Abstract: In the CHY-frame for the amplitudes, there are two kinds of singularities we need to deal with. The first one is the pole singularities when the kinematics is not general, such that some of $S_A \to 0$. The second one is the collapse of locations of points after solving scattering equations (i.e., the singular solutions). These two types of singularities are tightly related to each other, but the exact mapping is not well understood. In this paper, we have initiated the systematic study of the mapping. We have demonstrated the different mapping patterns using three typical situations, i.e., the factorization limit, the soft limit and the forward limit.

Keywords: CHY, scattering equations

1 Motivation

In past years, there are huge processes in the effective computation and deep understanding of scattering amplitudes using the so-called "on-shell program". Among these on-shell methods, the CHY-formalism provides a fantastic angle to study scattering amplitudes. In the CHY-formalism, the tree-level amplitude is given by

\[ A_n = \int \frac{\prod_{i=1}^{n} dz_i}{\text{vol}(SL(2,\mathbb{C}))} \Omega(\mathcal{E}) F(z) = \int \frac{\prod_{i=1}^{n} dz_i}{d\omega} \Omega(\mathcal{E}) F, \]

where the integration is done over \( z_i \)'s, which describe the locations of \( n \)-external particles living on \( \mathbb{CP}^1 \). Although there are \( n \) variables, because the Möbius \( SL(2,\mathbb{C}) \) symmetry,
three variables should be fixed, thus we need to divide the $d\omega = \frac{dz_1 dz_2 dz_3}{z_r z_s z_t}$ with $z_{ij} = z_i - z_j$ by the gauge fixing. The $\Omega(\mathcal{E})$ is given by

$$\Omega(\mathcal{E}) \equiv z_{ij} z_{jk} z_{ki} \prod_{a \neq i,j,k} \delta(\mathcal{E}_a) ,$$

where $\mathcal{E}_a$’s are the scattering equations defined as

$$\mathcal{E}_a \equiv \sum_{b \neq a} \frac{S_{ab}}{z_a - z_b} = 0, \quad a = 1, 2, ..., n ,$$

with $S_{ab} = (k_a + k_b)^2 = 2k_a \cdot k_b$, and $k_a, a = 1, 2, ..., n$ as $n$ massless momenta for $n$-external particles. The $\mathcal{F}$ is called the CHY-integrand, which defines the particular theory we are considering. Since there are $(n - 3)$ delta-functions for $(n - 3)$ variables, there is, in fact, no integration to be done in $(1.1)$ and amplitudes are calculated as

$$A_n = \sum_{sol} z_{ij} z_{jk} z_{ki} z_{rs} z_{st} z_{tr} \left( \prod_{i+j+k+r+s+t} |\Phi|^{rst}_{ijk} \mathcal{F} \right) ,$$

where three arbitrary indices $i, j, k$ correspond to three removed scattering equations while three arbitrary indices $r, s, t$ correspond to three fixed locations mentioned above. The sum is over the solution set of the scattering equations, which is generically a discrete set of points. Furthermore, in the above, the Jacobi matrix $\Phi$ is calculated as ($a$ for rows and $b$ for column)

$$\Phi_{ab} = \frac{\partial \mathcal{E}_a}{\partial z_b} = \begin{cases} \frac{S_{ab}}{z_a - z_b} & a \neq b \\ - \sum_{c \neq a} \frac{S_{ac}}{z_a - z_c} & a = b \end{cases} ,$$

and $|\Phi|^{rst}_{ijk}$ is the determinant of $\Phi$ after removing the $i$-th, $j$-th and $k$-th rows and $r$-th, $s$-th and $t$-th columns.

From the above brief introduction, one can see that unlike the familiar off-shell Lagrangian formalism where the Feynman diagrams give a very intuitive picture to see the interaction by vertexes and propagators, all physical information in the CHY-formalism is coded by universal scattering equations and special rational CHY-integrand of a given theory. Thus it is crucial to understand how these two total different descriptions are mapped to each other. For example, the general tree-level amplitudes have the factorization property, easily seen from the Feynman diagrams when putting a particular propagator on-shell. How do we see this in the CHY-formalism? Since it is a general property, it can not depend on $\mathcal{F}$, and thus from (1.4), the information must be coded in the solutions of scattering equations.

There are many works on studying scattering equations, and their solutions [11–30]. By these studies, now we have an obvious picture about the factorization property in the CHY-formalism. As shown in [13], if all $S_A \neq 0$, the values of the $z_a$’s are distinct (i.e, $z_i \neq z_j, \forall i,j$) in every solution for all $(n - 3)!$ solutions of scattering equations. However, suppose there is one and only one $S_A = 0$, which corresponds to a particular factorization
channel. In that case, we will find that there are \((n_A - 2)! \times (n - n_A - 2)!\) solutions \([8]\), where \(z_i = z_0, \forall i \in A^2\). For later convenience, we will call a solution "regular" if all \(z_i\)'s are distinct and a solution to be "singular" if some \(z_i\) collapse to the same value. Using this terminology, one can say the solution singularity reflects that pole singularities. The understanding of factorization in the CHY-formalism is crucial because, through its study, the "integration rule" for simple poles and its generalization for higher poles have been proposed \([31–33]\) and we can read out the analytic expression for any CHY-integrand without solving the scattering equations. One crucial concept coming out from the "integration rule" is the pole index

\[
\chi(A) := L[A] - 2(|A| - 1) \quad (1.6)
\]

where \(L[A]\) be the number\(^2\) of lines connecting these nodes inside \(A\) and \(|A|\) is the number of nodes. The condition

\[
\chi(A) \geq 0 \quad (1.7)
\]

will be called the pole condition for a given subset. More explicitly, each subset gives a possible nonzero pole contribution when and only when \(\chi(A) \geq 0\), and the pole will be \(\frac{1}{S_A^{(A)} + 1}\), where \(S_A = (p_{a_1} + p_{a_2} + \cdots + p_{a_m})^2\) for massless momentum \(p_i^4\).

Factorization singularity is just one type of singularity of tree-level amplitudes. There are other types of singularities, for example, soft singularity and forward singularity. In fact, forward singularity appearances naturally in the construction of loop-level CHY-formalism and dealing with it is important for the whole construction \([15, 25, 34–38, 41–50, 53, 59–62]\). Different from factorization singularity, where we can arrange kinematics so there is one and only one \(S_A = 0\), both soft and forward limits will have multiple poles going to zero simultaneously. For example, if \(k_n \rightarrow 0\), we will have all \(S_{ni} \rightarrow 0, i = 1, ..., n - 1\). Similarly, for forward limit \(k_+ = -k_-\), we will have all \((k_+ + k_- + k_i)^2 \rightarrow 0\). It is natural to ask what is the solution behaviour under these limits. For forward limit, beautiful analysis has been done in \([62]\). Motivated by these observations, in this note, we will start a systematical discussion about the relation of the following two things: the kinematic singularities and the singular solutions of scattering equations. More explicitly, at one side, starting from the singular kinematic configuration with one or more singular poles, we will ask:

- (A1) If there will be singular solutions of scattering equations?
- (A2) If there are, how many singular solutions?

\(^2\)In fact, because the gauge fixing of three \(z_i\)'s, between the two subsets of \(A, \overline{A}\), it is the one containing at most one gauge fixing point having \(z_i = z_0\).

\(^3\)Again more accurately it is the difference of number between solid lines and dashed lines, which represent the factor \(z_{ij} = z_i - z_j\) in the denominator or the numerator respectively.

\(^4\)Because the momentum conservation, we will treat the subset \(A\) to be equivalent to its complement \(\overline{A} = \{1, 2, \ldots, n\} - A\) when taking the pole. However, as we will show, the behaviour of solutions will be very different between \(A, \overline{A}\).
• (A3) What is the exact behaviour of these singular solutions? Are all of them have similar behaviour or different patterns?

• (A4) What are the contributions of these singular solutions when putting them into CHY-integrands?

• (A5) Do regular solutions contribute to a singular part of scattering amplitudes?

On another side, starting from a given singular solution, we will ask:

• (B1) Is there a singular kinematic configuration implied by the solution?

• (B2) If there are, how many different singular kinematic configurations? Are these poles compatible or not compatible?

Although we can not answer the above questions in this note, we will illustrate cases where two side problems can be theoretically analyzed. Besides theoretical analysis, we also provide numerical checking to support our arguments.

The plan of the note is following. In the second section, we have discussed from singular solutions what is the kinematic configuration we can infer. From the second three to section five, we use factorization limit, soft limit and forward limit to demonstrate how to get pieces of information of singular solutions from the singular kinematics. Finally, a summary is given in section six. In this paper, to better understand the theoretical analysis, we have offered several numerical computations. In the appendix, how to implement the numerical kinematic configuration has been carefully discussed.

2 From singular solutions to kinematics

As discussed in the previous section, we will discuss relations between singular solutions and kinematics in this note. This section will assume the behaviour of singular solutions and derive the corresponding consequence of the kinematics, especially the pole structure. Let us consider an asymptotic behaviour of the kinematics $k_i$’s such that when $\epsilon \to 0$, the kinematics will reach the one we want:

$$ k_i = \sum_{a=0}^{a} \epsilon^a_{k_i(a)} $$ (2.1)

With this asymptotic behaviour, solutions $z_i$ have also asymptotic behaviour like:

$$ z_i = \sum_{a=0}^{a} \epsilon^a_{z_i(a)} $$ (2.2)

Singular solutions will correspond to $z_i^{(0)} \to z_S$ for some $i \in S$ where the subset $S$ has at least two elements.

A first important observation made in [13] is that if there is at least one singular solution, then at least one kinematic pole goes to zero. The argument in [13] is following. Assuming there is at least one singular solution in (2.2) satisfying following condition:

Cond A : $z_i^{(0)} = z_S$, $a \in S$; $z_{ab}^{(0)} \neq 0$, $z_{\tilde{b}b}^{(0)} \neq 0$, $\forall a \in S$, $b, \tilde{b} \not\in S$  (2.3)
Putting this back, the scattering equations (1.3) will be factorized into two parts. For $a \in S$, we will have
\[
\mathcal{E}_a = \sum_{t \neq a} \frac{k_a \cdot k_t}{z_a - z_t} = \sum_{t \neq a, t \notin S} \frac{k_a \cdot k_t}{z_a - z_t} + \sum_{t \notin S} \frac{k_a \cdot k_t}{z_a - z_t} = \frac{1}{\epsilon} \left\{ \sum_{t \neq a, t \notin S} \frac{K^{(0)}_{at}}{z_{at}^{(1)}} \right\} + \sum_{t \notin S} \frac{K^{(0)}_{at}}{z_{at}^{(1)}} + \mathcal{O}(\epsilon) (2.4)
\]
where for simplicity we have defined $z_{ij}^{(a)} \equiv z_i^{(a)} - z_j^{(a)}$ and $K_{ij}^{(ab)} \equiv k_i^{(a)} \cdot k_j^{(b)}$, while for $a \notin S$, we have
\[
\mathcal{E}_a = \sum_{t \neq a, t \notin S} \frac{k_a \cdot k_t}{z_a - z_t} + \sum_{t \in S} \frac{k_a \cdot k_t}{z_a - z_t} = \sum_{t \neq a, t \notin S} \frac{K^{(0)}_{at}}{z_{at}^{(1)}} + \sum_{t \in S} \frac{K^{(0)}_{at}}{z_{at}^{(1)}} + \mathcal{O}(\epsilon) (2.5)
\]
An important point is that scattering equation should hold for each order of $\epsilon$, thus from the leading order of (2.4), we get the relation
\[
\mathcal{E}_{a, \epsilon^{-1}} = \sum_{t \neq a, t \in S} \frac{K^{(0)}_{at}}{z_{at}^{(1)}} = 0 (2.6)
\]
Using this result, we can see
\[
(K_S^{(0)})^2 \equiv \left( \sum_{a \in S} k_a^{(0)} \right)^2 = \sum_{a,b \in S} \frac{z_a^{(1)} - z_b^{(1)}}{z_a^{(1)} - z_b^{(1)}} \cdot \frac{z_b^{(1)} - z_a^{(1)}}{z_b^{(1)} - z_a^{(1)}} \left( \sum_{a \neq b} k_a^{(0)} \cdot k_b^{(0)} \right) = 2 \sum_{a \in S} z_a^{(1)} \frac{k_a^{(0)}}{z_a^{(1)} - z_b^{(1)}} = 2 \sum_{a \in S} z_a^{(1)} \mathcal{E}_{a, \epsilon^{-1}} = 0 (2.7)
\]
In other words, assuming the singular solution with behaviour (2.3) we have derived the kinematic information $(K_S^{(0)})^2 = 0$.

Above derivation is beautiful, but if one check it carefully, one can find a hidden assumption having been made, i.e., all $z_a^{(1)} - z_b^{(1)} \neq 0$ for $a, b \in S$. In other words, points in the subset $S$ going to the same location with the same order of speed, i.e., there is no subset such that points of this subset collapse to each other faster. If there is a subset violating the assumption, the leading term in (2.4) will be at least the order of $\frac{1}{\epsilon^2}$ and the conclusion will be modified. With this in mind, we consider various generalizations of the above derivation with different singular solution behaviours.

### 2.1 The first case

Let us start with the simplest generalization. Again, let us assume there is at least one singular solution satisfying the condition A given in (2.3). However, for these points going together, a subset of points collapses to each other faster, i.e., they satisfy one more condition.

\[\text{Cond B: } z_i^{(1)} = z_{S1} (i.e., z_{a}^{(1)} = 0), \quad z_{aa}^{(2)} \neq 0 \quad \forall \ a, \tilde{a} \in S_1 \subset S;\]
With these two conditions, the scattering equation (2.5) is not modified, but equation (2.4) should be refined as

\[
\mathcal{E}_a = \sum_{t \neq a, t \in S_1} \frac{k_a \cdot k_t}{z_a - z_t} + \sum_{t \in S \setminus S_1} \frac{k_a \cdot k_t}{z_a - z_t} + \sum_{t \in S} \frac{k_a \cdot k_t}{z_a - z_t} = \frac{1}{\epsilon^2} \left\{ \sum_{t \neq a, t \in S_1} K_{at}^{(0)} \right\} + \frac{1}{\epsilon} \left\{ \sum_{t \neq a, t \in S_1} \frac{K_{at}^{(01)}}{z_{at}^{(2)}} + \sum_{t \neq a, t \in S_1} \frac{K_{at}^{(010)}}{z_{at}^{(2)}} + \sum_{t \in S \setminus S_1} \frac{K_{at}^{(00)}}{z_{at}^{(1)}} \right\} + \mathcal{O}(\epsilon^0) \quad (2.9)
\]

when \( a \in S_1 \) and

\[
\mathcal{E}_a = \sum_{t \neq a, t \in S_1} \frac{k_a \cdot k_t}{z_a - z_t} + \sum_{t \in S_1} \frac{k_a \cdot k_t}{z_a - z_t} + \sum_{t \in S} \frac{k_a \cdot k_t}{z_a - z_t} = \frac{1}{\epsilon} \left\{ \sum_{t \neq a, t \in S} \frac{K_{at}^{(00)}}{z_{at}^{(1)}} \right\} + \left\{ \sum_{t \neq a, t \in S_1} \frac{K_{at}^{(01)}}{z_{at}^{(1)}} + \sum_{t \neq a, t \in S_1} \frac{K_{at}^{(10)}}{z_{at}^{(2)}} + \sum_{t \in S \setminus S_1} \frac{K_{at}^{(00)}}{z_{at}^{(1)}} \right\} + \mathcal{O}(\epsilon^{10})
\]

when \( a \in S \setminus S_1 \). From the refined scattering equations (2.9) and (2.10), we obtain following identities

\[
\mathcal{E}_{a \in S_1, \epsilon^{-2}} = \sum_{t \neq a, t \in S_1} K_{at}^{(00)} = 0 \quad (2.11)
\]

\[
\mathcal{E}_{a \in S_1, \epsilon^{-1}} = \sum_{t \neq a, t \in S_1} \frac{K_{at}^{(01)}}{z_{at}^{(2)}} + \sum_{t \neq a, t \in S_1} \frac{K_{at}^{(10)}}{z_{at}^{(2)}} + \sum_{t \in S \setminus S_1} \frac{K_{at}^{(00)}}{z_{at}^{(1)}} \quad (2.12)
\]

\[
\mathcal{E}_{a \in S \setminus S_1, \epsilon^{-1}} = \sum_{t \neq a, t \in S} \frac{K_{at}^{(00)}}{z_{at}^{(1)}} = \sum_{t \neq a, t \in S_1} \frac{K_{at}^{(00)}}{z_{at}^{(1)}} + \sum_{t \neq a, t \in S \setminus S_1} \frac{K_{at}^{(00)}}{z_{at}^{(1)}} \quad (2.13)
\]

\[
\mathcal{E}_{a \in S \setminus S_1, \epsilon^{0}} = \sum_{t \neq a, t \in S} \frac{K_{at}^{(01)}}{z_{at}^{(1)}} + \sum_{t \neq a, t \in S_1} \frac{K_{at}^{(10)}}{z_{at}^{(2)}} + \sum_{t \neq a, t \in S \setminus S_1} \frac{K_{at}^{(00)}}{z_{at}^{(0)}} \quad (2.14)
\]

Now mimic previous argument, first suing (2.11) one can show

\[
k_{S_1}^{(0)} = \left( \sum_{a \in S_1} k_{a}^{(0)} \right)^2 = \sum_{a,b \in S_1} \frac{k_{a}^{(0)} \cdot k_{b}^{(0)}}{z_{a}^{(2)} - z_{b}^{(2)}} = \sum_{a,b \in S_1} \frac{2k_{a}^{(0)} \cdot k_{b}^{(0)}}{z_{a}^{(2)} - z_{b}^{(2)}} = 0 \quad (2.15)
\]

Secondly, let us consider following combination

\[
2K_{S_1} \cdot K_{S \setminus S_1} + K_{S \setminus S_1}^2 = \sum_{a \in S_1} \frac{2k_{a}^{(0)} \cdot k_{b}^{(0)}}{z_{a}^{(0)} - z_{b}^{(0)}} + \sum_{a,b \in S \setminus S_1} \frac{2k_{a}^{(0)} \cdot k_{b}^{(0)}}{z_{a}^{(0)} - z_{b}^{(0)}}
\]

\[
-6-
\]
\[ \epsilon^0 \quad \epsilon^1 \quad \epsilon^2 \]

\[ z_{S_1} \]

\[ z_S \]

\[ \vdots \]

\[ S \backslash S_1 \]

\[ \vdots \]

\[ \overline{S} \]

**Figure 1.** The pictorial representation of conditions A and B exhibited in (2.3) and (2.8). Since \( z_{i \in S}^{(0)} \)'s are different values, we represent them by a node under the column of \( \epsilon^0 \). For the subset \( S \), they have the same \( z_{i \in S}^{(0)} = z_S \), which is represented by a node with several lines under the column of \( \epsilon^0 \). Similarly, for the subset \( S_1 \), they have the same \( z_{i \in S_1}^{(1)} = z_{S_1} \), which is represented by a node with several lines under the column of \( \epsilon^1 \). The ending of each line has meaning too. Different positions in a given column mean the different \( z \)'s at the given order of \( \epsilon \). For the subset \( \overline{S} \), the ending under the column of \( \epsilon^0 \) means that all \( z_{i \in S}^{(0)} \) and \( z_S \) are different, so the leading scattering equation is at the order of \( \epsilon^0 \) as given in (2.5). Similarly, for the subset \( S \backslash S_1 \), the ending under the column of \( \epsilon^1 \) means the leading scattering equation is at the order of \( \epsilon^1 \) as given in (2.13), while for the subset \( S_1 \), the ending under the column of \( \epsilon^2 \) means the leading scattering equation is at the order of \( \epsilon^2 \) as given in (2.11).

