Abstract

We present a lattice calculation of the electromagnetic form factor of the pion obtained using the tree-level Symanzik improved gauge action with two flavors of dynamical twisted Wilson quarks. The simulated pion masses range approximately from 260 to 580 MeV and the lattice box sizes are chosen in order to guarantee that $M_\pi L \gtrsim 4$. Accurate results for the form factor are obtained using all-to-all quark propagators evaluated by a stochastic procedure. The momentum dependence of the pion form factor is investigated up to values of the squared four-momentum transfer $Q^2 \simeq 0.8$ GeV$^2$ and, thanks to the use of twisted boundary conditions, down to $Q^2 \simeq 0.05$ GeV$^2$. Volume and discretization effects on the form factor appear to be within the statistical errors. Our results for the pion mass, decay constant and form factor are analyzed using (continuum) Chiral Perturbation Theory at
next-to-next-to-leading order. The extrapolated value of the pion charge radius is \( \langle r^2 \rangle^{\text{phys}} = 0.456 \pm 0.030_{\text{stat}} \pm 0.024_{\text{syst}} \) in nice agreement with the experimental result. The extrapolated values of the pion form factor agree very well with the experimental data up to \( Q^2 \simeq 0.8 \text{ GeV}^2 \) within uncertainties which become competitive with the experimental errors for \( Q^2 \gtrsim 0.3 \text{ GeV}^2 \). The relevant low-energy constants appearing in the chiral expansion of the pion form factor are extracted from our lattice data, which come essentially from a single lattice spacing, adding the experimental value of the pion scalar radius in the fitting procedure. Our findings are in nice agreement with the available results of ChPT analyses of \( \pi - \pi \) scattering data as well as with other analyses of our collaboration.
1 Introduction

The investigation of the physical properties of the pion, which is the lightest bound state in Quantum Chromodynamics (QCD), can provide crucial information on the way low-energy dynamics is governed by the quark and gluon degrees of freedom. In this respect for space-like values of the squared four-momentum transfer, \( Q^2 \equiv -q^2 \geq 0 \), the electromagnetic (e.m.) form factor of the pion, \( F_\pi(Q^2) \), provides important insights on the distribution of its charged constituents, namely valence and sea light quarks. At momentum transfer below the scale of chiral symmetry breaking (\( Q^2 \lesssim 1 \text{ GeV}^2 \)) the pion form factor represents therefore an important test of non-perturbative QCD.

The current experimental situation is as follows. For values of \( Q^2 \lesssim 0.2 \text{ GeV}^2 \) the pion form factor has been determined quite precisely at CERN SPS \([1]\) by measuring directly the scattering of high-energy pions off atomic electrons in a fixed target. At higher values of \( Q^2 \) the pion form factor is extracted from cross section measurements of the reaction \( ^1H(e,e'\pi^+)+n \), that is from electron quasi-elastic scattering off virtual pions in a proton. The separation of the longitudinal and transverse response functions as well as the extrapolation of the observed scattering from virtual pions to the one corresponding to on-shell pions have to be carefully considered for estimating the systematic uncertainties. Using the electroproduction technique the pion form factor has been determined for \( Q^2 \) values in the range \( 0.4 \div 9.8 \text{ GeV}^2 \) at CEA/Cornell \([2]\), for \( Q^2 = 0.35 \) and \( 0.70 \text{ GeV}^2 \) at DESY \([3, 4]\) and, more recently, for \( Q^2 \) in the range \( 0.6 \div 1.6 \text{ GeV}^2 \) \([5]\) and for \( Q^2 = 1.60, 2.15 \) and \( 2.45 \text{ GeV}^2 \) \([6]\) at the Thomas Jefferson National Acceleration Facility (JLab). A careful reanalysis of the systematic uncertainties for the data of Refs. \([3, 4, 5]\) has been carried out in Refs. \([7, 8]\).

It is well known that at small values of \( Q^2 \) the pion form factor can be reproduced qualitatively by a simple monopole ansatz inspired by the Vector Meson Dominance (VMD) model with the contribution from the lightest vector meson (\( M_\rho \simeq 0.77 \text{ GeV} \)) only. This is not too surprising in view of the fact that in the time-like region the pion form factor is dominated by the \( \rho \)-meson resonance \([9]\).

More interesting is the quark mass dependence of the pion form factor, which can be addressed by QCD simulations on the lattice and by Chiral Perturbation Theory (ChPT). The latter, which is known at next-to-leading (NLO) \([10]\) and next-to-next-to-leading (NNLO) order \([11]\) for the pion form factor, can be used as a guide to extrapolate the lattice results from the simulated pion masses down to the physical point, obtaining at the same time an estimate of the relevant low-energy constants (LEC’s) of the effective theory.

Initial studies of the pion form factor using lattice QCD dates back to the late 80’s \([12, 13]\) giving strong support to the vector-meson dominance hypothesis at low \( Q^2 \). Within the quenched approximation, which neglects the effects of
the sea quarks, several lattice investigations have been carried out using Wilson
[14], Sheikholeslami-Wohlert [15], twisted Wilson [16] and Ginsparg-Wilson [17]
fermions. The effects of the quenched approximation might be limited because,
thanks to charge-conjugation and isospin symmetries, the e.m. pion form factor
receives no contribution from the so-called disconnected diagrams in which the
vector current is attached directly to a non-valence quark (see Ref. [13]). However
there are effects from sea quarks which do not interact directly with the external
current, and they can be taken into account only by performing unquenched gauge
simulations.

There are few results for two flavors of dynamical fermions from JLQCD [18]
and QCDSF/UKQCD [19] collaborations adopting Clover fermions and again from
JLQCD [20] using overlap quarks. Finally only two studies with three flavors of
dynamical quarks are available to date, namely from Ref. [14], where domain-wall
valence quarks and Asqtad sea quarks are mixed, and from Ref. [21], where the
domain-wall formulation is used for both sea and valence quarks.

As far as the lattice results for the (squared) pion charge radius at the physical
point are concerned, the present situation is a bit puzzling. Some collaborations
[14, 18] have found that their extrapolations underestimate significantly (up to
≃ 30%) the well-known experimental value \( \langle r^2 \rangle_{exp.} = 0.452 \pm 0.011 \text{ fm}^2 \) [22], while
other collaborations [19, 20, 21] have obtained values consistent with experiment
within the errors.

The European Twisted Mass (ETM) collaboration has recently produced a
large number of gauge configurations with two flavors of dynamical quarks [23, 24,
25] using the Wilson twisted-mass fermionic action [26] and the tree-level Symanzik
improved (tlSym) gauge action [27]. In order to obtain (almost) automatic \( \mathcal{O}(a) \)
improvement the Wilson twisted-mass fermions have been tuned to maximal twists
[28]. An intensive, systematic program of calculations of three-point correlation
functions relevant for the determination of meson form factors both in the light
and in the heavy sectors has then been started. Preliminary results, concerning
the vector and scalar form factors of the pion, the Isgur-Wise universal function
and the transition form factors relevant in \( K_{\ell 3} \) and \( D \to \pi(K) \) semileptonic decays
have been presented in Ref. [29].

In this paper we concentrate on the e.m. form factor of the pion and we present
the results of several measurements performed with pion masses in the range from
≃ 260 MeV to ≃ 580 MeV, using six values of the quark mass at a lattice spacing
of ≃ 0.09 fm and two values of the quark mass at a lattice spacing of ≃ 0.07 fm.
The lattice box sizes are chosen in order to guarantee that \( M_\pi L \gtrsim 4 \) for minimizing
as much as possible finite size effects. Thanks to the use of all-to-all propagators
evaluated by the stochastic procedure of Ref. [30] (see also [24]) the statistical pre-
cision of the extracted form factor is quite impressive. The momentum dependence
of the pion form factor is investigated up to values of the squared four-momentum transfer \( Q^2 \simeq 0.8 \text{ GeV}^2 \) and, thanks to the use of twisted boundary conditions (BC’s) \([31, 32]\), down to \( Q^2 \simeq 0.05 \text{ GeV}^2 \). The \( Q^2 \)-shape at the simulated pion masses is well reproduced by a single monopole ansatz with a pole mass lighter by \( \approx 10\% \div 15\% \) than the lightest vector-meson mass. Volume and discretization effects on the form factor are estimated using few simulations at different volumes and lattice spacings, and they turn out to be within the statistical errors.

The extrapolation of our results for the pion mass, decay constant and form factor to the physical point is carried out using (continuum) ChPT at NNLO \([11]\). The extrapolated value of the (squared) pion charge radius is \( \langle r^2 \rangle_{\text{phys}} = 0.456 \pm 0.030_{\text{stat.}} \pm 0.024_{\text{syst.}} \) in nice agreement with the experimental result \( \langle r^2 \rangle_{\text{exp.}} = 0.452 \pm 0.011 \text{ fm}^2 \) \([22]\). The extrapolated values of the pion form factor agree very well with the experimental data up to \( Q^2 \simeq 0.8 \text{ GeV}^2 \) within uncertainties which become competitive with the experimental errors for \( Q^2 \gtrsim 0.3 \text{ GeV}^2 \). The relevant low-energy constants (LEC’s) appearing in the chiral expansion of the pion form factor are extracted from our lattice data adding in the fitting procedure the experimental value of the pion scalar radius \([11]\). The latter helps constraining one the LEC’s \( \bar{\ell}_4 \), which in turn is beneficial for reducing the uncertainties of the other LEC’s. We get: \( \bar{\ell}_1 = -0.4 \pm 1.3 \pm 0.6, \bar{\ell}_2 = 4.3 \pm 1.1 \pm 0.4, \bar{\ell}_3 = 3.2 \pm 0.8 \pm 0.2, \bar{\ell}_4 = 4.4 \pm 0.2 \pm 0.1, \bar{\ell}_6 = 14.9 \pm 1.2 \pm 0.7 \), where the first error is statistical and the second one systematic. Our findings are in nice agreement with the results of ChPT analyses of \( \pi - \pi \) scattering data \([33]\). The values found for \( \bar{\ell}_3 \) and \( \bar{\ell}_4 \) agree very well both with earlier ETMC results from Refs. \([23, 24]\) and with the recent ETMC determination of Ref. \([34]\). This is quite reassuring because different kinds of systematic uncertainties may affect the two analyses: the present one being a NNLO analysis limited mainly to data from a single lattice spacing, and that of Ref. \([34]\) having two values of the lattice spacing but limited mainly to NLO in ChPT.

The plan of the paper is as follows. In the next Section we briefly discuss the implementation of twisted BC’s for the quark fields. In Section 3 we present the calculation of two- and three-point correlation functions performed in the Breit reference frame, where the values of four-momentum transfer \( Q^2 \) are independent of the simulated pion mass. We also briefly show the stochastic procedure used for our unbiased estimate of the all-to-all propagators employed in this work.

In Section 4 we firstly illustrate the very precise results obtained for the renormalization constant of the vector current and then we compare them with other determinations. Our accurate results for the momentum dependence of the pion form factor for the various simulated pion masses are presented and both volume and discretization effects are investigated.

In Section 5, using a single monopole ansatz to fit the momentum dependence of
the form factor, the charge radius and the curvature are calculated at the simulated pion masses and analyzed both in terms of the ChPT expansion at NNLO from Ref. [11] and adopting a simple polynomial fit.

The mass and momentum dependencies of our lattice points for the pion form factor are analyzed in Section 6 without any model assumption, but using only the functional forms dictated by ChPT at NNLO.

In Section 7 the final values of the relevant LEC’s, including the estimate of the systematic errors, are presented and it is shown that the extrapolated form factor at the physical point agrees very well with the experimental data in the whole range of values of $Q^2$ considered. Finally Section 8 is devoted to our conclusions.

## 2 Lattice all-to-all quark propagators with twisted boundary conditions

In lattice QCD simulations the spatial components of the hadronic momenta $p_j$ ($j = 1, 2, 3$) are quantized. The specific quantized values depend on the choice of the BC’s applied to the quark fields. The most common choice is the use of periodic BC’s in the spatial directions

$$\psi(x + \hat{e}_j L) = \psi(x),$$

that leads to

$$p_j = n_j \frac{2\pi}{L},$$

where the $n_j$’s are integer numbers. Thus the smallest non-vanishing value of $p_j$ is given by $2\pi/L$, which depends on the spatial size of the (cubic) lattice ($V = L^3$). For instance a current available lattice may have $L = 32$ $a$, where $a$ is the lattice spacing, and $a^{-1} \simeq 2.5$ GeV leading to $2\pi/L \simeq 0.5$ GeV. Such a value may represent a strong limitation of the kinematical regions accessible for the investigation of momentum dependent quantities, like e.g. form factors.

In Ref. [31] it was proposed to use twisted BC’s for the quark fields

$$\tilde{\psi}(x + \hat{e}_j L) = e^{2\pi i \theta_j} \tilde{\psi}(x)$$

which allows to shift the quantized values of $p_j$ by an arbitrary amount equal to $2\pi \theta_j/L$, namely

$$\tilde{p}_j = p_j + \theta_j \frac{2\pi}{L} = n_j \frac{2\pi}{L} + \theta_j \frac{2\pi}{L}.$$
fields satisfying usual periodic BC’s (the Aharonov-Bohm effect). In Ref. [32] the twisted BC’s were firstly implemented in a lattice QCD simulation of two-point correlation functions of pseudo-scalar mesons. The energy-momentum dispersion relation was checked confirming that the momentum shift $\frac{2\pi\theta_j}{L}$ is a physical one. In Ref. [35] the twisted BC’s were firstly applied to the calculation of the vector and scalar form factors relevant to the $K \rightarrow \pi$ semileptonic decay. It was shown that the momentum shift produced by the twisted BC’s does not introduce any additional noise and easily allows to determine the form factors with good accuracy at quite small values of $Q^2$, which are not accessible when periodic BC’s are considered.

On the lattice, for a given flavor, the all-to-all quark propagator $S(x,y) \equiv \langle \psi(x) \bar{\psi}(y) \rangle$, where $\langle \ldots \rangle$ indicates the average over gauge field configurations weighted by the lattice QCD action, satisfies the following equation

$$\sum_z D(x,z) S(z,y) = \delta_{x,y}$$

(5)

where $D(x,z)$ is the Dirac operator whose explicit form depends on the choice of the lattice QCD action. In what follows we work with the fermionic twisted-mass Lattice QCD (tmLQCD) action with two flavors of mass-degenerate quarks given in Ref. [23], tuned at maximal twist in the way described in full details in Ref. [24]. Therefore, in the so-called physical basis the operator $D(x,z)$ is given explicitly by

$$D(x,z) = K(x,z) + i\gamma_5 \tau_3 \, W(x,z) + am \, \delta_{x,z} ,$$

(6)

$$K(x,z) = \frac{1}{2} \sum_{\mu=1}^{4} \gamma_{\mu} \left\{ \delta_{x,z-a\mu} \, U_\mu(x) - \delta_{x,z+a\mu} \, U_\mu^\dagger(z) \right\} ,$$

(7)

$$W(x,z) = (4r + am_{\text{crit}}) \, \delta_{x,z} - \frac{r}{2} \sum_{\mu=1}^{4} \left\{ \delta_{x,z-a\mu} \, U_\mu(x) + \delta_{x,z+a\mu} \, U_\mu^\dagger(z) \right\} ,$$

(8)

where $U_\mu(x)$ is the gauge link, $m$ is the bare twisted quark mass, $m_{\text{crit}}$ is the critical value of the untwisted quark mass (needed to achieve maximal twist), $\tau_3$ is the third Pauli matrix acting in flavor space, and $r$ is the Wilson parameter, which is set to $r = 1$ in our simulations.

We now want to consider the case in which a valence quark field satisfies the twisted BC’s in the spatial directions and is anti-periodic in time. This is at variance with what has been done in the production of the ETMC gauge configurations, which include two sea quarks with periodic BC’s in space and anti-periodic

---

1 We mention that a new application of twisted BC’s to the evaluation of the vector form factor at zero-momentum transfer has been proposed in Ref. [21].

2 We omit in this Section color and Dirac indices for simplicity.
ones in time [24]. However it has been recently shown [36] that for many physical quanti-
ties, which do not involve final state interactions (like, e.g., meson masses, decay constants, semileptonic form factors and e.m. transitions), the use of dif-
ferent BC’s on valence and sea quarks produce finite-volume effects which remain exponentially small. In this way there is no need for producing new gauge config-
urations for each quark momentum, and this is quite relevant in the case of gauge config-
urations with dynamical fermions.

