(dx dP) = \delta_{P+\nabla \phi(x)} \otimes \rho(x)dx$ where $\phi$ is the classical solution of the elliptic equation.

$$\nabla [\rho(\nabla_x \phi + P)] = 0 \quad \text{on} \ T^n.$$ \hfill (4.6)

**Remark 4.2.** Equation (4.6) is strongly elliptic equation if $\rho > 0$, so it has a unique (up to a constant), classical solution. See, e.g. [GT].

**Remark 4.3.** As a by-product we obtain the relation

$$F^*(\mu, J) = \inf_{\phi \in C^1(T^n)} \mathcal{E}(\mu, J, \phi),$$

see Lemma 5.1-(3).

**Example 1:** If $\mu(dx) = \alpha \rho(x)dx + (1 - \alpha)\delta_{x_0}$ then the weak solution associated with $P \in \mathbb{R}^n$ is

$$\nu = \delta_{P+\nabla \phi} \otimes \alpha \rho(x)dx + (1 - \alpha)\delta_0 \otimes \delta_{x_0},$$

where $\phi$ is the classical solution of (4.6).

We may observe that $F$ is concave on $\overline{M}$ for fixed $P \in \mathbb{R}^n$. In particular, it is *upper-semi-continuous* in the $C^*$ topology of $\overline{M}$:

$$\lim_{n \to \infty} F(\mu_n, P) \leq F(\mu, P)$$ \hfill (4.7)

whenever $\mu_n \to \mu$ in $C^*(\mathbb{T}^n)$.

**Example 2:** If $\mu_n$ is an atomic measure then $F(\mu_n, P) = 0$ for any $P \in \mathbb{R}^n$. In particular, if $\mu_n = n^{-1} \sum_{j=1}^n \delta_{x_j^{(n)}}$ is a sequence of empirical measures approximating $\mu \in \overline{M}$ then the L.H.S of (4.7) is identically zero.

In Theorem 4.2 and Corollary 4.1 we demonstrate that, in an appropriate sense, any weak solution is a limit of classical ones.

**Theorem 4.2.** If $\lim \mu_j = \mu$ in $C^*(\mathbb{T}^n)$ and

$$\lim_{j \to \infty} F(\mu_j, P) = F(\mu, P)$$ \hfill (4.8)
holds, then there exists a subsequence of weak solutions \( \nu_j \) of \( F(\mu_j, P) \) along which
\[
\lim_{j \to \infty} \nu_j = \nu \tag{4.9}
\]
holds in \( C^*(\mathbb{T}^n \times \mathbb{R}^n) \), where \( \nu \) is a weak solution of \( F(\mu, P) \).

Moreover, there exists a sequence of smooth measures \( \mu_j = \rho_j dx \) so that \( \rho_j \in C^\infty(\mathbb{T}^n) \) and \( \rho_j > 0 \) on \( \mathbb{T}^n \), for which (4.8) holds for any \( P \in \mathbb{R}^n \).

**Corollary 4.1.** The weak solution of \( F(\mu, P) \) is the weak limit
\[
\lim_{j \to \infty} \delta_{P - \nabla \phi_j} dp \otimes \rho_j dx = \nu
\]
where \( \phi_j \) are the solutions of
\[
\nabla \cdot (\rho_j(\nabla \phi_j + P)) = 0
\]
and \( \mu_j = \rho_j dx \to \mu \) as guaranteed by Theorem 4.2.

**Definition 4.3.** Given a continuous function \( \Xi \in C(\mathbb{T}^n) \),
\[
\hat{H}_\Xi^*(J) := \sup_{\mu \in \mathcal{M}} \int \Xi d\mu - F^*(\mu, J) \tag{4.10}
\]
Likewise
\[
\hat{H}_\Xi(\mu) := \sup_{\mu \in \mathcal{M}} \int \Xi d\mu + F(\mu, P) \tag{4.11}
\]

**Lemma 4.1.** \( \hat{H}_\Xi^* \) is the negative of the convex dual of \( \hat{H}_\Xi \) with respect to \( \mathbb{R}^n \). Than is:
\[
\hat{H}_\Xi^*(J) = -\sup_{P \in \mathbb{R}^n} \left\{ P \cdot J - \hat{H}_\Xi(\mu) \right\}.
\]

**Proposition 4.1.** \( \hat{H}_\Xi(\mu) \geq \max_{\mathbb{T}^n} \Xi \) and \( \hat{H}_\Xi^*(J) \geq \max_{\mathbb{T}^n} \Xi \) hold for any \( P, J \in \mathbb{R}^n \). If \( |P| \) (res. \( |J| \)) is large enough, then the inequality is strong.

**Open problem:** Is \( \hat{H}_\Xi(\mu) > \max_{\mathbb{T}^n} \Xi \) for any \( P \neq 0 \)?

**Lemma 4.2.** For any \( \Xi \in C(\mathbb{T}^n) \) \( P \in \mathbb{R}^n \) there exists \( \mu_0 \in \mathcal{M} \) verifying the maximum in (4.11). There exists \( J \in \partial F(\mu_0, \Xi) \subset \partial \hat{H}_\Xi(\cdot) \) for which \( \mu_0 \) verifies the maximum in (4.10).
We end this section by stating the connection between maximizers of $\hat{H}_\Xi$ and $\hat{H}_\Xi^*$ and the minimal invariant measures of the weak-KAM theory:

**Theorem 4.3.** If $\Xi$ is smooth enough (say, $\Xi \in C^2(\mathbb{T}^n)$) and $\nu$ is a Mather measure \((2.7)\) of the Lagrangian $L = |p|^2/2 - \Xi(x) - p \cdot P$ on $\mathbb{T}^n \times \mathbb{R}^n$ and $\mu = \pi_#\nu$ then $\nu$ is weak solution of $F(\mu, P)$, and is a maximizer of $\hat{H}_\Xi(P)$ in \((4.11)\).

Moreover, $\nu$ verifies \((2.0)\) where $J$ is the rotation number $\alpha(\nu)$ given by \((2.5)\).

### 4.2 Extension to time dependent measures

We now extend the definition of $F$ and $F^*$ to the set of $\overline{\mathcal{M}}$–valued orbits on the interval $[0, T]$.

Define, for $\hat{\mu} \in \overline{\mathcal{M}}_T$

$$F(\hat{\mu}, P, T) := \frac{1}{T} \inf_{\phi \in C^1_0(\mathbb{T}^n \times (0, T))} \int_0^T \int_{\mathbb{T}^n} \left[ \frac{\partial \phi}{\partial t} + \frac{1}{2} |\nabla x \phi + P|^2 \right] d\mu(t) dt . \quad (4.12)$$

Let also $\mathcal{E}$ a function on $\overline{\mathcal{M}}_T \times \mathbb{R}^n \times C^1(\mathbb{T}^n \times (0, T))$ defined as:

$$\mathcal{E}(\hat{\mu}, J, \phi, T) := \left\{ \frac{1}{2} J - \frac{1}{T} \int_0^T \int_{\mathbb{T}^n} \nabla \phi d\mu(t) dt \right\}^2 - \frac{1}{T} \int_0^T \int_{\mathbb{T}^n} \left( \phi_t + \frac{1}{2} |\nabla \phi|^2 \right) d\mu(t) dt \right\} . \quad (4.13)$$

The analog of Definition 4.1 is

**Definition 4.4.**

1. The set $\hat{\Lambda}_T \subset \mathcal{M}_T$ consists of all orbits of probability measures $\hat{\nu} : [0, T] \to \mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n)$, $\hat{\nu}_{|t} := \nu_{|t} \in \mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n)$, for which

$$\int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} (\theta_t + p \cdot \nabla x \theta(x, t)) d\nu(t) dt = 0 \quad \forall \theta \in C^1_0(\mathbb{T}^n \times (0, T)) \text{ and } \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}} |p|^2 d\nu(t) dt < \infty .$$

2. Given $\hat{\mu} \in \overline{\mathcal{M}}_T$, the set $\hat{\Lambda}_{T;\hat{\mu}} \subset \Lambda$ of liftings of $\hat{\mu}$ is composed of all $\hat{\nu} \in \hat{\Lambda}_T$ for which $\pi_#\hat{\nu} = \hat{\mu}$, that is, $\pi_#\nu_{|t} = \mu_{|t}$ for any $t \in [0, T]$.

