Abstract Expression of ABCA1 is regulated by transcription of the gene and calpain-mediated proteolytic degradation, and inhibition ABCA1 degradation results in increased ABCA1 and HDL biogenesis in vitro. We examined whether this approach could be a potential antiatherogenic treatment. Although probucol inhibits both the activity and degradation of ABCA1, its oxidized products, spiroquinone and diphenoquinone, reduce degradation of ABCA1 without inhibiting its activity or altering transcription of the ABCA1 gene. Accordingly, both compounds enhanced apolipoprotein A1/ABCA1-dependent generation of HDL in vitro, and increased hepatic ABCA1 and plasma HDL without increasing antioxidant activity in plasma when given to rabbits. Both compounds also decreased vascular lipid deposition in cholesterol-fed rabbits. We therefore conclude that stabilization of ABCA1 against calpain-mediated degradation is a novel and potentially important strategy to increase HDL formation and prevent atherosclerosis. Spiroquinone and diphenoquinone are potential seeds for development of such drugs.—Arakawa, R., M. Tsujiita, N. Iwamoto, C. Ito-Ohsumi, R. Lu, C-A. Wu, K. Shimizu, T. Aotsuka, H. Kanazawa, S. Abe-Dohmae, and S. Yokoyama. Pharmacological inhibition of ABCA1 degradation increases HDL biogenesis and exhibits antiatherogenesis. J. Lipid Res. 2009. 50: 2299–2305.

Supplementary key words ATP binding cassette transporter A1 • high density lipoprotein • atherosclerosis • calpain • probucol

HDL plays a central role in the catabolic pathway of cholesterol by transporting it from extrahepatic cells to the liver for conversion to bile acids, and accordingly, is thought to be antiatherogenic. Apolipoprotein-mediated generation of new HDL from cellular lipids is one of the major events in the initial step of this pathway, cellular cholesterol release (1, 2). This reaction was found to be defective in genetic HDL deficiency, Tangier disease (3, 4), and mutations were identified in the gene of ABCA1 as the cause of this disorder (5–7).

Expression of ABCA1 is regulated at the transcriptional level and posttranslationally by calpain-mediated proteolysis. ABCA1 is stabilized against this degradation by helical apolipoproteins (8–10), and destabilized by unsaturated fatty acid (11) or excess unesterified cholesterol (12). Inhibition of calpain increases HDL formation by cultured cells (8), suggesting inhibition of proteolytic degradation of ABCA1 is a potential drug target for increasing HDL. ABCA1 degradation takes place intracellularly and its inhibition results in increased ABCA1 recycling to the cell surface (13). Direct inhibition of internalization of ABCA1 also causes its accumulation in the cell surface (13). HDL formation increases in both cases, indicating that it takes place at the cell surface (13). Inhibition of ABCA1 degradation or internalization would therefore be a potential strategy to increase HDL biogenesis for prevention and/or regression of atherosclerosis.

The hypolipidemic drug, probucol, is known to reduce plasma HDL (14) by inhibiting ABCA1-mediated HDL biogenesis (15) and producing a Tangier disease-like state (16). Interestingly, probucol causes not only inactivation of ABCA1 but also inhibits its degradation (17). We found in preliminary experiments that the crude oxidized products of probucol enhanced HDL formation by cultured cells rather than inhibiting it. Based on these findings, we
hypothesized that some of the compounds in this mixture may function as inhibitors of ABCA1 degradation without inhibiting its activity. We therefore investigated the functions of spiroquione (SQ) and diphenoquinone (DQ), the two potential oxidized metabolites of probucol (supplementary Material I) (18), in their ability to alter ABCA1 activity and degradation as well as HDL formation in vitro and in vivo, and to alter the development of atherosclerosis in a rabbit model.