The corresponding quark propagator \( \tilde{S}(x, y) \equiv \langle \tilde{\psi}(x) \overline{\psi}(y) \rangle \) still satisfies Eq. (5) with the same Dirac operator \( D(x, z) \) but with different BC’s:

\[
\sum_z D(x, z) \tilde{S}(z, y) = \delta_{x,y} \tag{9}
\]

Technically in order to work always with fields satisfying periodic BC’s in space and time we follow Refs. [31, 32] by introducing a new quark field as

\[
\psi_{\tilde{\theta}}(x) = e^{-\frac{2\pi i}{L} \tilde{\theta} \cdot \vec{x}} \tilde{\psi}(x) \tag{10}
\]

where the four-vector \( \tilde{\theta} \) is given by \((L/2T, \tilde{\theta})\). In such a way the new quark propagator \( S^{\tilde{\theta}}(x, y) \equiv \langle \psi_{\tilde{\theta}}(x) \overline{\psi}_{\tilde{\theta}}(y) \rangle \) satisfies the equation

\[
\sum_z D^{\tilde{\theta}}(x, z) S^{\tilde{\theta}}(z, y) = \delta_{x,y} \tag{11}
\]

with a modified Dirac operator \( D^{\tilde{\theta}}(x, z) \) but periodic BC’s in both space and time. The new Dirac operator is related to Eq. (6) by a simple re-phasing of the gauge links

\[
U_\mu(x) \rightarrow U^{\tilde{\theta}}_\mu(x) \equiv e^{2\pi i a \tilde{\theta}_\mu / L} U_\mu(x) \tag{12}
\]

In terms of \( S^{\tilde{\theta}}(x, y) \), related to the quark fields \( \psi_{\tilde{\theta}}(x) \) with periodic BC’s, the all-to-all quark propagator \( \tilde{S}(x, y) \), corresponding to the quark fields \( \tilde{\psi}(x) \) with twisted BC’s, is simply given by

\[
\tilde{S}(x, y) = e^{2\pi i \tilde{\theta} \cdot (x-y) / L} S^{\tilde{\theta}}(x, y) \tag{13}
\]

3 Two- and three-point correlation functions

We are interested in the calculation of the vector form factor of a charged pion defined through the relation

\[
\langle \pi^+(p')| \overline{\psi}_\mu(0) |\pi^+(p) \rangle = F_\pi(q^2) \ (p + p')_\mu \tag{14}
\]
where \( p (p') \) is the initial (final) pion four-momentum, \( q^2 = (p - p')^2 \) is the squared four-momentum transfer and \( \hat{V}_\mu \) is a conserved e.m. current on the lattice. Splitting \( \hat{V}_\mu \) into an isovector and an isoscalar part, it is easy to show that the matrix elements of the isoscalar component between pion states is vanishing in the continuum limit, thanks to charge conjugation and isospin symmetries.

Thus, up to discretization effects we take \( \hat{V}_\mu \) at a generic (Euclidean) space-time point \( x = (t_x, \vec{x}) \) in the following form

\[
\hat{V}_\mu (x) = Z_V V_\mu (x),
\]

(15)

\[
V_\mu (x) = \frac{1}{2} \left[ \bar{u}(x)\gamma_\mu u(x) - \bar{d}(x)\gamma_\mu d(x) \right]
\]

(16)

with \( Z_V \) being the renormalization constant of the isovector part of the vector current at maximal twist (cf. Ref. [28]).

The insertion of the current (16) generates two types of Feynmann diagrams, the so-called connected and disconnected diagrams. In the former the external current is attached to the valence quarks, whereas in the latter the current interacts with the sea quarks. However, in the continuum limit the vanishing of the pion-to-pion matrix element of the isoscalar current \( (\bar{u}\gamma_\mu u + \bar{d}\gamma_\mu d) \) implies that the connected diagrams stemming from the u- and d-quark terms of the current (16) are equal in absolute value and opposite in sign, while their disconnected counterparts are vanishing for each quark flavor. Thus, in tmLQCD the disconnected diagrams for the e.m. pion form factor represent a pure discretization effect, which turns out to be of order \( O(a^2) \) (see later on). Therefore, up to discretization effects, it is enough to consider only the connected insertion of one single flavor of Eq. (16).

From Eq. (14) the pion form factor can be extracted from both the time and the spatial components of the vector current. However for reasons which will become clear during this Section, we work in the Breit reference frame where \( \vec{p}' = -\vec{p} \), so that the spatial components of the vector current are vanishing identically. Therefore we limit ourselves to consider the following two- and three-point correlation functions

\[
C^\pi(t, \vec{p}) = \sum_{x,z} \langle O_\pi(x) O_\pi^\dagger(z) \rangle \delta_{t,t_x-t_z} e^{-i\vec{p} \cdot (\vec{x} - \vec{z})},
\]

(17)

\[
C^{\pi\pi}_0(t, t', \vec{p}, \vec{p}') = \sum_{x,y,z} \langle O_\pi(y) V_0(x) O_\pi^\dagger(z) \rangle \delta_{t,t_x-t_z} \delta_{t',t_y-t_z} \cdot e^{-i\vec{p} \cdot (\vec{x} - \vec{z}) + i\vec{p}' \cdot (\vec{y} - \vec{z})},
\]

(18)

\footnote{Note that in tmLQCD the charge conjugation symmetry is preserved, while the isospin one is broken at finite lattice spacings.}

\footnote{The terms “connected” and “disconnected” refer to fermionic lines only.}
where $V_{0}(x) = \bar{u}(x)\gamma_{0}u(x)$ and $O_{\gamma}^{1}(z) = \bar{u}(z)\gamma_{5}d(z)$ is the operator interpolating the $\pi^{+}$ mesons. Note that, since we want to use all-to-all propagators, in Eqs. (17) and (18) there is an additional sum over the space-time lattice volume, which helps improving the signal quality with respect to the case of a fixed-point source ($z = 0$).

Using the completeness relation and taking $t$ and $(t' - t)$ large enough, one gets

$$
C_{\pi}^{\pi}(t, \bar{p}) \xrightarrow{t \to \infty} \frac{Z_{\pi}}{2E_{\pi}(\bar{p})} e^{-E_{\pi}(\bar{p})t},
$$

$$
C_{0}^{\pi\pi}(t, t', \bar{p}, \bar{p}') \xrightarrow{(t' - t) \to \infty} \frac{Z_{\pi}}{2E_{\pi}(\bar{p})} \frac{1}{Z_{V}} \langle \pi^{+}(p')|\hat{V}_{0}|\pi^{+}(p)\rangle e^{-E_{\pi}(\bar{p})t} e^{-E_{\pi}(\bar{p}')((t' - t))},
$$

where, up to discretization effects, $E_{\pi}(\bar{p}) = \sqrt{M_{\pi}^{2} + |\bar{p}|^{2}}$ and $\sqrt{Z_{\pi}} = \langle 0|O_{\pi}(0)|\pi^{+}\rangle$ is independent on the meson momentum $\bar{p}$. Note that in tmLQCD at maximal twist the value of the coupling constant $Z_{\pi}$ determines the pion decay constant $f_{\pi}$ without the need of the knowledge of any renormalization constant, namely

$$
f_{\pi} = 2m\sqrt{Z_{\pi}} \frac{M_{\pi}}{2},
$$

where $m$ is the bare twisted quark mass.

Taking advantage of the choice of the Breit frame where $\bar{p}' = -\bar{p}$, it follows

$$
\frac{C_{0}^{\pi\pi}(t, t', \bar{p}, -\bar{p})}{C_{\pi}(t', \bar{p})} \xrightarrow{(t' - t) \to \infty} \frac{1}{Z_{V}} \frac{\langle \pi^{+}(p')|\hat{V}_{0}|\pi^{+}(p)\rangle}{2E_{\pi}(\bar{p})} = \frac{1}{Z_{V}} F_{\pi}(q^{2}),
$$

where

$$
q^{2} \equiv [E_{\pi}(\bar{p}) - E_{\pi}(\bar{p}')]^{2} - |\bar{p} - \bar{p}'|^{2} - 4|\bar{p}|^{2}
$$

is independent of the simulated pion mass.

The vector renormalization constant can be obtained from Eq. (22) by using the absolute normalization of the pion form factor at $q^{2} = 0$, namely $F_{\pi}(q^{2} = 0) = 1$, which implies

$$
Z_{V} \xrightarrow{(t' - t) \to \infty} \frac{C_{\pi}(t', \bar{0})}{C_{0}^{\pi}(t, t', \bar{0}, \bar{0})}.
$$

Combining Eqs. (22) and (24) one gets

$$
R_{0}(t, t'; q^{2}) \equiv \frac{C_{0}^{\pi\pi}(t, t', \bar{p}, -\bar{p})}{C_{0}^{\pi\pi}(t, t', \bar{0}, \bar{0})} \frac{C_{\pi}(t', \bar{0})}{C_{\pi}(t', \bar{p})} \frac{C_{\pi}(t, \bar{0})}{C_{\pi}(t, \bar{p})} \xrightarrow{(t' - t) \to \infty} F_{\pi}(q^{2})
$$
which means that the pion form factor can be obtained directly from the plateau of the double ratio given by the l.h.s. of Eq. (25) at large time distances. Note that in this way the normalization condition \( F_\pi(q^2 = 0) = 1 \) is fulfilled at all quark masses, lattice volumes and spacings.

The (mass-dependent) renormalization constant \( Z_V \) can be obtained alternatively using the 3-point correlation function calculated in a frame in which the initial and final pions have the same momentum \( \vec{p} \), i.e. from the plateau of the ratio \( C_0^\pi(t', \vec{p}) / C_0^{\pi\pi}(t, t', \vec{p}, \vec{p}) \) at large time distances. In this way the pion form factor can be extracted from the plateau of a ratio of 3-point correlation functions only, i.e. from \( C_0^{\pi\pi}(t, t', \vec{p}, \vec{p}) / C_0^{\pi\pi}(t, t', \vec{p}, \vec{p}) \). Such an alternative approach has been tested in Ref. [21] and shown to have a statistical precision similar to the one based on Eq. (25).

In terms of the all-to-all quark propagators \( S_u(x, z) \), where the flavor labels \( u \) and \( d \) correspond to \( \tau_3 = \pm 1 \) in Eq. (6), the two-point function \( C_\pi(t, \vec{p}) \) of the charged pion becomes

\[
C_\pi(t, \vec{p}) = \sum_{x, z} \langle Tr[S_u(x, z)\gamma_5S_d(z, x)\gamma_5] \rangle e^{-i\vec{p}(\vec{x} - \vec{z})}.
\]  

(26)

For the tmLQCD action the \( \gamma_5 \)-hermiticity property

\[
S_d(z, x) = \gamma_5 S_u^\dagger(x, z) \gamma_5
\]  

(27)

holds with the dagger operator acting in the (suppressed) color and Dirac spaces.

As for the three-point correlation function \( C_0^{\pi\pi}(t_x, t_y, \vec{p}, -\vec{p}) \), according to the discussion on the disconnected diagrams made before Eq. (18), up to discretization effects one gets

\[
C_0^{\pi\pi}(t, t', \vec{p}, -\vec{p}) = \sum_{x, z} \langle Tr[S_u(x, z)\gamma_5\Sigma_{du}(z, t; -\vec{p})\gamma_0] \rangle \delta_{t, t_x - t_z} e^{-2i\vec{p}(\vec{x} - \vec{z})},
\]  

(28)

where \( \Sigma_{du}(z, t; -\vec{p}) = \gamma_5[\Sigma_{du}(z, t; -\vec{p})]^\dagger \gamma_5 \) and

\[
\Sigma_{du}(x, z; t; \vec{p}) = \sum_y S_d(x, y)\gamma_5S_u(y, z) e^{-i\vec{p}(\vec{z} - \vec{y})} \delta_{t', t_y - t_z}.
\]  

(29)

The sequential propagator \( \Sigma_{du}(x, z; t'; \vec{p}) \) satisfies the equation

\[
\sum_y D_d(x, y) \Sigma_{du}(y, z; t'; \vec{p}) = \gamma_5 S_u(x, z) \delta_{t', t_x - t_z} e^{i\vec{p}(\vec{x} - \vec{z})}.
\]  

(30)

As it has been shown in Ref. [28], the calculation of correlation functions of parity symmetric operators is automatically \( O(a) \) improved at maximal twist.
Thus for non-vanishing values of the spatial momenta the $O(a)$ terms can be eliminated by appropriate averaging of the correlation functions over initial and final momenta of opposite sign. Using the symmetry of correlation functions under the spatial inversion and the simultaneous exchange of u and d quarks (which is fulfilled only after gauge averaging at maximal twist in the physical basis) as well as the charge conjugation symmetry and the $\gamma_5$-hermiticity property, one gets that: i) the correlators (26) and (28) are real, and ii) $C^\pi(t', \vec{p}) = C^\pi(t', -\vec{p})$ and $C^\pi\pi(t', \vec{p}, \vec{p}) = C^\pi\pi(t', -\vec{p}, \vec{p})$. Thus discretization effects in both $C^\pi(t', \vec{p})$ and $C^\pi\pi_0(t, t', \vec{p}, -\vec{p})$ start automatically at order $O(a^2)$.

Let us now consider the case of quark fields with twisted BC’s. Equations (26)-(30) hold as well by simply replacing the propagators $S$ and $\Sigma$ with the corresponding twisted ones, $\tilde{S}$ and $\tilde{\Sigma}$, and by taking into account the change of the quantized momenta, namely $p_j \rightarrow \tilde{p}_j$ [see Eq. (1)]. The two- and three-point correlators can be expressed in terms of quark propagators satisfying periodic BC’s, e.g. in terms of $S^{\theta}$ [see Eq. (13)]. We now write down the explicit formulae for sake of completeness.

In order to work in the Breit frame we consider three choices of the twisting four-vector $\tilde{\theta}$, namely $\tilde{\theta} = \tilde{\theta}_\pm = (L/2T, \pm \vec{\theta})$ and $\tilde{\theta} = \tilde{\theta}_0 = (L/2T, \vec{0})$ for various values of $\vec{\theta}$. Writing $\vec{p}$ in the generic form $\vec{p} = 2\pi \vec{\theta}/L$, we get

$$C^\pi(t, \frac{2\pi}{L} \vec{\theta}) = \sum_{x,z} \langle Tr[S^{\theta}_u(x, z) \gamma_5 S^{\theta}_d(z, x) \gamma_5]\rangle \delta_{t, t_x - t_z}, \quad (31)$$

$$C^\pi\pi_0(t, t', \frac{2\pi}{L} \vec{\theta}, -\frac{2\pi}{L} \vec{\theta}) = \sum_{x,z} \langle Tr[S^{\theta}_u(x, z) \gamma_5 \Sigma^{\theta}_d(z, x; t') \gamma_0]\rangle \delta_{t, t_x - t_z}, \quad (32)$$

where thanks to the $\gamma_5$-hermiticity property one has

$$\Sigma^{\theta}_d(z, x; t') = \gamma_5 [\Sigma^{\theta}_d(z, x; t') \gamma_0]^\dagger \delta_{t, t_x - t_z} \quad (33)$$

and the sequential propagator $\Sigma^{\theta}_d(z, x; t')$ satisfies the modified Dirac equation

$$\sum_y D^{\theta}_d(x, y) \Sigma^{\theta}_d(y, z; t') = \gamma_5 \Sigma^{\theta}_d(z, x; t') \delta_{t, t_x - t_z}. \quad (34)$$

Note that, because of Eq. (13), no exponential factors appear in the r.h.s. of Eqs. (31)-(34) and the dependence on the vector $\tilde{\theta}$ is totally embedded in the twisted quark propagators $S^{\theta}$ and $\Sigma^{\theta}$. 5

---

5 This result holds as well in all reference frames and it explains the findings shown in Fig. 12 of Ref. [16], where the correlation functions with opposite momenta have been calculated explicitly and found to be identical within statistical errors.
3.1 Stochastic procedures

The next point to be addressed is the evaluation of the all-to-all propagator $S^\tilde{\theta}(x, z)$ which is the solution of the modified Dirac equation (11). Restoring color and spin indices, denoted by Latin and Greek letters respectively, one has

$$\sum_y [D^\tilde{\theta}(x, y)]_{\alpha\beta}^{ab} [S^\tilde{\theta}(y, z)]^{bc}_{\beta\gamma} = \delta_{x,z} \delta_{a,c} \delta_{\alpha,\gamma} .$$  \hspace{1cm} (35)

The computation of exact all-to-all quark propagators is a formidable task well beyond present computational capabilities, because it involves a huge number of inversions of the Dirac equation for all possible locations of the source in space and time. Consequently most of the lattice computations of connected 2- and 3-point correlation functions are till now carried out using the point-to-all propagator by fixing the source at some space-time point, referred to as the origin. To get the expressions of our 2- and 3-point correlators in terms of point-to-all propagators it is enough to limit the sum over the variable $z$ to $z = 0$ everywhere in Eqs. (31)-(34). The basic advantage of the all-to-all propagator with respect to the point-to-all one relies in the fact that the former contains all the information on the gauge configuration, which in turn means that the calculation of 2- and 3-point functions using all-to-all propagators is expected to have much less gauge noise.

An efficient way to estimate the all-to-all propagator is based on stochastic techniques with the help of variance reduction methods to better separate the signal from the noise (see Ref. [37] and references therein). In recent years new stochastic methods have been developed, like the dilution method of Ref. [38] and the so-called ”one-end-trick” of Ref. [30]. The latter, already applied by the ETM collaboration to the calculation of neutral meson masses (see Refs. [24] and [39]), allows to achieve a great reduction of the noise-to-signal ratio and it will be applied in this work to the calculation of 3-point correlation functions (see also Refs. [29] and [40]).