\(^3\)See point 6 in section 3.1.
3. For each $J \in \mathbb{R}^n$, the set $\hat{\Lambda}_{T,\mu}$ is defined as all $\hat{\nu} \in \hat{\Lambda}_{T,\mu}$ which satisfies

$$T^{-1} \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} p \nu_{(t)} dt = J.$$ 

Definition 4.5. For given $P \in \mathbb{R}^n$, $\hat{\nu} \in \hat{\Lambda}_{T,\mu}$ is a weak solution of $F(\hat{\mu}, P, T)$ provided

$$\int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} \left[ \frac{|p|^2}{2} - p \cdot P \right] d\nu_{(t)} dt \leq \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} \left[ \frac{|p|^2}{2} - p \cdot P \right] d\xi_{(t)} ; \forall \xi \in \hat{\Lambda}_{T,\mu}.$$ 

The $T-$orbit analogue of Theorem 4.1 is

Proposition 4.2. For any $\hat{\mu} \in \mathcal{M}_T$ and $P \in \mathbb{R}^n$, there exists a unique weak solution $\hat{\nu}^{(0)} \in \hat{\Lambda}_{T,\mu}$ of $F(\hat{\mu}, P, T)$. Moreover,

$$F(\hat{\mu}, P, T) = -\frac{1}{T} \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} \left[ \frac{|p|^2}{2} - p \cdot P \right] d\nu_{(0)} dt = -\inf_{\hat{\nu} \in \hat{\Lambda}_{T,\mu}} \frac{1}{T} \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} \left[ \frac{|p|^2}{2} - p \cdot P \right] d\nu_{(t)} dt. \tag{4.14}$$

The Legendre transform of $F(\hat{\mu}, P, T)$ with respect to $P$ is

$$F^*(\hat{\mu}, J, T) = \sup_{\phi \in C^1_0(T^n \times (0,T))} \mathcal{E}(\hat{\mu}, J, \phi) = \frac{1}{T} \inf_{\hat{\nu} \in \hat{\Lambda}_{T,\mu}} \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} \left[ \frac{|p|^2}{2} - p \cdot P \right] d\nu_{(t)} dt, \tag{4.15}$$

where the RHS of (4.15) is attained for the weak solution of $F(\hat{\mu}, P, T)$, provided $J \in \partial_P F(\hat{\mu}, P, T)$.

If $\mu_{(t)}(dx) = \rho(x, t)dx$ where $\rho \in C_0^1(T^n \times (0,T))$ and $\rho > 0$ on $T^n \times [0,T]$ then a weak solution $\hat{\nu}$ of $F(\hat{\mu}, P, T)$ takes the form $\nu_{(t)} = \delta_{p - P - \nabla_x \phi(x,t)} dp \otimes \rho(x, t)dx$ where $\phi$ is the classical solution of the elliptic equation.

$$\nabla_x [\rho(\nabla_x \phi + P)] = -\rho_t. \tag{4.16}$$

Definition 4.6. Given $\mu_1, \mu_2 \in \mathcal{M}$, $P \in \mathbb{R}^n$ and $\Xi \in C(T^n)$, define

$$H_{\Xi,T}(\mu_1, \mu_2, P) := \sup_{\hat{\mu} \in \mathcal{M}_T(\mu_1, \mu_2)} \left[ \frac{1}{T} \int_0^T \int_{\mathbb{T}^n} \Xi d\mu_{(t)} dt + F(\hat{\mu}, P, T) \right]. \tag{4.17}$$

$^4$Recall section 3.1 (15).
Likewise, for any $J \in \mathbb{R}^n$:

$$H^\ast_{\Xi,T}(\mu_1, \mu_2, J) := \sup_{\hat{\mu} \in \overline{\mathcal{M}}(\mu_1, \mu_2)} \left[ \frac{1}{T} \int_0^T \int_{\mathbb{T}^n} \Xi d\mu(t) dt - F^\ast(\hat{\mu}, J, T) \right]. \quad (4.18)$$

If $\mu_1 = \mu_2 \equiv \mu \in \overline{\mathcal{M}}$ then $H_{\Xi,T}(\mu, P) := H_{\Xi,T}(\mu, \mu, P)$ and $H^\ast_{\Xi,T}(\mu, J) := H^\ast_{\Xi,T}(\mu, \mu, J)$.

If $\Xi \equiv 0$, set $F_T(\mu, P) := H^0_{\Xi,T}(\mu, P)$ and $F^\ast_T(\mu, J) := -H^\ast_{0,T}(\mu, J)$.

**Proposition 4.3.** For any $\Xi \in C(\mathbb{T}^n)$, $P \in \mathbb{R}^n$ and $\mu_1, \mu_2 \in \overline{\mathcal{M}}$ there exists an orbit $\hat{\mu} \in \overline{\mathcal{M}}(\mu_1, \mu_2)$ realizing (4.17). Likewise, for any $J \in \mathbb{R}^n$ there exists an orbit $\hat{\mu} \in \overline{\mathcal{M}}(\mu_1, \mu_2)$ realizing (4.18).

**Proposition 4.4.** For any $T > 0$, $\Xi \in C(\mathbb{T}^n)$, $P \in \mathbb{R}^n$ and $\mu \in \overline{\mathcal{M}}$,

$$H_{\Xi,T}(\mu, P) \geq \int_{\mathbb{T}^n} \Xi d\mu + F_T(\mu, P) \geq \int_{\mathbb{T}^n} \Xi d\mu + F(\mu, P), \quad (4.19)$$

but

$$\sup_{\mu \in \overline{\mathcal{M}}} H_{\Xi,T}(\mu, P) = \hat{H}_\Xi(P) := \sup_{\mu \in \overline{\mathcal{M}}} \int_{\mathbb{T}^n} \Xi d\mu + F(\mu, P) = \sup_{\mu \in \overline{\mathcal{M}}} \int_{\mathbb{T}^n} \Xi d\mu + F_T(\mu, P) \forall T > 0, \quad (4.20)$$

and the maximizer of $\hat{H}_\Xi(P)$ (4.11) is the same as the maximizer of $H_{\Xi,T}(\mu, P)$ for any $T > 0$.

**4.3 Optimal transportation**

Recall the definition of the action associated with the Lagrangian (2.1):

$$A^\Xi_P : \mathbb{T}^n \times \mathbb{T}^n \times \mathbb{R} \to \mathbb{R}:
A^\Xi_P(y, x, T) = \inf_{x(t)} \left\{ \frac{1}{T} \int_0^T \left( \frac{|\dot{x} - P|^2}{2} - \Xi(x(s)) \right) ds \right\} ; \quad x(0) = y, x(t) = x, \right\} \quad (4.21)
$$

**Definition 4.7.** For $P \in \mathbb{R}^n$, $\mu_1, \mu_2 \in \overline{\mathcal{M}}$ define the Monge-Kantorovich distance with respect to the action $A^\Xi$:

$$D^T_{P}(\mu_1, \mu_2, \Xi) := \min_{\sigma \in \overline{\mathcal{M}}(\mu_1, \mu_2)} \int_{\mathbb{T}^n} A^\Xi_P(x, y, T) d\sigma(x, y). \quad (4.22)$$

---

5 Recall section 3.1-7.
If \( \mu_1 = \mu_2 \equiv \mu \in \mathcal{M} \) we denote
\[
D_T^P(\mu, \Xi) := \min_{\sigma \in \mathcal{M}^{[2]}(\mu)} \int_{\mathbb{T}^n} A^P_\Xi(x, y, T)d\sigma(x, y). \tag{4.23}
\]

**Example 4.1.** If \( \Xi \equiv 0 \) then \( A^P_0(y, x, T) = \|x - y - TP\|^2/(2T^2) \), where \( \| \cdot \| \) is the Euclidian metric on \( \mathbb{T}^n \). In particular
\[
D_T^P(\mu) := D_T^P(\mu, 0) = \min_{\sigma \in \mathcal{M}^{[2]}(\mu)} \frac{1}{2T^2} \int_{\mathbb{T}^n} \|x - y - TP\|^2d\sigma(x, y). \tag{4.24}
\]

**Proposition 4.5.** For any \( \mu_1, \mu_2 \in \mathcal{M}, \Xi \in C(\mathbb{T}^n), P \in \mathbb{R} \) and \( T > 0 \)
\[
H_{\Xi, T}(\mu_1, \mu_2, P) = \frac{|P|^2}{2} - D_T^P(\mu_1, \mu_2, \Xi). \]
In particular
\[
H_{\Xi, T}(\mu, P) = \frac{|P|^2}{2} - D_T^P(\mu, \Xi). \tag{4.25}
\]

**Lemma 4.3.** \( D_T^P : \mathcal{M} \times C(\mathbb{T}^n) \to \mathbb{R} \) is continuous in both the weak \( C^* \) topology of \( \mathcal{M} \) and in the sup topology of \( C(\mathbb{T}^n) \).