MATERIALS AND METHODS

Cell lines and culture conditions

THP-1 cells were maintained in 10% fetal bovine serum-RPMI1640 (Sigma) in a humidified atmosphere of 5% CO2 and 95% air at 37°C. Human monocyte cell line cells THP-1 were differentiated to macrophages (THP-1 macrophages) by culturing the cells at a density of 1.0 × 10^6 cells/ml in the presence of 3.2 × 10^{-7} M phorbol 12-myristate 13-acetate (Wako) for 24 h (8, 10). Balb/3T3 fibroblasts and HEK293 cells were maintained in 10% fetal bovine serum-DMEM (Sigma). The cells were seeded in culture plates at a density of 3 × 10^5 cells/ml and cultured for 3 days before use.

Treatment of cells with probucol and its metabolites

Probucol was purchased from Shiono Finesse Co., Ltd., Osaka, Japan. Its oxidant products, SQ and DQ, were synthesized and isolated by the oxidation of probucol (18) and by reduction of 2,6-di-tert-butylphenol (19), respectively. SQ and DQ were chemically stable under the experimental conditions used (details are described in supplementary Material I). Probucol, SQ or DQ were delivered to cells either after incorporation into acetylated low density lipoprotein (acLDL) as a vehicle (15, 17) or directly as a solution in 2-butanol. Drug-containing acLDL was prepared as described previously (15). Briefly, human LDL was incubated with sonicated lipid microemulsion composed of egg phosphatidylcholine (Avanti), triolein (Wako), and the selected compound in the presence of lipoprotein-free human plasma fraction, reisolated by a dextran sulfate-cellulose column and ultracentrifugation, and acetylated with acetic anhydride. The final preparation contained approximately 0.5 μg of the respective compound per 100 μg protein. THP-1 macrophages were preloaded with probucol or metabolites by incubating with the acLDLs for 24 h. The compounds were alternatively delivered to cells by adding them from stock solutions in 2-butanol to produce a final solvent concentration in the culture medium of 0.5%.

Cellular lipid release by ApoA-I

Apolipoprotein (apo)A-I was isolated from the human HDL fraction as described previously (20). THP-1 macrophages were preloaded with probucol, SQ or DQ by incubating the compound-containing acLDL and incubated in media containing 0.2% BSA (Sigma) and 10 μg/ml of apoA-I for 24 h. The compounds were also given as a 2-butanol solution as mentioned above by incubating the cells in the presence of the compounds and apoA-I for 24 h. Cholesterol and choline-containing phospholipids released into the media were measured enzymatically (Wako) (21). The cells were dissolved in 0.1N NaOH for protein determination by bicinchoninic acid (BCA) method (Pierce).

Western blotting

After the cells were incubated to load the compounds, they were suspended in 5 mM Tris-HCl buffer (pH 8.5) containing protease inhibitor cocktail (Sigma) and placed on ice for 30 min. The cell suspension was centrifuged at 650 g for 5 min, and the supernatant was centrifuged at 105,000 g for 30 min to precipitate the total membrane fraction. Twenty μg wet-weight liver specimens of the rabbits were treated in the same manner as preparation of the membrane fraction. Protein in these fractions was analyzed by Western blotting using specific polyclonal antibodies against ABCA1 (8), scavenger receptor class B type 1 (SR-B1; Novus Biologicals), and β-actin (Sigma) and visualized by a chemiluminescence method (Amersham Life Science).

Real time quantitative PCR

ABCA1 mRNA was measured by using probes previously reported for human and mouse (8) in a 7300 Real Time PCR System (Applied Biosystems). Cultured cells were lysed in the presence of phenol and guanidine thiocyanate. cDNAs were synthesized by SuperScript R First-Strand Synthesis Systems (Invitrogen). For rabbit ABCA1, total RNA was purified from rabbit liver and cDNA was synthesized as described above. A partial sequence of ABCA1 was amplified with synthetic oligonucleotide primers (5′-ACA ATA GTT GTA CGA GCA GGG-3′, 5′-CTC ATC CTC TAG AAA AGA TGT GAG-3′) and cloned into pGEM™-T Easy Vector (Promega). Because the sequence of the partial clone of rabbit ABCA1 analyzed by a capillary sequencer 3100 (ABI) was 97% homologous to human ABCA1, these primers were used for the real-time quantitative PCR. ABCA1 expression was standardized to glyceraldehyde-3-phosphate dehydrogenase and β-actin.