The starting point of all stochastic approaches is to consider random sources $\eta_r^a(x)$, which, for reasons that will become clear later on, we take independent of both the spin variable and the twisting vector $\tilde{\theta}$ (i.e., of the quark momentum). The index $r$ ($r = 1, ..., N$) enumerates the generated random sources, which must satisfy the following constraint

$$\lim_{N \to \infty} \frac{1}{N} \sum_{r=1}^{N} \eta_r^a(x) [\eta_r^b(y)]^* = \delta_{a,b} \delta_{x,y} .$$  \hspace{1cm} (36)

In this work we adopt for the sources a random choice of $\pm 1$ values. Then one introduces the “$\phi$-propagator”

$$[\phi_r^a(x)]_{\alpha\beta}^a = \sum_y [S^\tilde{\theta}(x, y)]_{\alpha\beta}^{ab} \eta_r^b(y) ,$$  \hspace{1cm} (37)
which is solution of the equation
\[ \sum_y [D^\theta(x,y)]^{ab}_{\alpha\beta} [\phi_r^\theta(y)]^b_{\beta\gamma} = \eta_r^\theta(x) \delta_{\alpha\gamma}. \] (38)

where the sum over repeated color or spin indices is understood. As explained in details in Ref. [24], the quantity \((1/N) \sum_{r=1}^N [\phi^\theta_r(x)]^{a}_{\alpha\beta} [\eta^\theta_r(y)]^a_{\beta\gamma}\) is an unbiased estimator of the all-to-all propagator \([S^\theta_r(x,y)]^{ab}_{\alpha\beta}\). However, while the signal is of order \(O(1)\), the noise is of the order \(\sqrt{V/N}\) (where \(V\) is the space-time volume) and therefore a huge number of random sources and inversions of Eq. (38) would be required.

The “one-end-trick” is based on the observation that the product of two \(\phi\)-propagators is an unbiased estimator of the product of two all-to-all propagators summed over the intermediate space-time points. In this case, however, the signal is of order \(V\), while the noise is of order \(V/\sqrt{N}\), so that it is even sufficient to employ one random source per gauge configuration, as we do in this work.

Choosing the random source \(\eta^\theta_r(x)\) to be non-vanishing only for a randomly-chosen time slice, located at \(t_r\), the 2-point correlation function (31) can be estimated as
\[ C^\pi(t, \frac{2\pi}{L}) = \sum_{\vec{x}, t_x} \langle [\phi^\theta_{u,t}^r(\vec{x}, t_x)]^{a}_{\alpha\beta} \{ [\phi^\theta_{u,t}^0(\vec{x}, t_x)]^{a}_{\beta\alpha} \}^* \delta_{t, t_x - t_r} \rangle \] (39)

where we notice that the two \(\phi\)’s have the same flavor. Looking at the above equation the \(\phi\)-propagator \([\phi^\theta_r(x)]^{a}_{\alpha\beta}\) plays a role quite similar to the one of the point-to-all propagator \([S^\theta_r(x, 0)]^{ab}_{\alpha\beta}\) with only one color index, being the other one carried by the random source. This means that the time needed for the calculation of the \(\phi\)-propagator is \(1/3\) of the one required for the point-to-all propagator. Note also that both \(\phi^\theta_r(x)\) and \(\phi^\theta_0(x)\) are solutions of Eq. (38) with the same random source \(\eta_r(x)\). This is essential to properly get the r.h.s. of Eq. (39). Moreover the independence of the random source from spin indices allows to evaluate 2-point correlation functions with interpolating fields of the form \((\bar{q} \Gamma q')\) for any Dirac matrix \(\Gamma\).

The stochastic estimate of the 3-point correlation function (32) requires the introduction of the sequential “\(\Phi\)-propagator”
\[ [\Phi^\theta_{du,x} (x; t')]^{a}_{\alpha\beta} = \sum_y [\Sigma^\theta_{du,x} (x, y; t')]^{ab}_{\alpha\beta} \eta^\theta_r(y), \] (40)

The random choice of the time slice at \(t_r\) is mainly motivated by the reduction of autocorrelations observed for fermionic quantities using the ETM gauge ensembles (see Ref. [24]).
which is solution of the equation
\[ \sum_y \left[D^y_d(x,y) \right]_{\alpha\beta} [\Phi^y_{\alpha\beta}(y; t')]_{\gamma\delta} = [\gamma_5]_{\alpha\gamma} [\Phi^y_{\alpha\gamma}(x)]_{\gamma\delta} \delta_{t', t_x - t_r}. \] (41)

One gets
\[ C^\pi\pi_{00}(t,t',\frac{2\pi}{L}\vec{\theta},-\frac{2\pi}{L}\vec{\theta}) = \sum_{\vec{x},t_x} \langle [\Phi^\dag_{\alpha\beta}(\vec{x},t_x)\gamma\delta_{t,t_x - t_r} \cdot [\gamma_5]_{\gamma\delta} \delta_{t,t_x - t_r} \rangle. \] (42)

Note that: i) the quark propagators required in Eqs. (39) and (42) are those of one single flavor, while the other quark flavor appears only in the modified Dirac operator of Eq. (41), and ii) for each value of the quark momentum injected via the twisted BC’s a new inversion of the Dirac operator is required.

4 The charged pion form factor

As already mentioned in the Introduction, the ETM collaboration has started an intensive, systematic program of calculations of three-point correlation functions relevant for the determination of meson form factors at low, intermediate and heavy quark masses. In this work we concentrate on the results obtained for the vector form factor of the pion.

In Table 1 we collect the simulation set-up for all the runs carried out at \( \beta = 3.9 \) and for the two runs performed at a finer lattice spacing (\( \beta = 4.05 \)). Approximate values of the (charged) pion mass \( M_\pi \) in physical units as well as of the quantity \( M_\pi L \), which governs finite volume effects in the so-called \( p \)-regime of ChPT, are reported for each run.

The gauge configurations used for the measurements are selected from the trajectories produced by the ETM collaboration (see Refs. [23, 24, 25]) at various values of the sea (bare) quark mass, \( a m_{sea} \). We have chosen 1 configuration out of at least 20 (equilibrated) trajectories in all cases except for the run at the lightest pion mass (1 out of 10).

Volume effects can be checked through the runs \( R_{2a} \) and \( R_{2b} \) (see later subsection 4.4), while lattice artifacts can be studied by means of the runs \( R_{2b} \) and \( R_{2c} \) at a pion mass around 300 MeV and of the runs \( R_{5a} \) and \( R_{5b} \) for \( M_\pi \approx 480 \) MeV (see later subsection 4.5).

In this work at each value of the (bare) quark mass, \( a m = a m_{sea} \), the statistical errors are evaluated with the jackknife procedure, while a bootstrap sampling will be applied in order to combine the jackknives for different quark masses (see later Section 5).
4.1 Vector renormalization constant $Z_V$

In tmLQCD tuned at maximal twist the constant $Z_V$ renormalizes both the isovector part of the (local) e.m. current [see Eq. (16)] and the isovector off-diagonal components of the (local) axial current, e.g. $A_\mu(x) = \bar{d}(x)\gamma_\mu\gamma_5 u(x)$. Therefore the renormalization constant $Z_V$ can be calculated in two ways. The first one is from Eq. (24), which makes use of 2- and 3-point correlation functions and is equivalent to fix the absolute normalization of the pion form factor, $F_\pi(0) = 1$. The second way is from the non-singlet axial Ward Identity ($WI$), which, up to discretization effects, in tmLQCD at maximal twist reads as [28]

$$Z_V \partial_\mu A_\mu(x) = 2amP_5(x)$$

where $am$ is the bare quark mass and $P_5(x) = \bar{d}(x)\gamma_5 u(x)$ is the bare pseudo-scalar density. The presence of bare operators in the r.h.s. of Eq. (43) is due to the fact that at maximal twist the mass renormalization constant is equal to the inverse of the pseudo-scalar renormalization constant, i.e. $Z_m = Z_p^{-1}$. At zero momentum it follows

$$Z_V = 2am \frac{C^\pi(t,0)}{\partial_\tau A^\pi(t,0)}$$

with $A^\pi(t,0) = \sum_{x,z} \langle A_0(x) P_5(z) \rangle \delta_{t,t_x-t_z}$.

The results obtained for the ratio given by the r.h.s. of Eq. (24), evaluated for all the runs at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48 a^4$, are shown in Fig. (1a). The time distance $t'$ between the time slices of the source and the sink is fixed at $t' = T/2$, so that the 3-point correlation function (18) becomes antisymmetric with respect to

| $\beta$ | $a$ (fm) | Run Refs. | $am_{sea}$ | $V \cdot T / a^4$ | $M_\pi$ (MeV) | $M_\pi L$ | No. gauge config. |
|--------|---------|-----------|------------|-----------------|---------------|----------|-----------------|
| 3.9 $\approx 0.09$ | $R_1$ $B_7$ | 0.0030 | $32^3 \cdot 64$ | $\approx 260$ | $\approx 3.7$ | 240 |
| $R_{2a}$ | $B_6$ | 0.0040 | $32^3 \cdot 64$ | $\approx 300$ | $\approx 4.2$ | 240 |
| $R_{2b}$ | $B_1a,b,c$ | 0.0040 | $24^3 \cdot 48$ | $\approx 300$ | $\approx 3.2$ | 480 |
| $R_3$ | $B_2$ | 0.0064 | $24^3 \cdot 48$ | $\approx 380$ | $\approx 4.0$ | 240 |
| $R_4$ | $B_3a,b$ | 0.0085 | $24^3 \cdot 48$ | $\approx 440$ | $\approx 4.7$ | 240 |
| $R_{5a}$ | $B_4$ | 0.0100 | $24^3 \cdot 48$ | $\approx 480$ | $\approx 5.1$ | 240 |
| $R_6$ | $B_{5a,b}$ | 0.0150 | $24^3 \cdot 48$ | $\approx 580$ | $\approx 6.1$ | 240 |
| 4.05 $\approx 0.07$ | $R_{2c}$ | $C_1$ | 0.0030 | $32^3 \cdot 64$ | $\approx 300$ | $\approx 3.4$ | 240 |
| $R_{5b}$ | $C_3$ | 0.0080 | $32^3 \cdot 64$ | $\approx 480$ | $\approx 5.4$ | 240 |

Table 1: Set-up of the lattice simulations for the various runs considered in this work.
$t = T/2$ and it can be appropriately averaged to reduce the statistical fluctuations. Moreover for finite time extension $T$ the 2-point correlation function $C^\pi(t, \vec{p})$ is symmetric with respect to $t = T/2$, so that a second exponential $e^{-E_\pi(\vec{p})(T-t)}$ appears in Eq. (19) and a factor $1/2$ has to be applied to the r.h.s of Eq. (24).

From the plateau region denoted by the vertical dotted lines in Fig. 1(a) an estimate of the renormalization constant $Z_V$ can be obtained at each value of the bare quark mass. The results are reported in Fig. 1(b) and compared with the corresponding results obtained from the WI using Eq. (44) (see Ref. [41]). Both methods exhibit an extremely high statistical precision of the order of 0.3%.

![Graph](image)

**Fig. 1:** (a) Ratio of 2-point and 3-point correlation functions given by the r.h.s. of Eq. (24), evaluated for $t' = T/2$ at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48 a^4$, versus the (Euclidean) time $t$ in lattice units. (b) The vector renormalization constant $Z_V$ as obtained at different values of the bare quark mass in lattice units. Open dots correspond to the values extracted from the plateau region denoted by the vertical dotted lines in (a). Open squares are the results obtained from the WI using Eq. (44) in Ref. [41]. The solid and dashed lines are simple linear interpolations of the lattice points and the full markers denote the corresponding values at the chiral point.

The quark mass dependence visible in Fig. 1(b) is a pure discretization effect and is different between the two methods. It appears to be linear in both cases, which is not in contradiction with the $O(a)$ improvement, since terms proportional to $a^2 m \Lambda_{QCD}$ may be dominant with respect to terms proportional to $a^2 m^2$.

The extrapolations to the chiral limit should therefore coincide, providing the value of the renormalization constant $Z_V$, which is indeed defined in such a limit.
From Fig. 1(b) it can be seen that the values obtained by a simple linear fit at the chiral point coincide nicely within quite small statistical errors, namely $Z_V = 0.61088(14)$ from Eq. (24) and $Z_V = 0.61076(19)$ from the WI [Eq. (44)].

### 4.2 Momentum dependence of the 2-point correlation function

The 2-point correlation function (39) has been calculated for various values of the twisting angle $\vec{\theta}$ chosen always in the symmetric form $\vec{\theta} = (\theta, \theta, \theta)$ with $\theta = \{0.0, 0.11, 0.19, 0.27, 0.35, 0.44\}$. The time behavior of the effective mass (or logarithmic slope) $aM_{\text{eff}}(t)$, defined as

$$aM_{\text{eff}}(t) \equiv \log \left[ \frac{C^\pi(t, 2\pi \vec{\theta}/L)}{C^\pi(t + a, 2\pi \vec{\theta}/L)} \right], \quad (45)$$

is shown in Fig. 2 for two (representative) values of $M_\pi$ at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48 \ a^4$.

![Fig. 2: Effective mass of the pion (45) versus the (Euclidean) time distance in lattice units for $M_\pi \sim 300$ MeV (a) and $M_\pi \sim 440$ MeV (b) at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48 \ a^4$. The twisting angle $\vec{\theta}$ is chosen in the symmetric form $\vec{\theta} = (\theta, \theta, \theta)$. The dots, squares, diamonds, triangles, the full dots and the full squares correspond to $\theta = \{0.0, 0.11, 0.19, 0.27, 0.35, 0.44\}$, respectively. The dashed vertical line is drawn at $t/a = 10$, where the ground state starts to dominate.](image)

It can be seen that the statistical precision is remarkably high and it allows to
extract quite precisely the energy $E_{\pi}(\vec{p})$ [see Eq. (19)] corresponding to the pion ground state, which starts to dominate from $t/a = 10$.

The values obtained for the pion energy $E_{\pi}(\vec{p})$ are shown in Fig. 3 as a function of the pion momentum given by $\vec{p} \equiv 2\pi\theta/L$, always at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48$ $a^4$. The lattice points appear to be in remarkable agreement with the continuum-like dispersion relation $E_{\pi}(\vec{p}) = \sqrt{M_{\pi}^2(L) + |\vec{p}|^2}$, where $M_{\pi}(L)$ is the charged pion mass at finite volume. We have also checked that, assuming the continuum dispersion relation for the energy, all the 2-point correlation functions of moving pions can be simultaneously fitted very well together with the one at rest using a single momentum-independent matrix element $Z_{\pi}$ [see Eq. (19)]. These findings clearly indicate that, at least for $t/a \geq 10$, where the ground state dominates, and for the pion momenta considered in this study, the discretization effects on the 2-point correlation functions $C_{\pi}(t, 2\pi\theta/L)$ are almost the same as those affecting the correlator at rest $C_{\pi}(t, \vec{0})$, which were investigated in Ref. [25] and found to be small.

![Fig. 3: Squared pion energy $E_{\pi}^2(\vec{p})$ in lattice units, obtained from the time plateaux of the effective mass shown in Fig. 2 (by choosing the time interval $10 \leq t/a \leq 21$), versus the squared pion momentum $p^2 \equiv 3(2\pi\theta/L)^2$ in lattice units, for $M_{\pi} \simeq 300$ MeV (a) and $M_{\pi} \simeq 440$ MeV (b) at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48$ $a^4$. The solid line is the continuum-like dispersion relation $E_{\pi}^2(\vec{p}) = M_{\pi}^2(L) + |\vec{p}|^2$, while the dashed line in (a), which can be hardly distinguished from the solid one, represents the modified dispersion relation (46) predicted by partially twisted and partially quenched ChPT at NLO elaborated in Ref. [42].](image)

The use of twisted BC’s is expected to produce finite volume corrections to
the continuum-like dispersion relation. Such corrections have been investigated in Ref. [42] using partially quenched ChPT at NLO. In the case of charged pion and adopting twisted BC’s for one flavor only, the pion momentum \( \vec{p} \) acquires an additive correction term \( \vec{K} \), namely

\[
E_{\pi}^2(\vec{p}) = M_{\pi}^2(L) + (\vec{p} + \vec{K})^2
\]

where the components of the vector \( \vec{K} \) are given by \((i \neq j \neq k)\)

\[
K_i = -\frac{1}{\sqrt{\pi f_{\pi}^2 L^3}} \int_0^{\infty} d\tau \frac{1}{\sqrt{\tau}} e^{-\tau \left( \frac{M_{\pi} L}{2\pi} \right)^2} \Theta(\tau, \theta_i) \Theta(\tau, \theta_j) \Theta(\tau, \theta_k)
\]

with \( \Theta(\tau, \theta) \) and \( \Theta(\tau, \theta) \) being the elliptic Jacobi function and its derivative. Explicitly one has \( \Theta(\tau, \theta) \equiv \sum_{n=-\infty}^{\infty} e^{-\tau(n+\theta)^2} \) and \( \Theta(\tau, \theta) = \sum_{n=-\infty}^{\infty} e^{-\tau(n+\theta)^2} \).