**Proposition 4.6.** For any \( \mu \in \mathcal{M}, \Xi \in C(\mathbb{T}^n), P \in \mathbb{R} \)
\[
\lim_{T \to 0} H_{\Xi, T}(\mu, P) = \int_{\mathbb{T}^n} \Xi d\mu + F(\mu, P). \tag{4.26}
\]

As a corollary to (4.26) and Lemma 4.3 evaluated for \( \Xi = 0 \), we obtain

**Theorem 4.4.** The functional \( H_{\Xi, T} \) (Definition 4.6) is continuous on \( \mathcal{M} \) with respect to the \( C^* \) topology. In addition
\[
\lim_{T \to 0} H_{\Xi, T}(\mu, P) = H_{\Xi}(\mu, P)
\]
for any \( \mu \in \mathcal{M}, P \in \mathbb{R}^n \).

By definition 4.6 and Theorem 4.3

**Corollary 4.2.**
\[
\lim_{T \to 0} F_T(\mu, P) = F(\mu, P)
\]
for any \( \mu \in \mathcal{M}, P \in \mathbb{R}^n \).
4.4 A combinatorial search algorithm

Next, Birkhoff’s Theorem implies

**Lemma 4.4.** Given $x_1, \ldots, x_j \in T^n$. For $\mu_j := j^{-1} \sum_{i=1}^{j} \delta_{x_i}$,

$$D_P^T(\mu_j, \Xi) = \min_{\sigma \in \Pi_j} \sum_{i=1}^{j} A^\Xi_P(x_i, x_{\sigma(i)}; T)$$

where $\Pi_j$ is the set of all permutations of $\{1, \ldots, j\}$. In particular

$$D_P^T(\mu_j) = \frac{1}{2T^2} \min_{\sigma \in \Pi_j} \sum_{i=1}^{j} \|x_i - x_{\sigma(i)} - TP\|^2.$$ 

By Proposition 4.5, Theorem 4.4, Corollary 4.2 and Lemma 4.4 we obtain the following algorithm for evaluation of $H_\Xi(\mu, P)$ and $F(\mu, P)$:

**Theorem 4.5.** Let $\mu_j := j^{-1} \sum_{i=1}^{j} \delta_{x_{\sigma(i)}}$ is a sequence of measures converging $C^*$ to $\mu \in \mathcal{M}$. Then

$$\lim_{T \to 0} \lim_{j \to \infty} D_P^T(\mu_j, \Xi) = \frac{|P|^2}{2} - H_\Xi(\mu, P). \quad (4.27)$$

In particular

$$\lim_{T \to 0} \lim_{j \to \infty} \frac{1}{2T^2} \min_{\sigma \in \Pi_j} \sum_{i=1}^{j} \|x_i - x_{\sigma(i)} - T P\|^2 = \frac{|P|^2}{2} - F(\mu, P).$$

We may use now Theorem 4.5 to evaluate the effective Hamiltonian $\hat{H}_\Xi(P)$. In fact, we do not need to take the limit $T \to 0$, as shown below:

**Definition 4.8.** Given $j \in \mathbb{N}$, let

$$D_P^T(j, \Xi) := \min_{x_1, \ldots, x_j \in T^n} \min_{\sigma \in \Pi_j} \sum_{i=1}^{j} A^\Xi_P(x_i, x_{\sigma(i)}; T)$$

where $\Pi_j$ as defined in Lemma 4.4. Let also

$$\overline{D}_P^T(j, \Xi) := \min_{x_1, \ldots, x_j \in T^n} \min_{\sigma \in \Pi_j} \sum_{i=1}^{j} \left[(2T^2)^{-1} \|x_i - x_{\sigma(i)} - T P\|^2 + j^{-1} \Xi(x_i)\right]. \quad (4.28)$$

In particular, for $\Xi = 0$,

$$D_P^T(j, 0) = \overline{D}_P^T(j, 0) := D_P^T(j).$$
Theorem 4.6. For any \( \Xi \in C(\mathbb{T}^n) \), \( P \in \mathbb{R}^n \) and \( T > 0 \),
\[
\hat{H}_\Xi(P) = \frac{|P|^2}{2} - \lim_{j \to \infty} D_P^T(j, \Xi) .
\] (4.29)

5 Proof of the main results

5.1 Duality

The key duality argument for minimizing convex functionals under affine constraints is summarized in the following proposition. This is a slight generalization of Proposition 4.1 in [W1]. The proof is sketched in the appendix of [W1]).

Proposition 5.1. Let \( C \) a real Banach space and \( C^* \) its dual. Let \( Z \) a subspaces of \( C \). Let \( h \in C^* \). Let \( Z^* \subset C^* \) given by the condition \( z^* \in Z^* \) iff \( < z^* - h, z >= 0 \) for any \( z \in Z \). Let \( F : C^* \to \mathbb{R} \cup \{\infty\} \) a convex function and
\[
E := \inf_{c^* \in Z^*} F(c^*) .
\] (5.1)

Then
\[
\sup_{z \in Z} \inf_{c^* \in C^*} [F(c^*) - < c^* - h, z >] \leq E ,
\] (5.2)
and if \( A_0 := \{c^* \in C^* ; F(c^*) \leq E\} \) is compact (in the *- topology of \( C^* \)), then there is an equality in (5.2).

In particular, \( E < \infty \) if and only if \( Z^* \neq \emptyset \). In this case there exists \( z^* \in Z^* \) for which \( E = F(z^*) \).

Remark 5.1. The case \( E < \infty \) does not implies, in general, the existence of \( z \in Z \) realizing (5.2) .

5.2 An Auxiliary result

Lemma 5.1. .
1. F is convex on $\mathbb{R}^n$ as function of $P$ and concave on $\overline{M}$ as function of $\mu$.

2. $F^*$ is convex on both $\mathbb{R}^n$ (as a function of $J$) and $\overline{M}$.

3. $F^*(\mu, J) = \inf_{\phi \in C^1(\mathbb{T}^n)} \mathcal{E}(\mu, J, \phi)$.

4. The sub-gradients $\partial_P F(\mu, \cdot)$ and $\partial_J F^*(\mu, \cdot)$ are non-empty convex cones in $\mathbb{R}^n$ for any $\mu \in \overline{M}$ and $P \in \mathbb{R}^n$ (res. $J \in \mathbb{R}^n$) and satisfies $P \in \partial_J F^*(\mu, \cdot)$ iff $J \in \partial_P F(\mu, \cdot)$.

5. $F$ is upper-semi-continuous in the $C^\ast$ topology of $\overline{M}$ for any $P \in \mathbb{R}^n$, and $F^*$ is lower-semi-continuous for the same topology for any $J \in \mathbb{R}^n$.

In particular, from point (5) of this Lemma:

**Corollary 5.1.** If $x_0 \in \mathbb{T}^n$ and $\mu_n \to \delta_{x_0}$ then $\lim_{n \to \infty} F(\mu_n, P) = F(\delta_{x_0}, P) = 0$.

**Proof of Lemma 5.1.** Concavity of $F$ on $\overline{M}$ is a result of its definition as a n infimum of functionals over this convex set. The strict convexity on $\mathbb{R}^n$ follows from its quadratic dependence:

$$\frac{|P_1 + \nabla \phi_1|^2}{2} + \frac{|P_2 + \nabla \phi_2|^2}{2} \geq \left| \frac{P_1 + P_2}{2} + \frac{\nabla \phi_1 + \nabla \phi_2}{2} \right|^2,$$

holds for any $P_1, P_2 \in \mathbb{R}^n$ and any $\phi_1, \phi_2 \in C^1(\mathbb{T}^n)$. If $\phi_1$ approximates the maximizer of $F(\mu, P_1)$ (res. $\phi_2$ approximates the maximizer of $F(\mu, P_2)$), then integrating the above inequality with respect to $\mu$ yields

$$F(\mu, P_1) + F(\mu, P_2) \geq \int_{\mathbb{T}^n} \left| \frac{P_1 + P_2}{2} + \frac{\nabla \phi_1 + \nabla \phi_2}{2} \right|^2 d\mu \geq 2F\left(\mu, \frac{P_1 + P_2}{2}\right).$$