\[ \sum_{a \in S_1, b \in S_\backslash S_1} \frac{z_{ab}^{(1)}}{z_{ab}^{(1)}} k_{a}^{(0)} \cdot k_{b}^{(0)} + \sum_{b, i \in S_\backslash S_1, b \neq i} \frac{(z_{b}^{(1)} - z_{S_1}^{(1)}) - (z_{i}^{(1)} - z_{S_1}^{(1)})}{z_{b}^{(1)} - z_{i}^{(1)}} 2k_{b}^{(0)} \cdot k_{i}^{(0)} \]

\[ = \sum_{a \in S_1, b \in S_\backslash S_1} \frac{z_{b}^{(1)} - z_{S_1}^{(1)}}{z_{b}^{(1)} - z_{S_1}^{(1)}} 2k_{a}^{(0)} \cdot k_{b}^{(0)} + \sum_{b, i \in S_\backslash S_1, b \neq i} \frac{(z_{b}^{(1)} - z_{S_1}^{(1)})}{z_{b}^{(1)} - z_{i}^{(1)}} 2k_{b}^{(0)} \cdot k_{i}^{(0)} \]

\[ = \sum_{b \in S_\backslash S_1} 2(z_{b}^{(1)} - z_{S_1}) \left( \sum_{a \in S_1} \frac{1}{z_{b}^{(1)} - z_{S_1}} k_{a}^{(0)} \cdot k_{b}^{(0)} + \sum_{b, i \in S_\backslash S_1, b \neq i} \frac{1}{z_{b}^{(1)} - z_{i}^{(1)}} k_{b}^{(0)} \cdot k_{i}^{(0)} \right) \]

\[ = \sum_{b \in S_\backslash S_1} 2(z_{b}^{(1)} - z_{S_1}) \mathcal{E}_{b \in S_\backslash S_1} x^{(1)} = 0 \quad (2.16) \]

Combining (2.15) and (2.16) we have

\[ (k_S^{(0)})^2 = \sum_{a, b \in S_1} 2k_{a}^{(0)} \cdot k_{b}^{(0)} + \sum_{a \in S_1, b \in S_\backslash S_1} 2k_{a}^{(0)} \cdot k_{b}^{(0)} + \sum_{b, i \in S_\backslash S_1, b \neq i} 2k_{b}^{(0)} \cdot k_{i}^{(0)} = 0 \quad (2.17) \]

In other words, under the limit \( \epsilon \rightarrow 0 \), two poles go to zero at the same time.

The above case can be generalized to more configurations. To see that, let us first rephrase the condition A and B in (2.3) and (2.8) in Figure 1. With the pictorial representation, we consider the more general one given in Figure 2. We will call it the "Type A" structure, where each node has several branches, but at most, one branch has a substructure. From Figure 2, we can read out the following kinematic information. First, using the
leading order part (at the order \( \epsilon^{-(k)} \)) of scattering equations of the subset \( S_k \).

\[
\mathcal{E}_{a \in S_k; \epsilon^{-(k)}} = \sum_{t \neq a, t \in S_k} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(k)} - z_t^{(k)}} = 0 \tag{2.18}
\]

we can derive

\[
(k_{S_k}^{(0)})^2 \equiv \sum_{a,b \in S_k \atop a < b} 2k_a^{(0)} \cdot k_b^{(0)} = \sum_{a,b \in S_k \atop a \neq b} \frac{z_a^{(k)}}{z_a^{(k)} - z_b^{(k)}} 2k_a^{(0)} \cdot k_b^{(0)} = 2 \sum_{a \in S_k} z_a^{(k)} \mathcal{E}_{a \in S_k; \epsilon^{-(k)}} = 0 \tag{2.19}
\]

Next we consider the leading order part (at the order \( \epsilon^{-(k-1)} \)) of scattering equations of the subset \( S_{k-1} \)

\[
\mathcal{E}_{a \in S_{k-1}; \epsilon^{-(k-1)}} = \sum_{t \in S_k} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(k-1)} - z_s} + \sum_{t \neq a, t \in S_{k-1}} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(k-1)} - z_t^{(k-1)}} = \frac{k_a^{(0)} \cdot K_{S_k}^{(0)}(0)}{z_a^{(k-1)} - z_{S_k}} + \sum_{t \neq a, t \in S_{k-1}} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(k-1)} - z_t^{(k-1)}} = 0 \tag{2.20}
\]

Using it, we can show

\[
2K_{S_k} \cdot K_{S_{k-1}} + K_{S_{k-1}}^2 = 2 \sum_{a \in S_{k-1}} \frac{z_a^{(k-1)} - z_{S_k}}{z_a^{(k-1)} - z_{S_k}} k_a^{(0)} \cdot K_{S_k}^{(0)} + 2 \sum_{t \neq a, t \in S_{k-1}} \frac{(z_a^{(k-1)} - z_{S_k}) k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(k-1)} - z_t^{(k-1)}} = 2 \sum_{a \in S_{k-1}} (z_a^{(k-1)} - z_{S_k}) \mathcal{E}_{a \in S_{k-1}; \epsilon^{-(k-1)}} = 0 \tag{2.21}
\]

When combining (2.19) and (2.21), we reach \( K_{S_k}^2 \cup S_{k-1} = 0 \). Similarly from the leading order part (at the order \( \epsilon^{-(k-2)} \)) of scattering equations of the subset \( S_{k-2} \)

\[
\mathcal{E}_{a \in S_{k-2}; \epsilon^{-(k-2)}} = \frac{k_a^{(0)} \cdot K_{S_k}^{(0)} \cup S_{k-1}}{z_a^{(k-2)} - z_{S_{k-2}}} + \sum_{t \neq a, t \in S_{k-2}} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(k-2)} - z_t^{(k-2)}} = 0, \tag{2.22}
\]

we can derive \( 2K_{S_k} \cup S_{k-1} \cdot K_{S_{k-2}} + K_{S_{k-2}}^2 = 0 \) and further \( K_{S_k}^2 \cup S_{k-1} \cup S_{k-2} = 0 \). Iterating the procedure, one can easily see that from the Figure 2, we can derive

\[
K_{\bigcup_{j=1}^{k} S_i}^2 = 0, \quad j = 1, \ldots, k \tag{2.23}
\]

An important point of above iterating procedure is that when going to the lower orders of \( \epsilon \), see for example (2.22), the detail structure of the node \( z_{S_{k-1}} \) does not appear. In other words, we can treat the subset \( S_k \cup S_{k-1} \) as an effective single leg when considering the subset \( S_{k-2} \).
Figure 2. The pictorial representation of the Type A generalization. For this type, where each node has several branches, but at most one branch has substructure. We have also used the $z$ to denote the common position at each order of $\epsilon$.

2.2 The second case

In the first case, we have required that in the pictorial representation of solution $z_i$'s, although each node has several branches, there is at most one branch having a substructure. Now we consider the case that there are at least two branches having substructures. For simplicity, let consider the situation given in Figure 3. For $a \in S_3$, we have the scattering equations as

$$
E_{a \in S_3; \epsilon^{-2}} = \sum_{t \neq a, t \in S_3} \frac{k_a^0 \cdot k_t^0}{z_a^2 - z_t^2} = 0
$$

(2.25)

Thus we get

$$
E_{a \in S_3; \epsilon^{-1}} = \sum_{t \neq a, t \in S_3} \frac{k_a^0 \cdot k_t^1 + k_a^1 \cdot k_t^0}{z_a^2 - z_t^2} + \sum_{t \neq a, t \in S_3} \frac{-(z_a^3 - z_t^3)(k_a^0 \cdot k_t^0)}{(z_a^2 - z_t^2)^2}
$$

$$
+ \sum_{t \in S_1} \frac{k_a^0 \cdot k_t^0}{z_a^2 - z_t^2} + \frac{k_a^0 \cdot K_{S_2}}{z_a^2 - z_{S_2}} = 0
$$

(2.26)
Similarly, for $a \in S_2$ we get

$$
\mathcal{E}_{a \in S_2; \epsilon^{-2}} = \sum_{t \neq a, t \in S_2} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(2)} - z_t^{(2)}} = 0 \quad (2.27)
$$

$$
\mathcal{E}_{a \in S_2; \epsilon^{-1}} = \sum_{t \neq a, t \in S_2} \frac{k_a^{(0)} \cdot k_t^{(1)} + k_a^{(1)} \cdot k_t^{(0)}}{z_a^{(2)} - z_t^{(2)}} + \sum_{t \neq a, t \in S_2} \frac{-(z_a^{(3)} - z_t^{(3)})(k_a^{(0)} \cdot k_t^{(0)})}{(z_a^{(2)} - z_t^{(2)})^2}
$$

$$
+ \sum_{t \in S_1} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(1)} - z_t^{(1)}} + \frac{k_a^{(0)} \cdot K_{S_3}}{z_a^{(1)} - z_{S_3}} = 0 \quad (2.28)
$$

For $a \in S_1$ we get

$$
\mathcal{E}_{a \in S_1; \epsilon^{-1}} = \sum_{t \neq a, t \in S_1} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(1)} - z_t^{(1)}} + \sum_{t \in S_1} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(1)} - z_{S_2}} + \sum_{t \in S_3} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(1)} - z_{S_3}} = 0 \quad (2.29)
$$

Now let us see which kinematic information can be derived using above identities.

First, using (2.25) and (2.27) we get

$$
K_{S_2}^2 = 0, \quad K_{S_3}^2 = 0 \quad (2.30)
$$

Secondly using (2.26) and (2.28) we get

$$
0 = \sum_{a \in S_3} \mathcal{E}_{a \in S_3; \epsilon^{-1}} = \sum_{t \in S_1} \frac{K_{S_3}^{(0)} \cdot k_t^{(0)}}{z_{S_3}^{(1)} - z_t^{(1)}} + \frac{K_{S_3}^{(0)} \cdot K_{S_2}^{(0)}}{z_{S_3} - z_{S_2}} \quad (2.31)
$$

$$
0 = \sum_{a \in S_2} \mathcal{E}_{a \in S_2; \epsilon^{-1}} = \sum_{t \in S_1} \frac{K_{S_2}^{(0)} \cdot k_t^{(0)}}{z_{S_2}^{(1)} - z_t^{(1)}} + \frac{K_{S_2}^{(0)} \cdot K_{S_3}^{(0)}}{z_{S_2} - z_{S_3}} \quad (2.32)
$$

Now we consider

$$
2K_{S_2}^{(0)} \cdot K_{S_3}^{(0)} + 2 \sum_{a \in S_1} (K_{S_3}^{(0)} \cdot k_a^{(0)} + K_{S_2}^{(0)} \cdot k_a^{(0)}) + 2 \sum_{t < a, t \in S_1} k_a^{(0)} \cdot k_t^{(0)}
$$

Figure 3. The pictorial representation of one simple case of the Type B, where a node has two branches having substructure.
where (2.31) has been used to reach the last line. When combining (2.33) with (2.30) we arrive

\[ K_{S_1 \cup S_2 \cup S_3}^2 = 0 \]  \hspace{1cm} (2.34)

We can generalize above argument for more than two branches having substructure. Let us assume that (1) when \( i \in S \), \( z_i^{(0)} = z_0 \); (2) when \( i \in S_j \subset S \), \( z_i^{(1)} = z_{S_j} \) with \( j = 1, \ldots, m \); (3) \( S = S_0 \cup S_1 \cup \ldots \cup S_m \). For each \( a \in S_j, j = 1, \ldots, m \), we have following two identities

\[ \mathcal{E}_{a \in S_j; \epsilon^2} = \sum_{t \neq a, t \in S_j} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(2)} - z_t^{(2)}} = 0 \]  \hspace{1cm} (2.35)

\[ \mathcal{E}_{a \in S_j; \epsilon^1} = \sum_{t \neq a, t \in S_j} \frac{k_a^{(0)} \cdot k_t^{(1)}}{z_a^{(2)} - z_t^{(2)}} + \sum_{t \neq a, t \in S_j} \frac{-(z_a^{(3)} - z_t^{(3)}) (k_a^{(0)} \cdot k_t^{(0)})}{(z_a^{(2)} - z_t^{(2)})^2} \]

\[ + \sum_{t \in S_0} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_t^{(1)} - z_t^{(1)}} + \sum_{p=1, p \neq j}^m \frac{k_a^{(0)} \cdot K_{S_p}^{(0)}}{z_{S_j} - z_{S_p}} = 0 \]  \hspace{1cm} (2.36)

and using them we get

\[ 0 = K_{S_j}^2, \quad 0 = \sum_{a \in S_j} \mathcal{E}_{a \in S_j; \epsilon^1} = \sum_{t \in S_0} \frac{K_{S_j}^{(0)} \cdot k_t^{(0)}}{z_{S_j} - z_t^{(1)}} + \sum_{p=1, p \neq j}^m \frac{K_{S_j}^{(0)} \cdot K_{S_p}^{(0)}}{z_{S_j} - z_{S_p}} \]  \hspace{1cm} (2.37)

For \( a \in S_0 \), the leading part of scattering equations is

\[ \mathcal{E}_{a \in S_0; \epsilon^1} = \sum_{t \neq a, t \in S_0} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(1)} - z_t^{(1)}} + \sum_{j=1}^m \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(1)} - z_t^{(1)}} \]

\[ = \sum_{t \neq a, t \in S_0} \frac{k_a^{(0)} \cdot k_t^{(0)}}{z_a^{(1)} - z_t^{(1)}} + \sum_{j=1}^m \frac{k_a^{(0)} \cdot K_{S_j}^{(0)}}{z_a^{(1)} - z_{S_j}} = 0 \]  \hspace{1cm} (2.38)
One important point of expressions (2.37) and (2.38) is that the subset \( S_j \) has been effectively treated as a single leg. This fact is very useful to see in an arbitrary tree graph, how the computation done explicitly here is generalized. Using above results, we can see

\[
\sum = \sum_{1 \leq i < j \leq m} K_{S_i}^{(0)} \cdot K_{S_j}^{(0)} + \sum_{j=1}^{m} \sum_{t \in S_0} K_{S_j}^{(0)} \cdot k_t^{(0)} + \sum_{t < a | a \in S_0} k_a^{(0)} \cdot k_t^{(0)} \\
= \sum_{t < a | a \in S_0} \left( \sum_{1 \leq i < j \leq m} \frac{z_a^{(1)} - z_i^{(1)}}{z_a^{(1)} - z_t^{(1)}} k_t^{(0)} \cdot k_i^{(0)} \right) + \sum_{i \neq j} \left( \sum_{j=1}^{m} \frac{z_i - z_S}{z_i - z_S} K_{S_i}^{(0)} \cdot K_{S_j}^{(0)} + \sum_{j=1}^{m} \frac{z_a^{(1)} - z_S}{z_a^{(1)} - z_S} K_{S_j}^{(0)} \cdot k_a^{(0)} \right) \\
= \sum_{a \in S_0} \sum_{t \neq a | t \in S_0} \frac{z_a^{(1)} - z_t^{(1)}}{z_a^{(1)} - z_t^{(1)}} k_t^{(0)} \cdot k_i^{(0)} + \sum_{j=1}^{m} \sum_{a \in S_0} \frac{z_a^{(1)} - z_S}{z_a^{(1)} - z_S} K_{S_j}^{(0)} \cdot k_a^{(0)} \\
= 0
\]

where (2.38) and (2.37) have been used to reach the last line. When combining (2.39) and (2.37) we get

\[
K_S^2 = 0
\]  

**Summary:** Although we have considered only a tree graph with two levels for Type B, it is easy to see combining results for Type A and B. The above observation can be easily generalized to a tree graph with an arbitrary structure. The basic conclusion is that for each node in the tree graph, we have \( \sum_{i \in \text{node}} k_i = 0 \). One important remark is that for all subsets \( S_i \) with \( K_{S_i}^2 = 0 \), they are compatible to each others, i.e., either \( S_i \cap S_j = \emptyset \) or \( S_i \subset S_j \).

With results in this section, one can also show that if \( k_S^2 \neq 0 \) for all subsets \( S \) with between 2 and \( (N - 2) \) elements, the values of the \( z_a, a \in A \), are distinct, i.e., there are no singular solutions. This claim is proved in [13] by contradiction. Assuming there is a singular solution, by analysis in this section, we will reach at least one \( S_A \to 0 \) no matter which configuration of the singular solution is.

### 3 From singular kinematics to solutions I: the factorization limit

Starting from this section, we discuss what we can learn about the solutions of scattering equations when there are one or more poles going to on-shell.

#### 3.1 With only one \( S_A \to 0 \)

This case has been well studied in [8, 13]. Under the limit \( \epsilon \to 0 \), assuming there is one and only one \( S_A \to 0 \), what we can say about the solutions of scattering equations? Under the limit, we could have two possibilities: (R1) There is still no singular solution;(R2) There are some singular solutions.
Let us argue that the possibility (R1) could not be true first. We could assign a particular CHY-integrand, such as the multiplication of two PT-factors, which produces amplitude containing one and only one cubic Feynman diagram having the pole $S_A$. Since $S_A \to 0$, the amplitude will be divergent. Now let us check the expression (1.4) for the amplitude with gauge choice $(ijk) = (rst)$ and three fixed points at the finite locations. We see that the numerator $(z_{ij} z_{jk} z_{ik})^2$ is not divergent, as well as the factor $\frac{1}{|\Phi|_{ijk}}$ and the particular CHY-integrand if the possibility (R1) is true. Thus by the contradiction, we see that the possibility (R1) could not be true.

Now the possibility (R2) is realized, and we discuss the properties of singular solutions. For a given singular solution, from the careful analysis in section two, we see that (a) the singular set can be and only be the subset $A^3$; (b) there is no substructure in $A$, i.e., every point in $A$ going to the same location with the same speed. If (a) is not true, we will have $S_B \to 0$ with $B \neq A$. If (b) is not true, we will have other $S_B \to 0$ with $B \subset A$. In fact more information is given in [8]: the number of singular solution is $(n_A + 1 - 3)! \times (n_A + 1 - 3)!$ where $n_A, n_{\overline{A}}$ are the number of elements in the subsets $A, \overline{A}$. The counting of the number of singular solutions can be easily seen from the left picture given in Figure 4.