We have evaluated Eq. (47) for the run \( R_{2b} \), which has the smallest value of \( M_{\pi} L \) (see Table 1). The results are reported in Fig. 3(a) (dashed line) and they clearly indicate the smallness of the volume corrections to the pion momentum and therefore to the continuum dispersion relation expected at NLO. Thus finite size effects may be limited mainly to the pion mass and thus expected to be small (see Refs. [23, 24]). This is confirmed by the lattice results shown in Fig. 4, where the pion energies obtained in case of the runs \( R_{2a} \) and \( R_{2b} \), which differs only for the lattice size, are compared.

4.3 Momentum dependence of the pion form factor

The advantage of calculating the pion form factor using all-to-all propagators, evaluated by the one-end-trick procedure with twisted BC’s, with respect to the standard procedure based on point-to-all propagators with fixed sources and (spatially) periodic BC’s is illustrated in Fig. 5. From the run \( R_{2b} \) we choose a different number of gauge configurations for the stochastic and non-stochastic procedures in order to get the same total computational time.\(^7\)

Despite the more limited ensemble of gauge configurations the stochastic approach provides a much better precision at the two lowest values of \( q^2 \) (a factor between \( \sim 2 \) and \( \sim 3 \)). It also allows a very good determination of the form factor at the two highest values of \( q^2 \) considered in this study, where the procedure based on point-to-all propagators fails to give reliable signals even in the presence of a larger ensemble of gauge configurations.

As discussed in the previous Section, the pion form factor \( F_\pi(q^2) \) can be determined from the plateau of the ratio \( R_0(t, t'; q^2) \), defined by Eq. (25), at large

\(^7\)Let us remind that the one-end-trick requires less computational time for a single inversion of the Dirac operator (a factor of about 1/3), but for each quark momentum a new inversion is needed by the use of twisted BC’s.
The quality of the time plateaux is illustrated in Fig. 6, while the momentum dependence of the extracted pion form factor $F_\pi(q^2)$ is shown in Fig. 7 for various values of $M_\pi$ at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48 a^4$. We have checked that different choices of the time interval for the plateau region lead to values of $F_\pi(q^2)$ which are largely consistent within the statistical precision. The values of the pion form factor obtained for all the simulations of Table 1 are reported in the Appendix.

In the whole range of values of both $q^2$ and the quark mass, considered in this work, our lattice data can be fitted very nicely using a simple pole ansatz

$$F_\pi^{(pole)}(q^2) = \frac{1}{1 - q^2/M_{pole}^2},$$

as it is shown in Fig. 7. For comparison we also show the predictions of the Vector Meson Dominance (VMD) model, in which the parameter $M_{pole}$ is fixed at the value of the lightest vector-meson mass ($M_{VMD}$) taken from Ref. 43. The values obtained for $M_{pole}$ by fitting our lattice points at $\beta = 3.9$ are given in Table 2.

From Fig. 7 it can be seen that the VMD prediction, which considers the contribution of the lowest vector resonance only, is not exactly fulfilled, since $M_{pole}$ turns out to be systematically lower than $M_{VMD}$. However such a comparison might be plagued by systematic uncertainties affecting the lattice determination.
Fig. 5: Pion form factor $F_{\pi}(q^2)$ versus $q^2$ in lattice units for a simulated pion mass of $\simeq 300$ MeV. The full dots are the results obtained using twisted BC’s in the Breit frame and the one-end-trick procedure for calculating the all-to-all propagators for an ensemble of 80 gauge configurations taken from the run $R_{2b}$. The open squares correspond to the results of the standard procedure based on point-to-all propagators with fixed sources for 120 gauge configurations of the run $R_{2b}$. In this case spatially periodic BC’s are applied in the frame where the final pion is at rest ($\vec{p}' = 0$) and the momentum of the initial pion is given by $\vec{p} = 2\pi/L \{(1,0,0), (1,1,0), (1,1,1), (2,0,0)\}$. At the two smallest values of $q^2$ and for the ensemble of gauge configurations considered, only the stochastic procedure provides time plateaux of enough good quality to allow the extraction of the pion form factor.

of the lightest vector-meson mass particularly at the lowest values of the pion mass (see Ref. [43]). Nevertheless, a simple extrapolation of $M_{\text{pole}}$ to the physical point, based on a polynomial fit in terms of quark masses (see later subsection 5.3), yields the value $M_{\text{pole}}^{\text{phys}} = 0.713 \pm 0.044$ GeV, which is lower than the VMD prediction $M_{\text{VMD}}^{\text{phys}} = M_\rho = 0.776$ GeV from PDG [22].

Note also that, defining the squared pole radius in terms of Eq. (48) as

$$r_{\text{pole}}^2 \equiv 6/M_{\text{pole}}^2 = 6 \left[ \frac{dF_{\pi}^{\text{pole}}(q^2)}{dq^2} \right]_{q^2=0},$$

Eq. (49)

the VMD model leads at the physical point to $r_{\text{pole}}^2 = 6/M_\rho^2 \simeq 0.388$ fm$^2$, which underestimates by $\simeq 15\%$ the (quite precise) experimental value of the squared
Fig. 6: Ratio $R_0(t, t'; q^2)$, defined by Eq. (22), at $t' = T/2$ versus the time distance $t$ in lattice units, for $M_\pi \approx 300$ MeV (a), $M_\pi \approx 380$ MeV (b), $M_\pi \approx 440$ MeV (c), $M_\pi \approx 480$ MeV (d) at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48 \ a^4$. The full dots, open squares, full diamonds, open diamonds and full squares correspond to $a^2 q^2 = -0.01, -0.03, -0.06, -0.10$ and $-0.16$, respectively. The dashed vertical lines identify the region $10 \leq t/a \leq 14$, where both the initial and the final pion ground states are isolated, so that the pion form factor $F_\pi(q^2)$ can be extracted.

Pion charge radius, $\langle r^2 \rangle_{\text{exp.}} = 0.452 \pm 0.011 \ \text{fm}^2$ [22]. On the contrary the value $M_{\text{pole}} = 0.713 \pm 0.044 \ \text{GeV}$ implies $r_{\text{pole}}^2 = 0.459 \pm 0.057 \ \text{fm}^2$ in nice agreement with the experimental charge radius.
Fig. 7: Pion form factor $F_{\pi}(q^2)$, extracted from the plateau region $10 \leq t/a \leq 14$ of the ratio $R_0(t,T/2; q^2)$ (see Fig. 6), versus the squared 4-momentum transfer $q^2$ in lattice units, for $M_\pi \simeq 300$ MeV (a), $M_\pi \simeq 380$ MeV (b), $M_\pi \simeq 440$ MeV (c), $M_\pi \simeq 480$ MeV (d) at $\beta = 3.9$ and $V \cdot T = 24^3 \cdot 48$ $a^4$. The solid line is the pole behavior (48) with the parameter $M_{\text{pole}}$ fitted to the lattice points, while the dashed line is the VMD prediction with $M_{\text{pole}}$ fixed at the value of the lightest vector-meson mass taken from Ref. [43].

4.4 Finite size effects

We have investigated the effects of the finite spatial extension $L$ of our lattice boxes by comparing the results of runs $R_{2a}$ and $R_{2b}$. In our simulations the latter has the
Run | $M_\pi$(MeV) | $V \cdot T / a^4$ | $a_{M_{pole}}$
---|---|---|---
$R_1$ | $\approx 260$ | $32^3 \cdot 64$ | $0.359 \pm 0.016$
$R_{2a}$ | $\approx 300$ | $32^4 \cdot 64$ | $0.363 \pm 0.011$
$R_{2b}$ | $\approx 300$ | $24^4 \cdot 48$ | $0.379 \pm 0.010$
$R_3$ | $\approx 380$ | $24^4 \cdot 48$ | $0.399 \pm 0.014$
$R_4$ | $\approx 440$ | $24^4 \cdot 48$ | $0.420 \pm 0.012$
$R_{5a}$ | $\approx 480$ | $24^4 \cdot 48$ | $0.419 \pm 0.011$
$R_6$ | $\approx 580$ | $24^4 \cdot 48$ | $0.440 \pm 0.005$

Table 2: Values of the fit parameter $M_{pole}$ appearing in Eq. (48) obtained at $\beta = 3.9$ in lattice units.

The smallest value of the quantity $M_\pi L$, which governs finite size effects (FSE) in the p-regime. The physical extension of the two boxes is $L \approx 2.8$ fm and $L \approx 2.1$ fm, respectively. The values of the angle $\theta$ are chosen differently at the two volumes in order to keep the values of $q^2$ fixed.

The results for the pion form factor are shown in Fig. 8, while a direct comparison of the results for the pion mass and decay constant as well as for the squared pole radius, $r_{pole}^2$, is illustrated in Table 3.

Fig. 8: Pion form factor $F_\pi(q^2)$ obtained for the runs $R_{2a}$ (open squares) and $R_{2b}$ (full dots), which correspond to different lattice boxes of size $L \approx 2.8$ fm and $L \approx 2.1$ fm, respectively. The solid and dashed lines are the results of the pole fit (48).
| Run  | $L$ (fm) | $aM\pi$ | $af\pi$ | $r_{pole}/a^2$ |
|------|----------|----------|----------|----------------|
| $R_{2a}$ | $\approx 2.8$ | 0.13377 (24) | 0.06625 (16) | 45.5 ± 2.8 |
| $R_{2b}$ | $\approx 2.1$ | 0.13623 (65) | 0.06459 (37) | 41.7 ± 2.3 |

Table 3: Values of the pion mass and decay constant from the high-statistics work of Ref. [24] and of the squared pole radius [see Eq. (49)] in lattice units for the runs $R_{2a}$ and $R_{2b}$.

It can clearly be seen that FSE effects are larger on the pion form factor (or, equivalently, on the pole radius) with respect to the case of the pion mass and decay constant. They indeed amount to $\approx 8\%$ on $r_{pole}^2$ in contrast to a $\approx 2\%$ effect in the case of $M\pi$ and $f\pi$. However we notice that FSE effects on $r_{pole}^2$ are comparable to our statistical precision ($\approx 6\%$), while they are much larger in the case of $M\pi$ and $f\pi$ (0.2±0.6%). Thus it is mandatory to include volume corrections to our results at least on the pion mass and decay constant.

On the theoretical side FSE on $M\pi$ and $f\pi$ have been studied with ChPT at NLO in Ref. [44] and using a resummed asymptotic formula in Ref. [45], where both leading and subleading exponential terms are taken into account and the chiral expansion is applied to the $\pi - \pi$ forward scattering amplitude. When the leading chiral representation of the latter is considered, the resummed approach coincides with the NLO result of Ref. [44]. Viceversa at NNLO the resummation technique includes only a part of the two-loop effects as well as of higher-loop effects. Recently the resummed approach has been positively checked against a full NNLO calculation of the pion mass in Ref. [46], showing that the missing two-loop contributions are actually negligible.

The volume corrections predicted by the resummed approach have been already considered in the analysis of the ETMC results for $M\pi$ and $f\pi$ carried out in Refs. [23, 24, 25].

On the contrary, till now, the theoretical investigation of FSE on the pion form factor is limited to the application of ChPT at NLO only. The case of periodic BC’s is considered in Ref. [47], while twisted BC’s are studied in Refs. [42, 48] adopting two different reference frames, namely the rest frame of the final meson [42] and the Breit one [48].

The sign of the volume effects on the pion form factor depends crucially on the absolute value and the spatial direction of the twisting vector $\vec{\theta}$. The sign of FSE on the charge radius turns out to be opposite between the cases of periodic (Ref. [47]) and twisted (Refs. [42, 48]) BC’s. When periodic BC’s are used the extraction of the charge radius requires the use of the smallest available momentum, which is equal to $2\pi/L$. Such a restriction is absent with twisted BC’s and therefore volume
effects are different.

Moreover the volume corrections depend on the reference frame: in the rest frame, besides the usual term related to the difference between the infinite volume loop integral and the sum over quantized momenta, there are two further contributions [12] arising from isospin and hypercubic invariance breakings generated by flavor-dependent twisted BC’s. Such two terms are vanishing in the Breit frame as shown in Ref. [18].

Only the results of Ref. [18], in which both the twisted BC’s and the Breit reference frame are considered, can be directly applied to our data. Thus one gets

\[
F_\pi(q^2; L) - F_\pi(q^2; \infty) = \frac{1}{f_\pi^2} \left\{ \int_0^1 dx \left[ (1 - 2x)\frac{2\pi \vec{\theta}}{L}; M_\pi^2 - x(1 - x)q^2 \right] - I_{1/2} \left( \frac{2\pi \vec{\theta}}{L}; M_\pi^2 \right) \right\} - 
\]

(50)

with \( q^2 = -4(2\pi \vec{\theta}/L)^2 \) and

\[
I_{1/2} \left( \frac{2\pi \vec{\theta}}{L}; M_\pi^2 \right) = \frac{1}{2\pi^{3/2}L^2} \int_0^\infty d\tau \frac{1}{\sqrt{\tau}} e^{-\tau(M_\pi L)^2} \left[ \prod_{i=1}^3 \Theta(\tau, \theta_i) - \left( \frac{\tau}{\pi} \right)^{3/2} \right] 
\]

(51)

where \( \Theta(\tau, \theta) \) is defined after Eq. (47). The NLO volume corrections on the pion form factor expected for our run \( R_{2b} \) do not exceed half of the statistical error, and they are even smaller in the case of the run \( R_{2a} \) at the largest volume. The FSE’s predicted by Eqs. (50,51) are quite small and have the same sign for all the choices of the twisting angle \( \vec{\theta} \) made in this work. The NLO corrections go to the right direction decreasing slightly the differences between the pion form factor obtained at the two box sizes.

As for the squared pole radius, the shift with the lattice volume reported in Table [3] has the same sign expected from the volume correction (50). However the FSE calculated at NLO for the run \( R_{2b} \) corresponds to an increase of \( \simeq 3\% \) only, that is almost a factor 3 less than the observed FSE \( (\simeq 8\%) \). This suggests that higher-order chiral effects might be relevant on the pion form factor still for \( M_\pi L \simeq 3 \), although our statistical precision \( (\simeq 6\%) \) does not exclude FSE’s on \( r_{pole}^2 \) as small as the ones predicted at NLO by Eq. (50).

In the case of our runs \( R_1 \) and \( R_{2a} \), which correspond to \( M_\pi L \simeq 4 \), the NLO volume corrections on \( r_{pole}^2 \) are expected to be \( \simeq 1\% \). After multiplying such a value by a factor \( \approx 3 \) in order to take into account conservatively higher-loop effects, the expected FSE remains well below the statistical precision.

Therefore in this work we decide to analyze our form factor data using only simulations with \( M_\pi L \gtrsim 4 \), which means in practice that the run \( R_{2b} \) is excluded.
from our analyses of the pion form factor. On the contrary in case of the pion mass and decay constant we keep the run \( R_{2b} \) in the set of fitted data, but the FSE’s, calculated through the resummed asymptotic formula of Ref. [45] at the NNLO accuracy for the \( \pi - \pi \) forward scattering amplitude, will be taken into account (see Sections 5 and 6).

4.5 Discretization effects

We have investigated the impact of lattice artifacts on the pion form factor by considering the runs \( R_{2c} \) and \( R_{5b} \) at the finer spacing \( a \approx 0.07 \) fm (see Table 1). These runs correspond to pion masses equal to \( M_\pi \approx 300 \) MeV and \( M_\pi \approx 480 \) MeV, respectively, which are very similar to those of the runs \( R_{2b} \) and \( R_{5a} \) at \( a \approx 0.09 \) fm, while the physical lattice size is almost kept fixed (\( L \approx 2.1 \) fm). Our results are shown in Fig. 9 in terms of the Sommer parameter \( r_0 \) instead of the lattice spacing \( a \). The ratio \( r_0/a \) has been determined in the chiral limit at the two lattice spacings in Ref. [25], obtaining \( r_0/a = 5.22 \pm 0.02 \) at \( \beta = 3.9 \) and \( r_0/a = 6.61 \pm 0.03 \) at \( \beta = 4.05 \).

Fig. 9: Results of the pion form factor \( F_\pi(q^2) \) versus \( q^2 \) in units of the Sommer parameter \( r_0 \), obtained for the runs \( R_{2b} \) (full dots) and \( R_{2c} \) (open squares) at \( M_\pi \approx 300 \) MeV in (a), and for the runs \( R_{5a} \) (full dots) and \( R_{5b} \) (open squares) at \( M_\pi \approx 480 \) MeV in (b). The physical lattice size is the same in both runs (\( L \approx 2.1 \) fm). The solid and dashed lines are the results of the pole fit (48), while the dotted line in (a) corrects the dashed one for the pion mass difference (see text).