The same arguments apply to $F^*$. In addition, from (1.1, 1.2)

$$F^*(\mu, J) = \sup_{P \in \mathbb{R}^n} [P \cdot J - F(\mu, P)] = \sup_{P \in \mathbb{R}^n} \left\{ \sup_{\phi \in C^1(\mathbb{T}^n)} \left[ P \cdot J - \frac{1}{2} \int_{\mathbb{T}^n} |P + \nabla \phi|^2 d\mu \right] \right\},$$

and from

$$\mathcal{E}(\mu, J, \phi) = \sup_{P \in \mathbb{R}^n} \left[ P \cdot J - \frac{1}{2} \int_{\mathbb{T}^n} |P + \nabla \phi|^2 d\mu \right]$$

we obtain (3). (4-6) follow from (1,2).
5.3 Proof of Theorem 4.1

We now apply Proposition 5.1 as follows:

Let $C$ the space of all continuous functions on $\mathbb{T}^n \times \mathbb{R}^n$, equipped with the norm

$$\|q\| := \sup_{(x,p) \in \mathbb{T}^n \times \mathbb{R}^n} \left\{ \frac{|q(x,p)|}{1 + |p|} \right\}.$$ 

Define

$$Z := \{ p \cdot \nabla_x \phi \; , \; \phi \in C^1(\mathbb{T}^n) \} \tag{5.3}$$

The dual space $C^*$ contains the set $\mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n)$ of finite Borel measures on $\mathbb{T}^n \times \mathbb{R}^n$ which admit a finite first moment. If $\nu \in C^*$ is such a measure then the duality relation is given by

$$\langle \nu, q \rangle = \int_{\mathbb{T}^n \times \mathbb{R}^n} q d\nu \; \forall q \in C.$$ 

Given a probability measure $\mu \in \overline{\mathcal{M}}$, define

$$\mathcal{F}_\mu(\nu) = \begin{cases} \int_{\mathbb{T}^n \times \mathbb{R}^n} \left( \frac{|p|^2}{2} - P \cdot p \right) d\nu & \text{if } \nu \in \mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n) \cap C^* \text{ and satisfies } \nu(dx, \mathbb{R}^n) = \mu(dx) \\ \infty & \text{otherwise} \end{cases}$$

(recall Definition 4.1). Evidently, $\mathcal{F}_\mu$ is a convex function on $C^*$. Note also that the set $\overline{A}_0 := \{ c^* ; \mathcal{F}_\mu(c^*) < E \} \subset C^*$ is compact for any $E < \infty$ by Prokhorov Theorem.

**Lemma 5.2.** $\nu \in Z^*$ and $\mathcal{F}_\mu(\nu) < \infty$ if and only if $\nu \in \Lambda_\mu$.

Substitute this $\mathcal{F}_\mu$ for $\mathcal{F}$ in (5.1) where $h \equiv 0$ it follows that

$$E = \inf_{\nu \in \Lambda_\mu} \int_{\mathbb{T}^n \times \mathbb{R}^n} \left( \frac{|p|^2}{2} - P \cdot p \right) \nu(dx) \; . \tag{5.4}$$

On the other hand

$$\inf_{c^* \in C^*} \mathcal{F}(c^*) - < c^*, z > = \inf_{\nu \in C^*} \int_{\mathbb{T}^n \times \mathbb{R}^n} \left( \frac{1}{2} |p|^2 - p \cdot (\nabla_x \phi + P) \right) d\nu$$

$$= \inf_{\nu \in \Lambda_\mu} \frac{1}{2} \int_{\mathbb{T}^n \times \mathbb{R}^n} |p - \nabla_x \phi|^2 d\nu - \frac{1}{2} \int_{\mathbb{T}^n} |\nabla_x \phi + P|^2 d\mu \; . \tag{5.5}$$
We choose \( \nu = \delta_p(\mathbf{P} + \nabla_x \phi) \otimes \mu \), so the first term in (5.5) is zero. Then
\[
\sup_{z \in \mathbb{Z}} \inf_{c \in \mathcal{C}} F(c^*) - <c^*, z> = \sup_{\phi \in C^1(T^n)} \left[ -\frac{1}{2} \int_{T^n} |\nabla_x \phi + \mathbf{P}|^2 \mu \right] := -F(\mu, \mathbf{P}) . \tag{5.6}
\]
where \( F \) as defined in (4.1). The last part of Proposition 5.1 implies the existence of a weak solution \( \nu \in \Lambda_\mu \) of \( F(\mu, \mathbf{P}) \).

To show the uniqueness of the weak solution, note that any Borel measure \( \nu \) on \( T^n \times \mathbb{R}^n \) whose \( T^n \) marginal is \( \mu \) can be written as \( \nu(dxdp) = \mu(dx)Q_x(dp) \) where \( Q_x \) is a Borel probability measure on \( \mathbb{R}^n \) defined for \( \mu \)-a.e. \( x \in T^n \). If \( \nu \) satisfies Definition 4.2, then \( Q_x = \delta_{v(x)} \) where \( v(x) := \int_{\mathbb{R}^n} \mathbf{p}Q_x(dp) \) is a Borel vector field, defined \( \mu \)-a.e. If there are \( \nu_1 \neq \nu_2 \) which realize the minimum in Definition 4.2 and \( v_1, v_2 \) the corresponding vector fields, then
\[
F(\mu, \mathbf{P}) = \frac{1}{2} \int_{T^n} |v_1|^2 d\mu = \frac{1}{2} \int_{T^n} |v_2|^2 d\mu
\]
implies
\[
\frac{1}{2} \int_{T^n} \left| \frac{v_1 + v_2}{2} \right|^2 d\mu < F(\mu, \mathbf{P}) ,
\]
unless \( v_1 = v_2 \) \( \mu \)-a.e., which contradicts the minimality of \( \nu_1 \) and \( \nu_2 \).

From (5.6) it follows that the Legendre transform of the function \( F(\mu, \cdot) \) is
\[
F^*(\mu, \mathbf{J}) = \sup_{\mathbf{P} \in \mathbb{R}^n} \sup_{\phi \in C^1(T^n)} \left[ \mathbf{P} \cdot \mathbf{J} - \frac{1}{2} \int_{T^n} |\nabla_x \phi + \mathbf{P}|^2 d\mu \right]
= \sup_{\phi \in C^1(T^n)} \sup_{\mathbf{P} \in \mathbb{R}^n} \left[ \mathbf{P} \cdot \mathbf{J} - \frac{1}{2} \int_{T^n} |\nabla_x \phi + \mathbf{P}|^2 d\mu \right] = \sup_{\phi \in C^1(T^n)} \mathcal{E}(\mu, \mathbf{J}, \phi) \tag{5.7}
\]
where \( \mathcal{E} \) as defined in (4.3).

To prove the last part, note that \( \nu_0 := \rho(x)dx \otimes \delta_{(\mathbf{p} - \nabla_x \mathbf{P})}d\mathbf{p} \in \Lambda_\mu \) whenever \( \psi \) is the solution of (4.6). Indeed, by (4.6) and integration by parts
\[
\int_{T^n \times \mathbb{R}^n} \nabla \phi \cdot \mathbf{p} d\nu_0 = \int_{T^n} \nabla \phi \cdot (\mathbf{P} + \nabla \psi) \rho(x) dx = \int_{T^n} \phi \nabla \cdot [(\mathbf{P} + \nabla \psi) \rho(x)] dx = 0 \tag{5.8}
\]
for any \( \phi \in C^1(T^n) \). Hence, (5.4) implies
\[
E \leq \int_{T^n \times \mathbb{R}^n} \left( |\mathbf{p}|^2/2 - \mathbf{P} \cdot \mathbf{p} \right) d\nu_0 = \frac{1}{2} \int_{T^n} |\nabla \psi + \mathbf{P}|^2 \rho(x) dx - \mathbf{P} \cdot \int_{T^n} (\nabla \psi + \mathbf{P}) \rho(x) dx . \tag{5.9}
\]
However, $\psi$ realizes the infimum in (4.1), so (5.4, 5.6) and Proposition 5.1 imply

$$E = -\frac{1}{2} \int_{\mathbb{T}^n} |\nabla \psi + P|^2 \rho(x) dx$$

which, together with (5.9), imply

$$\int_{\mathbb{T}^n} |\nabla \psi + P|^2 \rho(x) dx - P \cdot \int_{\mathbb{T}^n} (\nabla \psi + P) \rho(x) dx \geq 0.$$  

However, (5.8) with $\phi = \psi$ implies the equality above, hence the equality in (5.9) as well. In particular, $\nu_0$ minimizes (5.4).  

