Abstract: Nuclear import receptors, also called importins, mediate nuclear import of proteins and chaperone aggregation-prone cargoes (e.g., neurodegeneration-linked RNA-binding proteins [RBPs]) in the cytoplasm. Importins were identified as modulators of cellular toxicity elicited by arginine-rich dipeptide repeat proteins (DPRs), an aberrant protein species found in C9orf72-linked amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Mechanistically, the link between importins and arginine-rich DPRs remains unclear. Here, we show that arginine-rich DPRs (poly-GR and poly-PR) bind directly to multiple importins and, in excess, promote their insolubility and condensation. In cells, poly-GR impairs Impβ/β'-mediated nuclear import, including import of TDP-43, an RBP that aggregates in C9orf72-ALS/FTD patients. Arginine-rich DPRs promote phase separation and insolubility of TDP-43 in vitro and in cells, and this pathological interaction is suppressed by elevating importin concentrations. Our findings suggest that importins can decrease toxicity of arginine-rich DPRs by suppressing their pathological interactions.

In Brief
Hutten et al. show that arginine-rich dipeptide repeat proteins (DPRs) associated with the neurodegenerative diseases ALS and FTD bind directly to importins, promote their condensation, and interfere with importin function. Elevated importin levels can shield arginine-rich DPRs and suppress DPR-induced phase separation of TDP-43 and RNA.

Highlights
- Importins directly bind to arginine-rich dipeptide repeat proteins (R-rich DPRs)
- R-rich DPRs induce importin and TDP-43 condensation
- Poly-GR impairs TDP-43 nuclear import
- Elevated importin levels shield R-rich DPRs from pathological interactions
Nuclear Import Receptors Directly Bind to Arginine-Rich Dipeptide Repeat Proteins and Suppress Their Pathological Interactions

INTRODUCTION

Amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD) are progressive and eventually fatal neurodegenerative diseases. A common molecular hallmark of ALS and FTD is the pathological mislocalization and aggregation of ubiquitously expressed RNA-binding proteins (RBPs), such as TAR DNA-binding protein of 43 kDa (TDP-43) (DPRs), an aberrant protein species found in C9orf72-linked amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Mechanistically, the link between importins and arginine-rich DPRs remains unclear. Here, we show that arginine-rich DPRs (poly-GR and poly-PR) bind directly to multiple importins and, in excess, promote their insolubility and condensation. In cells, poly-GR impairs Imp nuclear import, including import of TDP-43, an RBP that aggregates in C9orf72-ALS/FTD patients. Arginine-rich DPRs promote phase separation and insolubility of TDP-43 in vitro and in cells, and this pathological interaction is suppressed by elevating importin concentrations. Our findings suggest that importins can decrease toxicity of arginine-rich DPRs by suppressing their pathological interactions.

SUMMARY

Nuclear import receptors, also called importins, mediate nuclear import of proteins and chaperone aggregation-prone cargoes (e.g., neurodegeneration-linked RNA-binding proteins [RBPs]) in the cytoplasm. Importins were identified as modulators of cellular toxicity elicited by arginine-rich dipeptide repeat proteins (DPRs), an aberrant protein species found in C9orf72-linked amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Mechanistically, the link between importins and arginine-rich DPRs remains unclear. Here, we show that arginine-rich DPRs (poly-GR and poly-PR) bind directly to multiple importins and, in excess, promote their insolubility and condensation. In cells, poly-GR impairs Imp nuclear import, including import of TDP-43, an RBP that aggregates in C9orf72-ALS/FTD patients. Arginine-rich DPRs promote phase separation and insolubility of TDP-43 in vitro and in cells, and this pathological interaction is suppressed by elevating importin concentrations. Our findings suggest that importins can decrease toxicity of arginine-rich DPRs by suppressing their pathological interactions.

There is evidence that the combination of defective nuclear import and aberrant phase transitions of RBPs may give rise to the cytosolic RBP aggregates seen in post mortem brains of ALS and FTD patients (Dormann and Haass, 2011; Dormann et al., 2010; Lin et al., 2015; Mollieux et al., 2015; Murakami et al., 2015; Patel et al., 2015; Zhang et al., 2019a). This hypothesis obtained strong support in recent years, when multiple groups studied the pathomechanism of the most frequent genetic cause of ALS and FTD, a large hexanucleotide repeat expansion in the C9orf72 gene (DeJesus-Hernandez et al., 2011; Renton et al., 2011), and identified compelling links to both the nuclear transport machinery and liquid-liquid phase separation (LLPS) (Boeynaems et al., 2016a; Freibaurm et al., 2015; Jovičić et al., 2015; Zhang et al., 2015). Healthy individuals have ≤11 repeats of a GGGGCC sequence in the first intron of the C9orf72 gene, whereas patients with C9-ALS/FTD (the collective term for C9orf72-associated diseases) have hundreds to thousands of GGGGCC repeats.
The expanded repeat sequence is bidirectionally transcribed into repeat RNA, which is then translated in every reading frame via repeat-associated non-AUG (RAN) translation, giving rise to five different dipeptide repeat proteins (DPRs; poly-GR, poly-GA, poly-GR, poly-PA, and poly-PR) (Ash et al., 2013; Mori et al., 2013). DPRs form predominantly cytoplasmic inclusions in brains of C9-ALS/FTD patients and are thought to cause proteotoxicity through a variety of different mechanisms (Balendra and Isaacs, 2018), although other toxicity mechanisms involving repeat RNAs and reduced C9orf72 expression may also contribute to neurodegeneration in C9-ALS/FTD (Balendra and Isaacs, 2018; Swinnen et al., 2019; Webster et al., 2018). Among the different DPR species, arginine-rich (R-rich) DPRs were shown to be particularly toxic in both cell and animal models (Boeynaems et al., 2016a; Jovičić et al., 2015; Kramer et al., 2018; Kwon et al., 2014; Lee et al., 2016; Mizielska et al., 2017; Tao et al., 2015; Wen et al., 2014; Zhang et al., 2018b). Although it is still debated whether neurodegeneration is linked to expression of specific DPRs (Mackenzie et al., 2013, 2015; Mann et al., 2013; Schlu et al., 2015), some studies have reported poly-GR to correlate with neurodegeneration and to be present in clinically related brain regions (motor cortex, frontal cortex, and spinal cord) (Gittings et al., 2020; Saberi et al., 2018; Sakae et al., 2018), supportive of a pathogenic role of R-rich DPRs.

Two major pathomechanisms appear to contribute to the toxicity of R-rich DPRs. First, independent genetic modifier screens in Drosophila and yeast revealed that poly-GR and poly-PR toxicity is strongly modulated by overexpression or reduction of different components of the nuclear transport machinery, including nucleoporins (Nups), nuclear transport receptors (NTRs), and regulators of the Ran system (Boeynaems et al., 2016a; Jovičić et al., 2015; Kramer et al., 2018; Lee et al., 2016). On the basis of these findings, it was proposed that R-rich DPRs may impair nucleocytoplasmic transport (NCT) and hence cause RBP mislocalization in C9-ALS/FTD (Boeynaems et al., 2016a, 2016b; Jovičić et al., 2015; Kim and Taylor, 2017; Zhang et al., 2016). However, the mechanistic link between R-rich DPRs and the NCT machinery remains elusive; that is, it is unclear whether poly-GR and poly-PR directly interact with components of the transport machinery (or rather indirectly via RBPs) and whether they indeed cause impaired nuclear import of C9-ALS/FTD-linked RBPs, such as TDP-43. Second, several proteomic studies have shown that R-rich DPRs interact with numerous intrinsically disordered proteins (IDPs) with low-complexity domains (LCDs) (Boeynaems et al., 2017; Lee et al., 2016; Lin et al., 2016). This interaction can alter LLPS of various IDPs, as demonstrated for NPM1/B23, hnRNPA1, TIA-1 (Lee et al., 2016; White et al., 2019), and the LCD of FUS (Boeynaems et al., 2017). In line with these findings, cellular expression of or incubation of cells with short R-rich DPRs (GR configure, PR configure, or GR configure) disturbs the dynamics of several membrane-less organelles, including nucleoli, stress granules (SGs), nuclear speckles, and Cajal bodies (Lee et al., 2016; White et al., 2019). Whether phase separation of RBPs that aggregate in C9-ALS/FTD patients, such as TDP-43 (Murray et al., 2011; Simón-Sánchez et al., 2012; Stewart et al., 2012), is affected by poly-GR and poly-PR has so far not been examined.