It can clearly be seen that the size of discretization effects is comparable to
the statistical error at both pion masses. At the lowest pion mass there is a slight mismatch between the values of $M_\pi r_0$ corresponding to the runs $R_{2b}$ and $R_{2c}$. Using the ChPT formulae at NNLO evaluated in Ref. [11], which will be used in the next Sections, and adopting for the relevant LEC’s the values given in Ref. [33] we have estimated the correction due to the pion mass difference and applied it to the results of the run $R_{2c}$ (see dotted line in Fig. 9). The correction is small, but reduces the impact of discretization effects, which now in terms of $r_{\text{pole}}^2$ do not exceed $\simeq 5\%$ at both pion masses.

A more complete investigation of the scaling properties of the pion form factor, which requires the study of its mass dependence at two additional values of the lattice spacing, is needed and it is in progress.

In the next Sections continuum ChPT will be applied to the chiral extrapolation of the results of the runs $R_1$, $R_{2a}$, $R_3$, $R_4$, $R_{5a}$ and $R_6$, which correspond to a single lattice spacing ($a \simeq 0.09\text{ fm}$) and to a pion mass range between $\simeq 260\text{ MeV}$ and $\simeq 580\text{ MeV}$ with $M_\pi L \gtrsim 4$. The impact of lattice artifacts will be estimated by substituting the results of the runs $R_{2a}$ and $R_{5a}$ with those of the runs $R_{2c}$ and $R_{5b}$, respectively.

5 Slope and curvature of the pion form factor

The slope $s$ and the curvature $c$ of the pion form factor are defined from the expansion in $q^2$

$$F_\pi(q^2) = 1 + s q^2 + c q^4 + O(q^6) .$$

In terms of the pole ansatz (48) the slope is given by

$$s_{\text{pole}} = \frac{1}{M_{\text{pole}}^2} = \frac{r_{\text{pole}}^2}{6} ,$$

while the curvature is constrained to be

$$c_{\text{pole}} = s_{\text{pole}}^2 = \frac{1}{M_{\text{pole}}^4} = \left( \frac{r_{\text{pole}}^2}{6} \right)^2 .$$

We have therefore compared the slope and curvature obtained from the pole ansatz (48) with those of a simple cubic fit in $q^2$

$$F_{\pi}^{(cub)}(q^2) = 1 + s_{\text{cub}} q^2 + c_{\text{cub}} q^4 + d_{\text{cub}} q^6 .$$

The results obtained by including in the fitting procedure the form factor corresponding to the four highest, negative values of $q^2$ are shown in Fig. 10 (see also...
It can be seen that the two determinations of the slope are in very good agreement and the results for the curvature are consistent within the statistical errors, which turn out to be lower in the case of the pole fit.

Fig. 10: The slope $s$ (dots) and the curvature $c$ (squares) of the pion form factor [see Eq. (52)] versus the squared pion mass in lattice units, for the runs $R_1$, $R_{2a}$, $R_3$, $R_4$, $R_{5a}$ and $R_6$. Open dots and squares correspond to the results of the pole fit given by Eqs. (53) and (54), respectively. Full markers are the results obtained with the cubic fit (55).

In what follows we take as our best estimates the values of the slope and the curvature coming from the pole ansatz. The former ones, expressed in physical units using the value $a = 0.087$ fm from Ref. [23], are collected in the third column of Table 4 and shown in Fig. 11, where they are compared with the available results of other lattice collaborations that employ O(a)-improved lattice actions and unquenched gauge configurations. It can be seen that all the determinations of the pion charge radius exhibit a quite similar mass dependence, indicating that lattice artifacts are presumably under control. The results labeled as “QCDSF/UKQCD” in Fig. 11 do not correspond to the original ones reported in Ref. [19]. There the lattice spacing, instead of the Sommer parameter $r_0$, was assumed to depend on the sea quark mass and such a procedure reintroduces non-negligible lattice artifacts. The “QCDSF/UKQCD” results shown in Fig. 11 are obtained after properly

---

8The lattice points at the lowest, negative value of $q^2$ are the noisiest data (see Fig. 7 and also Fig. 6 for the corresponding time plateaux). The inclusion of these data in the fitting procedure does not change significantly the determination of the various parameters appearing in Eqs. (53) and (54).
extrapolating the ratio $r_0/a$ to the chiral limit\(^8\).

| Run | $M_\pi$ (MeV) | $r_{\text{pole}}^2 \equiv 6s_{\text{pole}}$ (fm$^2$) | $c_{\text{pole}}$ (10$^{-3}$ fm$^4$) | $r_{\text{cub}}^2 \equiv 6s_{\text{cub}}$ (fm$^2$) | $c_{\text{cub}}$ (10$^{-3}$ fm$^4$) |
|-----|--------------|-----------------|-----------------|-----------------|-----------------|
| $R_1$ | 265 | 0.352 ± 0.030 | 3.44 ± 0.59 | 0.364 ± 0.028 | 4.20 ± 1.12 |
| $R_{2a}$ | 304 | 0.345 ± 0.021 | 3.30 ± 0.40 | 0.333 ± 0.020 | 2.45 ± 0.82 |
| $R_3$ | 383 | 0.285 ± 0.019 | 2.25 ± 0.31 | 0.278 ± 0.023 | 1.85 ± 0.54 |
| $R_4$ | 441 | 0.258 ± 0.015 | 1.85 ± 0.22 | 0.249 ± 0.021 | 1.36 ± 0.49 |
| $R_{5a}$ | 477 | 0.259 ± 0.014 | 1.87 ± 0.20 | 0.254 ± 0.018 | 1.45 ± 0.44 |
| $R_6$ | 584 | 0.234 ± 0.006 | 1.53 ± 0.07 | 0.225 ± 0.010 | 1.14 ± 0.26 |

Table 4: Values of the pion mass, charge radius and curvature, determined from the pole (53-54) and cubic (55) fits, for the various ETMC runs. Physical units are used taking for the lattice spacing the value $a = 0.087$ fm from Ref. [23]. The uncertainties are statistical (jackknife) errors.

5.1 ChPT formulae at NNLO

In Ref. [11] the pion form factor, as well as the pion mass and decay constant, have been calculated in continuum SU(2) ChPT at NNLO in infinite volume using a modified minimal subtraction ($\overline{MS}$) scheme to regulate the infinities. Using the quark mass $\hat{m}$ as the expansion parameter, one has

\[
M_\pi^2 = 2B\hat{m} + [M_\pi^2]_{\text{NLO}} + [M_\pi^2]_{\text{NNLO}} + \mathcal{O}(\hat{m}^4), \tag{56}
\]

\[
[M_\pi^2]_{\text{NLO}} = 2B\hat{m} \cdot 2x_2 \left[2\ell_3^r + \frac{1}{2}L(\mu)\right], \tag{57}
\]

\[
[M_\pi^2]_{\text{NNLO}} = 2B\hat{m} \cdot 4x_2^2 \left\{ \frac{1}{N} \left[\ell_4^r + 2\ell_2^r - \frac{13}{3}L(\mu)\right] + \frac{163}{96} \frac{1}{N^2} \right. \\
- \frac{7}{2}k_1 + 2k_2 + 4\ell_3^r (\ell_4^r - \ell_3^r) - \frac{9}{4}k_3 + \frac{1}{4}k_4 \\
+ \left. r_M^r + \Delta_M \left(\Delta_M - \Delta_F + \frac{1}{2N}\right)\right\}, \tag{58}
\]

\[
f_\pi = F + [f_\pi]_{\text{NLO}} + [f_\pi]_{\text{NNLO}} + \mathcal{O}(\hat{m}^3), \tag{59}
\]

\[
[f_\pi]_{\text{NLO}} = 2F \cdot x_2 \left[\ell_4^r - L(\mu)\right], \tag{60}
\]

\(^8\)We thank J. Zanotti for providing us the extrapolated values of $r_0/a$ at the chiral point.
Fig. 11: The squared pion charge radius versus the squared pion mass. Open dots: this work (see third column of Table 4). Open squares: results from Ref. [19] corrected as explained in the text. Open diamonds, full triangles, full diamonds correspond to Refs. [21, 14, 20], respectively. The full dot represents the experimental value of the squared pion charge radius $\langle r^2 \rangle_{\text{exp.}} = 0.452 \pm 0.011$ fm$^2$ from PDG [22].

$$[f_\pi]_{\text{NNLO}} = 4F^2 x_2^2 \left\{ \frac{1}{N} \left[ -\frac{1}{2} \ell_1^r - \ell_2^r + \frac{29}{12} L(\mu) \right] - \frac{13}{192} \frac{1}{N^2} \right. $$

$$+ \frac{7}{4} k_1 + k_2 + 2\ell_4^r (\ell_4^r - \ell_3^r) - \frac{5}{4} k_4$$

$$+ \frac{r_F^r}{2} \Delta_F (\Delta_M - \Delta_F) - \frac{1}{N} \Delta_M \right\}, \quad (61)$$

$$\langle r^2 \rangle = [\langle r^2 \rangle]_{\text{NLO}} + [\langle r^2 \rangle]_{\text{NNLO}} + O(\hat{m}^2), \quad (62)$$

$$[\langle r^2 \rangle]_{\text{NLO}} = -\frac{2}{F^2} \left( 6\ell_6^r + L(\mu) + \frac{1}{N} \right), \quad (63)$$
\[ [\langle r^2 \rangle]_{\text{NNLO}} = 4 \frac{x_2}{F^2} \left\{ \frac{1}{N} \left[ -2\ell_4' + \frac{31}{6} L(\mu) + \frac{13}{192} - \frac{181}{48N} \right] \right. \\
- 3k_1 + \frac{3}{2}k_2 - \frac{1}{2}k_4 + 3k_6 - 12\ell_4'\ell_6' \\
+ \left. 6r_1' + \Delta_F \left( 6\ell_6' + L(\mu) + \frac{1}{N} \right) - \frac{1}{N}\Delta_M \right\}, \quad (64) \]

c = [c]_{\text{NLO}} + [c]_{\text{NNLO}} + O(\hat{m}), \quad (65)
\]
\[ [c]_{\text{NLO}} = \frac{2}{60NF^4 x_2}, \quad (66) \]
\[ [c]_{\text{NNLO}} = \frac{4}{F^4} \left\{ \frac{1}{N} \left[ -\frac{13}{540} L(\mu) + \frac{1}{720} - \frac{8429}{25920N} \right] \right. \\
+ \left. \frac{1}{12}k_1 - \frac{1}{24}k_2 + \frac{1}{24}k_6 + \frac{1}{3N} \left( \ell_1' - \frac{1}{2}\ell_2' + \frac{1}{10}\ell_4' + \frac{1}{2}\ell_6' \right) \right\} \\
+ r_2' - \frac{1}{60N}(\Delta_M + \Delta_F), \quad (67) \]

where \(2B\hat{m}\) is the celebrated GMOR term, \(F\) is the pion decay constant in the chiral limit (\(f_\pi\) is normalized such that \(f_\pi \approx 130\) MeV at the physical point) and

\[ N \equiv (4\pi)^2, \]
\[ x_2 \equiv \frac{2B\hat{m}}{F^2}, \]
\[ L(\mu) \equiv \frac{1}{N} \log \left( \frac{2B\hat{m}}{\mu^2} \right), \]
\[ k_i \equiv [4\ell_i' - \gamma_i L(\mu)] L(\mu), \]
\[ \Delta_M \equiv 2\ell_3' + \frac{1}{2}L(\mu), \]
\[ \Delta_F \equiv 2[\ell_4' - L(\mu)]. \quad (68) \]

The constants \(\ell_i'\) are the finite part of the coupling constants appearing in the \(O(p^4)\) Lagrangian after the application of the \(\overline{MS}\) procedure and their values depend on the renormalization scale \(\mu\) through the anomalous dimensions \(\gamma_i\) as \(\mu^2 d\ell_i' / d\mu^2 = -\gamma_i/2N\). The coefficients \(\gamma_i\) are calculated in Ref. [10] and those relevant in this work are given by: \(\gamma_1 = 1/3, \quad \gamma_2 = 2/3, \quad \gamma_3 = -1/2, \quad \gamma_4 = 2, \quad \gamma_6 = -1/3\). The four constants \(r_M', r_F', r_1', r_2'\) denote the contributions of the \(O(p^6)\) Lagrangian after \(\overline{MS}\) subtraction. Though the values of all the above constants depend on \(\mu\), at each order in the chiral expansion the physical observables are independent (as they should be) of the value of the renormalization scale \(\mu\).
At LO only two chiral parameters appear, namely $B$ (related to the chiral condensate) and $F$. At NLO three further LEC’s, $\ell_3$, $\ell_4$, and $\ell_6$, are present. At NNLO the total number of LEC’s increases up to 11 due to the inclusion of $\ell_1$, $\ell_2$, $r_m^*$, $r_F^*$, $r_1^*$, and $r_2^*$.

We notice that the NNLO terms for the charge radius (64) and the curvature (67) do not depend upon the LEC’s $\ell_1$ and $\ell_2$ separately, but only through the linear combination $(\ell_1^* - \ell_2^*/2)$. However different linear combinations of $\ell_1^*$ and $\ell_2^*$ appear in the NNLO terms of both the pion mass (58) and decay constant (61). Therefore the LEC’s $\ell_1^*$ and $\ell_2^*$ can be determined by a simultaneous analysis of the charge radius (and/or the curvature) together with the pion mass and decay constant.

In what follows the $O(p^4)$ constants $\ell_i^*$ will be substituted by scale-invariant quantities, $\bar{\ell}_i$, defined via the relations

$$\ell_i^* \equiv \frac{\gamma_i}{2N} \left[ \bar{\ell}_i + NL(\mu) \right]. \quad (69)$$

The new quantities, which depend (logarithmically) on the quark mass, can be expressed as $\bar{\ell}_i = \log(\Lambda_i^2/2B\hat{m})$ and their values are commonly given at the physical point.

We notice that in Ref. [11] the quark mass is not actually used as the expansion parameter. Instead of it the physical pion mass and decay constant are adopted. In order to recover the formulae of Ref. [11] it’s enough to replace in Eqs. (56)-(68) $x_2$ with $M_\pi^2/f_\pi^2$, $L(\mu)$ with $(1/N) \cdot \log(M_\pi^2/\mu^2)$ and to set $\Delta_M = \Delta_F = 0$ wherever they appear explicitly.

As explained in Sec. 4.4 we apply to the pion mass and decay constant the corrections for FSE computed in Ref. [45]. Using again the quark mass $\hat{m}$ as the expansion parameter, one gets

$$\frac{M_\pi(L) - M_\pi}{M_\pi} = \frac{2x_2}{N} \sum_{n=1}^{\infty} \frac{m(n)}{\lambda_n} \left\{ K_1(\lambda_n) - 2 \frac{x_2}{N} \left[ K_1(\lambda_n) \left( -\frac{55}{18} + 4\bar{\ell}_1 + \frac{8}{3}\bar{\ell}_2 - \frac{5}{2}\bar{\ell}_3 - 2\bar{\ell}_4 \right) + \frac{K_2(\lambda_n)}{\lambda_n} \left( \frac{112}{9} - \frac{8}{3}\bar{\ell}_1 - \frac{32}{3}\bar{\ell}_2 \right) + \frac{1}{3} g_0 K_1(\lambda_n) - \frac{1}{3} (40g_0 + 32g_1 + 26g_2) \frac{K_2(\lambda_n)}{\lambda_n} + \frac{N}{2} [\Delta_M \lambda_n K_0(\lambda_n) + 2\Delta_F K_1(\lambda_n)] \right\} + O(\hat{m}^3), \quad (70)$$

34
\[
\frac{f_\pi(L) - f_\pi}{f_\pi} = -2 \frac{2x_2}{N} \sum_{n=1}^{\infty} \frac{m(n)}{\lambda_n} \left\{ 2K_1(\lambda_n) - \frac{2x_2}{N} \left[ K_1(\lambda_n) \left( -\frac{7}{9} + 2\ell_1 + \frac{4}{3}\ell_2 - 3\ell_4 \right) + \frac{K_2(\lambda_n)}{\lambda_n} \left( \frac{112}{9} - \frac{8}{3}\ell_1 - \frac{32}{3}\ell_2 \right) + \frac{1}{6} (8g_0 - 13g_1) K_1(\lambda_n) - \frac{1}{3} (40g_0 - 12g_1 - 8g_2 - 13g_3) \frac{K_2(\lambda_n)}{\lambda_n} + N [\Delta M \lambda_n K_0(\lambda_n) + 2\Delta_F K_1(\lambda_n)] \right\} + O(\hat{m}^3),
\]

where \( K_{0,1,2} \) are modified Bessel functions, the values of the multiplicities \( m(n) \) are given in Ref. [45] and

\[
\lambda_n \equiv \sqrt{n} \sqrt{2B\hat{m}} L, \\
g_0 \equiv 2 - \frac{\pi}{2}, \\
g_1 \equiv \frac{\pi}{4} - \frac{1}{2}, \\
g_2 \equiv \frac{1}{2} - \frac{\pi}{8}, \\
g_3 \equiv \frac{3\pi}{16} - \frac{1}{2}.
\]

Notice that in Eqs. (70)-(71) no further LEC is introduced with respect to Eqs. (56)-(61).