Metabolic analysis of ABCA1

To examine degradation of ABCA1, THP-1 macrophages or Balb/3T3 cells were incubated for 24 h with 9-cis-RA (Sigma) to increase the expression of ABCA1 and treated with SQ or DQ for 30 min in 0.2% BSA-RPMI1640. Cells were washed once with PBS and incubated in 0.2% BSA-RPMI1640 containing 140 μM cycloheximide (Sigma) for the indicated periods, and ABCA1 protein analyzed by Western blotting as described above (8). ABCA1 in the cell surface was analyzed by biontination of the surface protein and its precipitation with avidin-beads followed by Western blotting (13). Internalization of ABCA1 was analyzed by biontination of surface ABCA1 and cleavage of the biontination of ABCA1 that remains in the surface after incubation as described elsewhere (13). To visualize intracellular localization of ABCA1, an expression vector containing ABCA1-green fluorescent protein (GFP) hybrid cDNA was transfected and expressed in HEK295 cells as described previously (22). Expression of ABCA1-GFP protein was confirmed by Western blotting with anti-ABCA1 antibody and with anti-GFP antibody. Intracellular localization of ABCA1-GFP was visually demonstrated as fluorescence images of the cells, placed on a 50-nm round coverslip for mounting in a temperature-controlled chamber at 37°C, and viewed with a LSM510 PASCAL laser scanning confocal microscope (Carl Zeiss). The averaged fluorescent intensity of ABCA1 in the plasma membrane was measured for 60 randomly selected cells using the software of the LSM510 PASCAL microscope.

Animal experiments

Three-month-old male New Zealand White rabbits were fed with LRC-4 diet containing SQ and DQ for 7 days. Plasma lipoproteins were analyzed for HDL and nonHDL fractions separated by ultracentrifugation at densities above and below 1.063 g/ml. The purity of each fraction was verified by agarose electrophoresis, and its cholesterol was measured by the enzymatic method. Expression of ABCA1 in the liver was determined by quantitative PCR for mRNA and by Western blotting for protein as described.
Increase of HDL by inhibition of ABCA1 degradation

above. For high-cholesterol experiments, 3-month-old male New Zealand White rabbits were fed with 0.5% cholesterol-containing diet supplemented with SQ or DQ for 8 weeks. Plasma lipoproteins were measured as described above and also analyzed by HPLC as previously described at Skylight Biotech, Tokyo, Japan (23). Aortas were extracted and fixed with 10% neutral buffered formalin solution and lipid deposition in the intima was stained with Oil Red O. The atherogenic effect of the drugs was evaluated by measuring the Oil Red O-stained area in the thoracic and abdominal regions. The digitized images were analyzed using Adobe Photoshop and NIH Image to estimate the relative area of lipid deposition.

Antioxidant activity in plasma

To measure antioxidant activity of the compounds in vivo, 3-month-old WHHL rabbits were fed LRC4 diet containing SQ or probucol for 1 month. Five μl of the serum was used for estimation of the antioxidant activity by reducing Cu²⁺ to Cu⁺ by measuring absorbance at 490 nm of a stable complex of Cu⁺/bathocuproine (24) based upon the principle developed by MED.DIA, Italy, and modified by the Japan Institute for The Control of Aging, Nikken SEIL Corporation, according to the manufacturer’s instruction.