We and others have recently shown that nuclear import receptors (importins) have a dual function and not only mediate nuclear import of nuclear localization sequence (NLS)-containing cargo proteins but also “chaperone” aggregation-prone RBPs, such as FUS, TDP-43, hnRNPA1, and other hnRNPs linked to the ALS-FTD spectrum (Guo et al., 2018; Hofweber et al., 2018; Qamar et al., 2018; Yoshizawa et al., 2018). Several importins are known to bind to highly positively charged arginine- or lysine-rich NLSs. Thus, importins might directly bind to and chaperone the highly basic and R-rich DPR species poly-GR and poly-PR.

Here, we demonstrate that several importins, but not CRM1/Exportin-1, directly bind to R-rich DPRs and that this interaction can affect the biophysical properties of importins. Poly-GR and poly-PR peptides in molar excess reduce the solubility of several importins in vitro and in cytosol and cause importin condensation. Poly-GR, but not poly-PR, impairs nuclear import of a TDP-43 import reporter and of other classical NLS (cNLS)-containing model cargoes in intact cells. This import defect may act synergistically with aberrant phase separation of TDP-43 elicited by poly-GR and poly-PR. Interestingly, we find that increasing the concentration of importins can shield R-rich DPRs and thereby suppress their pathological aggregation with TDP-43 and RNA in vitro and under physiological conditions. This finding raises the possibility that a decrease in the endogenous concentration of importins, which may arise during physiological aging (Mertens et al., 2015; Nishimura et al., 2010; Pujol et al., 2002), could contribute to the pathogenesis of C9-ALS/FTD, and suggests that importins are promising therapeutic targets.

RESULTS

Importins Directly Bind to R-Rich DRPs

Several studies have identified NTRs as potential interactors of R-rich DPRs in proteomic approaches using total cell lysates (Boeynaems et al., 2017; Hayes et al., 2020; Lee et al., 2016). As NTRs continuously shuttle between the nucleus and cytosol, they could encounter DPRs in both compartiments. In patients, however, DPRs are mostly found in the cytoplasm and less frequently in the nucleus (Ash et al., 2013; Gendron et al., 2013; Mackenzie et al., 2015; Mori et al., 2013), hence the interaction is more likely to occur in the cytosol. To investigate whether NTRs can interact with DPRs in the cytoplasm, we prepared cytosol from HeLa cells and incubated it with biotinylated DPR peptides as bait in a pull-down (PD) assay using physiological buffer conditions. Indeed, several NTRs bound to R-rich DPRs (GR, PR, GR) but not to the non-charged control DPR GR. Importantly, Imp7, Impβ, and Imp3 were bound equally to both poly-GR and poly-PR, while TNPO1 and TNPO3 bound preferentially to poly-GR (Figure 1A). Binding of the export receptor CRM1 to R-rich DPRs could not be detected, likely because its concentration in HeLa cytosol was too low (data not shown).

Although these findings confirm importins as physiological interactors of R-rich DPRs, it is still unclear whether this interaction is mediated by direct binding or conveyed indirectly (e.g., by RBPs or other cargoes). As NTRs are negatively charged (Cansizoglu et al., 2007; Lott and Cingolani, 2011) and hence could directly bind to positively charged R-rich DPRs, we investigated whether our biotinylated DPR peptides directly interact with purified, recombinant NTRs in in vitro PD assays. After stringent washing, we detected prominent binding of TNPO1 and Impβ.
to both poly-GR and poly-PR, but not poly-GP (Figures 1B and 1C). Moreover, recombinant Imp5, Imp7, Imp9, and TNPO3 strongly bound to R-rich DPRs but not poly-GP (Figures S1A–S1D). We also tested direct binding of R-rich DPRs to Impx. We observed direct binding of two Impx isoforms, Impx3 (Figure 1D) and Impx1 (Figure S1E), preferentially to poly-GR. In contrast, no binding of the purified export receptor CRM1 to the tested DPRs could be detected (Figure 1E).

To further characterize the interaction of poly-GR and poly-PR with importins, we measured the binding affinity of GR<sub>25</sub> or PR<sub>25</sub> to TNPO1, an importin involved in nuclear import of many RBPs, using fluorescence polarization (Moerke, 2009). Here, both R-rich DPRs displayed similar affinity binding to TNPO1 (k<sub>D</sub> ~ 200 nM; Figure 1F). Together, our data demonstrate that several importins, but not the exportin CRM1, directly bind to the R-rich DPRs poly-GR and poly-PR with high affinity.

**R-Rich DPRs Cause the Formation of Solid-like Importin Condensates**

We next characterized the consequences of the DPR-importin interaction at the molecular level. R-rich DPRs were shown to promote aberrant phase separation of RBPs and to change the biophysical properties of their interacting proteins (Boeynaems et al., 2017; Lee et al., 2016; Shi et al., 2017), hence we tested whether increasing concentrations of poly-GR or poly-PR affect the solubility of Impβ, the best characterized import receptor for cNLS-containing cargo proteins. In a sedimentation assay, both Impβ and its adaptor protein Impx were detected in the supernatant (S) in the absence of R-rich DPRs, reflecting their high solubility (Figures S2A and S2C). However, upon addition of increasing concentrations of either GR<sub>25</sub> (Figures S2A and S2B) or PR<sub>25</sub> (Figures S2C and S2D), both Impx and Impβ shifted progressively into the pellet fraction (P), indicating reduced solubility in the presence of high GR or PR concentrations. Notably, Impx appeared more sensitive than Impβ to an excess of R-rich DPRs, as higher concentrations of GR<sub>25</sub> or PR<sub>25</sub> peptides were required for efficient precipitation of Impβ (Figures S2A–S2D). To determine whether this effect is specific for R-rich DPRs, we compared the sedimentation behavior of Impβ in the presence of a 10-fold excess of GR<sub>25</sub>, PR<sub>25</sub>, or GP<sub>25</sub> (Figures 2A and 2B). Compared with poly-GR, poly-PR was slightly less efficient in precipitating Impx but showed a similar effect toward Impβ. The non-charged DPR species poly-GP had no effect on the solubility of either Impx or Impβ, indicating the importance of arginine in this process. Interestingly, a shorter GR peptide (GR<sub>10</sub>) had only a minor effect on the solubility of Impx and no effect on Impβ, suggesting that a certain minimum number of GR repeats is required for efficient precipitation of Impβ. Longer GR repeats, which are likely found in C9-ALS/FTD patients, could be even more potent in reducing Impx/β solubility and in promoting phase separation in general.

To address whether R-rich DPRs also reduce the solubility of other NTRs, we analyzed TNPO1, Impβ (in the absence of Impx), Impx (in absence of Impβ), and CRM1 in the sedimentation assay. Among these NTRs, Impx and TNPO1 were efficiently precipitated by 10-fold molar excess of GR<sub>25</sub> and PR<sub>25</sub>, but not by poly-GP. A shorter GR peptide (GR<sub>10</sub>) showed no or only a minor effect, emphasizing the importance of the repeat length (Figures 2C and 2D). In contrast, Impβ and CRM1 remained mainly soluble in presence of either poly-GR or poly-PR. Titration of GR<sub>25</sub> and PR<sub>25</sub> showed enhanced susceptibility of both TNPO1 (Figures S2E–S2H) and Impβ alone (Figures S2I–S2K) to already small molar excess (5×) of R-rich peptides, whereas Impβ and CRM1 exhibited only partial or no precipitation even at extremely high concentrations of poly-GR and poly-PR (Figures S2E–S2H).