In order to recover the formulae of Ref. [45], where the physical pion mass and decay constant are adopted as expansion parameters, it is enough to replace in Eqs. (70)-(71) \( x_2 \) with \( M_\pi^2/f_\pi^2 \), \( \lambda_n \) with \( \sqrt{n} M_\pi L \) and to set \( \Delta M = \Delta F = 0 \).

### 5.2 Chiral fits

Let us now apply Eqs. (56)-(67) to the analyses of the quark mass dependence of our results. As explained in the previous Section the set of lattice data chosen for the fitting procedure is given by the results of the runs \( R_1, R_{2a}, R_3, R_4, R_{5a} \) and \( R_6 \) for four quantities: the pion mass and decay constant, the charge radius and the curvature of the pion form factor. In case of the pion mass and decay constant also the results of the run \( R_{2b} \) are considered and the FSE corrections given by Eqs. (70)-(71) are applied.

Since each run corresponds to an independent ensemble of gauge configurations a bootstrap procedure is applied in order to combine all the jackknives in different
ways (1000 samples are used in practice). The statistical uncertainties, which are reported here after, are therefore bootstrap errors.

In order to fix the lattice spacing and the up/down quark mass the experimental values of the pion mass and decay constant \( M_{\text{phys.}}^\pi = 134.98 \text{ MeV} \) and \( f_{\pi}^{\text{phys.}} = 130.7 \pm 0.4 \text{ MeV} \) from Ref. [22]) are used\(^{10}\). We determine firstly the value of the bare quark mass \( a m_{\pi} \), at which the pion assumes its physical mass, by requiring that the ratio \( M_{\pi}/f_{\pi} \) from Eqs. (56) and (59) takes the experimental value \( 134.98/130.7 \approx 1.033 \). Secondly, using the physical value \( f_{\pi}^{\text{phys.}} \) the lattice spacing \( a \) is determined. The value of the renormalized light quark mass in the \( \overline{\text{MS}} \) scheme, \( m_{\overline{\text{MS}}}(2 \text{ GeV}) \), is obtained from \( a m_{\pi} \) by considering the determination of the non-perturbative (multiplicative) renormalization constant \( Z_m = 1/Z_F \), evaluated using the RI-MOM scheme in Ref. [41], and the matching factor with the \( \overline{\text{MS}} \) scheme, which is known up to four loops [51].

We start with a ChPT analysis at NLO including our lattice data only for the pion mass and decay constant up to \( M_{\pi} \approx 500 \text{ MeV} \) in order to compare with the ETMC NLO analyses of Refs. [23, 24, 34]. The main differences are: i) the use of a single lattice spacing \( (a \approx 0.09 \text{ fm}) \) both in the present work and in Refs. [23, 24], while the results obtained from two lattice spacings \( (a \approx 0.07 \text{ and } 0.09 \text{ fm}) \) are taken into account in Ref. [34]; ii) a better statistical accuracy of the data for \( M_{\pi} \) and \( f_{\pi} \) in Refs. [23, 24, 34] due to the use of all the (correlated) trajectories produced by the ETM collaboration with respect to the present work in which only a subset of 240 (uncorrelated) trajectories are employed; iii) the presence of the results of the run \( R_1 \) at \( M_{\pi} \approx 260 \text{ MeV} \) in the present work and in Ref. [34] at variance with Refs. [23, 24].

Following Ref. [24] the FSE correction can be evaluated beyond NLO using Eqs. (70)-(71) and adopting for the unknown LEC’s \( \bar{\ell}_1 \) and \( \bar{\ell}_2 \) the central values given in Ref. [33]. The values obtained for the fitting parameters (the LEC’s of the chiral Lagrangian) are given in the second column of Table [5] while the best fit at NLO, including the FSE corrections given by Eqs. (70)-(71), is shown in Fig. [12] by the dashed lines.

It can be seen that the values of all the chiral parameters, in particular of the LEC’s \( \bar{\ell}_3 \) and \( \bar{\ell}_4 \), as well as the values of the lattice spacing \( a \) and the light quark mass \( \hat{m}_{\overline{\text{MS}}} \), are consistent with the findings of Refs. [23, 24, 34]. Note also that the statistical precision of the extracted values of \( \bar{\ell}_3 \) and \( \bar{\ell}_4 \) are very similar in this work and in Refs. [23, 24, 34].

The theoretical evaluation of FSE effects given by Eqs. (70)-(71) appears to work quite well. Indeed after applying the FSE corrections, the pion masses and decay constants corresponding to the runs \( R_{2a} \) (at \( L = 32a \)) and \( R_{2b} \) (at \( L = 24a \))

\(^{10}\)In order to account for the e.m. isospin breaking effects which are not introduced in the lattice simulations, we use the experimental value of the neutral pion mass in accord with Refs. [49, 50].
Table 5: Values of the chiral parameters, the lattice spacing and the renormalized quark mass \( \hat{m} = m_{\text{MS}}(2 \text{ GeV}) \) at the physical point for various ChPT analyses (see text). For consistency with \( \hat{m} \), the parameter \( B \) is given in the \( \overline{\text{MS}} \) scheme at a scale equal to 2 GeV. The values of the parameters \( r_{M}^r \), \( r_{P}^r \), \( r_{1}^r \) and \( r_{2}^r \) are given at the \( \rho \)-meson mass scale. In the case of the NLO analysis the parameters \( \ell_{1} \) and \( \ell_{2} \) are used only for evaluating FSE’s, while the parameter \( \ell_{6} \) is fixed by the experimental value of the pion charge radius. The latter is not included in the NNLO analyses. The uncertainties are statistical (bootstrap) errors only.

become consistent within one standard deviation, as shown in Table 6.

Table 6: Values of the quantities \( aM_{\pi}(L = 24a)/aM_{\pi}(L = 32a) - 1 \) and \( af_{\pi}(L = 24a)/af_{\pi}(L = 32a) - 1 \) from the runs \( R_{2a} \) and \( R_{2b} \) at a pion mass of \( \approx 300 \text{ MeV} \). The lattice results correspond to the values given in Table 5. The theoretical results are those corresponding to Eqs. (70)-(71) using for the relevant LEC’s the values reported in the second column of Table 5.

We have checked that the full exclusion of the run \( R_{2b} \) from our analyses does
Fig. 12: The ratio of the squared pion mass to the renormalized quark mass $\hat{m} = m^{\overline{MS}}(2 \text{ GeV})$ (a) and the pion decay constant (b) versus $\hat{m}$ in physical units. The points at the highest value of $\hat{m}$ are not included in the analysis. The dots are the ETMC results, corrected by the FSE effects given by Eqs. (70)-(71), and the squares represent the experimental value for each quantity from Ref. [22]. The dashed lines correspond to the region selected at $1\sigma$ level by the ChPT analysis at NLO [see Eqs. (56)-(57) and (59)-(60)]. The values of the fitting parameters are listed in the second column of Table [5].

not have any significant impact on the chiral fits as well as on the values obtained for the chiral parameters. Therefore, since the runs $R_{2a}$ and $R_{2b}$ are compatible once theoretical FSE’s are included through Eqs. (70)-(71), in what follows we shall not show the results of the run $R_{2b}$ in the figures (i.e. we show only lattice data having $M_\pi L \gtrsim 4$) and we will always apply to the pion mass and decay constant the FSE corrections given by Eqs. (70)-(71).

The quality of the NLO fit shown in Fig. [12] is quite remarkable, leaving apparently little room for higher-order corrections even at the highest pion mass ($\simeq 580$ MeV), though the latter point is not included in the fitting procedure. However we now show that the same does not hold for the charge radius and the curvature of the pion form factor.

The NLO prediction for the charge radius [see Eq. (63)] depends in practice only on one LEC, $\ell_6$, being $F$ fixed by the analysis of the pion decay constant with a precision of the level of $\simeq 1\%$ (see the second column of Table [5]). Note also that both the derivative of $\langle r^2 \rangle_{\text{NLO}}$ with respect to the quark mass and the curvature $\langle c \rangle_{\text{NLO}}$ (see Eq. 60) are independent of $\ell_6$ and therefore basically parameter-free.
The value of the LEC $\bar{\ell}_6$ can be determined from the experimental value of the squared charge radius, $\langle r^2 \rangle_{\text{exp.}} = 0.452 \pm 0.011 \text{ fm}^2$ \cite{22}, since the latter is expected to be dominated by the NLO term \cite{63}. This leads to $\bar{\ell}_6 = 14.59 \pm 0.03$ (see the second column of Table 5). The corresponding NLO predictions for the charge radius and the curvature are shown in Fig. 13 by the dashed lines. They significantly overestimate our lattice data for the charge radius and largely underestimate those for the curvature.

Alternatively we have excluded the experimental value of the charge radius and included in the fitting procedure the lattice data of the charge radius for pion masses up to $\simeq 500 \text{ MeV}$ (i.e. for $\hat{m} \lesssim 0.05 \text{ GeV}$) obtaining $\bar{\ell}_6 = 11.6 \pm 0.3$ (with $\chi^2$/d.o.f. $\simeq 1.2$). The corresponding NLO predictions are shown in Fig. 13 by the dotted lines. At the physical point the charge radius is $\langle r^2 \rangle_{\text{phys.}} = 0.352 \pm 0.008 \text{ fm}^2$ in clear contradiction with the experimental value.$^{11}$

Moreover, since the curvature is independent on $\bar{\ell}_6$, any NLO fit is unable to provide enough large values of the curvature consistent with the relation \cite{54}, i.e. with the pole behavior of the pion form factor observed in subsection 4.3. Such a finding suggests that a NLO analysis of the pion form factor is applicable only to quite low values of $|q^2|$ (see later Section 6).

Thus, both the NLO results shown in Fig. 13 and the smallness of the systematic effects due to finite volumes and lattice spacings, estimated in subsections 4.4 and 4.5 indicate that the quark mass dependences of our lattice data for both the charge radius and the curvature require to take into account chiral effects beyond the NLO.

The results of the fit performed using ChPT at NNLO [i.e. based on Eqs. (56)-(67)] are shown in Fig. 14, while the values of the fitting parameters are listed in the third column of Table 5 with the renormalization scale $\mu$ fixed at the physical $\rho$-meson mass. Notice that the experimental value of the pion charge radius is not included in the fitting procedure.

As already found in Ref. [24], the inclusion of NNLO effects leads to quite large uncertainties in the values of all the LEC’s, in particular both for the LEC’s $\bar{\ell}_3$ and $\bar{\ell}_4$ appearing at NLO and NNLO, and for the LEC’s $\bar{\ell}_1$ and $\bar{\ell}_2$ appearing only at NNLO. Nevertheless the uncertainties in the chiral fits shown in Fig. 14 are of the order of the statistical errors in the mass range of the lattice points. This means that the large uncertainties reported in the third column of Table 5 are strongly correlated; the effect of the variation of one fitting parameter can be always compensated by those generated by the variations of the other parameters. However when we extrapolate the chiral predictions for the pion mass and decay

$^{11}$If only the lattice data of the charge radius for the two lowest pion masses ($M_\pi \lesssim 300 \text{ MeV}$) are considered, the value of $\bar{\ell}_6$ becomes $12.8 \pm 0.5$ (with $\chi^2$/d.o.f. $\simeq 0.65$) and the predicted charge radius at the physical point is $\langle r^2 \rangle_{\text{phys.}} = 0.393 \pm 0.017 \text{ fm}^2$, which still deviates from the experimental value by three standard deviations.
Fig. 13: The squared charge radius (a) and the curvature (b) of the pion form factor versus the renormalized quark mass \( \hat{m} \) in physical units. The dots are our lattice results and the square represents the experimental value of the squared charge radius \([22]\). The dashed and dotted lines represent the region selected at 1σ level by the ChPT predictions at NLO given by Eqs. (63) and (66). In the case of the dashed lines the value of the LEC \( \ell_6 \) is fixed by the experimental charge radius, while in the case of the dotted lines it is obtained by including in the fitting procedure our lattice data of the charge radius for pion masses up to \( \simeq 500 \) MeV (i.e. for \( \hat{m} \lesssim 0.05 \) GeV).

constant outside the mass range of the lattice data towards the chiral point we end up with rather large uncertainties as shown in Fig. 14.

Such a situation is clearly unsatisfactory both for a precise extraction of the LEC’s and for the extrapolation to the physical point. The inclusion of the experimental values of the pion charge radius and curvature in the set of fitted data can obviously reduce the uncertainties in the extraction of the chiral parameters, but in this way the predictive power of the chiral fits is lost.

Thus we look for an observable which should be: i) unrelated to the vector form factor of the pion, ii) known experimentally and iii) whose chiral expansion at NLO contains one of the LEC’s, let’s say \( \ell_3 \) or \( \ell_4 \). In this way the experimental value of such an observable, expected to be dominated by the NLO contribution, can constrain sufficiently the range of the variability of one of the LEC’s. In turn this could be beneficial to reduce the uncertainties of all our fitting parameters.

A possible, appropriate choice is the squared radius \( \langle r^2 \rangle_S \) of the pion “scalar”
Fig. 14: The ratio $M_{\pi}^2/\hat{m}$ (a), the pion decay constant (b), the charge radius (c) and the curvature (d) of the pion form factor versus the renormalized quark mass $\hat{m}$ in physical units. The dots are our lattice results and the squares represent the corresponding experimental values from PDG [22]. The dashed lines correspond to the region selected at $1\sigma$ level by the ChPT fit at NNLO based on Eqs. (56)-(67). The values of the fitting parameters are listed in the third column of Table 5. The experimental value of the pion charge radius is not included in the fitting procedure.

form factor, defined as

$$\langle r^2 \rangle_S \equiv \frac{6}{F_\pi^S(0)} \left[ \frac{dF_\pi^S(q^2)}{dq^2} \right]_{q^2=0}, \quad (73)$$
where

\[ F^S_\pi(q^2) = \langle \pi^+(p')|\bar{u}u + \bar{d}d|\pi^+(p)\rangle \]  

Indeed, on one hand side the experimental value of the pion scalar radius is known quite accurately from the analysis of \( \pi^-\pi^+ \) scattering data (see Ref. [33]), which gives

\[ \langle r^2 \rangle^{\text{exp.}}_S = 0.61 \pm 0.04 \text{ fm}^2. \]  

On the other hand side the chiral expansion of \( \langle r^2 \rangle_S \), calculated at NNLO in Ref. [11], reads as

\[ \langle r^2 \rangle_S = \left[ \langle r^2 \rangle_{\text{NLO}} + \langle r^2 \rangle_{\text{NNLO}} + O(\hat{m}^2) \right], \]  

\[ \left[ \langle r^2 \rangle_{\text{NLO}} \right] = \frac{2}{F^2} \left( 6\ell_4' - 6L(\mu) - \frac{13}{2N} \right), \]  

\[ \left[ \langle r^2 \rangle_{\text{NNLO}} \right] = \frac{4}{F^2} \left\{ \frac{1}{N} \left[ 88\ell_1' + 36\ell_2' + 5\ell_3' - 13\ell_4' + \frac{145}{36}L(\mu) \right] - \frac{23}{192} + \frac{869}{108N} \right\} + 31k_1 + 17k_2 - 6k_4 + 12\ell_4'(\ell_4' - 2\ell_3') \]  

It can be seen that the LEC \( \bar{\ell}_4 \), which also governs the NLO correction to the pion decay constant [see Eq. (60)], appears in Eq. (77).

As already stressed, the experimental value \( \langle r^2 \rangle^{\text{exp.}}_S \) is expected to be dominated by the NLO contribution (77). Using the values of the relevant LEC’s of the second column of Table 5 one gets \( \langle r^2 \rangle^{\text{exp.}}_{\text{NLO}} = 0.716 \pm 0.014 \text{ fm}^2 \), which overestimates the experimental value (75) by almost three standard deviations. Thus we want to use the NNLO calculation of \( \langle r^2 \rangle_S \), also for consistency with the use of Eqs. (56)-(67) for the other observables. In order to do that we need to set the value of the parameter \( r_S^r \) appearing in Eq. (78). In Ref. [11] an estimate of \( r_S^r \) at the \( \rho \)-meson mass scale has been obtained using a resonance model, namely \( r_S^r \approx -0.3 \cdot 10^{-4} \). We have checked that using the above value or putting the parameter \( r_S^r \) equal to zero does not produce any significant difference in our chiral fits. This is not surprising since the effects of a non-vanishing value of \( r_S^r \) are expected to be relevant at large quark masses only. Thus in what follows the value \( r_S^r = 0 \) is assumed.