□

5.4 Proof of theorem 4.2

First, the sequence $\{\nu_j\}$ is tight in $\mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n)$ since $\mathbb{T}^n$ is compact and $\int_{\mathbb{T}^n \times \mathbb{R}^n} |p|^2 d\nu_j$ are uniformly bounded. By Prokhorov Theorem it follows that the weak limit $\nu_j \rightarrow \nu \in \mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n)$ exists (for a subsequence). Also, $\nu \in \Lambda_\mu$ since the condition given in Definition 4.1 is preserved under the weak-* convergence.

Next

$$-\lim_{j \rightarrow \infty} F(\mu_j, P) = \lim_{j \rightarrow \infty} \int_{\mathbb{T}^n \times \mathbb{R}^n} (|p|^2/2 - P \cdot p) d\nu_j \geq \int_{\mathbb{T}^n \times \mathbb{R}^n} (|p|^2/2 - P \cdot p) d\nu \geq \inf_{\xi \in \Lambda_\mu} \int_{\mathbb{T}^n \times \mathbb{R}^n} (|p|^2/2 - P \cdot p) d\xi = -F(\mu, P), \quad (5.10)$$

By assumption (4.8) it follows that the equality folds in (5.10). In particular, $\nu$ is the weak solution of $F(\mu, P)$.

To prove the second part, let $\eta_\varepsilon \in C^\infty(\mathbb{T}^n)$ a sequence of positive mollifiers on $\mathbb{T}^n$ satisfying $\lim_{\varepsilon \rightarrow 0} \eta_\varepsilon = \delta(\cdot)$, and $\mu_\varepsilon = \eta_\varepsilon \ast \mu$. Then $\mu_\varepsilon(dx) = \rho_\varepsilon(x) dx$ where $\rho_\varepsilon \in C^\infty(\mathbb{T}^n)$ are strictly positive on $\mathbb{T}^n$ and

$$\lim_{\varepsilon \rightarrow 0} \mu_\varepsilon = \mu.$$  

Next, let $\nu$ be a weak solution of $F(\mu, P)$ and $\nu_\varepsilon = \eta_\varepsilon \ast \nu$. If $\nu = \mu(dx) \nu_x(dp)$ and $q = q(p)$ any $\nu$ measurable function, then $\tilde{q}(x) := \int_{\mathbb{R}^n} q(p) \nu_x(dp)$ is $\mu$ measurable and

$$\int_{\mathbb{T}^n \times \mathbb{R}^n} q(p) d\nu = \int_{\mathbb{T}^n} \tilde{q}(x) \mu(dx).$$
while

\[
\int_{\mathbb{T}^n \times \mathbb{R}^n} q(p) \, d\nu_{\varepsilon} = \int_{\mathbb{T}^n \times \mathbb{R}^n} \int_{\mathbb{T}^n} dx \eta_{\varepsilon}(|y-x|) \mu(dy) \nu_{\varepsilon}(dp) q(p) \\
= \int_{\mathbb{T}^n} \int_{\mathbb{T}^n} \eta_{\varepsilon}(|x-y|) dx \mu(dy) \tilde{q}(y) = \int_{\mathbb{T}^n} dx \mu(dy) \tilde{q}(y) = \int_{\mathbb{T}^n \times \mathbb{R}^n} q(p) \, d\nu
\]  

(5.11)

for any \( \nu \)-measurable function \( q \) on \( \mathbb{R}^n \). Then

\[
\int_{\mathbb{T}^n \times \mathbb{R}^n} \nabla \theta \cdot p \, d\nu_{\varepsilon}(x) = \int_{\mathbb{T}^n \times \mathbb{R}^n} \nabla (\eta_{\varepsilon} \ast \theta) \cdot p \, d\nu(x) = 0
\]

for any \( \theta \in C^\infty(\mathbb{T}^n) \) hence \( \nu_{\varepsilon} \in \Lambda_{\mu_{\varepsilon}} \).

Define

\[
v_{\varepsilon}(x) = \rho_{\varepsilon}^{-1}(x) \int_{\mathbb{R}^n} \mathbf{p} \, d\nu_{\varepsilon}(x, dp), \quad x \in \mathbb{T}^n.
\]

Then \( v_{\varepsilon} \in C^\infty(\mathbb{T}^n) \) and \( \nabla \cdot (\rho_{\varepsilon} v_{\varepsilon}) = 0 \). Let \( \phi_{\varepsilon} \) be the unique solution of the elliptic equation

\[
\nabla \cdot (\rho_{\varepsilon} [\nabla \phi_{\varepsilon} + \mathbf{P}]) = 0
\]

(5.12)

Define

\[
\hat{\nu}_{\varepsilon}(dxdp) := \rho_{\varepsilon}(x) dx \otimes \delta_{(\mathbf{p} - \mathbf{P} - \nabla \phi_{\varepsilon})} \, d\mathbf{p}.
\]

Then (5.12) implies, as in (5.8), that \( \hat{\nu}_{\varepsilon} \in \Lambda_{\mu_{\varepsilon}} \). By (4.4) and (5.11) and the second part of Theorem 4.1

\[
- F(\mu, \mathbf{P}) := \int_{\mathbb{T}^n \times \mathbb{R}^n} (|\mathbf{p}|^2/2 - \mathbf{P} \cdot \mathbf{p}) \, d\nu = \int_{\mathbb{T}^n \times \mathbb{R}^n} (|\mathbf{p}|^2/2 - \mathbf{P} \cdot \mathbf{p}) \, d\nu_{\varepsilon} \\
\geq \int_{\mathbb{T}^n \times \mathbb{R}^n} (|\mathbf{p}|^2/2 - \mathbf{P} \cdot \mathbf{p}) \, d\hat{\nu}_{\varepsilon} = - F(\mu_{\varepsilon}, \mathbf{P}), \quad (5.13)
\]

hence

\[
\lim_{\varepsilon \to 0} F(\mu_{\varepsilon}, \mathbf{P}) \geq F(\mu, \mathbf{P}) \quad (5.14)
\]

for any \( \mathbf{P} \in \mathbb{R}^n \). But, since \( F \) is concave in \( \mu \) via Lemma 5.1 it follows that there is an equality in (5.14). \( \square \)
5.5 Proof of Lemma 4.1

Since $F$ is convex on $\mathbb{R}^n$ for fixed $\mu$ and concave on $\overline{M}$ for fixed $P$ we may use the Min-Max Theorem [H-L] to obtain

\[
\hat{H}_\Xi^*(J) = \sup_{\mu \in \overline{M}} \inf_{P \in \mathbb{R}^n} \left[ \int_{T^n} \Xi d\mu + F(\mu, P) - P \cdot J \right]
= \inf_{P \in \mathbb{R}^n} \left\{ \sup_{\mu \in \overline{M}} \left[ \int_{T^n} \Xi d\mu + F(\mu, P) \right] - P \cdot J \right\}
= \inf_{P \in \mathbb{R}^n} \left\{ P \cdot J - \hat{H}_\Xi(P) \right\}
\tag{5.15}
\]

□

5.6 Proof of Proposition 4.1

Let $\Xi(x_0) = \max_{T^n} \Xi(x)$. Let $\mu_n \to \delta_{x_0}$. By Lemma 5.1-(5) and (4.11) we obtain the weak inequality for $\hat{H}_\Xi(P)$. To obtain the strong inequality use, e.g., the uniform Lebesgue measure $\mu = dx$ on $T^n$. Then the minimizer $\phi$ of $F(\mu, P)$ verifies $\nabla \cdot (\nabla \phi + P) = 0$, that is, $\Delta \phi = 0$ on $T^n$ which implies $\nabla \phi \equiv 0$. Hence $F(dx, P) = |P|^2/2.$ We obtain the strong inequality if $|P|^2/2 + \int_{T^n} \Xi > \max_{T^n} \Xi$. The proof for $\hat{H}^*$ is analogous. □

5.7 Proof of Lemma 4.2

The existence of a maximizer $\mu$ of (4.10) follows from the lower-semi-continuity of $F^*$ (hence of $H_\Xi^*$) with respect to the $C^*$ topology of $\overline{M}$, as claimed in Lemma 5.1-(5).