**Figure 1. Importins Bind Directly to Arginine-Rich Dipeptide Repeat Proteins (DPRs)**

(A) Western blot showing binding of endogenous importins from HeLa cytosol to immobilized, biotinylated GR<sub>25</sub> and PR<sub>25</sub>, but not GP<sub>25</sub>, in a pull-down (PD).

(B–E) Direct binding of R-rich DPRs to the importins TNPO1 (B), Impβ (C), Impx3 (D), but not CRM1 (E) in pull-downs using biotinylated GR<sub>25</sub>, PR<sub>25</sub>, and GP<sub>25</sub> (bait) and purified importins (prey) visualized by Sypro-Ruby staining. Input represents 5% of the importin used in the PD. Ovalbumin (ovalb.) was used to prevent unspecific binding to the beads.

(F) Fluorescence polarization measurements of fluorescein isothiocyanate (FITC)-labeled GR<sub>25</sub> (black) or PR<sub>25</sub> (red) with increasing concentrations of TNPO1. Table shows calculated k<sub>D</sub> values assuming a 1:1 complex formation performed in technical triplicate ± SEM of the fit. See also Figure S1.
We also observed altered biophysical properties of TNPO1 in the presence of excess poly-GR and poly-PR using fluorescence microscopy. Upon mixing of GFP-TNPO1 with a 10-fold molar excess of tetramethylrhodamine (TMR)-labeled GR$_{25}$ or PR$_{25}$ peptides, small condensates containing both GFP-TNPO1 and TMR-GR$_{25}$ or TMR-PR$_{25}$ were observed using confocal microscopy (Figure 2E). TMR-GP$_{25}$ or a shorter GR peptide (TMR-GR$_{10}$), even at high molar excess (50×), caused no TNPO1 condensation (Figure 2E). In contrast to TNPO1 and in line with our sedimentation analysis, GFP-Imp$\beta$ condensed more efficiently with R-rich DPRs in the presence of Imp$\alpha$ (Figure 2F). To characterize GR- and PR-induced NTR condensates further, we first analyzed the dynamicity of poly-GR-induced TNPO1 condensates using fluorescence recovery after photobleaching (FRAP). No recovery of the bleached area in GFP-TNPO1 condensates could be detected within 5 min after the bleach, indicating low internal mobility (Figure 2G).

Moreover, semi-denaturing detergent agarose gel electrophoresis (SDD-AGE) showed that condensates of TNPO1 and Imp$\alpha$3 formed by 10-fold molar excess of poly-GR and poly-PR, but not poly-GP, represent SDS-resistant oligomers of TNPO1 and Imp$\alpha$3 (Figure 2H), suggesting crosslinking of individual TNPO1 and Imp$\alpha$3 molecules by R-rich DPRs. In line with our sedimentation and microscopy analysis, no oligomers could be detected for Imp$\beta$ in presence of R-rich DPRs (Figure 2H). Analysis of TNPO1 experimental radial density distributions ($P[r]$) in absence or presence of up to 2-fold molar excess of GR$_{25}$ or PR$_{25}$ showed that TNPO1 molecules that remained in solution under these conditions were monomeric (Figures S2L and S2M). Higher excess of DPRs with TNPO1 resulted in precipitation of TNPO1 and hence prohibited SAXS analysis.

Taken together, our data demonstrate that R-rich DPRs in a concentration- and repeat length-dependent manner affect the biophysical properties of importins and induce their precipitation and condensate formation. Interestingly, import receptors differ...
in their susceptibility toward R-rich DPRs, with TNPO1, Impx2, and Impxβ/δ being more susceptible than Impxα alone.

**Poly-GR Impairs Nuclear Import of a TDP-43 Reporter and Other cNLS-Containing Model Cargoes**

Nuclear depletion and cytoplasmic aggregation of TDP-43 is a pathological hallmark of C9-ALS/FTD (Murray et al., 2011; Simón-Sánchez et al., 2012; Stewart et al., 2012). TDP-43 contains a bipartite cNLS and is imported by Impxβ/δ (Nishimura et al., 2010; Winton et al., 2008). Considering the reduced solubility of Impxβ/δ in presence of R-rich DPRs (Figures 2A and 2B), we speculated that nuclear import of TDP-43 could be impaired by R-rich DPRs. Indeed, it has been previously suggested that reduced nuclear import of TDP-43 caused by DPRs could underlie the observed TDP-43 pathology (Khosravi et al., 2017; Solomon et al., 2018), but this hypothesis has not been addressed in bona fide nuclear import assays. To analyze the impact of R-rich DPRs on nuclear import of TDP-43 in intact cells, we made use of a hormone-inducible import system adapted from (Love et al., 1998). Here, the protein of interest is fused to two GFP moieties for visualization (GFPα and two hormone binding domains of the glucocorticoid receptor (GCRα). The GCR domains retain the reporter in the cytoplasm, but upon addition of a steroid hormone (dexamethasone), it is released and subsequently imported into the nucleus, dependent on the NLS in the protein of interest (Figure 3A). Indeed, a GCRα-GFPβ-TDP-43 reporter transiently expressed in HeLa cells localizes mainly to the cytoplasm but accumulates within minutes in the nucleus upon addition of dexamethasone, as visualized by live cell imaging (Figure 3B, control). To follow its nuclear import in the presence of poly-GR or poly-PR, we added 10 μM TMR-labeled GR25 or PR25 peptides to the culture medium, as they are known to enter cells because of their strong positive charge (Kwon et al., 2014) (Figure 3B, top row). Interestingly, after pre-incubation of cells with GR25 for 2 h, nuclear import of the TDP-43 reporter was strongly decelerated in GR-positive cells (Figure 3B; see Figure S3C for quantification of N/C ratio over time). In contrast, incubation of cells with the PR25 peptide had only a minor effect on TDP-43 import, indicating that the TDP-43 import defect was specifically induced by poly-GR. The observed import defect was not dependent on the presence of the LCD in TDP-43, as a TDP-43 reporter lacking this domain (GCRα-GFPβ-TDP-43 ΔLCD) still exhibited reduced nuclear import in presence of poly-GR (Figures S3A and S3B). Nuclear transport defects have previously been attributed to the presence of SGs, which contain essential nuclear transport factors (Zhang et al., 2018a). Hence, we examined cells expressing GCRα-GFPβ-TDP-43 after exposure to TMR-labeled DPRs for the presence of SGs by co-staining for the SG marker TIA-1. However, we could not detect enhanced TIA-1-positive foci in DPR-positive cells expressing the TDP-43 reporter (Figure S3C). Thus, poly-GR interferes with efficient nuclear import of TDP-43 independently of the presence of SGs.

To investigate whether poly-GR affects Impxβ/δ-mediated import in general, we next analyzed cells expressing GCRα-GFPβ-MBP-cNLS, a reporter with a similar size as GCRα-GFPβ-TDP-43. Nuclear import of the MBP-cNLS reporter was also significantly reduced by poly-GR (Figure 3D), suggesting a general import defect for cNLS-bearing cargoes caused by poly-GR. Also, a smaller reporter containing only the SV40 cNLS...
(GCR2-GFP-c-NLS) showed reduced nuclear import in presence of poly-GR (Figure S3D). Notably, diffusion of the reporter in absence of any NLS (GCR2-GFP) into the nucleus was only mildly affected by poly-GR (Figure S3D), indicating that poly-GR predominantly interferes with the functionality of Impβ/1. Moreover, the mobility of the GCR2-GFP2 reporter in the cytoplasm was unchanged by presence of poly-GR as evidenced by FRAP, indicating unchanged solubility of our reporter (Figure S3D). Nevertheless, we cannot fully exclude additional effects of poly-GR on the nuclear pore and/or on the GCR-reporter system. Taken together, our data support the idea that poly-GR impairs nuclear import of TDP-43 and potentially other cargoes requiring active, NLS- and importin-dependent import into the nucleus.