Including the experimental value \( \langle r^2 \rangle^{\text{exp.}}_S \) in the ensemble of fitted data and Eqs. (76)-(78) in the fitting procedure, we obtain the results shown in Fig. 15 with
the values of the fitting parameters reported in the fourth column of Table 5. Let us remind that the experimental value of the pion charge radius is not included in the fitting procedure.

Our expectation about the reduction of the uncertainties of the fitting parameters is fully confirmed. Thanks to the introduction of the experimental value $\langle r^2 \rangle_S^{\text{exp.}}$ the value of $\bar{\ell}_4$ is determined quite accurately and this is beneficial for reducing the uncertainties of all the other LEC’s (compare the third and the fourth columns of Table 5).

Fig. 15: As in Fig. 14, but including the experimental value of the pion scalar radius from Ref. [33] in the fitting procedure. The resulting values of the fitting parameters are listed in the fourth column of Table 5.
Note that with respect to the NLO analysis the values of both the parameter $B$ and the lattice spacing, obtained in the NNLO analysis which includes $\langle r^2 \rangle_{exp.}$, change beyond the corresponding statistical errors. On the contrary the values of the LEC’s $F, \ell_3, \ell_4$ and $\ell_6$ do not change significantly.

Since our data used for the curvature rely on the assumption of the monopole behavior (see Eq. (54)), we have checked that the values of the LEC’s, extracted by including the curvature data obtained from the cubic fit (55), change only slightly within the statistical errors with respect to the ones reported in the fourth column of Table 5.

The values of the charge radius and the curvature predicted at the physical point by the chiral fit shown in Fig. 15, are $\langle r^2 \rangle_{phys.} = 0.456 \pm 0.030 \text{ fm}^2$ and $\epsilon_{phys.} = (5.11 \pm 0.47) \cdot 10^{-3} \text{ fm}^4$. We perform a rough estimate of the systematic errors due to finite volume and discretization effects. Firstly we substitute the run $R_{2a}$ with the run $R_{2b}$ and fit the new set of data; the changes in the central values of the chiral parameters provide an estimate of the finite volume effects. Secondly we further substitute the runs $R_{2b}$ and $R_{5a}$ with the runs $R_{2c}$ and $R_{5b}$ at the finer lattice spacing, respectively, obtaining an estimate of discretization effects. Adding all the systematic uncertainties in quadrature, our final results are

$$\langle r^2 \rangle_{phys.} = 0.456 \pm 0.030 \pm 0.024 \text{ fm}^2,$$  

$$\epsilon_{phys.} = (5.11 \pm 0.47 \pm 0.41) \cdot 10^{-3} \text{ fm}^4.$$  

where the first error is statistical and the second one systematic. We remind that the findings (79) and (80) are not completely independent, because they are based on an ensemble of fitted data which satisfy Eq. (54).

The results for the pion charge radius at the physical point obtained by various lattice collaborations performing unquenched calculations are compared in Table 7 and in Fig. 16.

| collaboration | $N_f$ | Action | $V - T / a^4$ | $a (\text{fm})$ | $M_u (\text{MeV})$ | $\langle r^2 \rangle_{phys.} (\text{fm}^2)$ |
|--------------|------|--------|--------------|---------------|----------------|----------------------------------------|
| ETM [this work] | 2    | $tSym + tmW$ | $32 \cdot 64$ | $\sim 0.09$ | $\geq 260$ | $0.456 \pm 0.038$ |
| JLQCD [20] | 2    | Tc. + overlap | $16 \cdot 32$ | $\sim 0.12$ | $\geq 290$ | $0.404 \pm 0.031$ |
| JLQCD [18] | 2    | plaq. + Clover | $20 \cdot 48$ | $\sim 0.09$ | $\geq 350$ | $0.396 \pm 0.010$ |
| QCDSF/UKQCD [19] | 2    | plaq. + Clover | $24 \cdot 48$ | $\sim 0.08$ | $\geq 400$ | $0.441 \pm 0.019$ |
| UKQCD/ABC [2] | 2 + 1 | DWF | $16 \cdot 32$ | $\sim 0.12$ | $\geq 350$ | $0.418 \pm 0.031$ |
| LHP [14] | 2 + 1 | Asqtad + DWF | $20 \cdot 64$ | $\sim 0.12$ | $\geq 320$ | $0.340 \pm 0.046$ |

Table 7: Results for the pion charge radius extrapolated at the physical point by various lattice collaborations performing unquenched calculations. The uncertainty of the ETM result corresponds to the statistical and the systematic errors, given by Eq. (79), added in quadrature.
Our finding \((79)\) agrees very well with the experimental value \(\langle r^2 \rangle_{\text{exp.}} = 0.452 \pm 0.011 \text{ fm}^2\) \([22]\). It is also consistent within the errors with the results of JLQCD \((N_f = 2)\), QCDSF/UKQCD \((N_f = 2)\) and UKQCD/RBC \((N_f = 2 + 1)\) collaborations, while the difference with the result of LHP \((N_f = 2 + 1)\) collaboration is equal to \(\approx 2\) standard deviations.

We stress that the use of twisted BC’s and the inclusion of the NNLO terms in the ChPT analyses are two important features considered in this work. Note that twisted BC’s are used only in Ref. \([21]\) and a NNLO ChPT analysis is carried out only in Ref. \([20]\).

The ETMC result \((79)\) has been obtained by fitting the lattice data for values of the (squared) four-momentum transfer \(Q^2 = -q^2\) up to 0.5 GeV\(^2\) using the pole ansatz \((48)\) or equivalently the monopole functional form

\[
F^{(\text{monopole})}_\pi(Q^2) = \frac{1}{1 + \frac{\langle r^2 \rangle_{\text{phys.}}}{6} Q^2}.
\]  

An interesting question is at which value of \(Q^2\) the predictions based on Eq. \((81)\) start to deviate from the experimental data. Recently, thanks to the CEBAF facility at JLab, the pion form factor has been measured quite accurately up to few GeV\(^2\). The comparison with the monopole prediction \((81)\), using for the (squared) pion charge radius either the ETMC result \((79)\) or its experimental value from PDG \([22]\), is illustrated in Fig. 17.

It can clearly be seen that there is no hint of a deviation of the experimental data from the monopole ansatz up to \(Q^2 \approx 2 \div 3\) GeV\(^2\).

New experimental data up to \(Q^2 \simeq 6\) GeV\(^2\), expected to be taken after the completion of the JLab upgrade to 12 GeV \([52]\), may shed light on the range of
Fig. 17: Pion form factor times \( Q^2 = -q^2 \), \( Q^2 F_\pi(Q^2) \), versus \( Q^2 \) in physical units. The dots, squares and diamonds are experimental data from Refs. [1], [3, 4] and [5, 6, 7, 8], respectively. The dashed and solid lines correspond to the regions selected at 1\( \sigma \) level by the predictions of the monopole form (81) using \( \langle r^2 \rangle = \langle r^2 \rangle_{\text{exp.}} = 0.452 \pm 0.011 \text{ fm}^2 \) [22] and \( \langle r^2 \rangle = \langle r^2 \rangle_{\text{phys.}} = 0.456 \pm 0.038 \text{ fm}^2 \), respectively.

validity of the monopole ansatz.

5.3 Polynomial fit

We want to discuss briefly an alternative fit to our lattice data based on a simple polynomial form, which does not have any logarithmic term; namely

\[
M_\pi^2 = 2 \bar{B} \hat{m} \cdot [1 + C_1 \hat{m} + C_2 \hat{m}^2] , \tag{82}
\]

\[
f_\pi = \bar{F} \cdot [1 + D_1 \hat{m} + D_2 \hat{m}^2] , \tag{83}
\]

\[
\langle r^2 \rangle = 6/(M_0 + E_1 \hat{m} + E_2 \hat{m}^2)^2 . \tag{84}
\]

The results of such a fit, applied to our lattice data having \( M_\pi L \gtrsim 4 \) without applying any FSE correction, are illustrated in Figs. 18 and 19.

Among the fitting parameters we obtain \( 2\bar{B} = 4.79 \pm 0.08 \) GeV and \( \bar{F} = 126 \pm 2 \) MeV, while the lattice spacing turns out to be \( a = 0.0889 \pm 0.0010 \) fm and the (renormalized) up/down quark mass is \( \hat{m}_{\text{phys.}} = 3.8 \pm 0.1 \) MeV.

It can clearly be seen that the quality of the polynomial fit is quite similar to the one of the ChPT fit shown in Fig. 15 and therefore we have to conclude that our lattice results do not show a clear-cut evidence of chiral logs.
6 Chiral fits of the pion form factor

In this Section we present the ChPT analysis of our results for the pion form factor including its momentum dependence. The ChPT expansion of $F_\pi(q^2)$ has been calculated in Ref. [11] at NNLO, obtaining

$$F_\pi(q^2) = 1 + [F_\pi(q^2)]_{1\text{-loop}} + [F_\pi(q^2)]_{2\text{-loops}} + \mathcal{O}(\hat{m}^3), \quad (85)$$

$$[F_\pi(q^2)]_{1\text{-loop}} = 2x_2 \left[ \frac{1}{6}(w - 4)\bar{J}(w) - w \left( \ell_6^r + \frac{1}{6}L(\mu) + \frac{1}{18N} \right) \right], \quad (86)$$

$$[F_\pi(q^2)]_{2\text{-loops}} = 4x_2^2 \left\{ P_V(w) + U_V(w) - \Delta_M \bar{J}(w) - \Delta_F \left[ \frac{1}{6}(w - 4)\bar{J}(w) - w \left( \ell_6^r + \frac{1}{6}L(\mu) + \frac{1}{18N} \right) \right] \right\}, \quad (87)$$

Fig. 18: The ratio $M_\pi^2/\hat{m}$ (a) and the pion decay constant (b) versus renormalized quark mass $\hat{m}$ in physical units. The dots are the ETMC results, uncorrected for FSE effects, and the squares represent the experimental value for each quantity from PDG [22]. The dotted lines correspond to the region selected at 1σ level by the polynomial fits of the squared pion mass [82] and decay constant [83].
Fig. 19: The charge radius of the pion form factor versus the renormalized quark mass \( \hat{m} \) in physical units. The dots are the ETMC results and the squares represent the experimental value of the pion charge radius \([22] \), which is not included in the fitting procedure. The dotted lines correspond to the region selected at 1\( \sigma \) level by the polynomial fit \((84)\).

where \( w \equiv q^2/2B\hat{m} \). The polynomial part \( P_V(w) \) is given by

\[
P_V(w) = w \left[ -\frac{1}{2}k_1 + \frac{1}{4}k_2 - \frac{1}{12}k_4 + \frac{1}{2}k_6 + r_1^p \right. \\
+ \frac{1}{N} \left( \frac{23}{36}L(\mu) + \frac{5}{576} + \frac{37}{864N} \right) - \ell_4'^p \left( 2\ell_6'^p + \frac{1}{9N} \right) \left. \right]
+ w^2 \left[ \frac{1}{12}k_1 - \frac{1}{24}k_2 + \frac{1}{24}k_6 + r_2^p \right. \\
+ \frac{1}{9N} \left( \ell_1'^p - \frac{1}{2}\ell_2'^p + \frac{1}{2}\ell_6'^p - \frac{1}{12}L(\mu) - \frac{1}{384} - \frac{47}{192N} \right) \right],
\]

(88)

while the dispersive part \( U_V(w) \) reads as

\[
U_V(w) = \bar{J}(w) \left[ -\frac{1}{3}w(w - 4) \left( \ell_1'^p - \frac{1}{2}\ell_2'^p + \frac{1}{2}\ell_6'^p \right) + \frac{1}{3}\ell_5'^p (w - 4) \right. \\
- \frac{1}{36}L(\mu)(w^2 + 8w - 48) + \frac{1}{108N}(7w^2 - 97w + 81) \left. \right] + \frac{1}{9}H_1(w) \\
+ \frac{1}{9}H_2(w) \left( \frac{1}{8}w^2 - w + 4 \right) + \frac{1}{6}H_3(w) \left( w - \frac{1}{3} \right) - \frac{5}{3}H_4(w),
\]

(89)
where
\[ \bar{J}(w) = z h(z) + \frac{2}{N}, \]  
(90)
\[ H_1(w) = z h^2(z), \]  
(91)
\[ H_2(w) = z^2 h^2(z) - \frac{4}{N^2}, \]  
(92)
\[ H_3(w) = N \frac{z}{w} h^3(z) + \frac{\pi^2}{N} h(z) - \frac{\pi^2}{2N^2}, \]  
(93)
\[ H_4(w) = \frac{1}{wz} \left( \frac{1}{2} H_1(w) + \frac{1}{3} H_3(w) + \frac{1}{N} \bar{J}(w) + \frac{\pi^2 - 6}{12N^2} w \right), \]  
(94)
with \( z \equiv 1 - 4/w \) and
\[ h(z) = \frac{1}{N\sqrt{z}} \log \frac{\sqrt{z} - 1}{\sqrt{z} + 1}. \]  
(95)

Using the above formulae it is possible to test the momentum dependence of the pion form factor predicted by ChPT at NNLO. Such a dependence is analytical up to the inelastic threshold \( q^2_{thr} = 4M^2 \). Thus, in the chiral limit, terms of the form \( q^2 \log(-q^2) \) appear in the pion form factor, which becomes a non-analytic function of \( q^2 \). This is the origin of the divergency of both the charge radius and the curvature in the chiral limit [see Eqs. (62)-(67)].

It is easy to check that an expansion of Eqs. (85)-(87) in powers of \( q^2 \) leads to the result: \( F_\pi(q^2) = 1 + \langle r^2 \rangle q^2/6 + c q^4 + O(q^6) \), with \( \langle r^2 \rangle \) and \( c \) given by Eqs. (62)-(64) and Eqs. (65)-(67), respectively. Thus by using Eqs. (85)-(87) it is possible to take into account (at least partially) the effects of order \( O(q^6) \) in the momentum dependence of the pion form factor.

Note that the NNLO terms (87-89) do not depend upon the LEC’s \( \ell_1^r \) and \( \ell_2^r \) separately, but only through the linear combination \( (\ell_1^r - \ell_2^r/2) \). Since different linear combinations of \( \ell_1^r \) and \( \ell_2^r \) appear in the NNLO terms of both the pion mass (58) and decay constant (61), the LEC’s \( \ell_1^r \) and \( \ell_2^r \) can be determined by a simultaneous analysis of the form factor together with the pion mass and decay constant.

As already discussed in subsection 5.2 at NLO the pion form factor depends on one LEC, \( \ell_6 \), which governs only the linear term in \( q^2 \). The ChPT predictions at NLO corresponding respectively to \( \ell_6 = 14.59 \pm 0.03 \) and \( \ell_6 = 11.6 \pm 0.3 \) (with \( 2B = 5.21 \pm 0.05 \) GeV and \( F = 121.7 \pm 1.1 \) MeV), reported already in Fig. 13 in the case of the pion charge radius and curvature, are shown in Fig. 20 for various values of the pion mass. We remind that the value \( \ell_6 = 14.59 \pm 0.03 \) is fixed by the reproduction of the experimental charge radius, while the value \( \ell_6 = 11.6 \pm 0.3 \) is obtained by fitting our lattice data of the charge radius for pion masses up to \( \simeq 500 \) MeV. It can be seen that:
• the momentum dependence predicted by ChPT at NLO is almost linear at variance with the pole behavior (48) observed in our lattice data [see also Fig. 13(b)];

• using $\bar{\ell}_6 = 11.6 \pm 0.3$ the NLO approximation appears to work up to $Q^2 \equiv -q^2 \approx 0.15$ GeV$^2$ and for pion masses below $\approx 300$ MeV. With such a value of $\bar{\ell}_6$ the NLO formula (63) yields $\langle r^2 \rangle_{\text{phys.}} = 0.352 \pm 0.008$ fm$^2$, which underestimates significantly the experimental charge radius (see subsection 5.2). A slight improvement can be achieved by using directly the NLO formula (86) to fit our lattice data for the pion form factor at the lowest $Q^2$-value ($\approx 0.05$ GeV$^2$) and for the two lowest pion masses ($M_\pi \approx 260$ and $\approx 300$ MeV). We obtain $\bar{\ell}_6 = 12.2 \pm 0.5$ corresponding to $\langle r^2 \rangle_{\text{phys.}} = 0.373 \pm 0.017$ fm$^2$, which still deviates from the experimental value by four standard deviations;

• using $\bar{\ell}_6 = 14.59 \pm 0.03$, which instead reproduces the experimental value of the pion charge radius, the range of applicability of the NLO approximation reduces to values of $Q^2$ at least not larger than $\approx 0.03$ GeV$^2$ and to pion masses below $\approx 300$ MeV, which are not covered by our present lattice data ($Q^2 \gtrsim 0.05$ GeV$^2$). We notice that within the above restricted range of values of $Q^2$ and pion masses the deviation of the pion form factor from unity becomes smaller than few percent and therefore a particular attention should be paid to the statistical precision as well as to the systematic uncertainties related to cut-off and finite size effects.