Let

\[
H_\Xi(\mu, P) := \int \Xi d\mu + F(\mu, P), \quad H_\Xi^*(\mu, J) := \int \Xi d\mu - F^*(\mu, J).
\tag{5.16}
\]

Then, by Definition 4.3, $\hat{H}_\Xi(P) = H_\Xi(\mu_0, P) \geq H_\Xi(\mu, P)$ for any $\mu \in \overline{M}$, and $\hat{H}_\Xi^*(J) = \sup_{\mu \in \overline{M}} H_\Xi^*(\mu, J)$. By Lemma 4.1,

\[
\hat{H}_\Xi(P) - \hat{H}_\Xi^*(J') \geq P \cdot J'.
\]
holds for any $J' \in \mathbb{R}^n$, and the equality above takes place if and only if $J' = J \in \partial_p \hat{H}_\Xi(\cdot)$. Hence

$$H_\Xi(\mu_0, P) - H'_\Xi(\mu, J') \geq P \cdot J'$$

holds for any $\mu \in \overline{M}$ and any $J' \in \mathbb{R}^n$. The equality holds if and only if $J' = J \in \partial_p \hat{H}_\Xi(\cdot)$ and $\mu$ which verifies the maximum of $H'_\Xi(\cdot, J)$. From (5.16, 5.17)

$$F(\mu_0, P) + F^*(\mu, J') + \int_{T^n} \Xi(d\mu_0 - d\mu) \geq P \cdot J' .$$

(5.18)

Let now $\mu = \mu_0$. Then (5.18) implies

$$F(\mu_0, P) + F^*(\mu_0, J') \geq P \cdot J' ,$$

(5.19)

and, if there is an equality in (5.19) for some $J'$, then $J' \in \partial_p \hat{H}_\Xi(\cdot)$. However, we know, by definition of $F^*$ as the Legendre transform of $F$ with respect to $P$, that there is, indeed, an equality in (5.19) provided $J' \in \partial_p F(\mu_0, \cdot)$. This verifies $\partial_p F(\mu_0, \cdot) \subseteq \partial_p \hat{H}_\Xi$.

### 5.8 Proof of Theorem [4.3]

Assume $\nu \in \mathcal{M}_L$ is a Mather measure on $\mathbb{T}^n \times \mathbb{R}^n$. Theorem 5.1.2 of [F] implies the existence of a conjugate pair $\phi_+ \geq \phi_- \in \text{Lip}(\mathbb{T}^n)$ where the domain $\phi_+ = \phi_-$ contains the projected Mother set which, in turn, contains the support of the projection $\mu$ of $\nu$ on $\mathbb{T}^n$. In addition, Corollary 4.2.20 of [F] implies that either functions satisfies

$$\frac{1}{2} |\nabla \phi + P|^2 + \Xi \leq E ,$$

(5.20)

and for some $E \in \mathbb{R}$, with an equality on the projected Mather set (in particular, on the support of $\mu$).

We show that $\mu$ is also a maximizer of $\hat{H}_\Xi(P)$ (4.11).

Let $\phi$ be either $\phi_+$ or $\phi_-$. Let $\eta_\varepsilon \in C^\infty(\mathbb{T}^n)$ non-negative mollifier function on $\mathbb{T}^n$, supported in the ball $|x| < \varepsilon$ and satisfying $\int_{\mathbb{T}^n} \eta_\varepsilon = 1$. Let $\phi^\varepsilon := \phi * \eta_\varepsilon$. Then
\[ \phi^\varepsilon \in C^\infty(T^n) \] and \[ \nabla \phi^\varepsilon = \eta_{\varepsilon} \ast \nabla \phi. \] The Jensen’s inequality implies that
\[ \eta_{\varepsilon} \ast |\nabla \phi + P|^2 \geq |\nabla \phi^\varepsilon + P|^2, \] (5.21)
so, by (5.20, 5.21)
\[ \frac{1}{2} |\nabla \phi^\varepsilon + P|^2 + \Xi \leq E + \Xi - \eta_{\varepsilon} \ast \Xi. \]
Given \( \delta > 0 \), there exists \( \varepsilon > 0 \) for which \( |\Xi - \eta_{\varepsilon} \ast \Xi| < \delta \) on \( T^n \). Hence
\[ \frac{1}{2} |\nabla \phi^\varepsilon + P|^2 + \Xi \leq E + \delta. \]
So, for any \( \bar{\mu} \in \bar{M} \):
\[ E + \delta \geq \int_{T^n} \left( \frac{1}{2} |\nabla \phi^\varepsilon + P|^2 + \Xi \right) d\bar{\mu} \geq F(\bar{\mu}, \bar{P}) + \int_{T^n} \Xi d\bar{\mu} = \hat{H}_\Xi(\bar{P}), \]
where the second inequality follows from the definition (4.1) of \( F(\mu, P) \) and from \( \phi^\varepsilon \in C^1(T^n) \). Since \( \delta > 0 \) can be arbitrarily small it follows that \( \hat{H}_\Xi(P) \leq E \). Hence \( \mu = \pi_{\#} \nu \) is, indeed, a maximizer of \( \hat{H}_\Xi \) (4.11).

Finally, if \( J = \alpha(\nu) \) then \( J \in \partial P \hat{H}_\Xi \) and the last part of the Theorem follows from Lemma 4.2. \( \square \)

5.9 Proof of Proposition 4.2

The proof is analogous to this of Theorem 4.1 utilizing Proposition 5.1. We only sketch the new definitions involved, generalizing those given in the proof of Theorem 4.1 to the time periodic case.

Let \( C \) to be the space of all continuous functions on \( T^n \times \mathbb{R}^n \times [0, T] \), equipped with the norm
\[ \|q\| := \sup_{(x, p, t) \in T^n \times \mathbb{R}^n \times [0, T]} \left\{ \frac{|q(x, p, t)|}{1 + |p|} \right\}. \]
Define
\[ Z := \{ \phi_t + p \cdot \nabla_x \phi, \ \phi \in C^1_0(T^n \times (0, T)) \} \] (5.22)
The dual space $C^*$ contains the set $\overline{\mathcal{M}}_T$ of $\overline{\mathcal{M}}$-valued orbits on $[0, T]$ of bounded first moment. If $\hat{\nu} \in C^*$ is such an orbit then the duality relation is given by

$$\langle \hat{\nu}, q \rangle := \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} q d\nu(t) dt, \forall q \in C^*. $$

Given an orbit $\hat{\mu} \in \overline{\mathcal{M}}_T$, define

$$F_{\hat{\mu}}(\hat{\nu}, T) := \int_{\mathbb{T}^n \times \mathbb{R}^n \times [0, T]} (|p|^2/2 - P \cdot p) \ d\nu(t) dt $$

if $\hat{\nu} \in \mathcal{M}_T(\mathbb{T}^n \times \mathbb{R}^n \times [0, T]) \cap C^*$ and $\nu(t)(dx, \mathbb{R}^n) = \mu(t)(dx) \ a.e$

$$F_{\hat{\mu}}(\hat{\nu}, T) = \infty \ otherwise. \ (5.23)$$

The rest of the proof is equivalent to this of Theorem 4.1. \(\square\)

5.10 Proof of Proposition 4.3

First we note that $F_T(\mu, P) \geq 0$ for any $\mu \in \overline{\mathcal{M}}$ and $P \in \mathbb{R}^n$. Indeed, by Theorem 4.2

$$F_T(\mu, P) \geq F(\mu, P) \geq 0. \ (5.24)$$

Let $\hat{\mu}^{(n)}$ be a maximizing sequence of (4.17). By (4.14) and (5.24) it follows that there exists $C > 0$ for which

$$\frac{1}{T} \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} \left( \frac{|p|^2}{2} - P \cdot p \right) d\nu_{(t)}^{(n)} dt \leq C \ (5.25)$$

where $\nu_{(t)}^{(n)}$ are the weak solutions corresponding to $\hat{\mu}^{(n)}$.

Let

$$\|\hat{\mu}\|_T^2 := -\inf_{\phi \in C^1(\mathbb{T}^n \times [0, T])} \int_0^T \left( \phi_t + \frac{1}{2} |\nabla_x \phi|^2 \right) d\mu_{(t)} dt. $$

We recall form [W] that

$$\|\hat{\mu}\|_T^2 = \frac{1}{2} \inf_{\hat{\nu} \in \overline{\mathcal{M}}_T} \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} p^2 d\nu_{(t)} dt. \ (5.26)$$
Moreover, Lemma 2.2 in [W] implies that the set \( \{ \hat{\mu} \in \hat{\Lambda} \mid \|\hat{\mu}\|_T < C \} \) is uniformly bounded in the 1/2–Holder norm with respect to the Wasserstein metric:

\[
W_1(\mu_1, \mu_2) := \sup_{\phi \in C^1(\mathbb{T}^n), |\nabla \phi| \leq 1} \int_{\mathbb{T}^n} \phi(x)(d\mu_1 - d\mu_2) = \inf_{\sigma \in \mathcal{M}^{(2)}(\mu)} \int_{\mathbb{T}^n} \int_{\mathbb{T}^n} |x - y|_T d\sigma,
\]

(recall points (i) and (vi) in List of Symbols). Since The \( W_1 \)-Wasserstein metric is a metrization of the weak topology of measures on compact domains, it follows (see Corollary 2.1 in [W]) that the set \( \{ \hat{\mu} \in \hat{\Lambda} \mid \|\hat{\mu}\|_T < C \} \) is pre-compact in the topology of \( C^0([0, T]; C^*(\mathbb{T}^n)) \).