In fact, we can get more accurate information, i.e., the speed of every point in $A$ going to the same location. Assuming $|z_i - z_j| \sim t^N \forall i, j \in A$, let us study the $\epsilon$ order of various part in the formula\(^\text{6}\) (1.4). Without loss of generality, we choose $S_{12...k} \to 0$ and fix \{r, s, t\} = 1, 2, 3 and \{i, j, k\} = (n, n - 1, n - 2). And choose $S_{12...k} \to 0$. For the measure part

$$J = \frac{(z_r - z_s)(z_s - z_t)(z_t - z_r)(z_i - z_j)(z_j - z_k)(z_k - z_i)}{|\Phi|_{ijk}^{rst}}$$

where matrix $\Phi$ is defined in (1.5), one can check that

$$(z_1 - z_2)(z_2 - z_3)(z_3 - z_1)(z_n - z_{n-1})(z_{n-1} - z_{n-2})(z_{n-2} - z_n) \sim \begin{cases} \epsilon^N, & |A| = 2 \\ \epsilon^{3N}, & |A| \geq 3 \end{cases}$$

$$|\Phi|_{ijk}^{rst} \sim \begin{cases} \epsilon^0, & |A| = 2 \\ \epsilon^{-2(|A| - 3)N}, & |A| \geq 3 \end{cases}$$

$$J \sim \epsilon^{(2|A| - 3)N}$$

For the integrand part, the leading behaviour is $\epsilon^{-N|\mathbb{L}[A]|}$ where the $\mathbb{L}[A]$ is the linking number. Adding all together, we get the behaviour $\epsilon^{-N(|\mathbb{L}[A]| - 2(|A| - 1) + 1)} = \epsilon^{-N(|\mathbb{L}[A]| + 1)}$. From the integration rule [31–33], the behaviour is $S_A^{-\chi[A]+1} \sim \epsilon^{-\chi[A]+1}$, thus the match up of arbitrary choice of $\chi[A]$ requires $N = 1$. One interesting point of above analysis of contributions of singular solutions is that when $\chi[A] = -1$, we will have $\epsilon^0$. In other words, to get the right numerical result is the $\epsilon \to 0$ limit, we must include the contributions of singular solutions although analytic expression does not contain the pole $S_A$.

\(^6\) Again, we use $A$ to denote the one with at most one gauge fixed point among the subsets $A, \overline{A}$

\(^7\) For the regular solutions, both measure and integrand will give $\epsilon^0$ contributions.
3.1.1 The numerical checking

Now we present some numerical computations to verify the above analysis. In numerical computation, one key is the construction of the kinematics having the wanted limit behaviour. The detailed discussion has been given in Appendix A. For current case, i.e., with one and only one $S_A \to 0$, a straightforward way is to use the BCFW-deformation (see (A.8), (A.9) and (A.10)).

Example I: six points with $S_{123} \to 0$

The kinematics is given by

$$k_1 \to \{-0.152 - 0.593i, -1.019 - 0.981i, 0.106 + 2.464i, -0.560 + 1.268i, -2.642 + 0.175i\}$$

$$+ \{0.254, 0.4205, -0.238 - 0.484i, -0.1242 - 0.248i, 0.461 - 0.317i\} \epsilon$$

$$k_2 \to \{1.220, -0.852, -0.262, -0.825, 0.115\}$$

$$k_3 \to \{1.586, -0.999, -0.459, -0.664, 0.931\}$$

$$k_4 \to \{1.203, -0.240, 0.419, 0.968, 0.527\}$$

$$k_5 \to \{-1.416, -0.0899, -0.750, -0.688, 0.980\}$$

$$k_6 \to \{-2.441 + 0.5935i, 3.201 + 0.981i, 0.946 - 2.464i, -1.770 - 1.267i, 0.089 - 0.175i\}$$

$$- \{0.254, 0.4205, -0.238 - 0.484i, -0.1242 - 0.248i, 0.461 - 0.317i\} \epsilon$$

We fix the gauge of $z_4 = 1, z_5 = 0, z_6 = 1$. There are 6 solutions with one singular and 5 regular solutions. The solutions are shown below as the series of $\epsilon$ up to $\epsilon^1$ terms:

**Singular** (1)

$$\begin{cases}
  z_1 \to -(0.701112 - 0.144145i) + (-3.14275 - 0.280886i) \epsilon \\
  z_2 \to -(0.701112 - 0.144145i) + (-3.20442 - 0.255032i) \epsilon \\
  z_3 \to -(0.701112 - 0.144145i) + (-3.18786 - 0.260227i) \epsilon
\end{cases}$$

**Regular** (1)

$$\begin{cases}
  z_1 \to (0.0452115 + 0.636781i) - (0.0913283 + 0.0933938i) \epsilon \\
  z_2 \to -(2.63638 + 0.252226i) + (1.32192 + 0.064034i) \epsilon \\
  z_3 \to -(8.15521 - 3.66499i) + (7.11037 - 9.61685i) \epsilon
\end{cases}$$

**Regular** (2)

$$\begin{cases}
  z_1 \to (0.0308196 + 0.774219i) - (0.0791472 + 0.145376i) \epsilon \\
  z_2 \to -(0.71447 + 6.1477i) + (-6.30372 + 0.80879i) \epsilon \\
  z_3 \to -(1.67537 - 0.0415368i) + (0.253797 - 0.132973i) \epsilon
\end{cases}$$

**Regular** (3)

$$\begin{cases}
  z_1 \to -(0.28604 - 0.376317i) + (-0.0471353 - 0.97799i) \epsilon \\
  z_2 \to -(4.08226 + 0.917673i) + (2.66599 + 1.09849i) \epsilon \\
  z_3 \to -(0.377007 - 0.515852i) + (-0.0729845 - 0.0909321i) \epsilon
\end{cases}$$

**Regular** (4)

$$\begin{cases}
  z_1 \to -(0.435329 - 0.28238i) + (0.0150451 - 0.0647125i) \epsilon \\
  z_2 \to -(0.29774 - 0.197556i) + (-0.0197837 - 0.00948061i) \epsilon \\
  z_3 \to -(3.40278 - 1.35514i) + (0.562885 - 0.896193i) \epsilon
\end{cases}$$
\[ z_1 \to -(0.72372 - 0.14116i) + (0.0430294 - 0.0225452i)\epsilon \]

\[ z_2 \to -(0.558638 - 0.130488i) + (-0.00452728 - 0.0035687i)\epsilon \] (3.9)

\[ z_3 \to -(0.855428 - 0.12072i) + (-0.0054946 - 0.00384179i)\epsilon \] (3.10)

The measure part of each solution is shown in table (1). which is indeed the behaviour

| Solution       | Measure                        |
|----------------|--------------------------------|
| Singular (1)   | \((1.08633 \times 10^{-7} - 3.24352 \times 10^{-8}i)\) \epsilon^3 |
| Regular (1)    | \((-516.832 + 220.062i)\)               |
| Regular (2)    | \(-6.23504 + 50.3245i\)               |
| Regular (3)    | \((0.0453058 - 0.141481i)\)           |
| Regular (4)    | \((0.0188278 + 0.0202573i)\)          |
| Regular (5)    | \(-3.4399 \times 10^{-6} + 8.80267 \times 10^{-6}i\) |

Table 1. The measure part of each solution

\[ \epsilon^{(2;A|-3)} = \epsilon^{2 \times 3 - 3} = \epsilon^3 \]. Now we choose three different CHY-integrands with pole index of \( \chi[S_{123}] = 0, -1, -2 \) respectively to calculate the contribution of each solution.

- \( I_1 = PT(123456)PT(124563) \) with \( \chi[S_{123}] = 0 \). The contribution of each solution is shown in table (2). Summing up all six solutions, we have

| Solution       | Integration                        |
|----------------|------------------------------------|
| Singular (1)   | \( \frac{1}{\epsilon}(0.0801588 + 0.0445719i)\) |
| Regular (1)    | \(-0.00189857 + 0.00277649i\)      |
| Regular (2)    | \((0.00417627 + 0.00436192i)\)     |
| Regular (3)    | \(-0.00185648 + 0.00211634i\)      |
| Regular (4)    | \(-0.00963083 - 0.000139444i\)     |
| Regular (5)    | \((0.0509707 + 0.00619341i)\)     |

Table 2. The contribution of each solution for the CHY-Integrand \( PT(123456)PT(124563) \)

\[ \frac{0.0801588 + 0.0445719i}{\epsilon} + O(\epsilon^0) \] (3.10)

If we substitute the numerical kinematics (3.3) to the analytic expression

\[ \frac{1}{S_{12}S_{45}S_{123}} + \frac{1}{S_{12}S_{56}S_{123}} = \frac{0.0802693 + 0.0448299i}{\epsilon} + O(\epsilon^0) \] (3.11)

This result is essentially in agreement with (3.10). For this case, the leading contribution comes from the singular solution only.

- \( I_2 = PT(123456)PT(124536) \) with \( \chi[S_{123}] = -1 \). The result is shown in table (3) The summation of six solutions is

\[ - (0.033591 + 0.0023464i) + O(\epsilon) \] (3.12)
\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
Solution & Integration \\
\hline
Singular (1) & $-(0.0188869 - 0.00321464i)$ \\
Regular (1) & $(0.00236768 + 0.00127038i)$ \\
Regular (2) & $-(0.00430291 + 0.00290199i)$ \\
Regular (3) & $(0.000865392 + 0.000279345i)$ \\
Regular (4) & $(0.011857 - 0.00567046i)$ \\
Regular (5) & $-(0.0254912 - 0.00146168i)$ \\
\hline
\end{tabular}
\caption{The contribution of each solution of CHY-Integrand $PT(123456)PT(124536)$ which is identical with the numerical result by substituting (3.3) to analytic expression}
\end{table}

\[
\frac{1}{S_{12}S_{45}S_{126}} + \frac{1}{S_{16}S_{45}S_{126}} = -(0.033591 + 0.0023464i) + O(\epsilon), \quad (3.13)
\]

This shown the correctness of (3.4) and (3.9). From table (3) we see all solutions (including the singular solution) gives $\epsilon^0$ contribution.

• $I_3 = PT(123456)PT(143526)$ with $\chi[S_{123}] = -2$. The result is shown in(4). The summation of all six solutions is

\[
-0.00529087 + O(\epsilon) \quad (3.14)
\]

which is identical to the analytic expression with the numerical kinematic (3.3)

\[
-\frac{1}{S_{16}S_{34}S_{126}} = -0.00529087 + O(\epsilon) \quad (3.15)
\]

where singular solution will give no contribution when $\epsilon \to 0$. 

\[ - 16 - \]
Example II: six points with $S_{12} \rightarrow 0$. The choice of numerical kinematics is

\[ k_1 \rightarrow \{0.111 + 0.384i, -1.887 - 0.493i, 0.221 - 2.605i, -0.751 - 1.544i, 2.344 - 0.627i\} + \{0.361, 0.755 + 0.428i, -0.363 + 0.731i, -0.123 + 0.466i, -0.589\} \epsilon \]

\[ k_2 \rightarrow \{0.894, -0.453, -0.411, 0.647, -0.0763\} \]

\[ k_3 \rightarrow \{1.065, -0.183, 0.780, 0.557, 0.427\} \]

\[ k_4 \rightarrow \{1.387, -0.0137, -0.981, 0.840, 0.504\} \]

\[ k_5 \rightarrow \{-1.7085, 1.1005, -1.083, 0.2038, -0.7025\} \]

\[ k_6 \rightarrow \{-1.748 - 0.384i, 1.436 + 0.493i, 1.475 + 2.605i, -1.497 + 1.544i, -2.497 + 0.627i\} - \{0.361, 0.755 + 0.428i, -0.363 + 0.731i, -0.123 + 0.466i, -0.589\} \epsilon. \]

(3.16)

We fix the gauge choice $z_4 = 1, z_5 = 0, z_6 = 1$, there are two singular and four regular solutions:

\[ \text{Singulart}(1) \]

\[ \begin{cases} z_1 \rightarrow (0.762074 + 0.364077i) - (0.0646452 + 0.838813i) \epsilon \\ z_2 \rightarrow (0.762074 + 0.364077i) + (0.515056 - 0.754896i) \epsilon \\ z_3 \rightarrow -(0.0322539 - 0.0615108i) + (0.01392 + 0.00452414i) \epsilon \\ z_1 \rightarrow (0.112028 - 0.54179i) - (0.047236 - 0.313822i) \epsilon \\ z_2 \rightarrow (0.112028 - 0.54179i) + (0.225107 + 0.143289i) \epsilon \\ z_3 \rightarrow (0.396924 + 0.0453154i) - (0.0887612 - 0.0250629i) \epsilon \\ \end{cases} \]

(3.17)

\[ \text{Regular}(1) \]

\[ \begin{cases} z_1 \rightarrow (1.05565 + 0.418985i) - (0.51277 + 0.296097i) \epsilon \\ z_2 \rightarrow (4.03218 + 1.32966i) + (6.55886 + 28.4338i) \epsilon \\ z_3 \rightarrow -(0.0320861 - 0.0733717i) + (0.0125772 + 0.00408331i) \epsilon \\ z_1 \rightarrow (0.305812 - 0.703593i) - (0.205823 - 0.327967i) \epsilon \\ z_2 \rightarrow -(4.30772 + 0.129581i) + (15.332 + 1.98828i) \epsilon \\ z_3 \rightarrow (0.452278 - 0.0114679i) - (0.109894 - 0.0917084i) \epsilon \\ z_1 \rightarrow (0.932462 + 0.508345i) - (0.0889137 + 0.704417i) \epsilon \\ z_2 \rightarrow -(0.147739 - 0.337423i) + (+0.0381437 + 0.0380429i) \epsilon \\ z_3 \rightarrow -(0.0558585 - 0.162427i) + (-0.0398685 - 0.025863i) \epsilon \\ \end{cases} \]

(3.18)

\[ \text{Regular}(3) \]

\[ \begin{cases} z_1 \rightarrow (0.290776 - 0.394965i) - (0.208807 - 0.274043i) \epsilon \\ z_2 \rightarrow (0.548109 + 0.0301496i) - (0.132396 - 0.052737i) \epsilon \\ z_3 \rightarrow (0.296957 + 0.0219136i) - (0.142326 - 0.0932441i) \epsilon \\ \end{cases} \]

The measure part of each solution is shown in table (5).

which agrees with our analysis $\epsilon^0$ for regular solutions and $\epsilon^{2|A|−3}$ for singular solutions. Again we choose three different CHY-Intergrands with pole index $\chi[S_{12}] = 0, -1, -2$ respectively.

- $I_1 = PT(123456)PT(124563)$ with $\chi[S_{12}] = 0$. The result is shown in (6). The
Solution | Measure
---|---
Singular (1) | $-(0.000529048 + 0.0005798i)\epsilon$
Singular (2) | $(0.000892278 + 0.000357788i)\epsilon$
Regular (1) | $-(0.186684 + 0.928303i)$
Regular (2) | $-(1.95152 - 1.51335i)$
Regular (3) | $-(0.0000405857 - 0.000616897i)$
Regular (4) | $-(0.000169266 - 0.0000142748i)$

**Table 5.** The measure part of each solution for $S_{12} \to 0$.

| Solution | Integration |
|---|---|
| Singular (1) | $\frac{1}{\epsilon}(0.00333026 + 0.00227831i)$
| Singular (2) | $-\frac{1}{\epsilon}(0.0142701 - 0.0137308i)$
| Regular (1) | $-(0.00260062 - 0.0012496i)$
| Regular (2) | $(0.00122598 - 0.00527255i)$
| Regular (3) | $-(0.000501431 - 0.000889243i)$
| Regular (4) | $(0.0115214 - 0.00241242i)$

**Table 6.** The contribution of each solution of CHY-Intergrand $PT(123456)PT(124563)$

The summation of six solutions is

$$-\frac{0.0109398 - 0.0160991i}{\epsilon} + O(\epsilon) \quad (3.19)$$

which is identical with the analytic expression with the numerical kinematic (3.16)

$$\frac{1}{S_{12}S_{45}S_{123}} + \frac{1}{S_{12}S_{56}S_{123}} = -\frac{0.0109398 - 0.0160991i}{\epsilon} + O(\epsilon) \quad (3.20)$$

where the leading contribution comes from the singular solutions only.

• $I_2 = PT(123456)PT(134526)$ with $\chi[S_{12}] = -1$. The result is shown in (7). The fact

| Solution | Integration |
|---|---|
| Singular (1) | $-(0.000196838 - 0.000292468i)$
| Singular (2) | $-(0.000377502 - 0.0182017i)$
| Regular (1) | $-(0.000561198 - 0.000217058i)$
| Regular (2) | $(0.00839347 - 0.0144827i)$
| Regular (3) | $(0.00167404 - 0.00059116i)$
| Regular (4) | $-(0.00221397 + 0.00363733i)$

**Table 7.** The contribution of each solutions of CHY-Intergrand $PT(123456)PT(134526)$

that summation of six solutions

$$0.006718 + O(\epsilon) \quad (3.21)$$
is identical with analytic result
\[
\frac{1}{S_{16}S_{34}S_{126}} + \frac{1}{S_{16}S_{45}S_{126}} = 0.006718 + O(\epsilon)
\] (3.22)
shows that when \( \epsilon \to 0 \), both regular and singular solutions give nonzero contributions.

- \( I_3 = PT(132456)PT(134526) \) with pole index \( \chi[S_{12}] = -2 \). The result is shown in (8). The summation of six solutions is

| Solution       | Integration                                    |
|----------------|-----------------------------------------------|
| Singular (1)   | \(- (0.000557274 - 0.000151919i)\epsilon \)  |
| Singular (2)   | \(- (0.00394239 - 0.00346853i)\epsilon \)     |
| Regular (1)    | \((0.00033303 - 0.00039i)\)                   |
| Regular (2)    | \(- (0.00932611 + 0.00647014i) \)             |
| Regular (3)    | \(- (0.00153402 - 0.00062326i) \)             |
| Regular (4)    | \((0.00680103 + 0.00398464i) \)               |

Table 8. The contribution of each solutions of CHY-Intergrand \( PT(132456)PT(134526) \)

\[- (0.00372607 + 0.00225224i) + O(\epsilon) \] (3.23)

which agrees with the analytic result
\[
\frac{1}{S_{13}S_{45}S_{136}} + \frac{1}{S_{16}S_{45}S_{136}} = -(0.00372607 + 0.00225224i) + O(\epsilon)
\] (3.24)

For this case, when \( \epsilon \to 0 \), the regular solutions give whole contribution and singular solutions give no contributions.

### 3.2 With \( S_A, S_B \to 0 \)

Now we consider the factorization limit where two poles \( S_A, S_B \) go to zero at the same time. As discussed in the Appendix, a way to reach the kinematic configuration is to use two pairs of BCFW-deformations, for example,

\[
p_1(w_1) = p_1 + w_1 q_{1n}, \quad p_n(w_1) = p_n - w_1 q_{1n}, \quad q_{1n}^2 = q_{1n} \cdot p_1 = q_{1n} \cdot p_n = 0
\]
\[
p_2(w_2) = p_2 + w_2 q_{2m}, \quad p_m(w_2) = p_m - w_2 q_{2m}, \quad q_{2m}^2 = q_{2m} \cdot p_1 = q_{2m} \cdot p_m = 0
\] (3.25)

Using \( S_A = S_B = 0 \) we can solve \( w_1^*, w_2^* \), then we write \( w_1 = w_1^* + \epsilon \) and \( w_2 = w_2^* + \epsilon \) and \( \epsilon \to 0 \) will give \( S_A, S_B \to 0 \) at the same time.