From Fig. 20 it is clear that the description of our lattice data requires the inclusion of higher-order ChPT effects, which should be much larger than the finite volume corrections and the scaling violations observed in Figs. 8 and 9 for the values of $Q^2$ and $M_\pi$ considered in our calculations. We have therefore performed a simultaneous NNLO fit of the lattice data of the runs $R_1, R_{2a}, R_3, R_4, R_{5a}$ and $R_6$ for the quantities $M_\pi, f_\pi$ and $F_\pi(Q^2)$, including all values of $Q^2 \equiv -q^2$ from $\approx 0.05$ GeV$^2$ up to $\approx 0.8$ GeV$^2$. As in the previous Section, the constraint (75) on the pion scalar radius is included in the fitting procedure in order to reduce the uncertainties in the extracted values of the chiral parameters. The latter are given in the second column of Table 8. The nice quality of the NNLO fit is illustrated in Figs. 21 and 22. The corresponding value of the pion charge radius, calculated at the physical point using Eqs. (62-64), is $\langle r^2 \rangle_{\text{phys.}} = 0.438 \pm 0.029$ fm$^2$, in nice agreement with the finding (79), which, we remind, is based on the use of the pole ansatz (48) that describes very well the momentum dependence of our lattice data (see Figs. 7 and 20).

The comparison of the results shown in the fourth column of Table 5 and those in the second column of Table 8 clearly indicates that within the statistical uncertainties the extracted values of the chiral parameters are quite stable against
Fig. 20: Pion form factor $F_\pi(Q^2)$ versus the squared 4-momentum transfer $Q^2 \equiv -q^2$ in physical units, for the run $R_1$ at $M_\pi \simeq 260$ MeV (a), the run $R_{2a}$ at $M_\pi \simeq 300$ MeV (b), the run $R_3$ at $M_\pi \simeq 380$ MeV (c) and the run $R_4$ at $M_\pi \simeq 440$ MeV (d). For the lattice spacing the value $a = 0.0861$ fm is adopted from the second column of Table 5. The solid line is the pole behavior (48) with the parameter $M_{\text{pole}}$ fitted to the lattice points. The dashed and dotted lines are the regions selected at 1σ level by the ChPT predictions at NLO corresponding respectively to $\ell_6 = 14.59 \pm 0.03$ and $\bar{\ell}_6 = 11.6 \pm 0.3$ with $2B = 5.21 \pm 0.05$ GeV and $F = 121.7 \pm 1.1$ MeV (see text).

Chiral effects of order $O(q^6)$ in the pion form factor with the only exception of the parameter $r_2^*$, which instead exhibit a rather large variation. The latter will be
in our analysis we repeat the NNLO fit by limiting the range of values of \( Q^2 \), i.e. by including only lattice data with \( Q^2 \leq 0.5 \) GeV\(^2\) (see third column of Table 8) and \( Q^2 \leq 0.3 \) GeV\(^2\) (see fourth column of Table 8). It can clearly be seen that, within the statistical precision, the extracted values of all the chiral parameters are only slightly sensitive to the \( Q^2 \)-range used and therefore to higher-order effects.

Table 8: Values of the chiral parameters, the lattice spacing and the renormalized light quark mass \( m = m_{\overline{MS}}(2 \text{ GeV}) \) at the physical point, obtained from the simultaneous ChPT analysis of the pion mass, decay constant and form factor made at NNLO using Eqs. (56)-(61) and (85)-(87), including also the constraint (75) on the pion scalar radius. The second, third and fourth columns correspond to different \( Q^2 \)-ranges of the lattice data of the form factor considered in the fitting procedure. The values of the parameters \( r_M^r, r_F^r, r_1^r \) and \( r_2^r \) are given at the \( \rho \)-meson mass scale. The uncertainties are statistical (bootstrap) errors only.

| parameter | \( Q^2 \leq 0.8 \) GeV\(^2\) | \( Q^2 \leq 0.5 \) GeV\(^2\) | \( Q^2 \leq 0.3 \) GeV\(^2\) |
|-----------|----------------|----------------|----------------|
| \( 2B \) (GeV) | 4.89 ± 0.10 | 4.91 ± 0.07 | 4.90 ± 0.09 |
| \( F \) (MeV) | 122.6 ± 1.1 | 122.5 ± 0.8 | 122.5 ± 1.0 |
| \( \ell_3 \) | 3.14 ± 1.03 | 3.24 ± 0.53 | 3.19 ± 0.81 |
| \( \ell_4 \) | 4.37 ± 0.27 | 4.41 ± 0.10 | 4.39 ± 0.19 |
| \( \ell_6 \) | 15.0 ± 0.9 | 14.8 ± 1.1 | 14.8 ± 1.5 |
| \( \ell_1 \) | −0.54 ± 1.01 | −0.31 ± 1.12 | −0.28 ± 1.91 |
| \( \ell_2 \) | 4.40 ± 0.78 | 4.29 ± 1.00 | 4.23 ± 1.52 |
| \( r_M^r \cdot 10^4 \) | −0.48 ± 0.30 | −0.43 ± 0.23 | −0.44 ± 0.37 |
| \( r_F^r \cdot 10^4 \) | 0.11 ± 0.19 | 0.08 ± 0.10 | 0.08 ± 0.20 |
| \( r_1^r \cdot 10^4 \) | −0.98 ± 0.12 | −0.94 ± 0.13 | −0.90 ± 0.14 |
| \( r_2^r \cdot 10^4 \) | 0.43 ± 0.03 | 0.46 ± 0.03 | 0.52 ± 0.05 |
| \( a \) (fm) | 0.0883 ± 0.0006 | 0.0883 ± 0.0006 | 0.0883 ± 0.0007 |
| \( m_{\text{phys}} \) (MeV) | 3.80 ± 0.09 | 3.79 ± 0.07 | 3.79 ± 0.09 |
| \( \chi^2 / \text{d.o.f.} \) | 29 / 34 | 19 / 28 | 13 / 22 |

Effects from higher orders in the chiral expansion are expected to become more and more important as the value of \( Q^2 \) increases. In order to check their relevance in our analysis we repeat the NNLO fit by limiting the range of values of \( Q^2 \), i.e. by including only lattice data with \( Q^2 \leq 0.5 \) GeV\(^2\) (see third column of Table 8) and \( Q^2 \leq 0.3 \) GeV\(^2\) (see fourth column of Table 8). It can clearly be seen that, within the statistical precision, the extracted values of all the chiral parameters are only slightly sensitive to the \( Q^2 \)-range used and therefore to higher-order effects.
Fig. 21: The ratio of the squared pion mass to the renormalized quark mass \( \hat{m} \) (a) and the pion decay constant (b) versus \( \hat{m} \) in physical units. The dots are the ETMC results and the squares represent the experimental value for each quantity from Ref. [22]. The dashed lines correspond to the region selected at 1\( \sigma \) level by the NNLO ChPT analysis of the ETMC results for the pion mass, decay constant and e.m. form factor. The experimental value of the pion scalar radius (75) is added to the fitting procedure employing Eqs. (76)-(78). The values of the fitting parameters are listed in the second column of Table 8.

Before closing this Section we mention that in Refs. [24, 33, 34] a different definition of the LEC’s at NNLO is adopted, namely the constants \( r_M \) and \( r_F \) are replaced by the constants \( k_M \) and \( k_F \). Using the results of the second column of Table 8 we obtain \( k_M = -0.6 \pm 1.6 \) and \( k_F = 1.2 \pm 1.5 \).

7 Final results for the LEC’s

In this Section we provide the final estimates of the LEC’s from the present work. Our results, including both the statistical and the systematic uncertainties, are collected in the second column of Table 9. They have been evaluated by averaging the three central values reported in Table 8, using the quoted errors as the weights.

As in the case of the charge radius and curvature, discussed in the previous Section, we estimate the systematic errors due to both finite volume and discretization effects. Firstly we substitute the run \( R_{2a} \) with the run \( R_{2b} \) and fit the new set of data; the changes in the central values of the chiral parameters provide an estimate of the finite volume effects. Secondly we further substitute the runs \( R_{2b} \) and \( R_{5a} \).
with the runs $R_{2c}$ and $R_{5b}$ at the finer lattice spacing, respectively, obtaining an estimate of discretization effects. All the systematic errors, which include also the spread of the central values of Table 8, are finally added in quadrature.

In Table 9 our estimates of the chiral parameters are compared with available results from NNLO ChPT analyses of $\pi - \pi$ scattering data from Ref. [33], and with estimates obtained using VMD models in Ref. [11]. Our values for the LEC’s $\ell_1$, $\ell_2$, $\ell_3$ and $\ell_4$ agree nicely with those extracted in Ref. [33]. The uncertainties obtained in this work for the LEC $\ell_4$ is quite similar to the one from Ref. [33], while $\ell_1$ and $\ell_2$ are determined more precisely in Ref. [33] and $\ell_3$ in the present work.

On the contrary the estimates of the counter-terms $r_1^r$ and $r_2^r$ obtained in Ref. [11] adopting VMD models turn out to be much larger than our values by a factor $\approx 2 \div 3$. 

Fig. 22: ETMC results for the pion e.m. form factor versus the renormalized quark mass $\hat{m}$ at various values of $Q^2 \equiv -q^2$. The various lines correspond to the regions selected at 1σ level by the ChPT fit at NNLO based on Eqs. (85)-(87) with the fitting parameters given in the second column of Table 8. The experimental value of the pion scalar radius $<r^2>_s$ is added to the fitting procedure using Eqs. (76)-(78).
Table 9: Values of the LEC’s obtained from the NNLO ChPT analyses of the previous Section and compared with available estimates arising either from NNLO ChPT analyses of $\pi-\pi$ scattering data [33] or from VMD models [11]. The values of the parameters $r_M$, $r_F$, $r_1$ and $r_2$ are given at the $\rho$-meson mass scale. In the second column the first error is statistical and the second one systematic.

The results obtained for the lattice spacing, $a = 0.0883 \pm 0.0006$ fm, and the renormalized up/down quark mass, $m^\text{phys.} = 3.79 \pm 0.08 \pm 0.15$ MeV, are consistent within the errors with the findings of Refs. [23] and [50] obtained at the same value of $\beta$ ($= 3.9$). The values $2B = 4.90 \pm 0.09 \pm 0.20$ GeV and $F = 122.5 \pm 1.0 \pm 1.0$ MeV correspond to a light-quark condensate equal to

$$\langle q\bar{q}\rangle^{MS}_{(2 \text{ GeV})} = (-264 \pm 3 \pm 5 \text{ MeV})^3,$$  

moreover, the ratio $f^\text{phys.}/F$ is equal to

$$f^\text{phys.}/F = 1.067 \pm 0.009 \pm 0.009.$$  

The findings (96) and (97) are in agreement with the corresponding values obtained by the scaling analysis of Ref. [34].

Using for the LEC’s the values given in Table 9 we have calculated the values of the pion form factor at the physical point for the various values of $Q^2$ considered in this work. Our results, including both statistical and systematic uncertainties, are collected in Table 10 and shown in Fig. 23, where they are also compared with available experimental data from Refs. [1, 3, 4, 5, 6, 7, 8].
Table 10: Values of the pion form factor $F_{\pi}^{\text{phys.}}(Q^2)$, extrapolated to the physical point using for the LEC’s the results of Table 9, for various values of $Q^2$. The first error is statistical and the second one systematic.

| $Q^2$ (GeV$^2$) | $F_{\pi}^{\text{phys.}}(Q^2)$ |
|----------------|-------------------------------|
| 0.050          | 0.914 ± 0.005 ± 0.003         |
| 0.148          | 0.774 ± 0.013 ± 0.008         |
| 0.299          | 0.618 ± 0.019 ± 0.013         |
| 0.503          | 0.487 ± 0.022 ± 0.017         |
| 0.794          | 0.437 ± 0.030 ± 0.026         |

Fig. 23: Pion form factor $F_{\pi}(Q^2)$ versus $Q^2 = -q^2$ in physical units. The full dots are the NNLO ChPT results of Table 10, obtained at the physical point using for the LEC’s the values given in Table 9. The uncertainties of the ETMC results, illustrated also by the dashed lines, represent the statistical and the systematic errors of Table 10 added in quadrature. The open dots, squares and diamonds are experimental data from Refs. [1], [3, 4] and [5, 6, 7, 8], respectively.

It can be seen that our values are fully consistent with the experimental data in the whole range of values of $Q^2$ considered in this study. The agreement is particularly remarkable at low values of $Q^2$ ($Q^2 \lesssim 0.15$ GeV$^2$), where the experimental data are very precise, as well as at larger values of $Q^2$ ($Q^2 \gtrsim 0.3$ GeV$^2$), where the
uncertainties of our results become competitive with the experimental errors.

8 Conclusions

We have presented a lattice calculation of the electromagnetic form factor of the pion obtained using the tree-level Symanzik improved gauge action with two flavors of dynamical twisted Wilson quarks.

The simulated pion masses range from $\simeq 260$ to $\simeq 580$ MeV and the lattice box sizes are chosen in order to guarantee that $M_\pi L \gtrsim 4$.

Accurate results for the form factor are obtained using all-to-all quark propagators evaluated with the stochastic procedure of Ref. [30].

The momentum dependence of the pion form factor is investigated up to values of the squared four-momentum transfer $Q^2 \simeq 0.8$ GeV$^2$ and, thanks to the use of twisted boundary conditions, down to $Q^2 \simeq 0.05$ GeV$^2$. The $Q^2$-dependence at the simulated pion masses is well reproduced by a single monopole ansatz with a pole mass lighter by $\approx 10\% \div 15\%$ than the lightest vector meson mass.

Volume and discretization effects on the form factor have been directly evaluated performing simulations at different volumes and lattice spacings, and they turn out to be within the statistical errors. A more complete investigation of the scaling properties of the pion form factor, based on the study of its mass dependence at two additional values of the lattice spacing is however desirable. The corresponding measurements are in progress.

The extrapolation of our results for the pion mass, decay constant and form factor to the physical point has been carried out using (continuum) ChPT at NNLO [11]. The extrapolated value of the (squared) pion charge radius is $\langle r^2 \rangle_{phys} = 0.456 \pm 0.030_{\text{stat.}} \pm 0.024_{\text{syst.}}$ in nice agreement with the experimental result $\langle r^2 \rangle_{exp} = 0.452 \pm 0.011$ fm$^2$ [22]. The extrapolated values of the pion form factor agree very well with the experimental data up to $Q^2 \simeq 0.8$ GeV$^2$ within uncertainties which become competitive with the experimental errors for $Q^2 \gtrsim 0.3$ GeV$^2$.

The relevant low-energy constants appearing in the chiral expansion of the pion form factor are extracted from our lattice data adding only the experimental value of the pion scalar radius [11] in the fitting procedure. We get: $\bar{\ell}_1 = -0.4 \pm 1.3 \pm 0.6$, $\bar{\ell}_2 = 4.3 \pm 1.1 \pm 0.4$, $\bar{\ell}_3 = 3.2 \pm 0.8 \pm 0.2$, $\bar{\ell}_4 = 4.4 \pm 0.2 \pm 0.1$, $\bar{\ell}_6 = 14.9 \pm 1.2 \pm 0.7$, where the first error is statistical and the second one systematic. Our findings are in nice agreement with the results of the NNLO ChPT analysis of $\pi - \pi$ scattering data of Ref. [33]. The values found for the LEC’s $\bar{\ell}_3$ and $\bar{\ell}_4$ are consistent with the corresponding results of the ETMC analysis of Ref. [34]. This is quite reassuring because different kinds of systematic uncertainties may affect the two analyses: the present one being a NNLO analysis limited mainly to data from a single lattice spacing, and that of Ref. [34] having two values of the lattice spacing but limited
mainly to a NLO analysis.

It is the aim of our collaboration to reduce as much as possible all the uncertainties of the extracted low-energy constants in the next future. To this end, data at more values of the lattice spacing and calculations of other physical quantities, like e.g. the pion scattering lengths, will be considered. This may allow to avoid any input from experiments obtaining a first principle computation of the low-energy constants.

In this respect a very interesting strategy is to include lattice data for the scalar form factor of the pion, because almost the same low-energy constants enter the chiral expansion of both vector and scalar form factors \[1\]. In this way the use of the experimental value of the pion scalar radius in the fitting procedure can be avoided. However the lattice calculation of the scalar form factor requires the evaluation of both connected and disconnected diagrams. While the former have been already calculated on the ETMC gauge configurations, a precise evaluation of the latter is in progress. The results will be reported elsewhere.

Acknowledgments

We thank all the members of the ETM collaboration for very fruitful discussions and for a very enjoyable collaboration. We gratefully acknowledge also several discussions with H. Leutwyler and G. Colangelo. The computer time for this project was made available to us by the apeNEXT systems in Rome and Zeuthen. We thank these computer centres and their staff for the invaluable technical advice and help.

Appendix

In this Appendix we provide the values of the pion form factor \(F_\pi(Q^2)\) obtained for all the simulations (see Table II) and for the various values of the squared four-momentum transfer \(Q^2 \equiv -q^2\) considered in this work.