**R-Rich DPRs Promote Phase Separation and Insolubility of TDP-43**

R-rich DPRs have previously been shown to promote LLPS of diverse RBPs, such as TIA-1, NPM1/B23 and hnRNPA1 (Lee et al., 2016; White et al., 2019). Whether poly-GR and poly-PR also promote phase transition of TDP-43 has not been examined yet. TDP-43 is a highly aggregation-prone RBP, but can be purified as soluble protein via fusion to a cleavable MBP-His6 solubility tag (TDP-43-Tev-MBP-His6, Wang et al., 2018) allowing for controlled induction of phase separation by cleavage with Tev protease. To visualize TDP-43 condensates using fluorescence microscopy, we spiked in His6-MBP-Tev-TDP-43-GFP at substoichiometric concentrations. At low TDP-43 concentrations (2 μM TDP-43/TDP-43-GFP), no visible condensates were formed 30–60 min after Tev protease-mediated cleavage of the MBP solubility tag (Figure 4A). However, the presence of TMR-labeled R-rich DPRs led to the formation of condensates containing both TDP-43 and poly-GR or poly-PR, respectively, while poly-GP had no effect (Figure 4A).

To determine the effect of poly-GR and poly-PR on condensation of TDP-43 more quantitatively, we evaluated the sedimentation of TDP-43 in the absence or presence of DPRs in a sedimentation assay. We chose experimental conditions (200 mM NaCl) that resulted in only partial sedimentation of cleaved TDP-43 (~50% solubility; Figures 4B and 4C), allowing us to detect a promoting effect by poly-GR/PR. Already equimolar concentrations of both TMR-GR25 and TMR-PR25, but not TMR-GP25, significantly promoted the sedimentation of TDP-43 into the pellet fraction (Figures 4B and 4C). To examine whether enhanced insolubility of TDP-43 could also be observed in intact cells, we incubated HeLa cells with or without GR25 or PR25 peptides and subsequently analyzed TDP-43 solubility in RIPA buffer by western blot. Interestingly, incubation of cells for only 2 h with either GR25 or PR25 resulted in a significant increase of TDP-43 in the insoluble (pellet) fraction (Figures 4D–4F).

Collectively, our data demonstrate that R-rich DPRs promote phase separation and reduce the solubility of TDP-43, both in vitro and in cells.

**Increasing Importin Concentrations Can Shield R-Rich DPRs and Suppress Poly-GR-Induced Phase Separation of RBPs or RNA In Vitro**

Several Impβ-type importins have been found to execute a chaperoning function toward aggregation-prone proteins, including RBPs, FG-rich Nups, ribosomal proteins, and histones (Guo et al., 2018; Hofweber et al., 2018; Jäkel et al., 2002; Milles et al., 2013; Qamar et al., 2018; Yoshizawa et al., 2018). Having observed the direct interaction of R-rich DPRs with Impβ-type importins (Figure 1), we wondered whether importins could also shield R-rich DPRs and thus prevent them from promoting aberrant phase transitions of RBPs. To address this question, we first evaluated the formation of poly-GR- or poly-PR-induced TDP-43 condensates in the absence or presence of different NTRs in vitro using fluorescence microscopy. Indeed, equimolar concentrations of TNPO1, Impβ, or Impβ/1 could suppress the GR- or PR-induced formation of TDP-43 condensates, while CRM1 or Impx3 alone had no effect (Figures 5A and 54A). To confirm that TNPO1 and Impβ suppress TDP-43/GR25-phase transition by shielding poly-GR and not poly-GR itself, we tested whether these importins were able to suppress phase separation of TDP-43 alone. To this end, we examined TDP-43-Tev-MBP-MBP-Tev-TDP-43-GFP condensates (5 μM) in the presence or absence of different NTRs. Only Impβ/1, the cognate import receptor for TDP-43, could efficiently suppress phase separation of TDP-43, as described previously (Guo et al., 2018), whereas TNPO1, Impβ or CRM1 were unable to abolish condensate formation of TDP-43 (Figure S4B). These findings confirm that neither TNPO1 nor Impβ alone acts on TDP-43 directly but suppresses GR-induced phase transition of TDP-43 by binding to poly-GR.

To quantitatively validate that importins are able to suppress poly-GR-mediated phase separation of TDP-43 by sequestering poly-GR, we performed a sedimentation assay. Addition of TNPO1, Impβ, or Impβ/1 prior to Tev protease cleavage efficiently reverted the poly-GR-enhanced sedimentation of TDP-43, while CRM1 showed only minor shielding activity (Figures 5B and 5C). In accordance with the microscopic condensate assay, GST-GR25 was completely soluble in the absence of TDP-43, but moved efficiently into the pellet fraction in the presence of cleaved TDP-43 (Figures 5D and 5E). Furthermore, the solubility of GST-GR25 in the presence of TDP-43 was completely rescued by addition of equimolar concentrations of TNPO1, Impβ, or Impβ/1, whereas CRM1 was unable to rescue the TDP-43 induced precipitation of GST-GR25 (Figures 5D and 5E). GR-shielding activity of TNPO1 was also confirmed by turbidity assay in a time-sensitive manner. Here, TNPO1 effectively suppressed GR-mediated promotion of TDP-43 turbidity but did not affect the increase in TDP-43 turbidity in absence of GR after Tev cleavage of the MBP tag (Figures S4C and S4D).

R-rich DPRs have also been shown to form condensates with polyanions, such as RNA (Boeynaems et al., 2017, 2019), and the interactions of poly-GR/PR with nucleic acids were proposed to have detrimental consequences on RNA- and DNA-based processes and cause heterochromatin abnormalities (Boeynaems et al., 2019; Lafarga et al., 2019; Zhang et al., 2019b). We therefore tested whether importins are also able to suppress the formation of poly-GR/RNA condensates. Indeed, equimolar concentrations of either TNPO1 or Impβ/1 were able to suppress RNA-mediated condensation of poly-GR in vitro (Figure 5F). In contrast, poly-GR and
RNA still formed condensates in the presence of Impα3 or CRM1 (Figure 5F), consistent with our earlier observation with TDP-43.

In summary, several DPR-interacting importins of the Impβ family, but not Impα or the export receptor CRM1, are able to shield R-rich DPRs from binding to and enhancing phase separation of RBPs and RNA in vitro.

**Increasing Importin Concentrations Can Suppress DPR-Induced TDP-43 Precipitation in the Cytosol**

Having characterized the impact of R-rich DPRs on importins and TDP-43 using purified components in vitro, we sought to investigate whether R-rich DPRs can also induce precipitation of interacting importins and TDP-43 under more physiological conditions using HeLa cytosol instead of recombinant proteins in our sedimentation assay. Indeed, TNPO1, Impβ3, and TDP-43 were efficiently precipitated from HeLa cytosol by addition of poly-GR and poly-PR, but not poly-GP, in a concentration-dependent manner (Figures 6A and 6B), despite the presence of other cellular poly-GR/PR interactors. Importantly, this effect did not affect all cytosolic proteins, as GAPDH was not precipitated even by the highest GR/PR concentrations (Figures 6A and 6B).

Next, we tested whether increased concentration of importins can also suppress poly-GR-mediated precipitation of TDP-43 from HeLa cytosol. As shown in Figure 6C, addition of equimolar concentrations of TNPO1, Impβ, or Impα/β, but not CRM1, efficiently suppressed GR-induced precipitation of cytosolic TDP-43 (Figures 6C and 6D).