A new feature of two poles going to zero at the same time is that there are two different cases we should consider. The first case is that two poles are compatible, i.e., two poles appear in a single Feynman diagram. The second case is that two poles are not compatible, so there is no Feynman diagram containing them simultaneously. While the second case is that they are not compatible, let us discuss them one by one.
3.2.1 $S_A, S_B$ are not compatible

For this case, we will have $A \not\subset B$ and $A \not\subset B$, so at least one intersection $A \cap B$ or $A \cap B$ will be the true nonempty subset. Therefore, the first claim we can give is that there are singular solutions for $S_A$ and $S_B$. The second question is that are there "common singular solutions"? If there is a common singular solution, $z_i \rightarrow z_A, \forall i \in A$ and $z_j \rightarrow z_B, \forall j \in B$ will lead $z_A = z_B$, thus by the analysis in section two. We will get $S_{A \cup B} \rightarrow 0$, which is a conflict with our assumption of kinematic configuration. Therefore, we conclude that there is no common singular solution when $S_A, S_B$ are not compatible. This result should be easy to guess since there is no Feynman diagram containing them simultaneously.

Thirdly, we discuss the collapse speed of singular solutions, i.e., $|z_i - z_j| \sim \epsilon^N, \forall i, j \in A$. The analysis will be exact same as in previous subsection and we conclude that $N = 1$, thus contributions of singular solutions of $a_A$ will be the order $\epsilon^{-1+\chi(A)}$ (similar for $S_B$). Finally the number of singular solutions for $S_A$ and $S_B$ will be $(n_A - 2)!(n - n_A - 2)!$ and $(n_B - 2)!(n - n_B - 2)!$ respectively.

3.2.2 $S_A, S_B$ are compatible

For this case, we can make $A \cap B = \emptyset$. Again the first result is that there are singular solutions for $S_A$ and $S_B$. To see if there is any common singular solution, we can consider the CHY-integrands, which give Feynman diagrams containing both poles $S_A, S_B$. If there is no common singular solution, by the same analysis (see (5.4)), we can see that the measure gives either $\epsilon^{(2|A|-3)N_A}$ or $\epsilon^{(2|A|-3)N_B}$, thus the leading behavior will be either $\epsilon^{-N_A(\chi[A]+1)}$ or $\epsilon^{-N_B(\chi[A]+1)}$, but from Feynman diagrams, we see the leading behaviour $\epsilon^{-(\chi[A]+1)\epsilon^{-(\chi[B]+1)}}$. We cannot get the match result since $N_A, N_B$ are fixed while choosing different $\chi[A], \chi[B]$. Thus the contradiction tells us that there are common singular solutions.

One intuitive way to see the number of common singular solution is to draw the effective Feynman diagram (see Figure 4). For only one $S_A \rightarrow 0$, the left effective Feynman diagram gives the right accounting. For two compatible poles, the effective Feynman diagrams are given at the right hand side. Thus all legs have been divided into three part: the left part contains $n_A + 1$ external legs, the middle part contains $n_{A \cup B} + 2$ external legs, and the right part includes $n_B + 1$ external legs. With the picture, the whole $n$-point will contains $(n_A + 1 - 3)! \times (n_{A \cup B} + 2 - 3)! \times (n_B + 1 - 3)! = (n_A - 2)!(n_{A \cup B} - 1)!(n_B - 2)!$ common singular solutions.

Now we discuss the collapse speed of singular solutions, i.e., $|z_i - z_j| \sim \epsilon^N, \forall i, j \in A(B)$. For the three types of singular solutions, by matching up the singular behaviour of Feynman diagrams, one can see that for the singular solution of $S_A$ only, we will have $|z_i - z_j| \sim \epsilon, \forall i, j \in A$ and $|z_i - z_j| \sim \epsilon^0, \forall i, j \in B$\footnote{Noticing that we have assumed $A \cap B = \emptyset$. Otherwise, we use $B$ to replace $B$.} Similar result holds for singular solution of $S_B$ only, i.e., $|z_i - z_j| \sim \epsilon, \forall i, j \in B$ and $|z_i - z_j| \sim \epsilon^0, \forall i, j \in A$. For the common singular solutions, the analysis is tricky. Because the asymptotic behaviour depends on the choice of gauge fixing $z_i, z_j, z_k$, we can have two types of asymptotic behaviour. The first one is

$$\text{type - I : } z_i \in A \rightarrow z_A + a_i \epsilon^N, \quad |a_i - a_j| \neq 0, \quad i, j \in A$$

The second one is

$$\text{type - II : } z_i \in A \rightarrow z_A + a_i \epsilon^N, \quad |a_i - a_j| = 0, \quad i, j \in A$$
Figure 4. The effective Feynman diagrams: the above is for only one singular poles, while the below is for two compatible singular poles.

\[ z_{t\in B} \rightarrow z_B + a_t \epsilon^{N_2}, \quad |a_t - a_s| \neq 0, \quad t, s \in B, \quad z_A \neq z_B \]  

(3.26)

The second type is

\[ type-II : \quad z_{i\in A} \rightarrow z_B + z_A \epsilon^{N_1} + a_i \epsilon^{N_2}, \quad |a_i - a_j| \neq 0, \quad i, j \in A, \quad N_2 > N_1 \]

\[ z_{t\in B\setminus A} \rightarrow z_B + a_t \epsilon^{N_1}, \quad |a_t - z_A| \neq 0, |a_t - a_s| \neq 0, \quad t, s \in B\setminus A \]  

(3.27)

The type-I can be realised that if we take one gauge fixed point in \( A \), one gauge fixed point in \( B \) and the third point in \( A \cup B \) with the choice \( A \cap B = \emptyset \). The type-II can be realised by taking one gauge fixed point in \( B\setminus A \) and two gauge-fixed points in \( B \) with the choice \( A \subset B \). Suppose the gauge choice makes the type-I behaviour by analysing the leading behaviour of measure and integrand in the previous subsection. In that case, one can check that we should have \( N_1 = N_2 = 1 \) to match up the result from Feynman diagrams. If the gauge choice makes the type-II behaviour, a similar argument leads \( N_1 = 1, N_2 = 2 \).

Knowing the value of \( N_1, N_2 \), we see the measure part of the common singular solutions gives \( \epsilon^{2|A|-3} \cdot \epsilon^{2|B|-3} \), while the leading contribution gives \( \epsilon^{-(x|A|+1)} \cdot \epsilon^{-(x|B|+1)} \).

### 3.2.3 Numerical Check

In this part, we will present several numerical examples to demonstrate above analysis.

**Example I:** \( n = 7, S_{12} = S_{45} = 0 \)

We first consider the case of \( S_A \) is compatible with \( S_B \). We will choice \( n = 7, A = \)

---

*Although the asymptotic behaviour of type-I and type-II are different, their leading behaviour of measure and contribution have the same \( \epsilon \)-order. Which can be calculated by the same procedure of the previous subsection staring by staring with (3.26) and (3.27) respectively.*
\{1, 2\}, B = \{4, 5\}. The kinematics configuration is

\[
\begin{align*}
  &k_1 \to \{0.502 + 0.165i, -0.303 + 0.197i, -0.326 - 0.315i, -0.109 - 0.0949i, -0.409 - 0.0717i\} + \\
  &\quad \{0.616e, (0.336 - 0.195i)e, (-0.119 + 0.516i)e, (-0.719 - 0.177i)e, -0.269e\}
\end{align*}
\]

\[
\begin{align*}
  &k_2 \to \{1.2, -0.256, -0.731, 0.424, -0.818\}
\end{align*}
\]

\[
\begin{align*}
  &k_3 \to \{1.19 - 0.165i, 0.728 - 0.197i, 0.11 + 0.315i, -0.99 + 0.0949i, 0.102 + 0.0717i\} + \\
  &\quad \{-0.616e, (-0.336 + 0.195i)e, (0.119 - 0.516i)e, (0.719 + 0.177i)e, 0.269e\}
\end{align*}
\]

\[
\begin{align*}
  &k_4 \to \{0.361 + 0.689i, -0.646 - 0.902i, 0.705 - 0.421i, 0.0459 - 0.54i, -0.162 + 0.0756i\} + \\
  &\quad \{0.96e, (-0.779 + 0.414i)e, (-0.99 - 0.349i)e, (-0.0376 + 0.619i)e, 0.105e\}
\end{align*}
\]

\[
\begin{align*}
  &k_5 \to \{1., -0.394, 0.288, -0.796, 0.366\}
\end{align*}
\]

\[
\begin{align*}
  &k_6 \to \{-1.76, 0.214, -1.52, 0.246, -0.82\}
\end{align*}
\]

\[
\begin{align*}
  &k_7 \to \{-2.49 - 0.689i, 0.657 + 0.902i, 1.48 + 0.421i, 1.18 + 0.54i, 1.74 - 0.0756i\} + \\
  &\quad \{-0.96e, (0.779 - 0.414i)e, (0.99 + 0.349i)e, (0.0376 - 0.619i)e, -0.105e\}
\end{align*}
\]

(3.28)

We fix \(z_3 = 1, z_6 = 5, z_7 = -7\), thus the type-I behaviour is realized. There are 10 singular solutions in total:

\[
\text{Singular } S_{12} S_{45} \ (1) \quad \left\{ \begin{array}{l}
  z_1 \to (-0.19 + 7.49i) - (19.4 - 1.93i)e - (21.3 + 32.7i)e^2 \\
  z_2 \to (-0.19 + 7.49i) - (4.74 + 3.58i)e + (3.28 - 6.28i)e^2 \\
  z_4 \to (11.4 + 0.699i) + (7.43 - 8.4i)e + (2.68 - 4.86i)e^2 \\
  z_5 \to (11.4 + 0.699i) + (3.62 + 1.88i)e - (4.62 - 7.69i)e^2 \\
\end{array} \right.
\]

\[
\text{Singular } S_{12} S_{45} \ (2) \quad \left\{ \begin{array}{l}
  z_1 \to (8.16 - 2.93i) + (4.47 + 4.09i)e - (2.34 + 4.47i)e^2 \\
  z_2 \to (-8.16 - 2.93i) + (2.59 - 1.07i)e + (2.6 - 5.33i)e^2 \\
  z_4 \to (2.41 + 2.42i) + (1.69 + 6.53i)e - (1.56 + 0.25i)e^2 \\
  z_5 \to (2.41 + 2.42i) + (0.484 + 0.193i)e - (1.83 - 1.95i)e^2 \\
\end{array} \right.
\]

\[
\text{Singular } S_{12} \ (1) \quad \left\{ \begin{array}{l}
  z_1 \to (6.09 + 26.5i) - (147. - 111.i)e - (850. + 129.i)e^2 \\
  z_2 \to (6.09 + 26.5i) - (36.3 - 28.2i)e - (129. - 2.6i)e^2 \\
  z_4 \to (23.2 - 27.i) - (42.3 + 79.6i)e + (173. - 208.i)e^2 \\
  z_5 \to (2.47 + 1.81i) - (1.14 - 0.729i)e - (5.27 + 1.87i)e^2 \\
\end{array} \right.
\]

\[
\text{Singular } S_{12} \ (2) \quad \left\{ \begin{array}{l}
  z_1 \to (-0.326 + 7.62i) - (21.1 - 5.41i)e - (45.6 + 41.3i)e^2 \\
  z_2 \to (-0.326 + 7.62i) - (4.44 + 0.898i)e + (1. - 3.95i)e^2 \\
  z_4 \to (6.96 + 16.3i) - (11.6 - 14.i)e - (17.4 + 30.4i)e^2 \\
  z_5 \to (4.61 - 4.29i) - (2.76 + 1.31i)e + (1.47 - 1.54i)e^2 \\
\end{array} \right.
\]

\[
\text{Singular } S_{12} \ (3) \quad \left\{ \begin{array}{l}
  z_1 \to (-8.34 + 0.879i) - (3.38 + 4.78i)e + (7.54 + 1.71i)e^2 \\
  z_2 \to (-8.34 + 0.879i) - (5.22 + 2.61i)e - (2.47 + 2.18i)e^2 \\
  z_4 \to (1.54 + 1.85i) - (0.644 - 3.99i)e - (4.87 + 1.35i)e^2 \\
  z_5 \to (-4.29 - 5.26i) - (18.2 + 3.21i)e - (5.86 - 9.66i)e^2 \\
\end{array} \right.
\]

\[
\text{Singular } S_{12} \ (4) \quad \left\{ \begin{array}{l}
  z_1 \to (-7.12 + 3.13i) + (6.76 + 4.i)e - (10.1 + 10.1i)e^2 \\
  z_2 \to (-7.12 - 3.13i) + (6.87 - 1.01i)e - (0.647 + 10.5i)e^2 \\
  z_4 \to (1.67 + 1.96i) - (0.965 - 3.22i)e - (2.25 - 6.98i)e^2 \\
  z_5 \to (2.82 + 6.01i) + (5.02 + 19.3i)e + (30.2 - 13.2i)e^2 \\
\end{array} \right.
\]
Among them there are two common singular solutions, six solutions for $S_{12}$, six solutions for $S_{45}$. The quantity and the asymptotic behaviours confirm our claim. The measure part for common singular solutions are given by where for common singular solutions it is

\[
\begin{align*}
\text{Singular } S_{12} (1) & \quad \{z_1 \to (-2.33 + 29.4i) - (85.6 + 2.5i)\epsilon + (24.1 - 22.3i)\epsilon^2 \\
& \quad z_2 \to (0.596 + 6.55i) - (6.3 + 2.18i)\epsilon - (1.86 + 8.77i)\epsilon^2 \\
& \quad z_4 \to (14.4 + 2.23i) + (15.6 - 21.3i)\epsilon + (21.6 - 13.2i)\epsilon^2 \\
& \quad z_5 \to (14.4 + 2.23i) + (6.56 - 4.88i)\epsilon + (11.8 + 0.324i)\epsilon^2 \\
\text{Singular } S_{12} (2) & \quad \{z_1 \to (-0.959 + 1.13i) - (1.06 + 0.33i)\epsilon - (1.02 + 0.891i)\epsilon^2 \\
& \quad z_2 \to (4.6 + 6.79i) - (7.89 - 6.2i)\epsilon - (9.72 + 0.0344i)\epsilon^2 \\
& \quad z_4 \to (8.42 - 0.152i) + (5.02 - 4.83i)\epsilon + (3.21 - 5.33i)\epsilon^2 \\
& \quad z_5 \to (8.42 - 0.152i) + (4.05 - 0.0335i)\epsilon + (3.11 + 3.2i)\epsilon^2 \\
\text{Singular } S_{12} (3) & \quad \{z_1 \to (-2.69 + 1.77i) - (2.51 + 0.646i)\epsilon - (1.06 + 0.197i)\epsilon^2 \\
& \quad z_2 \to (-5.6 - 7.92i) - (2.68 - 2.24i)\epsilon + (1.2 + 5.65i)\epsilon^2 \\
& \quad z_4 \to (2.4 + 2.42i) + (1.74 + 6.79i)\epsilon - (0.271 - 3.09i)\epsilon^2 \\
& \quad z_5 \to (2.4 + 2.42i) + (0.631 + 0.616i)\epsilon - (2.43 - 3.81i)\epsilon^2 \\
\text{Singular } S_{12} (4) & \quad \{z_1 \to (1.06 + 2.21i) - (3.67 - 1.25i)\epsilon - (5.58 + 1.63i)\epsilon^2 \\
& \quad z_2 \to (-4.1 - 6.76i) - (0.276 - 0.326i)\epsilon - (1.36 - 0.429i)\epsilon^2 \\
& \quad z_4 \to (3.47 + 3.83i) + (3.84 + 5.81i)\epsilon + (0.612 + 0.62i)\epsilon^2 \\
& \quad z_5 \to (3.47 + 3.83i) + (0.535 + 0.828i)\epsilon - (2.6 - 0.521i)\epsilon^2 \\
\text{Singular } S_{45} (1) & \quad \{z_1 \to (-0.959 + 1.13i) - (1.06 + 0.33i)\epsilon - (1.02 + 0.891i)\epsilon^2 \\
& \quad z_2 \to (4.6 + 6.79i) - (7.89 - 6.2i)\epsilon - (9.72 + 0.0344i)\epsilon^2 \\
& \quad z_4 \to (8.42 - 0.152i) + (5.02 - 4.83i)\epsilon + (3.21 - 5.33i)\epsilon^2 \\
& \quad z_5 \to (8.42 - 0.152i) + (4.05 - 0.0335i)\epsilon + (3.11 + 3.2i)\epsilon^2 \\
\text{Singular } S_{45} (2) & \quad \{z_1 \to (1.06 + 2.21i) - (3.67 - 1.25i)\epsilon - (5.58 + 1.63i)\epsilon^2 \\
& \quad z_2 \to (4.6 + 6.79i) - (7.89 - 6.2i)\epsilon - (9.72 + 0.0344i)\epsilon^2 \\
& \quad z_4 \to (8.42 - 0.152i) + (5.02 - 4.83i)\epsilon + (3.21 - 5.33i)\epsilon^2 \\
& \quad z_5 \to (8.42 - 0.152i) + (4.05 - 0.0335i)\epsilon + (3.11 + 3.2i)\epsilon^2 \\
\text{Singular } S_{45} (3) & \quad \{z_1 \to (3.47 + 3.83i) + (3.84 + 5.81i)\epsilon + (0.612 + 0.62i)\epsilon^2 \\
& \quad z_2 \to (3.47 + 3.83i) + (3.84 + 5.81i)\epsilon + (0.612 + 0.62i)\epsilon^2 \\
& \quad z_4 \to (3.47 + 3.83i) + (0.535 + 0.828i)\epsilon - (2.6 - 0.521i)\epsilon^2 \\
\text{Singular } S_{45} (4) & \quad \{z_1 \to (3.47 + 3.83i) + (3.84 + 5.81i)\epsilon + (0.612 + 0.62i)\epsilon^2 \\
& \quad z_2 \to (3.47 + 3.83i) + (0.535 + 0.828i)\epsilon - (2.6 - 0.521i)\epsilon^2 \\
\text{Singular } S_{45} (5) & \quad \{z_1 \to (3.47 + 3.83i) + (3.84 + 5.81i)\epsilon + (0.612 + 0.62i)\epsilon^2 \\
& \quad z_2 \to (3.47 + 3.83i) + (0.535 + 0.828i)\epsilon - (2.6 - 0.521i)\epsilon^2 \\
\text{Singular } S_{45} (6) & \quad \{z_1 \to (3.47 + 3.83i) + (3.84 + 5.81i)\epsilon + (0.612 + 0.62i)\epsilon^2 \\
& \quad z_2 \to (3.47 + 3.83i) + (0.535 + 0.828i)\epsilon - (2.6 - 0.521i)\epsilon^2 \\
\end{align*}
\]

Table 9. Measure part of each singular solution of $S_{12} = S_{45} = 0$

\[e^{2|A|+2|B|}-6 = e^2, \text{ and for singular solutions of only one pole it is } e^{2|A|-3} = e^{2|B|-3} = e^1.\]

We choose a few CHY-integrand to see the effects of singular solutions. For the first Integrand

\[I_1 = \frac{1}{z_{12}^2 z_{17}^2 z_{23}^2 z_{24}^2 z_{35}^2 z_{36}^2 z_{45}^2 z_{46}^2 z_{56}^2 z_{67}^2} \quad (3.29)\]

with $\chi(12) = 0$ and $\chi(45) = -1$. The contribution of each singular solution is

The summation is

\[0.0839 + 0.0704i \quad \frac{e^0}{\epsilon} + O\left(e^0\right) \quad (3.30)\]
while the corresponding amplitude result by substitute numerical kinematics is

\[
\frac{1}{S_{12}S_{56}S_{127}S_{456}} + \frac{1}{S_{17}S_{56}S_{127}S_{456}} \frac{0.0839 + 0.0704i}{\epsilon} + (0.0809 + 0.209i) - (0.128 - 0.302i)\epsilon + O(\epsilon^2)
\] (3.31)