CETP mass in plasma

Cholesteryl ester transfer protein (CETP) mass in rabbit plasma was measured by enzyme-linked immuno-sorbent assay as described previously (25) using an assay system provided from Sekisui Medical Co., Ltd. (Tokyo, Japan).

Other methods

Intensity of each electrophoretic band was digitally scanned and semi-quantified by using an EPSON GT-X700 and Adobe Photoshop software. Statistical analysis of the data was performed by one-way ANOVA followed by Scheffe’s test. Values represent mean ± SD for at least three independent measurements.

RESULTS

Probucol, SQ, and DQ were incorporated into acLDL and fed to THP-1 macrophages and cellular lipid release by apoA-I was measured. Whereas release of cholesterol and phospholipid was inhibited by probucol (15, 17), SQ and DQ enhanced the lipid release (Fig. 1A). ABCA1 protein was markedly increased by probucol in spite of inhibition of HDL formation, consistent with our previous finding (17) (Fig. 1B). The increase in ABCA1 by SQ and DQ was also apparent in the presence of apoA-I (Fig. 1D). The amount of SQ and DQ in the cells was below the limit of our detection method (1 ng) (supplementary Material I) because of the low concentration of compounds and relatively small number of cells used in the experimental conditions.

Figure 2, A and B, shows the decay of ABCA1 in the presence of cycloheximide. Both SQ and DQ apparently retarded this process in a very similar manner to the effect observed with probucol (17). Figure 2C demonstrates inhibition of ABCA1 internalization by these compounds.

Fig. 1. The effect of probucol, spiroquinone (SQ) or diphenoquinone (DQ) in THP-1 macrophages: A: Cellular lipid release by apoA-I. Cells were incubated with acLDL containing each compound for 24 h at 100 μg/ml protein as 1.9 μM probucol, 2.0 μM SQ, and 2.4 μM DQ and incubated with 10 μg/ml apoA-I for another 24 h. Cholesterol (CH) and phospholipid (PL) in the medium were determined. B: ABCA1 protein in the same condition. Controls (C1 and C2) represent absence and presence of control acLDL. The numbers represent band intensity relative to C2. C: Time-dependent increase of ABCA1 after SQ and DQ were added as a 2-butanol solution (25 nM and 0.05 nM, respectively). The graph represents band intensity relative to time zero. D: Increase of ABCA1 by treatment with SQ and DQ (25 nM and 0.05 nM for 3 h) in the presence of 10 μg/ml apoA-I in the medium. The data represent the mean ± SE for three samples. * P < 0.05, ** P < 0.01 in comparison to control (A), C2 (B), and time zero (C).
In these conditions, SQ and DQ also increased the release of cellular lipid by apoA-I (Fig. 3C).

SQ and DQ were given to rabbits to examine their in vivo effects. Figure 4A shows an increase in plasma HDL-cholesterol and of hepatic ABCA1 protein (also in supplementary Fig. II) by SQ and DQ, with no increase in hepatic ABCA1 mRNA. Because probucol has strong antioxidant activity and its antiatherosclerotic effects are assumed to be due to this function, antioxidant activity of SQ, which supposedly has higher antioxidant activity than other

Internalization of surface ABCA1 prelabeled by biotinylation was inhibited by SQ and DQ shown in the left panel. In contrast, ABCA1 in the cell surface was increased by these compounds, shown in the right panel. Inhibition of ABCA1 degradation by these compounds was thus shown to be by inhibiting internalization of ABCA1 (13). The effect of SQ and DQ on intracellular localization of ABCA1 was further examined by using HEK293 cells in which ABCA1-GFP was overexpressed. Figure 3A shows an increase of transfected ABCA1-GFP by SQ and DQ. Fig. 3B shows an increase of fluorescence intensity of ABCA1-GFP as well as images of its intracellular localization. SQ and DQ increased the fluorescence intensity at the cellular surface.

In these conditions, SQ and DQ also increased the release of cellular lipid by apoA-I (Fig. 3C).