Taken together, we find that diverse importins suppress poly-GR-induced condensation of TDP-43 or RNA, suggesting that importins could have a broadly protective effect by buffering pathological interactions of poly-GR with other macromolecules, including disease-linked RBPs, nucleic acids, and potentially other interactors reported for R-rich DPRs (Boeynaems et al., 2017; Choi et al., 2019; Fumagalli et al., 2019; Hartmann et al., 2018; Lafarga et al., 2019; Lee et al., 2016; Moens et al., 2019; Zhang et al., 2019b).
DISCUSSION

R-Rich DPRs Directly Bind to Importins and Mediate Importin Condensation in a Concentration- and Repeat Length-Dependent Manner

Importins have been identified as strong genetic modifiers of poly-GR- and poly-PR-mediated cellular toxicity in several independent studies in Drosophila and yeast (Boeynaems et al., 2016a; Jovičić et al., 2015; Kramer et al., 2018; Lee et al., 2016). Additionally, several proteomic studies have previously identified importins as cellular interactors of poly-GR or poly-PR (Boeynaems et al., 2016a; Lee et al., 2016; Lin et al., 2016). So far, it has been unclear whether this interaction is direct or indirect (e.g., mediated by RBPs bound to importins), and the underlying mechanism for modification of cellular toxicity by importins has not been addressed. Using in vitro PDs with purified recombinant proteins, we now demonstrate that R-rich DPRs bind directly to a number of different importins, likely by charge-charge-driven interactions, but not to the export receptor CRM1. Binding of R-rich DPRs to TNPO1 was determined to be of relatively high affinity ($k_D$ in the low nanomolar range), suggesting this interaction is likely to happen in cells. Our data are in line with recent work showing direct binding of poly-PR and poly-GR to Impβ in vitro using FRET sensors and bead Halo assays (Hayes et al., 2019), but no other NTRs were analyzed in this study. Here, we find that multiple importins have the capacity to directly bind to R-rich DPRs.

Interestingly, the consequences of the direct importin-DPR interaction strongly depend on the molecular ratio of DPRs to importins. In excess, short R-rich DPR peptides (GR$_{25}$ and PR$_{25}$) reduce the solubility of several importins in a concentration-dependent manner, particularly Impβ, Impβ/Impα, and TNPO1. Longer DPR repeats, as they are likely found in C9-ALS/FTD patients, could have the same effect at even reduced concentrations. Notably, import receptors differ in their sensitivity toward poly-GR or poly-PR. Among the importins analyzed, TNPO1 and Impα appear particularly susceptible to precipitation by R-rich DPRs. DPR-driven precipitation of Impα also promotes insolubility of...
Impβ, as Impβ was precipitated more strongly by R-rich DPRs in the presence of Impα than in its absence. For all importins tested, poly-GP had no effect on solubility, underscoring the role of arginine in the interaction and precipitation of import receptors. Poly-GR/PR-induced phase separation has recently been reported for several RBPs with intrinsically disordered LCDs (Boeynaems et al., 2017; Lee et al., 2016; White et al., 2019). NTRs, however, are overall predominantly structured proteins (Christie et al., 2016) and have been suggested to have a very low intrinsic aggregation propensity (Frey et al., 2018). Strikingly, our data show that molar excess of GR25 and PR25 changes the biophysical properties of specific NTRs, most notably Impα/β.

we now demonstrate that this precipitation might be due to a direct effect of R-rich DPRs on importin solubility that can be reconstituted in vitro and could happen in the absence of aggregation-prone RBP cargoes bound to importins.

The DPR-induced precipitation of importins observed in our in vitro assays raises the question whether R-rich DPRs could trigger insolubility and aggregation of importins in C9-ALS/FTD patients. Interestingly, some Impα isoforms were found to colocalize with cytosolic poly-GR granules in a poly-GR200 mouse model (Cook et al., 2020). Also, Imp3 (KPNA4) pathology (i.e., nuclear depletion and cytoplasmic mislocalization of Imp3) has been reported in C9-ALS/FTD post mortem brain (Solomon et al., 2017; Hayes et al., 2019). Importantly, however, we now demonstrate that this precipitation might be due to a direct effect of R-rich DPRs on importin solubility that can be reconstituted in vitro and could happen in the absence of aggregation-prone RBP cargoes bound to importins.

The DPR-induced precipitation of importins observed in our in vitro assays raises the question whether R-rich DPRs could trigger insolubility and aggregation of importins in C9-ALS/FTD patients. Interestingly, some Impα isoforms were found to colocalize with cytosolic poly-GR granules in a poly-GR200 mouse model (Cook et al., 2020). Also, Imp3 (KPNA4) pathology (i.e., nuclear depletion and cytoplasmic mislocalization of Imp3) has been reported in C9-ALS/FTD post mortem brain (Solomon et al., 2017; Hayes et al., 2019). Importantly, however,
et al., 2018). Although this effect could be linked to DPR (in particular poly-GR) expression in the absence of any major NPC defects, it was also observed in absence of DPR pathology and thus proposed to be caused by TDP-43 pathology. However, reduced solubility of Impx observed by poly-GR, as observed in our in vitro assay, could undermine the cytoplasmic mislocalization and reduced solubility of Impx observed in C9-ALS/FTD patients (Solomon et al., 2019) and in poly-GR mice (Cook et al., 2020) and could result in reduced availability of Impx for nuclear import. Whether solubility of other importins, such as Impβ and TNPO1, is affected in C9-ALS/FTD patients remains elusive. Absence of Impβ pathology in C9-ALS was reported recently (Saberi et al., 2018), but a subtler insolubility of Impβ or other import receptors in affected brain regions cannot be excluded and remains to be addressed biochemically.

**Poly-GR Interferes with cNLS-Mediated Nuclear Import, Including Import of TDP-43**

Conflicting data exist as to whether R-rich DPRs impair NCT and hence could directly contribute to mislocalization of RBPs, such as TDP-43, in C9-ALS/FTD. Several studies have reported mislocalization of NCT factors, such as Ran, RanGAP, or Nups (Cook et al., 2020; Freibbaum et al., 2015; Odeh and Shorter, 2020; Zhang et al., 2015, 2016); nuclear accumulation of mRNA (Freibbaum et al., 2015; Shi et al., 2017); or genetic modulation of poly-GR/PR toxicity by NCT factors (Boeynaems et al., 2016a; Jovicić et al., 2015; Kramer et al., 2018; Lee et al., 2016) but have not addressed NCT defects explicitly by NCT assays. Recently, defective import of Impβ and TNPO1 model cargoes has been reported to occur with high DPR concentrations (50-100 μM of 10- or 20mers) using semi-permeabilized cells (Hayes et al., 2020). Some studies have used shuttling reporters (fluorescent protein fused to both an NLS and a nuclear export signal) and reported reduced import in C9-ALS/FTD patient-derived induced pluripotent stem cells (iPSCs) (Zhang et al., 2015) and in HeLa cells upon incubation with poly-PR peptides (Shi et al., 2017). In contrast, no import defect for a similar shuttling reporter was detected upon either cellular DPR expression or upon incubation of cells with GR20 or PR20 peptides, unless cells exhibited SGs (Vanneste et al., 2019). The latter finding is consistent with a previous report suggesting that SGs sequester various NCT factors and thus impair NCT (Zhang et al., 2018a). Whether SGs were elicited in the earlier studies reporting NCT defects in C9-ALS/FTD (Shi et al., 2017; Zhang et al., 2015) is not known.

Remarkably, it has not yet been addressed whether R-rich DPRs impair nuclear import of disease-linked RBPs, in particular TDP-43, the major aggregating protein in C9-ALS/FTD. Here, we have used a hormone-induced nuclear import reporter assay to demonstrate that TDP-43 nuclear import is impaired in cells exposed to poly-GR peptides. Importantly, this effect was not dependent on the presence of SGs, as we did not detect SGs under our assay conditions. Interestingly, we observed striking differences between poly-GR and poly-PR, as poly-PR only marginally interfered with import of the TDP-43 reporter, likely because it is sequestered more strongly than poly-GR by other cellular factors. This finding is in contrast with a previous finding suggesting a general block of NCT by poly-PR due to direct binding of FG-Nups and blocking of the NPC (Shi et al., 2017).