Next, since \( |p|^2 / 2 - P \cdot p \geq |p|^2 / 4 - |P|^2 \) it follows from (5.25) and (5.26) that

\[
C \geq \frac{1}{T} \inf_{\hat{\nu} \in \hat{\Lambda}(\mu)} \int_0^T \left( \frac{|p|^2}{2} - p \cdot P \right) d\nu(t) dt \geq \frac{1}{2T} \|\hat{\mu}^{(n)}\|_T^2 - |P|^2.
\]

Hence, the limit

\[
\hat{\mu} = \lim_{n \to \infty} \hat{\mu}^{(n)} \in \hat{\Lambda}
\]

exists in the weak topology of \( C^*([0, T]; C^*(\mathbb{T}^n)) \), along a subsequence of the maximizing sequence. Moreover, \( \hat{\mu} \) is a maximizer of (4.17) by concavity of \( F(\hat{\mu}, P, T) \) with respect to \( \hat{\mu} \).  

□

5.11 Proof of Proposition 4.4

The inequality (4.19) follows directly from (4.17), upon substituting the constant orbit \( \hat{\mu} \equiv \mu(t) \equiv \mu \) for \( t \in [0, T] \). To verify (4.20) we use (4.14) to write

\[
\sup_{\mu \in \mathcal{M}} H_{\Xi, T}(\mu, P) = \sup_{\hat{\nu} \in \hat{\Lambda}_T} \frac{1}{T} \int_0^T \int_{\mathbb{T}^n \times \mathbb{R}^n} \left\{ \Xi - \left[ \frac{|p|^2}{2} - p \cdot P \right] \right\} d\nu(t) dt .
\]

But, the RHS of (5.27) is unchanged if we replace \( \hat{\nu} \) by \( \nu := T^{-1} \int_0^T d\nu(t) \). Moreover, \( \nu \in \Lambda \) since Definition 4.4 is reduced to Definition 4.1 for \( \theta(x, t) \to \theta(x) := T^{-1} \int_0^T \theta(x, t) dt \).

Hence (5.27) is reduced into

\[
\sup_{\mu \in \mathcal{M}} H_{\Xi, T}(\mu, P) = \sup_{\nu \in \Lambda} \int_{\mathbb{T}^n \times \mathbb{R}^n} \left\{ \Xi - \left[ \frac{|p|^2}{2} - p \cdot P \right] \right\} d\nu ,
\]

which yields (4.20) via (4.14).  

□
5.12 Proof of Lemma 4.3

The lower-semi-continuity of $D^T_P$ with respect to $C^*(\overline{M})$ follows from the dual formulation

$$D^T_P(\mu) = \sup_{\psi_1,\psi_2} \left( \int_{\mathbb{T}^n} \psi_1 d\mu + \int_{\mathbb{T}^n} \psi_2 d\mu \right)$$

where the supremum above is taken over all pairs $\psi_1, \psi_2 \in C(\mathbb{T}^n)$ verifying $\psi_2(y) + \psi_1(x) \leq A^\Xi_P(x, y, T)$ for any $x, y \in \mathbb{T}^n$. For details, see [V], ch. 1.

The upper-semi-continuity follows directly from definition (4.23). Indeed, let $\sigma_j \in \overline{M}^{(2)}(\mu)$ verifies (4.23) for $\mu_i \in \overline{M}$ and $\mu_j \to \mu$ in $C^*(\overline{M})$, then the sequence $\sigma_j$ is compact in the set $\mathcal{M}(\mathbb{T}^n \times \mathbb{T}^n)$ in the weak topology. Let $\sigma$ be a limit of this sequence. Then $\sigma \in \overline{M}^{(2)}(\mu)$, and

$$D^T_P(\mu) \leq \int_{\mathbb{T}^n} A^\Xi_P(x, y, T) d\sigma = \lim_{j \to \infty} \int_{\mathbb{T}^n} A^\Xi_P(x, y, T) d\sigma_j = \lim_{j \to \infty} D^\Xi_P(\mu_j).$$

The continuity of $D^T_P$ with respect to $\Xi$ in the $C^0(\mathbb{T}^n)$ topology is verified by the continuous dependence of $A^\Xi_P$ on $\Xi$. □

5.13 Proof of Proposition 4.5

Definition 4.6 of $\hat{H}_T$ corresponds to Definition 3.1 of $L$ in [W]. In addition, Definition 3.3 [W] of $K$ corresponds to (4.22). Then, Proposition 4.6 is a result of the identity $L(\mu_1, \mu_2) = K(\mu_1, \mu_2)$, which follows from the Main Theorem of [W].

In fact, the extended Lagrangian $L$ is defined, in [W], for a Lagrangian $L = |p|^2/2 - \Xi(x)$, i.e. for $P = 0$, but the proof of the Main Theorem in [W] can be extended to $L = |P - p|^2/2 - \Xi$ in a direct way. □

5.14 Proof of Proposition 4.6

Since $\hat{H}_T(\mu, P, \Xi) \geq \int \Xi d\mu + F(\mu, P)$ by Definition 4.6 it follows from Proposition 4.5 that

$$\frac{|P|^2}{2} - D^T_P(\mu, \Xi) \geq \int_{\mathbb{T}^n} \Xi d\mu + F(\mu, P).$$
Thus, we only need to show that
\[
\lim_{T \to 0} D_T^P(\mu, \Xi) \geq \frac{|P|^2}{2} - \int_{\mathbb{T}^n} \Xi d\mu - F(\mu, P).
\]
We may reduce to the case $\Xi \equiv 0$, hence we need to verify
\[
\lim_{T \to 0} \frac{|P|^2}{2} - D_T^P(\mu) \leq F(\mu, P).
\] (5.28)
Indeed, from (4.21, 4.22) we observe
\[
\lim_{T \to 0} D_T^P(\mu, \Xi) = -\int_{\mathbb{T}^n} \Xi d\mu + \lim_{T \to 0} D_T^P(\mu).
\]
If $\sigma_T$ verifies the minimum in (4.22), then
\[
D_T^P(\mu) = \frac{1}{2T^2} \int_{\mathbb{T}^n} \int_{\mathbb{T}^n} \|y - x + PT\|^2 d\sigma_T(x, y) \leq \frac{|P|^2}{2}.
\] (5.29)
Let
\[
G := \{(x, y) \in \mathbb{T}^n \times \mathbb{T}^n ; \|y - x\|_\infty \geq 1/3\},
\]
where $\|x\|_\infty$ is the metric on $\mathbb{T}^n$ defined as $\min_{z \in \mathbb{Z}} |x - z|_\infty$. Then, for sufficiently small $T$, $\|y - x + PT\|^2 \geq 1/16$ for $(x, y) \in G$ so from (5.29)
\[
\int \int_G d\sigma_T(x, y) \leq 16T^2|P|^2.
\] (5.30)
Let $B^n \subset \mathbb{R}^n$ be the unite box $-1/2 \leq x_i \leq 1/2, i = 1, \ldots, n$. Let $\phi \in C_0(\mathbb{T}^n \times T^{-1}B^n/3)$. Extend $\phi$ to a function in $C_0(\mathbb{T}^n \times T^{-1}B^n)$ by $\phi(x, p) = 0$ if $p \in T^{-1}B^n - T^{-1}B^n/3$.
Further, extend $\phi$ into a function on $\mathbb{T}^n \times \mathbb{R}^n$ as a $T^{-1}$ periodic function in $p$, that is, $\phi$ is a function on $\mathbb{T}^n \times (\mathbb{T}^n/T)$. Set
\[
y = x + pT, \quad \hat{\phi}(x, y) := \phi \left( x, \frac{y - x}{T} \right)
\]
Then $\hat{\phi} \in C(\mathbb{T}^n \times \mathbb{T}^n)$. Given $\sigma_T$ which verifies the minimum in (4.22), we define a corresponding measure $\nu_T$ on $\mathbb{T}^n \times \mathbb{R}^n$, supported in $\mathbb{T}^n \times (B^n/(3T))$, as follows: For any $\phi \in C_0(\mathbb{T}^n \times B^n/(3T))$,
\[
\int_{\mathbb{T}^n} \int_{B^n/(3T)} \phi(x, p) d\nu_T(x, p) = \int_{\mathbb{T}^n} \int_{\mathbb{T}^n} \hat{\phi}(x, y) d\sigma_T(x, y).
\] (5.31)
By (5.30) we obtain
\[ 1 \geq \int_{\mathbb{T}^n} \int_{\mathbb{R}^n} d\nu_T \geq 1 - 16T^2|P|^2. \] (5.32)