SQ and DQ were given to rabbits to examine their in vivo effects. Figure 4A shows an increase in plasma HDL-cholesterol and of hepatic ABCA1 protein (also in supplementary Fig. II) by SQ and DQ, with no increase in hepatic ABCA1 mRNA. Because probucol has strong antioxidant activity and its antiatherosclerotic effects are assumed to be due to this function, antioxidant activity of SQ, which supposedly has higher antioxidant activity than other
probucol oxidation products, has been examined in vivo in comparison to probucol. Although antioxidant activity in plasma was substantially increased in the probucol-treated animals, no significant change was found in plasma antioxidant activity with a higher dose of SQ (Fig. 4A). Figure 4B and supplementary Fig. III show the results in cholesterol-fed rabbits for 8 weeks. Treatment with SQ and DQ did not cause significant change in food intake and body weight (supplementary Fig. IIIA). SQ and DQ increased HDL-cholesterol shown in a time course and in its integrated values for the entire experimental term of 8 weeks (Fig. 4B), as well as in the profile of the HPLC analysis (supplementary Fig. IIIB). SQ and DQ induced a significant increase in HDL-cholesterol, whereas neither compound caused significant change in non-HDL lipoprotein-cholesterol. The HDL-increasing effect seemed somewhat diminished after the 4-week treatment. Plasma CETP markedly increased with cholesterol feeding but did not show a difference among the treatment groups (supplementary Fig. IV). The increase in ABCA1 protein in the liver by SQ or DQ was retained at the end of the experiment, whereas SR-B1 protein showed no change (supplementary Fig. IV). There was no apparent adverse effect in the animals.

Figure 5 shows the effects of SQ and DQ on the vascular lesions in the cholesterol-fed rabbits characterized as above. Lipid deposition in aortic intima was examined by Oil Red O staining. Relative lipid deposit area was 0.46 ± 0.19 for the controls versus 0.27 ± 0.09 and 0.29 ± 0.13 for the SQ and DQ treatment groups (P = 0.02 and 0.03 against the control), respectively, including the aortic arch regions (supplementary Fig. V). The evaluation for the arch regions, however, may be inaccurate and unreliable as the wall cannot be set flat for photographs, so that further quantitative analysis was performed for the thoracic and abdominal regions of aorta (Fig. 5A). The lesion area was significantly decreased by SQ (Fig. 5B, left). When the lesion area was standardized for the integrated value of non-HDL-cholesterol in an individual animal, the reduction in lipid deposition was significant for both SQ and DQ.
treatment (Fig. 5B, middle). Lipid deposition was a function of (nonHDL-cholesterol)/(HDL-cholesterol) to yield similar parameters in linear regression for each SQ and DQ treatment group and total (Fig. 5B, right), so that the effect of SQ and DQ on the lipid deposition may be attributed to the increase of HDL in association with stabilization of ABCA1.

DISCUSSION

To examine whether inhibition of ABCA1 degradation increases HDL formation and plasma HDL level, we attempted to screen potential candidate chemicals that inhibit degradation of ABCA1, including oxidized products of the ABCA1 inactivator probucol (18). In our preliminary experiments, crude oxidative products of probucol increased cellular HDL formation rather than decreased it. Treatment of cells with SQ and DQ were found to increase ABCA1 protein and apoA-I-mediated HDL formation. Both compounds stabilized ABCA1 against calpain-mediated degradation without changing its transcription. They also increased expression of ABCA1-GFP in HEK293 cells expressing ABCA1-GFP with a nonphysiological promoter. The compounds increased plasma HDL in rabbits by increasing hepatic ABCA1 and suppressed lipid deposition in the arterial wall of cholesterol-fed rabbits. Thus, we conclude that these compounds increase HDL formation through protecting ABCA1 from degradation and thereby reduce atherogenesis in the experimental animals. The effects were apparently independent of antioxidant activity, previously considered to be one of the major antiatherogenic properties of probucol in similar animal models (26, 27), because these compounds did not exhibit significant antioxidant activity in plasma.