Furthermore, our data indicate that poly-GR impairs cNLS-mediated import in general, as also import of TDP-43 lacking the LCD domain or import of MBP-cNLS or a cNLS alone in the context of our hormone-sensitive import reporter was impaired by poly-GR. Diffusion of a reporter protein lacking an NLS across the NPC appeared unaffected or only mildly affected by the presence of poly-GR, suggesting that the import defect is caused predominantly by GR interfering with the functionality of Impβ and not by affecting TDP-43 directly, blocking the NPC or interfering with our reporter system per se. However, we cannot exclude that the nature of the tag or the large size of our reporter (>100 kDa) promotes the GR-specific import impairment. The latter possibility could explain the discrepancy between our data and that of Vanneste et al. (2019), as larger cargo more strongly depends on active nuclear import (Lyman et al., 2002) and hence might cause a higher sensitivity of our reporter system to treatment with short DPR peptides.

**R-Rich DPRs Promote Phase Separation of TDP-43**

Enhanced LLPS of RBPs, such as hnRNP-A1, TIA-1, and NPM1, by poly-GR and/or poly-PR has been previously reported (Boeynaems et al., 2017; Lee et al., 2016; Odeh and Shorter, 2020; White et al., 2019), but most of these RBPs have not been linked to C9-ALS/FTD. Our study, along with the work of Cook et al. (2020), reports DPR-induced phase separation of TDP-43, the most prevalent aggregated RBP in C9-ALS/FTD. Here, it is noteworthy that TDP-43, in contrast to other RBPs such as TIA-1, hnRNP-A1, and NPM1, forms irregularly shaped condensates in presence of R-rich DPRs. These condensates do not fuse, nor do they have a round, droplet-like appearance (see also Cook et al., 2020). Instead, TDP-43/GR condensates are amorphous and tend to stick to one another, indicative of a solid-like character. Importantly, we confirmed reduced solubility of endogenous TDP-43 upon addition of poly-GR and poly-PR in intact cells. Altered phase separation behavior of TDP-43 in the presence of poly-GR could contribute to the reduced accessibility of TDP-43 to Impβ, in addition to the effect of poly-GR on Impβ, which contributes to impaired Impβ-dependent TDP-43 import. As reported previously, Impβ acts as a chaperone, but can also disaggregate, prevent and even revert aberrant phase separation of TDP-43 (Guo et al., 2018). Therefore, the reduced solubility of Impβ by poly-GR could in turn also negatively affect TDP-43 solubility, thus exacerbating its cytoplasmic mislocalization and related toxicity. This hypothesis is consistent with the recently reported colocalization of TDP-43 with poly-GR in C9-ALS patients or mice (Chew et al., 2019; Cook et al., 2020; Saberi et al., 2018). However, it should be noted that the correlation of DPR inclusions in general with either neurodegeneration or TDP-43 pathology is still controversial and requires further investigation (Mackenzie et al., 2013, 2015; Mann et al., 2013; Saberi et al., 2018; Sakae et al., 2018; Schludi et al., 2015).

**Increased Concentration of Importins Can Shield R-Rich DPRs from Pathological Interactions**

Interestingly, we found that the outcome of the DPR-importin interaction strongly depends on the molecular ratio of DPRs and importins. Although GR20 and PR20 peptides in molar excess...
over importins result in precipitation and condensation of several importins, sufficiently high concentrations of importins can shield GR$_{25}$ and PR$_{25}$ from engaging in pathological interactions with TDP-43 or with RNA. These findings are in line with previous work demonstrating that importins can suppress phase transitions of aggregation-prone RBPs (Guo et al., 2018; Hofweber et al., 2018; Niaki et al., 2020; Qamar et al., 2018; Yoshizawa et al., 2018) and RNA-mediated aggregation of highly basic ribosomal proteins and histones (Jäkel et al., 2002). Our data now indicate that this chaperoning function extends toward R-rich DPRs, at least in vitro, raising the possibility that importins are broadly protective against pathological protein aggregation, particularly in C9-ALS/FTD.

As R-rich DPRs were reported to engage in pathological interactions with various macromolecules and cellular structures (e.g., mitochondria, heterochromatin, ribosomal proteins, and microtubules) (Choi et al., 2019; Fumagalli et al., 2019; Hartmann et al., 2018; Moens et al., 2019; Zhang et al., 2019b), it can be speculated that importins may have the capacity to buffer and suppress, at least to some extent, the pleiotropic poly-GR/PR interactions and hence counteract various pathological effects attributed to R-rich DPRs. Importantly, importins can exert this chaperoning function toward R-rich DPRs not only in vitro using recombinant factors, but also prevent GR-induced precipitation of endogenous TDP-43 from the cytosol under physiological cellular conditions. Whether importins can have similar protective effect in C9-patient-derived neurons will need to be investigated.

On the basis of our findings, two possible, non-mutually exclusive scenarios exist in C9orf72-linked ALS/FTD. On one hand, R-rich DPRs could sequester importins and hence result in cellular toxicity. On the other hand, reduced levels or reduced availability of import receptors could potentiate toxicity of R-rich DPRs. Notably, expression of an Imp$_x$ isoform, CAS and RanBP17 were found to be reduced in C9-ALS/FTD or aging fibroblasts and aged-preserved induced neurons (Mertens et al., 2015; Nishimura et al., 2010; Pujoil et al., 2002). Whether expression levels of other NTRs are also changed in the aging or diseased brain, for example in specific brain regions or vulnerable cell types, has not yet been directly addressed. Reduced importin levels during physiological aging could have direct implications for neurodegeneration in C9-ALS/FTD. Reduced importin levels could shift the DPR-importin ratio in a way that reduces the availability of import receptors, thereby promoting insolubility of certain RBPs and abrogating the chaperoning of R-rich DPRs and RBPs alike by import receptors. This effect, in turn, is expected to cause defective nuclear import of certain RBPs, RBP aggregation, and pathological interactions with other cellular structures (Boeynaems et al., 2016b, 2017; Choi et al., 2019; Fumagalli et al., 2019; Hartmann et al., 2018; Jovičić et al., 2015; Kim and Taylor, 2017; Lin et al., 2016; Moens et al., 2019; Shi et al., 2017; White et al., 2019; Yin et al., 2017; Zhang et al., 2016), contributing to neuronal dysfunction and neurodegeneration.

Importantly, however, our findings could have therapeutic implications, as they suggest that increasing the concentrations of import receptors or enhancing their performance toward aggregation-prone target molecules, might be a promising therapeutic approach in the treatment of C9-ALS/FTD (Guo et al., 2019).

**STAR METHODS**

Detailed methods are provided in the online version of this paper and include the following:

- **KEY RESOURCES TABLE**
- **RESOURCE AVAILABILITY**
  - Lead Contact
  - Materials Availability
  - Data and Code Availability
- **EXPERIMENTAL MODEL AND SUBJECT DETAILS**
- **METHOD DETAILS**
  - Transfection and viral transductions
  - Peptides
  - DNA constructs
  - Preparation of total RNA
  - Preparation of HeLa cytosol
  - Recombinant protein expression and purification
  - GST and GST-DPRs
  - (His$_6$)-TNPO1 and His$_6$-TNPO3
  - His$_{25}$-GFP-TNPO1
  - GST-Tev-TNPO1
  - His$_{25}$-S-Imp$\beta$ and His$_{25}$-GFP-Imp$\beta$
  - His$_{25}$-Imp$\beta$1 and His$_{25}$-Imp$\beta$3
  - CRM1
  - TDP-43-Tev-MBP-His$_6$
  - MBP-Tev-TDP-43-GFP-Tev-His$_6$
  - His$_{25}$-Tev
  - Biotin-DPR Pulldowns
  - Fluorescence Polarization Measurements
  - SAXS
  - In vitro phase separation assays
  - Sedimentation assay
  - Visualization of condensates by microscopy
  - Analysis of oligomer formation by SDD-AGE
  - Turbidity assay
  - Solubility assay of endogenous TDP-43 by RIPA extraction
  - Immunocytochemistry
  - Nuclear transport assay (Hormone-induced import assay)
- **MICROSCOPY**
  - Laser scanning confocal microscopy
  - Spinning disc confocal live cell microscopy
  - Fluorescence Recovery after Photobleaching (FRAP)
- **QUANTIFICATION AND STATISTICAL ANALYSIS**
  - Microscopy
  - FRAP analysis of cytoplasmic GCR$_{25}$-GFP$_2$ dynamics
  - Densitometry measurements (Sypro-Ruby, western blot)