The second Integrand as

\[
I_2 = \frac{1}{z_{12}z_{13}z_{17}z_{23}z_{26}z_{34}z_{35}z_{45}z_{47}z_{56}z_{67}^2} \frac{0.0112 - 0.00641i}{\epsilon} + (0.00411 + 0.0247i)\epsilon + O(\epsilon^2)
\] (3.32)

with \(\chi(12) = \chi(45) = 0\). The contribution of each singular solution is The summation is

**Table 10.** Contribution of each singular solution of \(I_1\)

| Solution | Contribution |
|----------|--------------|
| Singular \(S_{12}S_{45}\) (1) | \(-0.00817 - 0.00326\epsilon + O(\epsilon^0)\) |
| Singular \(S_{12}S_{45}\) (2) | \(-0.00828 - 0.00584\epsilon + O(\epsilon^0)\) |
| Singular \(S_{12}\) (1) | \(-0.000623 - 0.000173\epsilon + O(\epsilon^0)\) |
| Singular \(S_{12}\) (2) | \(-0.0013 - 0.000968\epsilon + O(\epsilon^0)\) |
| Singular \(S_{12}\) (3) | \(-0.000436 - 0.000344i + O(\epsilon^0)\) |
| Singular \(S_{12}\) (4) | \(-0.000663 - 0.00522i + O(\epsilon^0)\) |
| Singular \(S_{45}\) (1) | \(-0.0017 + 0.00104i + O(\epsilon^0)\) |
| Singular \(S_{45}\) (2) | \(-0.00234 + 0.00102i + O(\epsilon^0)\) |
| Singular \(S_{45}\) (3) | \(-0.00355 - 0.00477i + O(\epsilon^0)\) |
| Singular \(S_{45}\) (4) | \(-0.000814 + 0.000133i + O(\epsilon^0)\) |
| All Regulars | \(-0.0285 + 0.0362i - (0.0596 + 0.314i)\epsilon + O(\epsilon^2)\) |

**Table 11.** Contribution of each singular solution of \(I_2\)

\[
\frac{-0.000722 - 0.00721i}{\epsilon^2} + O\left(\frac{1}{\epsilon}\right)
\] (3.33)
while the amplitude result by substitute numerical kinematics is

\[
\frac{-1}{S_{12}S_{45}S_{67}S_{123}} - \frac{1}{\epsilon^2} \left( \frac{0.000722 - 0.00721i}{S_{12}S_{45}S_{67}S_{45}} \right) + \frac{0.00438 - 0.00799i}{\epsilon} - (0.0122 - 0.00712i) + O(\epsilon)
\]

(3.34)

From the result of these two Integrand, we can verify the behaviour of the singular solutions. The contribution of the common singular solution is exact \(\epsilon^{-2-\chi(12)}-\chi(45)\), \(\epsilon^{-1-\chi(12)}\) for the singular solutions of \(S_{12}\) and \(\epsilon^{-1-\chi(45)}\) for the singular solutions of \(S_{45}\), which agree with our analysis.

**Example II: n = 7, \(S_{123} = S_{12} = 0\)**

Next we consider another compatible case \(A \subset B\) with \(A = \{12\}, B = \{123\}\). Our gauge choice is that \(z_i, z_j, z_k \not\in B\), thus the type-II behaviour is realized. The kinematics of 7-point construction numerically we choose as

\[
\begin{align*}
k_1 & \to \{5.78 + 1.74i, 21.2 - 7.05i, 0.742 + 0.329i, -3.03 + 14.8i, -11.8 - 17.3i\} + \\
& \quad \{0.638\epsilon, (2.15 - 1.77i)\epsilon, 0.12\epsilon, (0.2 + 1.95i)\epsilon, (-2.23 - 1.53i)\epsilon\} \\
k_2 & \to \{1.27 + 0.0208i, -0.315 - 1.17i, 0.27 + 0.0766i, -0.115 + 0.124i, -1.69 + 0.206i\} + \\
& \quad \{0.106\epsilon, (0.0134 + 1.15i)\epsilon, 0.389\epsilon, (0.817 + 0.036i)\epsilon, (0.726 - 0.0618i)\epsilon\} \\
k_3 & \to \{0.875, 0.379, -0.717, 0.329, -0.00131\} \\
k_4 & \to \{1.7, -0.972, 0.513, -0.912, 0.918\} \\
k_5 & \to \{1.05 - 0.0208i, 0.283 + 1.17i, -0.234 - 0.0766i, 0.655 - 0.124i, 1.41 - 0.206i\} + \\
& \quad \{-0.106\epsilon, (-0.0134 - 1.15i)\epsilon, -0.389\epsilon, (-0.817 - 0.036i)\epsilon, (-0.726 + 0.0618i)\epsilon\} \\
k_6 & \to \{-7.17 - 1.74i, -20.1 + 7.05i, 0.435 - 0.329i, 5.4 - 14.8i, 13.6 + 17.3i\} + \\
& \quad \{-0.638\epsilon, (-2.15 + 1.77i)\epsilon, -0.12\epsilon, (-0.2 - 1.95i)\epsilon, (2.23 + 1.53i)\epsilon\} \\
k_7 & \to \{-3.51, -0.482, -1.01, -2.33, -2.37\}
\end{align*}
\]

(3.35)

We fix \(z_5 = 1, z_6 = 5, z_7 = -7\), the singular solutions are

**Singular \(S_{123} S_{12}\) (1)**

\[
\begin{align*}
z_1 & \to (4.96 - 0.203i) + (0.0866 + 0.743i)\epsilon + (17.9 + 39.6i)\epsilon^2 \\
z_2 & \to (4.96 - 0.203i) + (0.0866 + 0.743i)\epsilon - (94.6 - 51.5i)\epsilon^2 \\
z_3 & \to (4.96 - 0.203i) + (0.502 - 14.8i)\epsilon + (224. - 904. i)\epsilon^2 \\
z_4 & \to (3.51 + 1.78i) + (3.4 + 1.59i)\epsilon - (2.95 - 7.46i)\epsilon^2
\end{align*}
\]

**Singular \(S_{123} S_{12}\) (2)**

\[
\begin{align*}
z_1 & \to (4.89 - 0.552i) + (0.158 + 2.21i)\epsilon + (49. + 119. i)\epsilon^2 \\
z_2 & \to (4.89 - 0.552i) + (0.158 + 2.21i)\epsilon - (254. - 148. i)\epsilon^2 \\
z_3 & \to (4.89 - 0.552i) + (1.68 - 37.7i)\epsilon + (539. - 2460. i)\epsilon^2 \\
z_4 & \to (1.88 + 3.74i) + (3.94 + 3.07i)\epsilon + (59.4 - 0.813i)\epsilon^2
\end{align*}
\]

**Singular \(S_{12}\) (1)**

\[
\begin{align*}
z_1 & \to (4.9 + 0.163i) - (0.148 - 1.15i)\epsilon + (0.803 + 3.69i)\epsilon^2 \\
z_2 & \to (4.9 + 0.163i) - (2.89 + 0.276i)\epsilon - (18.6 - 1.77i)\epsilon^2 \\
z_3 & \to (1.46 - 0.781i) - (0.66 + 0.418i)\epsilon - (3.94 + 1.17i)\epsilon^2 \\
z_4 & \to (8.4 - 0.412i) + (20.3 - 13.4i)\epsilon + (55.5 - 60.9i)\epsilon^2
\end{align*}
\]
Singular $S_{12}$ (2)

\[
\begin{align*}
    z_1 &\to (4.99 - 0.209i) - (0.974 - 1.16i)\epsilon - (17. + 23.2i)\epsilon^2 \\
    z_2 &\to (4.99 - 0.209i) + (1.95 + 2.3i)\epsilon - (72.1 + 13.i)\epsilon^2 \\
    z_3 &\to (4.56 - 0.333i) + (13.8 - 7.47i)\epsilon + (44.9 + 397.i)\epsilon^2 \\
    z_4 &\to (3.47 + 1.82i) + (4.5 - 2.73i)\epsilon + (107. + 67.9i)\epsilon^2
\end{align*}
\]

Singular $S_{12}$ (3)

\[
\begin{align*}
    z_1 &\to (4.94 - 0.54i) - (3.24 - 0.525i)\epsilon + (11.7 - 45.7i)\epsilon^2 \\
    z_2 &\to (4.94 - 0.54i) + (3.78 + 3.17i)\epsilon - (77.5 + 23.5i)\epsilon^2 \\
    z_3 &\to (3.88 - 0.729i) + (28.6 - 16.3i)\epsilon + (208. + 725.i)\epsilon^2 \\
    z_4 &\to (1.99 + 3.72i) - (1.77 - 7.54i)\epsilon - (39.6 + 131.i)\epsilon^2
\end{align*}
\]

Singular $S_{12}$ (4)

\[
\begin{align*}
    z_1 &\to (4.81 - 0.807i) - (2.27 + 1.54i)\epsilon - (13.8 + 5.69i)\epsilon^2 \\
    z_2 &\to (4.81 - 0.807i) + (7.88 - 1.43i)\epsilon - (28.9 - 7.46i)\epsilon^2 \\
    z_3 &\to (2.35 + 0.69i) - (3.98 - 0.141i)\epsilon - (15.2 - 5.13i)\epsilon^2 \\
    z_4 &\to (1.46 + 5.15i) - (10.9 - 10.i)\epsilon - (44.2 - 60.1i)\epsilon^2
\end{align*}
\]

There are two common singular solutions and six solutions for $S_{12}$ only. The quantity and asymptotic behaviour are same as our analysis. The measure part is shown in table (12). The measure part of common singular solutions is exact $e^{2|A|+2|B|/6} = e^{2\times2+3\times3} = \epsilon^4$,

| Solution          | Measure                                                                 |
|-------------------|-------------------------------------------------------------------------|
| Singular $S_{123}S_{12}$ (1) | $(691000. - (5.97 \times 10^6) i) \epsilon^4 + O (\epsilon^5)$ |
| Singular $S_{123}S_{12}$ (2) | $-(3.53 \times 10^9 - (2.51 \times 10^9) i) \epsilon^4 + O (\epsilon^5) + O (\epsilon^2)$ |
| Singular $S_{12}$ (1)     | $-(50.8 + 792.i)\epsilon + O (\epsilon^2)$                           |
| Singular $S_{12}$ (2)     | $(158. + 104.i)\epsilon + O (\epsilon^2)$                            |
| Singular $S_{12}$ (3)     | $-(27300. + 65900.i)\epsilon + O (\epsilon^2)$                        |
| Singular $S_{12}$ (4)     | $(153000. + 66900.i)\epsilon + O (\epsilon^2)$                        |
| All Regulars            | $-(84300. + (3.87 \times 10^6) i) + (3.42 \times 10^7 - (1.04 \times 10^7) i) \epsilon + O (\epsilon^2)$ |

Table 12. Measure part of each singular solution of $S_{123} = S_{12} = 0$

and $e^{2|A|/3} = e^{2\times2-3} = \epsilon^1$ for the solutions only for pole $S_{12}$.

The first Integrand we have chosen is

\[
I_1 = -\frac{1}{z_{12} z_{13} z_{14} z_{17} z_{19} z_{23} z_{27} z_{34} z_{45} z_{56} z_{67}}
\]

with pole index $\chi(123) = 0, \chi(12) = -1$. The contribution of each solution is in table(13)

The summation is

\[
\frac{1.03 \times 10^{-6} - (1.88 \times 10^{-7}) i}{\epsilon} + O (\epsilon^0)
\]

(3.37)

We verify the summation with numerical kinematics

\[
\begin{align*}
    &\frac{1}{S_{23}S_{45}S_{67}S_{123}} - \frac{1}{S_{23}S_{45}S_{123}S_{1456}} - \frac{1}{S_{23}S_{56}S_{123}S_{456}} - \frac{1}{S_{23}S_{56}S_{123}S_{567}} - \frac{1}{S_{23}S_{67}S_{123}S_{567}} \\
    &= \frac{1.03 \times 10^{-6} - (1.88 \times 10^{-7}) i}{\epsilon} + (7.19 \times 10^{-7} - (5.16 \times 10^{-6}) i) + O (\epsilon)
\end{align*}
\]

(3.38)
Example III: \( n = 7, S_{123} = S_{234} = 0 \)
Now we consider the case two poles are not compatible with each other, we choose
\[ A = \{123\} \text{ and } B = \{234\}. \]
The numerical kinematics are
\[
k_1 \rightarrow \{-0.198 - 0.128 i, -0.0155 - 4.35 i, -3.65 + 0.112 i, -0.829 - 0.0698 i, -2.23 - 0.138 i\} + \{0.16 \epsilon, (0.0591 + 0.504 i) \epsilon, (0.499 - 0.06 i) \epsilon, (0.0301 + 0.00534 i) \epsilon, 0.172 \epsilon\}
k_2 \rightarrow \{1.54, 0.667, 0.963, 0.368, -0.931\}
k_3 \rightarrow \{1.17, -0.525, -0.27, 0.459, -0.902\}
k_4 \rightarrow \{0.524 - 0.123 i, 0.1 + 0.999 i, 0.406 - 0.0327 i, 0.343 - 0.73 i, -1.23 - 0.0812 i\} + \{0.839 \epsilon, (-0.951 - 0.84 i) \epsilon, (0.187 + 0.00511 i) \epsilon, (-0.942 + 0.85 i) \epsilon, 0.552 \epsilon\}
k_5 \rightarrow \{0.951, -0.376, -0.594, 0.164, -0.618\}
k_6 \rightarrow \{-1.17 + 0.123 i, 0.325 - 0.999 i, 1.23 + 0.0327 i, 0.0673 + 0.73 i, 1.12 + 0.0812 i\} + \{-0.839 \epsilon, (0.951 + 0.84 i) \epsilon, (-0.187 - 0.00511 i) \epsilon, (0.942 - 0.85 i) \epsilon, -0.552 \epsilon\}
k_7 \rightarrow \{-2.82 + 0.128 i, -0.176 + 4.35 i, 1.92 - 0.112 i, -0.573 + 0.0698 i, 4.78 + 0.138 i\} + \{-0.16 \epsilon, (-0.0591 - 0.504 i) \epsilon, (-0.499 + 0.06 i) \epsilon, (-0.0301 - 0.00534 i) \epsilon, -0.172 \epsilon\}
\]
(3.42)

We fix \( z_5 = 1, z_6 = 5, z_7 = -7 \), the singular solutions are

Singular \( S_{123} \) (1)
\[
\begin{aligned}
z_1 &\rightarrow (-6.59 + 5.61 i) + (0.988 - 7.57 i) \epsilon + (13.1 + 2.66 i) \epsilon^2 \\
z_2 &\rightarrow (-6.59 + 5.61 i) + (0.622 - 8.5 i) \epsilon + (16.5 + 10.3 i) \epsilon^2 \\
z_3 &\rightarrow (-6.59 + 5.61 i) + (0.143 - 8.57 i) \epsilon + (21.1 + 11.1 i) \epsilon^2 \\
z_4 &\rightarrow (5.71 + 5.41 i) - (2.95 - 11.1 i) \epsilon - (12. + 9.39 i) \epsilon^2
\end{aligned}
\]

Singular \( S_{123} \) (2)
\[
\begin{aligned}
z_1 &\rightarrow (-5.2 - 0.937 i) - (0.505 + 0.588 i) \epsilon - (1.03 + 0.394 i) \epsilon^2 \\
z_2 &\rightarrow (-5.2 - 0.937 i) - (0.839 + 0.422 i) \epsilon - (0.412 + 0.42 i) \epsilon^2 \\
z_3 &\rightarrow (-5.2 - 0.937 i) - (0.852 + 0.241 i) \epsilon - (0.226 + 0.714 i) \epsilon^2 \\
z_4 &\rightarrow (1.42 - 1.1 i) - (3.76 + 0.476 i) \epsilon - (2.6 + 0.484 i) \epsilon^2
\end{aligned}
\]

Singular \( S_{234} \) (1)
\[
\begin{aligned}
z_1 &\rightarrow (0.948 + 9.1 i) - (14.1 + 3.67 i) \epsilon - (40.7 + 39.5 i) \epsilon^2 \\
z_2 &\rightarrow (6.25 + 3.19 i) - (0.79 - 13.5 i) \epsilon - (31.8 - 47.6 i) \epsilon^2 \\
z_3 &\rightarrow (6.25 + 3.19 i) - (3.64 - 7.5 i) \epsilon - (32.8 - 22.1 i) \epsilon^2 \\
z_4 &\rightarrow (6.25 + 3.19 i) + (0.0579 + 8.31 i) \epsilon - (20.6 - 16.6 i) \epsilon^2
\end{aligned}
\]

Singular \( S_{234} \) (2)
\[

z_2 &\rightarrow (-2.7 - 1.43 i) - (4.19 - 3.88 i) \epsilon + (37.1 + 13.9 i) \epsilon^2 \\
z_3 &\rightarrow (-2.7 - 1.43 i) + (28.6 + 19.4 i) \epsilon - (9.49 + 134 i) \epsilon^2 \\
z_4 &\rightarrow (-2.7 - 1.43 i) + (10.2 + 28.8 i) \epsilon + (49.1 - 127 i) \epsilon^2
\end{aligned}
\]

The quantity and asymptotic behaviour is conform with our analysis. The measure part
given in the table shows \( \epsilon^{2|A| - 3} = \epsilon^{2|B| - 3} = \epsilon^{2 \times 3 - 3} = \epsilon^3 \), which fit our analysis.