We thus demonstrated that pharmacologic inhibition of ABCA1 degradation could increase ABCA1 and plasma HDL and counteract atherogenesis in a model of hypercholesterolemia in vivo. SQ and DQ were shown to cause retardation of ABCA1 degradation seemingly by inhibiting internalization of ABCA1, a prerequisite for calpain-mediated proteolysis (13), rather than by direct inhibition of the calpain reaction. At this stage, we do not have further mechanistic insight into the action of SQ and DQ. The effects might be similar to the effect of cytochalasin D observed in vitro in cultured cells, including an increase of ABCA1 in the cell surface even under conditions where ABCA1 degradation was retarded by the presence of apoA-I (13). Because both SQ and DQ are extremely hydrophobic and likely incorporated into the membrane, these compounds may induce conformational alteration of ABCA1 to stabilize it against internalization for its degradation. However, it is unclear whether SQ and DQ by themselves cause such an effect or their metabolites may secondarily do so. Indeed, such products as bisphenol and butylphenol did show similar activity, but to a lesser extent, as described in the results section. This point should further be examined. It is interesting that probucol inactivates ABCA1 for HDL formation while inhibiting ABCA1 degradation but SQ and DQ only induce the latter effect. There may be a hint in this discrepancy to solve the question on the reaction mechanism of these compounds.

The results demonstrated here showed a novel concept for drug development, enhancement of the function of a specific membrane protein such as transporters or receptors by inhibiting their biological degradation. SQ, DQ, or their related compounds can thus be potential drug candidates to increase HDL formation and prevention/cure of atherosclerosis by inhibiting ABCA1 degradation. Several issues remain to be addressed. The compounds are extremely hydrophobic and need to be improved for oral administration. The apparent tendency to diminish the HDL-raising effect over time may be a problem for long-term administration. Probucol has been used in the market for years, and SQ and DQ may be produced as its metabolites in vivo (18). Further investigation is still required for any unexpected in vivo effects of the compounds, such as their influence on metabolism of membrane proteins in general and the exact mechanism for inhibiting degradation of ABCA1. A wide and thorough survey is needed of their influence on gene expression.

Probucol decreases HDL by inhibiting the activity of ABCA1 (15–17, 28, 29). Despite this HDL-lowering effect, probucol was proposed to have specific antiatherosclerotic properties based on clinical findings of efficient regression of cutaneous and tendinous xanthomata in familial hypercholesterolemia (30). It is also proposed to inhibit atherogenesis in experimental animals because of its ability to inhibit oxidation of LDL (26, 27, 31). We previously discovered that probucol inactivates ABCA1’s ability to form HDL while inhibiting calpain-dependent degradation (17), the net result being a severe reduction in HDL. In contrast, we demonstrate here that oxidized products of probucol retain the ability to inhibit ABCA1 degradation but do not inhibit HDL formation by ABCA1. If SQ and/or DQ are produced during the in vivo oxidant metabolism of probucol, these products may induce an increase in active ABCA1 in some tissues. In addition to the effect on ABCA1, probucol has been proposed to induce an increase in activity of CETP (32) or SR-B1 (33) as the causes of the decrease of HDL. However, we found no change in SR-B1 protein by SQ or DQ in rabbit liver (supplementary Fig. IV) or in the mRNAs of apoA-I, LCAT, PLTP, or SR-B1 in the liver of the probucol-fed mice (16). Because the HDL-increasing effects of SQ and DQ were observed in mice as well in our preliminary experiments, the effect of SQ and DQ should not be related to CETP.

CETP markedly increased in the rabbit plasma regardless of the drug administration by cholesterol feeding (34) (supplementary Fig. IV) and this effect might somewhat mask the specific increase of plasma HDL by SQ and DQ in this particular model.