## STAR★METHODS

### KEY RESOURCES TABLE

| REAGENT or RESOURCE | SOURCE | IDENTIFIER |
|---------------------|--------|------------|
| **Antibodies**      |        |            |
| Rabbit anti Importin β | (Frohnhert et al., 2014), gift from Ralph Kehlenbach, University of Goettingen | N/A |
| Mouse anti TNPO1 clone D45 | Sigma | Cat# T0825, RRID:AB_262123 |
| Goat anti CRM1 | (Roloff et al., 2013), gift from Ralph Kehlenbach, University of Goettingen | N/A |
| Rabbit anti TDP-43 | Proteintech | Cat# 10782-2-AP, RRID:AB_615042 |
| Mouse anti TDP-43 | Proteintech | Cat# 60019-2-lg, RRID:AB_2200520 |
| Goat anti TIA-1 | Santa Cruz | Cat# sc-48371, RRID:AB_628358 |
| Rabbit anti GST | Proteintech | Cat# 10000-0-AP, RRID:AB_1104231 |
| Mouse anti His₆ | Abcam | Cat# ab18184, RRID:AB_444306 |
| Alexa 647 Donkey anti-goat | Thermo | Cat# A-21447, RRID:AB_141844 |
| IRDye® 680RD Donkey anti-Mouse IgG | LI-COR | Cat# P/N 926-68072, RRID:AB_10953628 |
| IRDye® 800RD Donkey anti-Rabbit IgG | LI-COR | Cat# P/N: 926-32213, RRID:AB_62184 |
| **Chemicals, Peptides, and Recombinant Proteins** |        |            |

RESOURCE AVAILABILITY

Lead Contact
Further information and requests for reagents may be directed to and will be fulfilled by the Lead Contact, Dorothee Dormann (dorothee.dormann@med.uni-muenchen.de).

Materials Availability
All unique/stable reagents generated in this study are available from the Lead Contact with a completed Materials Transfer Agreement.

Data and Code Availability
This study did not generate any unique datasets or code.

EXPERIMENTAL MODEL AND SUBJECT DETAILS

HeLa cells were grown in DMEM high glucose GlutaMAX (Invitrogen) supplemented with 10% dialyzed FBS, or 10% standard FBS and 10 µg/ml gentamicin, respectively. HeLa S3 were grown in suspension using DMEM high glucose (Sigma) with 10% standard FBS in spinner flasks. All cells were maintained in a humidified incubator at 37°C with 5% CO2.

To induce stress granule formation by proteasome inhibition, HeLa cells were incubated for 2 h in the presence of 10 µM MG132. TMR-labeled DPRs were directly added once into the cell medium lacking FBS at a final concentration of 10 µM and analyzed after 2 h.

METHOD DETAILS

Transfection and viral transductions
Transient transfections of HeLa cells were performed using Lipofectamine 2000 (Thermo) in the absence of gentamycin. To reduce cellular stress elicited by the transfection reagent, medium was changed after 4-6 h.

For immunostaining, HeLa cells were fixed 24 h after transfection.

Peptides
Chemically synthesized peptides were obtained as lyophilized powder, dissolved either in milli-Q water (for biotin- and TMR-labeled peptides), 1x PBS (for FLAG-tagged peptides), or in 50 mM Tris (pH 7.5), 200 mM NaCl, 2 mM TCEP, 1 mM MgCl2, 5% glycerol (for FITC-labeled peptides).

DNA constructs
Expression constructs for GST-GR25, was generated by Genscript as codon optimized sequences cloned into EcoRI and SalI sites of a pGex3X-backbone.

For amplification of GST-GR25, a recombinase deficient bacterial strain (Stbl2) was used.

To generate the expression construct His6-GFP-TNPO1 and -Impβ, the coding sequences of GFP, TNPO1 and Impβ were PCR amplified and cloned into a PET28a-backbone using NheI/BamHI, ApaI/BamHI and BamHI/NotI sites, respectively.

For generation of the expression construct coding for His6-Impα3, rat Impα3 (98.9% identical to human Impα3) was PCR-amplified from rat cDNA and cloned into XhoI/BamHI sites of pRSETb-backbone.

To generate a construct coding for MBP-Tev-TDP-43-GFP-His6, the GFP-Tev-His6 cassette was transferred from MBP-FUS-GFP-His6 (Hofweber et al., 2018) via BamHI/HindIII into a pMal-C2 backbone containing a Tev-cleavage site downstream of the MBP. Subsequently, the coding sequence of TDP-43 was inserted into the BamHI site. Note that we included a low-complexity linker between TDP-43 and GFP to reduce disturbance of the TDP-43 C terminus by the GFP-fusion. To generate GCR2-GFP2-TDP-43 lacking the LCD domain (GCR2-GFP2-TDP-43 aa1-260) and GCR2-GFP2-MBP-cNLS, the respective coding sequences were PCR amplified and inserted using EcoRV and BamHI.

Preparation of total RNA
Total RNA was purified from HeLa cells using Tri-Reagent (Sigma) and stored in RNase-free milli-Q water at −80°C.

Preparation of HeLa cytosol
HeLa cytosol was either prepared from adherent HeLa cells or HeLa S3 cells grown in suspension. Adherent HeLa cells (~0.5-1x10^8 cells) were harvested by trypsinization and washed in transport buffer (TPB; 20 mM HEPES pH 7.3-7.4, 110 mM KAc, 2 mM Mg(OAc)2, 1 mM EGTA supplemented with protease inhibitors and 2mM DTT). Cells were resuspended in equal volume of TPB and the plasma membrane selectively was permeabilized using digitonin. Successful permeabilization was controlled by trypan blue staining. Nuclei were separated from cytosol by centrifugation at 300 g for 5 min at 4°C, and the obtained cytosol subsequently cleared at 21,000 g for
10 min at 4°C. For cytosol derived from HeLa cells grown in suspension, the cells were grown to mid-log phase and collected by centrifugation. After several washes in PBS and once in TPB, cells were resuspended in 1 volume of lysis buffer (5 mM HEPES-KOH pH 7.3, 10 mM K-acetate, 2 mM Mg-acetate supplemented with 1 mM PMSF, 2 mM DTT and 1 μg/ml each of aprotinin, pepstatin and leupeptin. Cells were allowed to swell for 10 min on ice and then lysed by addition of digitonin. Nuclei were pelleted by centrifugation for 5 min at 300 g. The resulting cytosol was cleared by centrifugation for 15 min at 1,500 g and finally 60 min at 120,000 g before dialysis overnight against TPB supplemented with 2 mM DTT, 1 mM PMSF and 1 μg/ml each of aprotinin, leupeptin and pepstatin using 8,000 – 10,000 MWCO dialysis tubing. Cytosol concentration was determined by BCA assay. Before each experiment, cytosol was centrifuged at 21,000 g for 5-10 min at 4°C.

### Recombinant protein expression and purification

Protein concentrations were determined by their absorbance at 280 nm using their extinction coefficient (ε) predicted by the ProtParam tool. For all assays, 260/280 nm ratios of purified proteins were between 0.6 and 0.85.