We choose the first Integrand as
\[
I_1 = \frac{1}{z_12 z_{13} z_{14} z_{17} z_{18} z_{23} z_{24} z_{27} z_{34} z_{45} z_{56} z_{67}}
\]
with pole index \( \chi(123) = 0, \chi(234) = -1 \). The contribution of each singular solution is in

\[
\frac{0.188 - 0.277 i}{\epsilon} + O(\epsilon^0)
\]

(3.44)
The summation is which are same as the amplitude after putting the kinematics
\[
\chi_{(123)} = 0.
\]

All Regulars
\[- \left(1.62 \times 10^{11} + (2.12 \times 10^{11}) i \right) + \left(5.05 \times 10^{11} + (8.03 \times 10^{12}) i \right) \epsilon + O \left(\epsilon^2\right)\]

Table 15. Measure part of each singular solution of \(S_{123} = S_{234} = 0\)

| Solution      | Measure                                                                 |
|---------------|-------------------------------------------------------------------------|

| Singular \(S_{234}\) (2)  | \( -(0.000737 + 0.00856i) + O \left(\epsilon^0\right) \)          |
| All Regulars   | \( -(0.241 - 0.0685i) - (8.06 + 9.33i) \epsilon + O \left(\epsilon^2\right) \) |

which are same as the amplitude after putting the kinematics
\[
\frac{1}{\epsilon} \left(1 + \frac{1}{S_{17}S_{23}S_{167}S_{234}} - \frac{1}{S_{17}S_{34}S_{167}S_{234}} - \frac{1}{S_{23}S_{56}S_{167}S_{234}} - \frac{1}{S_{34}S_{67}S_{167}S_{234}} \right) \epsilon \left(0.0108 + 0.0421i \right) \epsilon + O \left(\epsilon^2\right)
\]

\[
\frac{1}{\epsilon} \left(1 + \frac{1}{S_{17}S_{23}S_{167}S_{234}} - \frac{1}{S_{17}S_{34}S_{167}S_{234}} - \frac{1}{S_{23}S_{56}S_{167}S_{234}} - \frac{1}{S_{34}S_{67}S_{167}S_{234}} \right) \epsilon \left(0.0108 + 0.0421i \right) \epsilon + O \left(\epsilon^2\right)
\]

\[
\frac{1}{\epsilon} \left(1 + \frac{1}{S_{17}S_{23}S_{167}S_{234}} - \frac{1}{S_{17}S_{34}S_{167}S_{234}} - \frac{1}{S_{23}S_{56}S_{167}S_{234}} - \frac{1}{S_{34}S_{67}S_{167}S_{234}} \right) \epsilon \left(0.0108 + 0.0421i \right) \epsilon + O \left(\epsilon^2\right)
\]
We choose the third Integrand as

$$I_3 = \frac{1}{z_{12}^2 z_{15}^2 z_{17}^2 z_{23}^2 z_{34}^2 z_{45}^2 z_{56}^2 z_{67}^2}$$

with pole index $\chi(123) = \chi(234) = 0$. The contribution of each singular solution is in Table (18). The summation is

| Solution     | Contribution |
|--------------|--------------|
| Singular $S_{123}$ (1) | $-\frac{0.0177+0.0131i}{\epsilon} + O(\epsilon^0)$ |
| Singular $S_{123}$ (2) | $-\frac{0.0223+0.00101i}{\epsilon} + O(\epsilon^0)$ |
| Singular $S_{234}$ (1) | $-\frac{0.000521-0.00342i}{\epsilon} + O(\epsilon^0)$ |
| Singular $S_{234}$ (2) | $-\frac{0.00196-0.00286i}{\epsilon} + O(\epsilon^0)$ |
| All Regulars | $(0.1 + 0.0492i) + (0.903 + 5.43i)\epsilon + O(\epsilon^2)$ |

Table 18. The contribution of each singular solution of $I_3$

$$-\frac{0.0424 + 0.0109i}{\epsilon} + O(\epsilon^0)$$

and the amplitude after putting the kinematics is

$$\frac{1}{S_{12} S_{34} S_{56} S_{67}} + \frac{1}{S_{12} S_{34} S_{56} S_{67}} + \frac{1}{S_{12} S_{34} S_{56} S_{67}} + \frac{1}{S_{12} S_{34} S_{56} S_{67}} + \frac{1}{S_{12} S_{34} S_{56} S_{67}}$$

$$= -\frac{0.0424 + 0.0109i}{\epsilon} - (0.154 + 0.0133i) - (0.397 - 0.0194i) \epsilon + O(\epsilon^2)$$

We found that the contribution of each singular solution is exact $\epsilon^{-1-\chi(A)}$ and $\epsilon^{-1-\chi(B)}$ respectively.

4 From singular kinematics to solutions II: the soft limit

Now we consider the second type of singularity, the soft limit, for example, the $k_1 \to 0$. Different from preview case, when $k_1 \to 0$, we have $S_{1i} \to 0$ for all $i = 2, ..., n$ automatically. If we naively use the picture from the previous section, we will conclude that there will be some singular solutions with $z_2 \to z_1$ and some other solutions with $z_3 \to z_1$, etc. Since poles $S_{1i}$ are not compatible, the singular solutions will be the union of all these $z_i \to z_1$. However, as will be shown in this section, the above naive picture is wrong. In fact, for the soft limit, there is no singular solution.

With the behaviour $k_1 \neq 0$ and $k_{a \neq 1} \neq 0$ when $\epsilon \to 0$, the scattering equation $E_1$ is

$$E_1 = \epsilon \left[ \sum_{a \in \{2, ..., N\}} \frac{k_1^{(1)} \cdot k_a^{(0)}}{z_1 - z_a} + O(\epsilon) \right] = 0.$$

Assuming there is at most one location, for example, $z_2 \to z_1$ while other $z_i$’s are separated from each other, the term $\frac{k_1^{(1)} \cdot k_2^{(0)}}{z_1 - z_2}$ in (4.1) will be singular comparing to other terms, since
in general \( k_a^{(0)} \neq 0, k_a^{(1)} \cdot k_a^{(0)} \neq 0 \) and all numerators in (4.1) are nonzero. Thus (4.1) could not be satisfied under above assumption.

There are two possibilities to make (4.1) true. The first possibility is that there are at least two locations, for example, \( z_i, z_j \rightarrow z_1 \). Then by our careful analysis given in section two, we will have \( S_A \rightarrow 0 \) with \( 3 \leq |A| \leq n - 3 \), which conflicts with our kinematic condition that under \( k_1 \rightarrow 0 \), only \( S_{1i} \rightarrow 0 \). Thus there is left with only another possibility, i.e., all \( z_i \)'s are separated from each other and \( z_1 \), so all terms in (4.1) will have equivalent weight to make it zero.

Having proved that there is no singular solution for scattering equations, we need to understand how soft singularities are produced in the amplitude. The key is the measure part. Unlike the one \( J \sim \epsilon^{2|A| - 3} \rightarrow 0 \) given in (5.4), for soft limit

\[
(z_1 - z_2)(z_2 - z_3)(z_3 - z_1)(z_n - z_{n-1})(z_{n-1} - z_{n-2})(z_{n-2} - z_n) \sim \epsilon^0
\]

\[
|\Phi|_{ij} \rightarrow \epsilon^1, \quad J \sim \epsilon^{-1}
\]

Thus it is the measure providing the singularity.

Now we present an example to demonstrate the behaviour of soft limit. First we construct the kinematics for the soft limit. According to the discussion given in the Appendix A, we construct \( \tilde{p}_i, i = 2, \ldots, n \) such that \( \sum_{i=2}^{n} \tilde{p}_i = 0 \), then we choose \( u, v \) such that

\[
p_1 = \epsilon(u + v), \quad p_2 = \tilde{p}_2 - \epsilon u \quad p_3 = \tilde{p}_3 - \epsilon v \quad p_a = \tilde{p}_a, \quad a = 4, \ldots, n
\]

(4.3)

The \( u \) and \( v \) are not arbitrary. To make all momenta on-shell, they need to satisfy

\[
u \cdot v = 0 \quad u^2 = v^2 = 0 \quad u \cdot \tilde{p}_2 = 0 \quad v \cdot \tilde{p}_3 = 0
\]

(4.4)

For space-time dimension \( D \geq 4 \), there are solutions for \( u, v \).

Using above frame, let us present one example, i.e., the six point case with following choice of kinematics

\[
\begin{align*}
k_1 &\rightarrow \{0.774, -2.039 + 1.645i, -2.358 - 2.948i, 2.216 - 1.623i, -0.0675\} \epsilon, \\
k_2 &\rightarrow \{1.125, 0.595, -0.105, 0.802, 0.507\} \\
&\quad + \{-0.162, -0.876, -0.059 - 0.969i, 0.454 - 0.127i, -0.0628i\} \epsilon, \\
k_3 &\rightarrow \{0.950, -0.683, -0.0312, -0.572, -0.329\} \\
&\quad + \{-0.612, 2.915 - 1.645i, 2.417 + 3.917i, -2.668 + 1.750i, 0.130\} \epsilon \\
k_4 &\rightarrow \{1.17, -0.617, -0.284, -0.951, 0.0575\}, \\
k_5 &\rightarrow \{-1.247, -0.299, 0.288, -0.936, -0.71\}, \\
k_6 &\rightarrow \{-1.999, 1.003, 0.132, 1.66, 0.475\}
\end{align*}
\]

(4.5)

We fix the gauge choice \( z_4 = 1, z_5 = 0, z_6 = -1 \) and find following six solutions
\[
\begin{align*}
\begin{cases}
z_1 & \rightarrow (-0.236755 - 0.255543i) - (1.47022 - 0.800113i)\epsilon + O(\epsilon^2) \\
z_2 & \rightarrow (-0.0108264 + 0.011729i) + (0.0134425 + 0.0210137i)\epsilon + O(\epsilon^2) \\
z_3 & \rightarrow (-0.28117 - 0.303133i) - (1.54701 - 0.967519i)\epsilon + O(\epsilon^2) \\
z_1 & \rightarrow (-0.00979118 + 0.0111499i) - (0.0327251 + 0.0713408i)\epsilon + O(\epsilon^2) \\
z_2 & \rightarrow (-0.0108264 + 0.011729i) + (0.0134425 + 0.0210137i)\epsilon + O(\epsilon^2) \\
z_3 & \rightarrow (-0.28117 - 0.303133i) - (1.54701 - 0.967519i)\epsilon + O(\epsilon^2)
\end{cases}
\end{align*}
\]

\[
\begin{align*}
\begin{cases}
z_1 & \rightarrow (-0.19289 + 0.33945i) - (0.36536 + 0.659837i)\epsilon + O(\epsilon^2) \\
z_2 & \rightarrow (-0.0108264 - 0.011729i) + (0.017517 + 0.0426134i)\epsilon + O(\epsilon^2) \\
z_3 & \rightarrow (-0.28117 + 0.303133i) - (0.225438 + 0.604153i)\epsilon + O(\epsilon^2) \\
z_1 & \rightarrow (-0.010308 - 0.0107239i) + (0.130698 + 0.227897i)\epsilon + O(\epsilon^2) \\
z_2 & \rightarrow (-0.0108264 - 0.011729i) + (0.017517 + 0.0426134i)\epsilon + O(\epsilon^2) \\
z_3 & \rightarrow (-0.28117 + 0.303133i) - (0.225438 + 0.604153i)\epsilon + O(\epsilon^2) \\
z_1 & \rightarrow (0.214106 + 0.185642i) - (0.276318 + 0.500216i)\epsilon + O(\epsilon^2) \\
z_2 & \rightarrow (-0.0108264 - 0.011729i) + (0.017517 + 0.0426134i)\epsilon + O(\epsilon^2) \\
z_3 & \rightarrow (-0.28117 + 0.303133i) - (0.225438 + 0.604153i)\epsilon + O(\epsilon^2)
\end{cases}
\end{align*}
\]

We have presented these six solutions into two groups. When checking carefully, one can see that the values of \(z_2, z_3\) are the same in each group. In fact, as shown in [7], for the general case of \(n\) points with soft limit \(k_1 \to 0\), all \((n - 3)\)! solutions can divided into \((n - 4)\)! groups: in each group the values of \(z_i, i = 2, 3, ..., n\) are same while the \((n - 3)\) values of \(z_1\) are different. More explicitly, at the leading order, the scattering equations become

\[
\mathcal{E}_a = \sum_{b=2, b\neq a}^{n} \frac{k_a \cdot k_b}{z_a - z_b} = 0.
\]

for \(a = 2, 3, ..., n\) and

\[
\mathcal{E}_1 = \epsilon \left[ \sum_{a \in \{2, ..., N\}} \frac{k_1^{(1)} \cdot k_a^{(0)}}{z_1 - z_a} + O(\epsilon) \right] = 0.
\]

Using (4.8) we get \((n - 4)!\) different solutions for \(z_i, i = 2, 3, ..., n\). Putting them to (4.9) we get \((n - 3)\) solutions for \(z_1\).
Using (4.6) and (4.7) the measure $J = \frac{212223242526}{|\epsilon|^{1/2}}$ of each solution is

\[
\begin{align*}
J_1 &= -\frac{8.28657 \times 10^{-6} + 5.97512 \times 10^{-6}i}{\epsilon} - (0.00010047 - 0.000143733i) + O(\epsilon) \\
J_2 &= \frac{9.27966 \times 10^{-9} + 1.71473 \times 10^{-8}i}{\epsilon} + (6.26664 \times 10^{-7} - 5.07552 \times 10^{-9}i) + O(\epsilon) \\
J_3 &= \frac{0.0000888246 + 0.0000219678i}{\epsilon} - (0.00413616 - 0.00188736i) + O(\epsilon) \\
J_4 &= -\frac{7.12674 \times 10^{-6} + 0.000270679i}{\epsilon} + (0.000134457 + 0.000191776i) + O(\epsilon) \\
J_5 &= \frac{1.73122 \times 10^{-8} - 4.0953 \times 10^{-9}i}{\epsilon} - (5.04811 \times 10^{-7} + 1.2758 \times 10^{-7}i) + O(\epsilon) \\
J_6 &= \frac{0.000631231 - 0.0000764316i}{\epsilon} - (0.0000541201 + 0.00243992i) + O(\epsilon)
\end{align*}
\]

where each one has the leading behaviour $\frac{1}{\epsilon}$ indeed. Now we choose two different CHY-Intergrands: one contains pole $S_{1a}$ and another does not.

\[ I_{CHY} = \frac{1}{z_{1a}z_{23}z_{24}z_{25}z_{26}z_{34}z_{35}z_{36}z_{45}z_{56}} \] with pole $S_{12}$. The analytic result gives

\[
\frac{1}{S_{12}S_{34}S_{56}} = \frac{1.83042 - 0.257211i}{\epsilon} + (6.21704 - 21.8651i) + O(\epsilon)
\]

after substituting (4.5). The contributions of each solution are

\[
\begin{align*}
S_1 &= \frac{0.00419196 - 0.00814611i}{\epsilon} - (0.00751988 - 0.0171901i) + O(\epsilon) \\
S_2 &= \frac{0.63558 - 1.40928i}{\epsilon} - (18.0379 + 34.6097i) + O(\epsilon) \\
S_3 &= \frac{0.0838495 - 0.0761965i}{\epsilon} - (0.293397 + 2.66308i) + O(\epsilon^2) \\
S_4 &= -\frac{0.0173534 + 0.0060881i}{\epsilon} + (0.0108633 + 0.0298797i) + O(\epsilon) \\
S_5 &= \frac{1.05731 + 1.13749i}{\epsilon} + (23.2755 + 14.1021i) + O(\epsilon) \\
S_6 &= \frac{0.0670696 + 0.105014i}{\epsilon} + (1.26947 + 1.25845i) + O(\epsilon) \\
\sum_{i=1}^{6} S_i &= \frac{1.83042 - 0.257211i}{\epsilon} + (6.21704 - 21.8651i) + O(\epsilon)
\end{align*}
\]

\[ I_{CHY} = \frac{1}{z_{1a}z_{13}z_{23}z_{25}z_{32}z_{34}z_{41}z_{45}z_{56}z_{61}z_{64}} \] without the pole $S_{1a}$. The analytic expression gives

\[
\frac{1}{S_{23}S_{56}S_{123}} = -0.00611146 - (0.00176926 + 0.00037693i)\epsilon + O(\epsilon^2)
\]
which is not divergence when $\epsilon \to 0$. The contributions of each solution are

$$
S_1 : \frac{0.0294162 + 0.0533801i}{\epsilon} - (0.15429 + 0.0531782i) - (0.399708 - 0.492001i)\epsilon + O(\epsilon^2)
$$

$$
S_2 : \frac{-0.0502886 - 0.00214344i}{\epsilon} - (0.0153742 + 0.0794493i) + (3.43002 + 0.885407i)\epsilon + O(\epsilon^2)
$$

$$
S_3 : \frac{-0.0243873 + 0.0555235i}{\epsilon} + (0.166609 + 0.697732i) - (37.8097 + 16.3499i)\epsilon + O(\epsilon^2)
$$

$$
S_4 : \frac{0.0936548 - 0.0110378i}{\epsilon} - (0.0469898 + 0.113523i) + (0.563917 - 0.0892481i)\epsilon + O(\epsilon^2)
$$

$$
S_5 : \frac{-0.00413562 + 0.00322131i}{\epsilon} - (0.0000649134 - 0.0756482i) - (0.337054 - 0.169771i)\epsilon + O(\epsilon^2)
$$

$$
S_6 : \frac{-0.0895192 - 0.0142591i}{\epsilon} + (0.043999 - 0.527229i) + (2.47751 + 42.7249i)\epsilon + O(\epsilon^2)
$$

$$
\sum_{i=1}^{6} S_i : -0.00611146 - (0.00176926 + 0.000337693i)\epsilon + O(\epsilon^2)
$$

(4.14)

For this CHY-integrand, the critical point is how the cancellation of $\frac{1}{\epsilon}$ part happens. When checking carefully, one can see the cancellation happens inside each group, i.e., for $S_1 + S_2 + S_3$ and $S_4 + S_5 + S_6$, the $\frac{1}{\epsilon}$ part disappears. This is a general phenomenon, and we can easily prove using the trick given in [7]:

$$
A_n(1, 2, ..., n)
$$

$$
= \prod_{i=1}^{n-3} dz_i \frac{z_{n-2,n-1}^2 z_{n,n-2}^2}{z_{1,2}^{\alpha_1} z_{1,\alpha_n}^{\beta_1} z_{2,\beta_2}^{\beta_2} \alpha_n \beta_2} \prod_{\alpha \neq n-2,1,n} \delta(\mathcal{E}_\alpha) PT(1, \alpha_2, \cdots, \alpha_n) PT(1, \beta_2, \cdots, \beta_n)
$$

$$
= \prod_{i=1}^{n-3} dz_i \delta(E_1) \frac{z_{\alpha_n \alpha_2} z_{\beta_n \beta_2}}{z_{1,2}^{\alpha_1} z_{2,\alpha_n}^{\alpha_1} z_{1,\beta_2}^{\beta_1} z_{2,\beta_2}^{\beta_2} \alpha_n \beta_2} \prod_{\alpha \neq 1,n-2,1,n} \delta(\mathcal{E}_\alpha) PT(\alpha_2, \cdots, \alpha_n) PT(\beta_2, \cdots, \beta_n) z_{n-2,n-1}^2 z_{n,n-2}^2
$$

$$
= \prod_{i=2}^{n-3} dz_i \prod_{\alpha \neq 1,n-2,1,n} \delta(\mathcal{E}_\alpha) PT(\alpha_2, \cdots, \alpha_n) PT(\beta_2, \cdots, \beta_n) z_{n-2,n-1}^2 z_{n,n-2}^2
$$

$$
= \prod_{i=2}^{n-3} dz_i \delta(E_1) \frac{z_{\alpha_n \alpha_2} z_{\beta_n \beta_2}}{z_{1,2}^{\alpha_1} z_{2,\alpha_n}^{\alpha_1} z_{1,\beta_2}^{\beta_1} z_{2,\beta_2}^{\beta_2} \alpha_n \beta_2} A_{n-1}(2, 3, ..., n)
$$

(4.15)

where at the leading part of $\epsilon$, the $\prod_{\alpha \neq 1,n-2,1,n} \delta(\mathcal{E}_\alpha)$ takes the form (4.8) so $A_{n-1}(2, 3, ..., n)$ can be treated as a constant. To carry out the contour integration of $z_1$, using (4.9)
we write $E_1 = \epsilon \sum_{i=2}^{n} k_i^{(1)} k_i^{(0)} z_i$, thus

\[
\int dz_1 \delta (E_1) \frac{z_{\alpha_1 \alpha_2}}{z_{1 \alpha_2} z_{1 \alpha_1} z_{2 \beta_2} z_{1 \beta_2} z_{1 \beta_1}} = \oint_{\Gamma_D} dz_1 \frac{z_{\alpha_2 \alpha_1}}{z_{1 \alpha_2} z_{1 \alpha_1} z_{2 \beta_2} z_{1 \beta_2} z_{1 \beta_1}} \tag{4.16}
\]

Where the contour $\Gamma_D$ means taking the sum only over poles coming from $f$. One can see that because the numerator $z_{12} z_{13} \cdots z_{1n}$, as long as all $\alpha_1, \alpha_n, \beta_2, \beta_n$ are different, there is no extra pole in the denominator besides those coming from $f$, thus by the Cauchy residue theorem\(^9\), the integral is zero, which is exact the case of the CHY-Integrand containing no poles of $S_{1a}$. On the other hand, if there are at least two labels of $\alpha_2, \alpha_n, \beta_2, \beta_n$ same, the integral is nonzero by the extra poles in the denominator, which corresponding to the CHY-Integrand with pole $S_{1a}$. One further point is that by (4.16), no matter if the $S_{1a}$ is a single-pole or poles of higher degrees, the leading behaviour is always $\frac{1}{\epsilon}$.