We now verify that
\[ \lim_{T \to 0} \nu_T = \nu_0 \in \Lambda_{\mu} \] (5.33)
(see Definition 4.1-(2)). First, we show that the sequence of measures on \( \mathbb{T}^n \times \mathbb{R}^n \) is tight. For this, we use (5.31) with \( \phi(x, p) = |p - P|^2 \cdot 1_{B^n/(3T)}(p) \) and (5.29) to obtain
\[ \frac{1}{2} \int_{\mathbb{T}^n} \int_{\mathbb{R}^n} |p - P|^2 d\nu_T < \frac{|P|^2}{2}. \]
This, and (5.32), imply that the limit (5.33) is a probability measure on \( \mathbb{T}^n \times \mathbb{R}^n \), that is \( \nu_0 \in \mathcal{M}(\mathbb{T}^n \times \mathbb{R}^n) \). Moreover, \( \nu_0(dx, \mathbb{R}^n) = \mu(dx) \). To show that \( \nu_0 \in \Lambda_{\mu} \), we proceed as follows: Let \( q \in C^\infty(\mathbb{R}^+) \) satisfies:

i) \( q \in C^\infty(\mathbb{R}^+) \).

ii) \( q(s) = 1 \) for \( 0 \leq s \leq 1/3 \).

iii) \( q(s) = 0 \) for \( 2/5 \leq s \leq 1/2 \).

iv) \( q(1/2 - s) = q(1/2 + s) \) for any \( s \in [0, 1/2] \).

v) \( q(s) \leq 1 \) for \( s \in [0, 1] \).

vi) \( q(s + 1) = q(s) \) for all \( s \in \mathbb{R}^+ \).

Let
\[ Q(p) = \prod_1^N q(|p_i|) \text{ for } p = (p_1, \ldots, p_n) \in \mathbb{R}^n, \quad Q_T(p) = Q(Tp). \]

Given \( \psi \in C^1(\mathbb{T}^n) \), set \( \phi_T^{(1)}(x, p) = \psi(x + pT)Q_T(p) \) and \( \phi_T^{(2)}(x, p) = \psi(x)Q_T(p) \) if \( p \in B^n/(3T) \), \( \phi_T = 0 \) otherwise. Then, by (5.31)
\[
\int_{\mathbb{T}^n} \int_{\mathbb{R}^n} \phi_T^{(1)}(x, p)d\nu_T(x, p) = \int_{\mathbb{T}^n} \int_{\mathbb{T}^n} Q(y - x)\psi(y)d\sigma_T(x, y) = \\
\int_{\mathbb{T}^n} \int_{\mathbb{T}^n} \psi(y)d\sigma_T(x, y) + \int_{\mathbb{T}^n} \int_{\mathbb{T}^n} (Q(y - x) - 1)\psi(y)d\sigma_T(x, y) \\
= \int_{\mathbb{T}^n} \psi(y)d\mu(y) + \int_{\mathbb{T}^n} \int_{\mathbb{T}^n} (Q(y - x) - 1)\psi(y)d\sigma_T(x, y). \] (5.34)
The same argument applies also to \(\phi^{(2)}\) and yields

\[
\int_{T^n} \int_{\mathbb{R}^n} \phi^{(2)}(x, p) d\nu_T(x, p) = \int_{T^n} \psi(x) d\mu(x) + \int_{T^n} \int_{T^n} (Q(y - x) - 1) \psi(x) d\sigma_T(x, y) .
\]

(5.35)

However, \(Q(y - x) - 1 = 0\) on the set \(G\) so, by (5.30)

\[
\int_{T^n} \int_{T^n} (Q(y - x) - 1) \psi(x) d\sigma_T(x, y) = \int_{T^n} \int_{T^n} (Q(y - x) - 1) \psi(y) d\sigma_T(x, y) \leq 16 T^2 |P|^2 |\psi|_\infty .
\]

(5.36)

Subtract (5.35) from (5.34), divide by \(T\) and let \(T \to 0\) and use (5.36) to obtain

\[
0 = \lim_{T \to 0} \int_{T^n} \int_{\mathbb{R}^n} \frac{\phi^{(2)}(x, p) - \phi^{(1)}(x, p)}{T} d\nu_T(x, p) = \lim_{T \to 0} \int_{T^n} \int_{\mathbb{R}^n} Q_T(p) \frac{\psi(x + Tp) - \psi(x)}{T} d\nu_T(x, p) = \int_{T^n} \int_{\mathbb{R}^n} \nabla \psi \cdot p d\nu_0(x, p) ,
\]

(5.37)

which implies for any \(\psi \in C^1(\mathbb{T}^n)\), hence \(\nu_0 \in \Lambda_\mu\) as claimed.

Let now consider \(\int_{T^n} Q_T(p)|p - P|^2 d\nu_T\). By (5.31)

\[
\frac{1}{2} \int_{T^n} \int_{B^n/(3T)} Q_T(p)|p - P|^2 d\nu_T(x, p) = \frac{1}{2} T^{-2} \int_{T^n} \int_{T^n} Q(x - y)\|x - y - TP\|^2 d\sigma_T(x, y) .
\]

(5.38)

Since \(\sigma_T\) is a minimizer of (4.24) and \(Q_T \leq 1\), it follows that

\[
\frac{1}{2} T^{-2} \int_{T^n} \int_{T^n} Q(x - y)\|x - y - TP\|^2 d\sigma_T(x, y) \leq D^T_P(\mu) .
\]

(5.39)

On the other hand, \(\nu_T\) is supported on \(B^n/(3T)\) by definition, so

\[
\frac{1}{2} \int_{T^n} \int_{B^n/(3T)} Q_T(p)|p - P|^2 d\nu_T(x, p) = \frac{1}{2} \int_{T^n} \int_{\mathbb{R}^n} |p - P|^2 d\nu_T(x, p) .
\]

(5.40)

On the other hand

\[
\lim_{T \to 0} \int_{T^n} \int_{\mathbb{R}^n} |p - P|^2 d\nu_T(x, p) \geq \int_{T^n} \int_{\mathbb{R}^n} |p - P|^2 d\nu_0(x, p) .
\]

(5.41)

From (5.38, 5.41) we obtain

\[
\frac{1}{2} \int_{T^n} \int_{\mathbb{R}^n} |p - P|^2 d\nu_0(x, p) \leq \lim_{T \to 0} D^T_P(\mu) ,
\]

39
hence
\[
\lim_{T \to 0} \left[ \frac{|P|^2}{2} - D_T^T(\mu) \right] \leq -\int_{\mathbb{T}^n} \int_{\mathbb{R}^n} \left( \frac{|p|^2}{2} - P \cdot p \right) d\nu_0(x, p) .
\] (5.42)

Since we already proved that \( \nu_0 \in \Lambda_{\mu} \), then Theorem 4.1 and (5.42) verify (5.28). \( \square \)

5.15 Proof of Theorem 4.6

To prove (4.29) we use (4.20) and (4.25) together with
\[
\lim_{j \to \infty} D_T^T(j, \Xi) = \min_{\mu \in \mathcal{M}} D_T^T(\mu, \Xi) .
\] (5.43)

To establish (5.43) note, first, that \( D_T^T(j, \Xi) \geq \inf_{\mu \in \mathcal{M}} D_T^T(\mu, \Xi) \) for any \( j \) by definition, so it is enough to establish the inequality
\[
\limsup_{j \to \infty} D_T^T(j, \Xi) \leq \inf_{\mu \in \mathcal{M}} D_T^T(\mu, \Xi) .
\]

Let now \( \{\mu_j\} \) be a sequence of empirical measures, where, for each \( j \), \( \mu_j \) contains exactly \( j \) atoms, and so that \( \mu = \lim_{j \to \infty} \mu_j \) in \( C^* \). Then \( D_T^T(\mu_j, \Xi) \geq D_T^T(j, \Xi) \) by definition, while \( \lim_{j \to \infty} D_T^T(\mu_j, \Xi) = D_T^T(\mu, \Xi) \) by Lemma 4.3.