5 From singular kinematics to solutions III: the forward limit

The last singular kinematics we will discuss in the paper is the forward limit

\[ k_1 + k_2 = cq \to 0. \tag{5.1} \]

As we have mentioned in the section on motivation, the forward limit is very useful when discussing the loop-level CHY-integrands. In this section, we will give a general discussion of forward limit first, and then apply it to the one-loop CHY-integrals.

5.1 The general discussion

Similarly to the soft limit, under the limit (5.1) we will have $S_{12i} \to 0$ for all $i = 3, ..., n$ automatically under the forward limit (5.1). As we will see, the forward limit can be considered as the mixture of the factorization limit and the soft limit. While all poles $S_{12i}$ are not compatible, all of them contain the common pole $S_{12} \to 0$. Now we ask what the implication of the singular kinematics to the is the behaviour of solutions of scattering equations?

Let us start with the singular kinematics $S_{12} \to 0$. Unlike the factorization limit where $S_A \to \epsilon^1$, the (5.1) implies $S_{12} \to \epsilon^2$. The difference will lead to the different behaviour of singular solutions, As given in [62], He and Yuan have shown that there are two kinds of singular solutions

\[\text{Singular } - I: \quad |z_1 - z_2| \sim \epsilon^1, \]
\[\text{Singular } - II: \quad |z_1 - z_2| \sim \epsilon^2. \tag{5.2}\]

\(^9\)The large $z_1$ behaviour is $\frac{z_1^{n-1}}{z_1^{n-1} + z_1^{n+1}} \sim \frac{1}{z_1}$, so there is no boundary contribution at $z_1 = \infty$. 

\[\text{– 35 –}\]
where each kind has \((n - 4)!\) solutions. In other words, like the factorization limit, the singular kinematics \(S_{12} \to 0\) implies the singular solution. The counting of \((n - 4)!\) of each type matches the counting of factorization limit of pole \(S_{12}\) too. However, unlike the factorization limit with only one type of singular solutions, there are two types of singular solutions, especially type II with the limit behaviour \(|z_1 - z_2| \sim \epsilon^2\).^10

Now we move to the automatic singular kinematics \(S_{12i} \to 0\). Do they imply the singular solution of \(z_1, z_2, z_i \to z\)? With the experience from the soft limit, we need to do more careful analysis. Assuming there is a singular solution where, for example, \(z_3\) tend to \(z_1, z_2\) while all other \(z_i\) are separated from each other. In the scattering equation

\[
\epsilon_1 = \frac{k_1 \cdot k_2}{z_1 - z_2} + \frac{k_1 \cdot k_3}{z_1 - z_3} + \frac{k_1 \cdot k_4}{z_1 - z_4} + \cdots + \frac{k_1 \cdot k_n}{z_1 - z_n} = 0. \tag{5.3}
\]

since \(k_1 \cdot k_2 = \frac{\epsilon^2}{2q}\), term \(\frac{k_1 \cdot k_2}{z_1 - z_2} \sim \epsilon^1/\epsilon^0\) depending if it is singular I or singular II solutions, while other terms \(\frac{k_1 \cdot k_i}{z_1 - z_i} \sim \epsilon^0, i \neq 2, 3\) because \(k_1 \cdot k_i \sim \epsilon^0\) and \(|z_1 - z_i| \sim \epsilon^0\). But the term \(\frac{k_1 \cdot k_3}{z_1 - z_3}\) will be singular because \(z_3 \to z_1\), unless \(S_{13} = 2k_1 \cdot k_3 \to 0\), which is conflict with our kinematic configuration. Therefore, we learned that there is no other \(z_i (i \neq 1, 2)\) tend to \(z_{1,2}\). The only possible asymptotic behaviour of singular solutions must be (5.1). Now let us consider the contributions of singular solutions to amplitudes. We chose \((rst) = (123)\) and \((ijk) = (n-2, n-1, n)\). For the measure part,

\[
(z_1 - z_2)(z_2 - z_3)(z_3 - z_1)(z_n - z_{n-1})(z_{n-1} - z_{n-2})(z_{n-2} - z_n) \sim \begin{cases} \epsilon^1, & \text{Singular I} \\ \epsilon^2, & \text{Singular II} \end{cases}
\]

\[
|\Phi|_{ijk}^{rst} \sim \epsilon^1
\]

\[
J \sim \begin{cases} \epsilon^0, & \text{Singular I} \\ \epsilon^1, & \text{Singular II} \end{cases}
\]

With above knowledge we summary the contributions of each type of solutions as follows

One interesting point is that the singular I solutions will contribute \(I_{CHY} \sim \frac{1}{(z_1 - z_2)^n}\)

^10 A naive understanding is that (5.1) implies there are two kinematic singularities simultaneously. The first one is the \((k_1 + k_2) \to eq\), which is the soft limit type. The second one is the \((k_1 - k_2) \to 2k_1\), which is more like the factorization limit.
\[
\begin{array}{|c|c|c|c|c|c|}
\hline
\text{measure} & I_{\text{CHY}} \sim \frac{1}{(z_1 - z_2)^2} & I_{\text{CHY}} \sim \frac{1}{(z_1 - z_2)^4} & I_{\text{CHY}} \sim \frac{1}{(z_1 - z_2)^6} \\
\hline
\text{Singular-I} & \epsilon & \epsilon^{-2} & \epsilon^{-4} & \epsilon^{-6} & 1 \\
\text{Singular-II} & \epsilon^2 & \epsilon & 1 & 1 & 1 \\
\text{Regular} & 1 & 1 & 1 & 1 & 1 \\
\text{Contribution of Singular-I} & & \epsilon^{-2} & \epsilon^{-1} & 1 & \\
\text{Contribution of Singular-II} & & \epsilon^{-3} & \epsilon^{-1} & \epsilon & \\
\text{Contribution of Regular} & 1 & 1 & 1 & 1 & 1 \\
\hline
\end{array}
\]

Table 19. Contribution of two Singular solutions and regular respectively

at the order \( \epsilon^0 \), just like the regular solutions. Thus we can not naively remove their contributions\(^{11}\)

Having the above discussion, we present one numerical example to show the above conclusions. The choice of kinematics has been given in Appendix A. We choose the six-point example since it is the simplest nontrivial case under the forward limit. The numerical kinematics is given by

\[
\begin{align*}
  k_1 & \rightarrow \{0.824, -0.421, 0.306, 0.283, -0.572, 0\} \\
  k_2 & \rightarrow \{1.169, 0.705, 0.291, 0.341, -0.817, 0\} \\
  k_3 & \rightarrow \{-0.677, 0.284, 0.136, -0.316, +0.509, 0\} \\
           & + \{ -0.323, -0.387 + 0.282i, -0.185 - 0.591i, -0.320, 0.496, 0\} \epsilon \\
  k_4 & \rightarrow \{-1.315, -0.568, -0.733, -0.309, 0.880, 0\} \\
           & + \{ -0.714, 0.417, 0.0996, -0.443 - 1.142i, 1.262 - 0.401i, 0\} \epsilon \\
  k_+ & \rightarrow \{0.410, -0.158, 0.186 + 0.0370i, -0.0794 + 0.0870i, -0.333, 0\} \\
           & + \{ 0.518, -0.0148 - 0.141i, 0.043 + 0.295i, 0.382 + 0.571i, -0.879 + 0.201i, 0.128 - 0.442i\} \epsilon \\
  k_- & \rightarrow - \{0.410, -0.158, 0.186 + 0.0370i, -0.0794 + 0.0870i, -0.333, 0\} \\
           & + \{ -0.518, -0.0148 - 0.141i, 0.043 + 0.295i, 0.382 + 0.571i, -0.879 + 0.201i, -0.128 + 0.442i\} \epsilon \\
\end{align*}
\]

We fix the gauge \( z_1 = 1, z_2 = 2, z_3 = 3 \). There are two singular-I solutions, two singular-II

\(^{11}\)In [61] it has been shown that although singular I solutions give nonzero contributions at the integrand level, it can be removed for some theories since the one-loop CHY-integrand is defined up to terms integrated to zero.
solutions and two regular solutions:

\[
\begin{align*}
\text{Regular (1)} & \quad \begin{cases}
    z_4 \to (1.925 - 0.124i) + (0.0527 + 0.0364i)\epsilon + (0.330 - 0.043i)\epsilon^2 \\
    z_+ \to (2.079 - 0.567i) + (0.654 + 0.288i)\epsilon + (1.460 + 1.530i)\epsilon^2 \\
    z_- \to (1.549 + 0.129i) - (0.590 - 0.787i)\epsilon + (0.296 + 1.238i)\epsilon^2
\end{cases} \\
\text{Regular (2)} & \quad \begin{cases}
    z_4 \to (1.996 + 0.0401i) + (0.0904 + 0.0436i)\epsilon + (0.141 - 0.512i)\epsilon^2 \\
    z_+ \to (2.049 + 0.132i) + (0.0966 - 0.0383i)\epsilon + (-0.346 - 1.292i)\epsilon^2 \\
    z_- \to (1.590 - 0.286i) - (0.123 - 2.415i)\epsilon + (9.723 - 7.520i)\epsilon^2
\end{cases}
\end{align*}
\]

\[(5.6)\]

\[
\begin{align*}
\text{Singular I (1)} & \quad \begin{cases}
    z_4 \to 1.911 - (0.267 - 0.265i)\epsilon + (-0.599 + 1.144i)\epsilon^2 \\
    z_+ \to (1.726 - 0.479i) + (0.112 - 1.692i)\epsilon + (-0.604 - 4.715i)\epsilon^2 \\
    z_- \to (1.726 - 0.479i) - (0.112 - 1.692i)\epsilon + (0.604 + 4.715i)\epsilon^2
\end{cases} \\
\text{Singular I (2)} & \quad \begin{cases}
    z_4 \to 1.911 + (0.152 + 0.0200i)\epsilon + (0.0931 - 0.514i)\epsilon^2 \\
    z_+ \to (1.785 + 0.232i) + (0.158 - 0.509i)\epsilon + (-1.055 - 0.466i)\epsilon^2 \\
    z_- \to (1.785 + 0.232i) - (0.158 - 0.509i)\epsilon + (1.055 + 0.466i)\epsilon^2
\end{cases} \\
\text{Singular II (1)} & \quad \begin{cases}
    z_4 \to 1.911 - (0.130 - 0.336i)\epsilon + (0.359 + 1.232i)\epsilon^2 \\
    z_+ \to (1.958 - 0.123i) + (0.285 - 0.0967i)\epsilon + (0.0694 + 0.129i)\epsilon^2 \\
    z_- \to (1.958 - 0.123i) + (0.285 - 0.0967i)\epsilon + (0.0694 + 0.129i)\epsilon^2
\end{cases} \\
\text{Singular II (2)} & \quad \begin{cases}
    z_4 \to 1.911 + (0.0151 - 0.0503i)\epsilon + (0.231 - 0.189i)\epsilon^2 \\
    z_+ \to (2.064 + 0.345i) + (0.0666 + 1.0254i)\epsilon - (0.223 - 0.747i)\epsilon^2 \\
    z_- \to (2.064 + 0.345i) + (0.0666 + 1.0254i)\epsilon + (0.223 - 0.747i)\epsilon^2
\end{cases}
\end{align*}
\]

\[(5.7)\]

\[(5.8)\]

The measure part of each solution is in table (20).

| Solution     | Measure                                      |
|--------------|----------------------------------------------|
| Regular (1)  | \(0.201709 + 0.315957i + O(\epsilon)\)     |
| Regular (2)  | \(0.00828429 + 0.000758566i + O(\epsilon)\)|
| Singular I (1)| \(0.09663 - 0.37947i + O(\epsilon)\)      |
| Singular I (2)| \(-0.022706 - 0.0106388i + O(\epsilon)\)  |
| Singular II (1)| \((-0.000290196 + 0.000092548i)\epsilon + O(\epsilon^2)\) |
| Singular II (2)| \((0.606991 + 0.0403871i)\epsilon + O(\epsilon^2)\) |

Table 20. The measure part of each solution in Forward limit

which agree with our computation (the third column of table (19)). Next we choose three different CHY-Integrands with pole index \(\chi[S_{+-}] = 0, -1, -2\) respectively to show the behaviour of table (19):

- \(I_1 = PT(1234 + -)PT(1342 - +)\) with \(\chi[S_{+-}] = 0\): For this example (see table 21), there are poles \(S_{+-} \sim \epsilon^{-2}\) and \(S_{1+-} \sim \epsilon^{-1}\), so the leading contribution comes only from Singular II solutions.
\[ I_2 = PT(1234 + -)PT(1 + 234 -) \] with \( \chi[S_{+-}] = -1 \): For this example (see table 22), there is pole \( S_{1+} \sim \epsilon^{-1} \), so the leading contribution comes from both Singular I and Singular II solutions.

\[
\begin{array}{|l|l|}
\hline
\text{Solution} & \text{Integration} \\
\hline
\text{Regular (1)} & -(9.3103 + 1.98347i) \\
\text{Regular (2)} & (2.81938 - 6.61778i) \\
\text{Singular I (1)} & -\frac{1}{\epsilon}(0.622372 + 0.426007i) \\
\text{Singular I (2)} & -\frac{1}{\epsilon}(0.726396 + 1.70513i) \\
\text{Singular II (1)} & \frac{1}{\epsilon}(0.657355 + 0.819951i) \\
\text{Singular II (2)} & -\frac{1}{\epsilon}(0.862234 - 0.0145693i) \\
\text{Summation} & -\frac{1}{\epsilon}(0.204879 - 0.83452i) \\
\text{Amplitude} & -\frac{1}{\epsilon}(s_{34}s_{2+} - s_{1+}) \\
\text{Numerical amplitude} & -\frac{1}{\epsilon}(0.204879 - 0.83452i) \\
\hline
\end{array}
\]

Table 21. The contribution of each solution of CHY-Integrand \( PT(1234 + -)PT(1342 - +) \)

\[ I_3 = PT(123 + 4 -)PT(1 + 423 -) \] with \( \chi[S_{+-}] = -2 \): For this example (see table 23), there is no singular pole, so the leading contribution comes from regular solutions as well as Singular I solutions.

\[
\begin{array}{|l|l|}
\hline
\text{Solution} & \text{Integration} \\
\hline
\text{Regular (1)} & -(2.00263 - 7.49773i) \\
\text{Regular (2)} & (3.43278 + 1.47441i) \\
\text{Singular I (1)} & -\frac{1}{\epsilon}(0.0475165 - 1.0134i) \\
\text{Singular I (2)} & -\frac{1}{\epsilon}(1.25809 + 1.02357i) \\
\text{Singular II (1)} & -\frac{1}{\epsilon}(0.423532 + 0.0715691i) \\
\text{Singular II (2)} & -\frac{1}{\epsilon}(0.524593 + 0.208376i) \\
\text{Summation} & \frac{1}{\epsilon}(1.20454 - 0.126638i) \\
\text{Amplitude} & \frac{1}{\epsilon}(s_{1+} - s_{3+} s_{1+}) + \frac{1}{\epsilon}(s_{1+} - s_{3+} s_{1+}) \\
\text{Numerical amplitude} & \frac{1}{\epsilon}(1.20454 - 0.126638i) \\
\hline
\end{array}
\]

Table 22. The contribution of each solution of CHY-Integrand \( PT(1234 + -)PT(1 + 234 -) \)

### 5.2 Applications in one-loop CHY-Integrands

One main motivation of our current study is to understand that under the forward limit, what is the contributions of singular solutions for one-loop CHY-integrands constructed using the forward limit method. In this subsection, we will use two types of one-loop CHY-integrands of the bi-adjoint scalar theory to provide some general picture, especially the different patterns of cancellation of singularities.
Table 23. The contribution of each solution of CHY-Integrand $PT(123 + 4 − )PT(1 + 423 − )$

### 5.2.1 The first type of integrands

In [61] the one-loop CHY-integrand is given by

$$m_n^{1\text{-loop}}[\pi | \rho] = \int \frac{d^D l}{(2\pi)^D} \frac{1}{l^{22}} \lim_{k_\perp \to \pm l} \sum_{\alpha \in \text{cyc}(\pi)} \sum_{\beta \in \text{cyc}(\rho)} m_{n+2}^{\text{tree}}[-\alpha + | -\beta +]$$  \(5.9\)

where $\alpha$ and $\beta$ are two PT factors and

$$m_{n+2}^{\text{tree}}[-\alpha + | -\beta +] = \int d\Omega_{CHY} PT(-, \alpha(1), \cdots, \alpha(n), +)PT(-, \beta(1), \cdots, \beta(n), +)$$  \(5.10\)

is the tree-level amplitudes of $(n + 2)$ particles defined by the CHY-integrand of two PT factors.

To have a concrete picture, let us consider a simple example, i.e., one loop integrands $m_4^{1\text{-loop}} [1234 | 1243]$. From (5.9), this loop integrand is given by the sum of all possible combinations of PT-factor sets $\{PT(1+ - 234), PT(12+ - 34), PT(123+ - 4), PT(1234+ - )\}$ and $\{PT(1+ - 243), PT(12+ - 43), PT(124+ - 3), PT(1243+ - )\}$. As in the previous section, a set of momentum with forward limit parameter $\epsilon$ has been taken as following:

\begin{align*}
  k_1 & \rightarrow \{1.04, 0.113, -0.156, 0.775, 0.667, 0\} \\
  k_2 & \rightarrow \{1.43, -0.913, -0.771, -0.727, -0.295, 0\} \\
  k_3 & \rightarrow \{-0.931, 0.383, -0.508, -0.344, -0.587, 0\} + \{-0.699\epsilon, (0.4 + 0.304i)\epsilon, (-0.529 + 0.23i)\epsilon, 0.0745\epsilon, -0.434\epsilon, 0\} \\
  k_4 & \rightarrow \{-1.54, 0.417, 1.43, 0.296, 0.215, 0\} + \{-1.15\epsilon, (0.354 - 0.641i)\epsilon, (1.22 + 0.186i)\epsilon, -0.191\epsilon, -0.342\epsilon, 0\} \\
  k_+ & \rightarrow \{0.45, -1.02 - 0.34i, -0.548, 0.287 - 1.21i, -0.597, 0\} + \{0.923\epsilon, (-0.377 + 0.168i)\epsilon, (-0.344 - 0.208i)\epsilon, 0.0584\epsilon, 0.388\epsilon, (0.714 - 0.0115i)\epsilon\} \\
  k_- & \rightarrow \{-0.45, 1.02 + 0.34i, 0.548, -0.287 + 1.21i, 0.597, 0\} + \{0.923\epsilon, (-0.377 + 0.168i)\epsilon, (-0.344 - 0.208i)\epsilon, 0.0584\epsilon, 0.388\epsilon, (-0.714 + 0.0115i)\epsilon\}
\end{align*}  \(5.11\)
For current example, there are \((n - 3)! = 6\) solutions. Under the forward limit, they are divided into three classes according to the asymptotic behaviour, i.e., regular solutions, singular-I and singular-II solutions, and each of them contains two solutions:

\[
\text{Regular (1)} \quad \begin{align*}
    z_4 &\to (1.99 + 0.074i) - (0.21 - 0.0669i)\epsilon + (0.0316 - 0.313i)\epsilon^2 \\
    z_+ &\to (2.3 + 0.135i) - (0.283 - 0.543i)\epsilon - (1.36 + 1.09i)\epsilon^2 \\
    z_- &\to (2.01 + 0.175i) - (0.0946 - 0.132i)\epsilon + (0.0981 - 0.0337i)\epsilon^2
\end{align*}
\]

\[
\text{Regular (2)} \quad \begin{align*}
    z_4 &\to (2.04 - 0.483i) - (0.496 + 0.172i)\epsilon - (0.182 - 1.33i)\epsilon^2 \\
    z_+ &\to (1.78 - 0.594i) - (0.234 - 0.198i)\epsilon + (0.678 + 1.02i)\epsilon^2 \\
    z_- &\to (2.52 + 0.273i) + (0.516 + 0.15i)\epsilon + (0.354 - 0.104i)\epsilon^2
\end{align*}
\]

\[
\text{SingularI (1)} \quad \begin{align*}
    z_4 &\to 1.89 - (0.0953 + 0.0598i)\epsilon - (0.469 + 0.562i)\epsilon^2 \\
    z_+ &\to (1.82 + 0.0335i) + (0.00702 - 0.103i)\epsilon + (0.207 - 0.0868i)\epsilon^2 \\
    z_- &\to (1.82 + 0.0335i) - (0.00702 - 0.103i)\epsilon - (0.207 - 0.0868i)\epsilon^2
\end{align*}
\]

\[
\text{SingularI (2)} \quad \begin{align*}
    z_4 &\to 1.89 - (0.0845 + 0.0676i)\epsilon - (0.0545 + 0.0212i)\epsilon^2 \\
    z_+ &\to (2.39 + 0.184i) - (0.344 - 0.0399i)\epsilon - (0.176 - 0.0308i)\epsilon^2 \\
    z_- &\to (2.39 + 0.184i) + (0.344 - 0.0399i)\epsilon - (0.176 - 0.0308i)\epsilon^2
\end{align*}
\]

\[
\text{SingularII (1)} \quad \begin{align*}
    z_4 &\to 1.89 - (0.0923 + 0.236i)\epsilon + (0.317 + 0.0928i)\epsilon^2 \\
    z_+ &\to (1.89 - 0.376i) + (0.103 + 0.191i)\epsilon - (6.61 - 1.44i)\epsilon^2 \\
    z_- &\to (1.89 - 0.376i) + (0.103 + 0.191i)\epsilon - (6.37 - 1.27i)\epsilon^2
\end{align*}
\]

\[
\text{SingularII (2)} \quad \begin{align*}
    z_4 &\to 1.89 - (0.0874 - 0.109i)\epsilon - (0.00897 - 0.265i)\epsilon^2 \\
    z_+ &\to (1.97 + 0.196i) + (0.0645 + 0.0918i)\epsilon - (2.57 - 1.42i)\epsilon^2 \\
    z_- &\to (1.97 + 0.196i) + (0.0645 + 0.0918i)\epsilon - (2.64 - 1.18i)\epsilon^2
\end{align*}
\]

For the numerical evaluation, we will take two different approaches. In the first approach, for each term in the 16 combinations of CHY-integrand (5.9), we sum over 6 solutions first, and the result is given in the table (24).

In the table (24), although most of the terms will have leading divergence \(\frac{1}{\epsilon}\), when summing over 16 terms, all divergences will cancel each other, and we are left with finite results under the forward limit as expected.

Although the divergence is not shown at the final, how the cancellation happens is not clear. To better understand, we take the second approach: for each solution, we put it to all 16 terms and sum them up first, and then sum up six solutions. One very interesting observation is that the divergence will cancel each other after summing 16 terms for each solution as shown in table (25). We could also verify this matter by summing 16 terms analytically, which is given by:

\[
N = \left( z_1 + z_2 + z_3 + z_4 + z_5 + \cdots + z_4 \right) - \left( z_1 + z_2 + z_3 + z_4 + z_5 + \cdots + z_4 \right) \times \left( z_1 + z_2 + z_3 + z_4 + z_5 + \cdots + z_4 \right) - \left( z_1 + z_2 + z_3 + z_4 + z_5 + \cdots + z_4 \right)
\]

\[
I = \frac{N}{N} (5.12)
\]
As one can check, for each solution, the $N$ will give $\epsilon^n$ factor to cancel the singular from the denominator and the measure.

The cancelation pattern observed above for the integrand (5.9) is not a coincident. In fact, in the construction of the CHY-integrand, the tadpole contribution under the forward limit is manifest avoid, while the massless bubble must be canceled by different terms in the combinations.
5.2.2 The second type of integrands

A different idea to remove the tadpole and massless bubble singularities has been used in [55]. Based on this idea, different one-loop CHY-integrand has been constructed by multiplying each term with the proper pole-picking operators. For the example $m_4^{1-\text{loop}} [1234 | 1243]$, there are only three terms as given in the table (26). By the construction, for each term, the cancellation of divergence comes from the summing over six solutions as shown in the second column of the table (26). More accurately, the cancellation happens when and only when summing over singular-I and singular-II solutions. Just summing over singular-I solutions or singular II solutions, the divergence will not be cancelled.

| Integrand                                                                 | Leading order          |

6 Conclusion

Motivated by our curiosity of the singular solutions and potential application to other frontiers of research, for example, the construction of two-loop CHY-integrands by double forward limits, in this paper, we have initiated the systematic study of the relation between the singular kinematic configurations and the singular solutions of scattering equations. We find that the singular solutions will always lead to singular kinematics. Furthermore, the layer structure of singular solutions gives a clear picture of the structure of singular kinematics. However, the reverse is not always transparent, as shown by the soft limit and forward limit. From these examples, we guess the compatibility of various singular poles can characterize the singular kinematics. Although we can not give rigorous proof, from the examples discussed in this paper, it seems that compatible singular poles will lead to singular solutions, but non-compatible will not give singular solutions.

Although we have discussed several types of singularities in this paper, it is obvious that there are many other types of singularities. One-by-one analysis can be done using the method presented in the paper. However, it is more desirable to have a systematical algorithm so that the relation between the singular kinematic configurations and the singular solutions of scattering equations can be well established.

Acknowledgments

We would like to thank Ye Yuan and Song He for very useful discussion. This work is supported by Qiu-Shi Funding and Chinese NSF funding under Grant No.11935013, No.11947301, No.12047502 (Peng Huanwu Center).
A Kinematics

In this note, we focus on solutions of scattering equations defined by (1.3) or the equivalent polynomial equations given in [13]

\[ 0 = h_m \equiv \sum_{S \in \mathcal{A}, |S| = m} k_S^2 z_S , \quad 2 \leq m \leq n - 2 , \]  \hfill (A.1)

Where the sum is over all \( \frac{n!}{(n-m)!m!} \) subsets \( S \) of \( \mathcal{A} = \{1, 2, ..., n\} \) with exactly \( m \) elements and \( k_S = \sum_{b \in S} k_b \) and \( z_S = \prod_{b \in S} z_b \). It is worth pointing out that there are exactly \( (n-3) \) independent equations of the form (A.1), since the cases of \( m = 1, n-1, n \) are trivially true by momentum conservation plus the on-shell conditions. For general kinematics, it is impossible to write down analytic results for \( n \geq 6 \), thus to study the properties of solutions, we need to rely on the numerical method. One important step of the numerical calculation is the parametrization of kinematics, especially when we try to study different limit processes, such as the factorization limit, the forward limit and the soft limit, etc.

There are two ways to define a kinematic configuration. The first way is to use the Lorentz invariant combination \( k_i \cdot k_j \). With momentum conservation and null conditions, there are \( \frac{n(n-3)}{2} \) independent contractions. To see it, using momentum conservation, we can eliminate \( p_n \). For remaining \( (n-1) \) momenta, there are \( \frac{(n-1)(n-2)}{2} \) contractions.

A further constraint comes from

\[ 0 = k_n^2 = (\sum_{i=1}^{n} k_i)^2 = \sum_{i<j} 2k_i \cdot k_j \]  \hfill (A.2)

thus we get \( \frac{(n-1)(n-2)}{2} - 1 = \frac{n(n-3)}{2} \) contractions. Let us apply this method to the kinematic configuration of forward limit of \( (n+2) \) legs defined by

\[ L_+ + L_- = 2eq, \quad L_+ \cdot L_- = 2e^2q^2, \quad q^2 \neq 0 \]  \hfill (A.3)

where \( t = 0 \) is the forward limit. For general \( t \neq 0 \), we take following data to parameterize kinematics:

\[ q^2; \quad P_i \cdot P_j, \quad 1 \leq i < j \leq n-1; \quad P_i \cdot q \cdot P_i, \quad i = 1, ..., n-1 \]  \hfill (A.4)

There are \( \frac{(n-1)(n-2)}{2} + 1 + 2(n-1) = \frac{(n+2)(n-1)}{2} + 1 \) combinations, thus they are not independent. One extra constraint comes from the on-shell condition \( P_n^2 = 0 \), i.e.,

\[ 0 = \frac{1}{2} \sum_{i=1}^{n-1} (P_i + 2eq)^2 = \sum_{1 \leq i < j \leq n-1} P_i \cdot P_j + 2eq \cdot \sum_{i=1}^{n-1} P_i + 2e^2q^2 \]  \hfill (A.5)

Using above data, other Lorentz contractions are given by

\[ L_- \cdot P_i = -L_+ \cdot P_i + 2eq \cdot P_i; \quad P_i \cdot P_n = -2eq \cdot P_i - \sum_{j=1,j \neq i}^{n-1} P_i \cdot P_j \]

\footnote{To get this counting, we have neglected the constraints coming from the dimension of space-time.}
\[ L_+ \cdot P_n = -2\epsilon^2 q^2 - \sum_{j=1}^{n-1} L_+ \cdot P_j; \quad L_- \cdot P_n = -2\epsilon^2 q^2 + \sum_{j=1}^{n-1} (L_+ \cdot P_j - 2\epsilon q \cdot P_j) \quad (A.6) \]

By momentum conservation. With the above choice, we need to determine how data in (A.4) depend on \( \epsilon \) to describe the limit process. This is not a trivial task. For example, a naive choice is to take \( q^2, L_+ \cdot P_i, q \cdot P_i \) as well as all \( P_i \cdot P_j \) except one by constraint (A.5) as invariant data under the limit. This naive choice will have the maximum number of combinations, which are independent of \( \epsilon \). However, this choice is wrong because now we will have \( L_+ \) to be invariant under the forward limit, thus

\[ L_-^2 = (-L_+ + 2\epsilon q)^2 = L_+^2 - 4\epsilon L_+ \cdot q + 4\epsilon^2 q^2 = -4\epsilon L_+ \cdot q + 4\epsilon^2 q^2 \quad (A.7) \]

can not be zero for all value of \( \epsilon \). The lesson from this example is the following. Although taking Lorentz invariant combinations to be the independent input data for the kinematics looks simple, it is not easy to determine how they depend on the parameter \( \epsilon \), which prescribes the limit process.

To avoid the above-mentioned subtlety, we take the second parametrization method, i.e., parametrising directly in the momentum component form. The first step to set up a general kinematic configuration is that there is no subset of \( A \) such that \( S_A = 0 \). Starting from this choice, we can make various limit procedure:

**The factorization limit:** For this case, we consider several situations. The first situation is there is one and only one \( S_A \rightarrow 0 \). To reach this goal, a simple way is to use BCFW-deformation, i.e., while keeping all other \( p_i \)'s invariant, we deform

\[ p_1(z) = p_1 + zq, \quad p_n(z) = p_n - zq, \quad q^2 = q \cdot p_1 = q \cdot p_n = 0 \quad (A.8) \]

For any subset \( 1 \in A, n \not\in A \), it is easy to know that when

\[ z_A = -\frac{p_A^2}{2P_A \cdot q} \implies S_A(z_A) = 0 \quad (A.9) \]

Now we parameterize the kinematic as

\[ p_1(\epsilon) \equiv p_1 + z_A q + \epsilon q, \quad p_n(\epsilon) = p_n - z_A q - \epsilon q, \quad q^2 = q \cdot p_1 = q \cdot p_n = 0 \quad (A.10) \]

so when \( \epsilon \rightarrow 0 \) the factorization limit has been reached. Similar idea can be used to putting several \( S_A \rightarrow 0 \) at the same time. For example, using two different pairs of BCFW deformations

\[ p_1(w_1) = p_1 + w_1 q_{1n}, \quad p_n(w_1) = p_n - w_1 q_{1n}, \quad q_{1n}^2 = q_{1n} \cdot p_1 = q_{1n} \cdot p_n = 0 (A.11) \]

\[ p_2(w_2) = p_2 + w_2 q_{23}, \quad p_3(w_2) = p_3 - w_2 q_{23}, \quad q_{23}^2 = q_{23} \cdot p_1 = q_{23} \cdot p_2 = 0 \quad (A.12) \]

we can set two poles \( S_A, S_B \rightarrow 0 \) with \( 1 \in A, n \not\in A \) and \( 2 \in B, 3 \not\in B \) at the same time. We want to emphasise that the poles \( S_A, S_B \) can be compatible or not compatible. Different patterns will give different behaviours of singular solutions. A
special variation of two BCFW-deformations is that they share one common node, for example, \( p_1 \), i.e.,

\[
\begin{align*}
p_1(w_1) &= p_1 + w_1 q_{1n} + w_2 q_{12}, & p_n(w_1) &= p_n - w_1 q_{1n}, & p_2(w_2) &= p_2 - w_2 q_{12}, \\
q_{1n}^2 &= q_{1n} \cdot p_1 = q_{1n} \cdot p_n = 0, & q_{12}^2 &= q_{12} \cdot p_1 = q_{12} \cdot p_2 = 0 & q_{1n} \cdot q_{12} = 0, \quad (A.13)
\end{align*}
\]

- **The forward limit:** For the pair of the forward limit, we take them as

\[
L_+ = (L + eq, \mu), \quad L_- = (-L + eq, -\mu) \quad q^2, L^2 \neq 0, \quad (A.14)
\]

where we have lifted \( L_\pm \) to be null in higher dimension. To make sure the null condition for any value of \( \epsilon \), we need to impose conditions

\[
q \cdot L = 0, \quad -\mu^2 = L^2 + \epsilon^2 q^2 \quad (A.15)
\]

For other \( n \) momenta, we find \( n \) pairs of \( p_i, q_i, i = 1, ..., n \) such that

\[
p_i^2 = q_i^2 = p_i \cdot q_i = 0, \quad i = 1, ..., n; \quad \sum_{i=1}^n p_i = 0, \quad \sum_{i=1}^n q_i = 2q \quad (A.16)
\]

and use them to define

\[
P_i = p_i - \epsilon q_i \quad (A.17)
\]

Above choice of the forward limit is very general. We can make a simple choice with the minimum numbers of \( P_i \) depending on \( \epsilon \). The procedure is following:

- (a1) First setting \( q_j = 0, j = 1, ..., n-2 \), so \( P_j = p_j \).
- (a2) Taking a null momentum \( k_{n-1} \), we construct

\[
p_{n-1} = -\frac{K^2}{2K \cdot k_{n-1}} k_{n-1}, \quad p_n = -K + \frac{K^2}{2K \cdot k_{n-1}} k_{n-1}, \quad K = \sum_{j=1}^{n-2} p_j \quad (A.18)
\]

- (a3) Taking null momenta \( q_{n-1}, q_n \) such that \( p_a \cdot q_a = 0, a = n-1, n \) and \( q_n \cdot q_{n-1} \neq 0 \) and choosing \( b_{n-1}, b_n \) such that \( L \cdot (\beta_{n-1} q_{n-1} + \beta_n q_n) = 0 \), we can write down

\[
P_{n-1} = p_{n-1} - 2\epsilon \beta_{n-1} q_{n-1}, \quad P_n = p_n - 2\epsilon \beta_n q_n, \quad q = \beta_{n-1} q_{n-1} + \beta_n q_n \quad (A.19)
\]

Above construction (A.18) and (A.19) have two exceptions. The first case is \( K = 0 \), i.e., the case \( n = 2 \). For this one, we can trivially take \( p_n = -p_{n-1} \) in (A.18). The second case is that \( K \neq 0 \), but \( K^2 = 0 \), which will happen when \( n = 3 \) (for general momentum configuration, it could not be true for \( n \geq 4 \)). For this one, we can take

\[
P_1 = -p_2 - p_3, \quad P_2 = p_2 - 2\epsilon q_2, \quad P_3 = p_3 - 2\epsilon q_3, \quad L_+ = (L + eq, \mu), \quad L_- = (-L + eq, -\mu) \quad q = q_2 + q_3, \quad \mu^2 = L^2 + \epsilon^2 q^2 \quad (A.20)
\]

with conditions

\[
p_i^2 = q_i^2 = 0 = p_3 \cdot p_2 = L \cdot q, \quad i = 2, 3
\]

\[
q_2 \cdot p_2 = 0 = q_3 \cdot p_3, \quad q_2 \cdot q_3, q_2 \cdot p_3, q_3 \cdot p_2 \neq 0 \quad (A.21)
\]
- **The soft limit:** The kinematic parametrization is following [56]. Assuming the $p_s$ is the soft particle, we take two arbitrary momenta, for example, $a,n$ and make the shifting

$$
\tilde{\lambda}_a(\epsilon) = \tilde{\lambda}_a + (1 - \epsilon)\frac{\langle n|s \rangle}{\langle n|a \rangle} \tilde{\lambda}_s, \quad \tilde{\lambda}_n(\epsilon) = \tilde{\lambda}_n + (1 - \epsilon)\frac{\langle a|s \rangle}{\langle a|n \rangle} \tilde{\lambda}_s, \quad \tilde{\lambda}_s(\epsilon) = \epsilon \tilde{\lambda}_s. \quad (A.22)
$$

It is easy to see that

$$
\lambda_a \tilde{\lambda}_a + \lambda_n \tilde{\lambda}_n + \lambda_s \tilde{\lambda}_s = \lambda_a \tilde{\lambda}_a(\epsilon) + \lambda_n \tilde{\lambda}_n(\epsilon) + \lambda_s \tilde{\lambda}_s(\epsilon) \quad (A.23)
$$

and $\epsilon \to 0$ gives the soft limit. Although we have used the spinor formalism special for $D = 4$, for general $D$-dimension, we can make the Lorenz transformation to put $p_n, p_a, p_s$ to the 4-dimensional subspace, thus above construction is general.