### GST and GST-DPRs

Expression of GST and GST-DPRs was induced in BL21 and BL21-DE3 Rosetta, respectively, overnight at 16°C using 0.5 mM IPTG. For GST-DPRs, cells were lysed in DPR-lysis buffer A (20 mM Na2HPO4/NaH2PO4, pH 7.5, 500 mM NaCl, 1 mM EDTA, 50 mM glutamic acid, 5 mM DTT and 1 μg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A) using sonication and lysozyme. GST-DPRs were purified using GSTrap columns (GE Healthcare). To remove contaminants and RNA from GST-GA25s and -PR25s, columns were washed stringently with DPR high salt wash buffers of increasing ionic strength (20 mM Na2HPO4/NaH2PO4, pH 7.5, 50 mM glutamic acid, 2 mM DTT and protease inhibitors containing 1 M NaCl or 2 M NaCl). For GST-GR25s, the column was additionally treated with > 250 U/μl benzonase in benzonase buffer (10 mM Na-phosphate pH7.5, 2 mM MgCl2, 2 mM DTT and aprotinin pepstatin A) overnight at 4°C, before applying the washes with DPR high salt buffers as described above. GST-DPRs were eluted in DPR elution buffer (20 mM Na2HPO4/NaH2PO4, pH 7.5, 150 mM NaCl, 50 mM glutamic acid, 2 mM DTT and protease inhibitors) supplemented with 10-15 mM glutathione and dialyzed against GST-DPR storage buffer (20 mM Na HPO4, 60 mM Na2HPO4, 14 mM K2SO4, 5 mM MgCl2, pH 7.2 adjusted with HCl and NaOH with 0.1 dilution of trace metals, cytosol was centrifuged at 21,000 g for 5-10 min at 4°C, and the supernatant was subjected to size exclusion chromatography step using a gel filtration column (Hiload 16/600 Superdex 200 pg, GE Healthcare) and subsequently concentrated to 50-140 mM. GST-DPRs were eluted in buffer supplemented with 1 M NaCl and subjected to size exclusion chromatography as described above. GST was purified using GSTrap columns (GE Healthcare), washed with DPR wash buffer (50 mM Tris pH7.5, 150 mM NaCl, 2 mM DTT and protease inhibitors) and eluted in wash buffer containing 10 mM glutathione. GST was dialyzed against GST-DPR storage buffer.

### (His6)-TNPO1 and His6-TNPO3

Recombinant His6-TNPO1 and -TNPO3 were essentially purified as described before for His6-TNPO1 (Hofweber et al., 2018). In brief, E. coli BL21-DE3 Star cells transformed with the respective plasmid were grown for 2-3 days in minimal medium (100 mM KH2PO4, 50 mM K2HPO4, 60 mM Na2HPO4, 14 mM K2SO4, 5 mM MgCl2, pH 7.2 adjusted with HCl and NaOH with 0.1 dilution of trace element solution (41 mM CaCl2, 22 mM FeSO4, 6 mM MnCl2, 3 mM CoCl2, 1 mM ZnSO4, 0.1 mM CuCl2, 0.2 mM (NH4)6Mo7O24, 17 mM EDTA) supplemented with 6 g of glucose and 3 g of NH4Cl. Subsequently, cells were diluted to an OD600 of 0.8 and induced with IPTG to induce protein expression at room temperature for 4-5 h (TNPO1) or overnight at 20°C (TNPO3). His6-tagged proteins were affinity purified using Ni-NTA agarose beads (QIAGEN) overnight at 4°C, before applying the washes with DPR high salt buffers as described above. GST-DPRs were eluted in DPR elution buffer (20 mM Na2HPO4/NaH2PO4, pH 7.5, 150 mM NaCl, 50 mM glutamic acid, 2 mM DTT and protease inhibitors) supplemented with 10-15 mM glutathione and dialyzed against GST-DPR storage buffer (20 mM Na2HPO4/NaH2PO4, pH 7.5, 150 mM NaCl, 50 mM glutamic acid, 2 mM β-mercaptoethanol). If GST-GR25 was concentrated above 100 μM, a storage buffer containing 0.5 M NaCl was used.

For purification of GST, cells were lysed in DPR lysis buffer B (20 mM Na2HPO4/NaH2PO4, pH 7.5, 500 mM NaCl, 1 mM EDTA, 2 mM DTT and 1 μg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A as protease inhibitors) using sonication and lysozyme. GST was purified using GSTrap columns (GE Healthcare), washed with DPR wash buffer (50 mM Tris pH7.5, 150 mM NaCl, 2 mM DTT and protease inhibitors) and eluted in wash buffer containing 10 mM glutathione. GST was dialyzed against GST-DPR storage buffer.

### His6-GFP-TNPO1

His-GFP-TNPO1 was expressed overnight at 18°C in BL21-DE3 Rosetta 2 using 0.35 mM IPTG and purified in 50 mM Tris pH 8, 250 mM NaCl, 2 mM MgCl2 supplemented with 4 mM β-mercaptoethanol and protease inhibitors (1 μg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A) using Ni-NTA agarose (QIAGEN). To remove contaminants, His-GFP-TNPO1 bound to Ni-NTA was washed with purification buffer containing 1 M NaCl and 20 mM imidazole. His-GFP-TNPO1 was eluted in buffer supplemented with 300 mM imidazole and subjected to size exclusion chromatography in 20 mM Na2HPO4/NaH2PO4 pH 7.5, 75 mM NaCl, 5% (v/v) glycerol, 2 mM DTT and protease inhibitors (1 μg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A). Purified His-GFP-TNPO1 was concentrated to > 100 μM and stored at –80°C.
GST-Tev-TNPO1

Recombinant GST-Tev-TNPO1 was purified as described previously (Chook and Blobel, 1999) with modifications. In brief, E. coli BL21-CodonPlus(DE3)-RIL cells (Agilent) were transformed with GST-Tev-TNPO1 plasmid and expression was induced overnight at 37 C with 1 mM IPTG. Cells were pelleted and resuspended in Tris buffer (50 mM Tris pH 7.5, 100 mM NaCl, 1 mM EDTA, 20% (v/v) glycerol, 2 mM DTT, supplemented with protease inhibitors), then lysed by sonication. Cell lysate was then loaded onto glutathione Sepharose™ 4 Fast Flow resin (GE Healthcare), and washed with Tris buffer, followed by ATP buffer (50 mM Tris pH 7.5, 100 mM NaCl, 1 mM EGTA, 0.5 mM MgCl2, 5 mM ATP, 20% glycerol, 2 mM DTT, supplemented with protease inhibitors), then washed and eluted with Buffer A (20 mM imidazole, 75 mM NaCl, 1 mM EDTA, 20% (v/v) glycerol, 2 mM DTT). Finally, the protein was cleaved with Tev protease and purified on a HiTrap Q HP column (GE Healthcare) using a salt gradient. Purified protein was concentrated, flash frozen, and stored at –80°C.

His6-S-Impβ and His6-GFP-Impβ

For expression of His-S-Impβ, BL21-DE3 Rosetta2 transformed with the respective expression plasmid were grown to OD600~1.2 and diluted to OD600 ~0.6 using ice cold medium and supplemented with 30 mM K2HPO4 and 2% EtOH before addition of 0.3-0.5 mM IPTG overnight at 18°C. His-S-Impβ was purified in Talon buffer (50 mM Tris pH 8, 250 mM NaCl, 2 mM MgCl2, 10% (v/v) glycerol, 20 mM imidazole supplemented with 4 mM β-mercaptoethanol and 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A using Ni-NTA agarose (QIAGEN). To remove contaminants, His-S-Impβ bound to Ni-NTA was washed in lysis buffer supplemented with 1M NaCl after an optional washing step with 20 mM imidazole, 10 mM ATP and 5 mM MgCl2 in presence of denatured protein. His-S-Impβ was eluted in lysis buffer supplemented with 300 mM imidazole and subjected to size exclusion chromatography (HiLoad 16/600 Superdex 200 pg, GE Healthcare) in 20 mM Na2HPO4/NaH2PO4 pH 7.5 or pH 8, 75 mM NaCl, 5% (v/v) glycerol, 2 mM DTT and 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A. If required, purified Impβ was concentrated to > 150 µM.

His6-Imp2x1 and His6-Imp2x3

Expression of His-Imp2x1 and Imp2x3 were induced in BL21-DE3 Rosetta-LysS or BL21-DE3 Rosetta, respectively, using 0.5 mM IPTG at OD600 ~0.8 for ~5h or at 18°C overnight. Purification of His-Imp2x1 was performed in 20 mM Tris pH7.5, 600 mM NaCl supplemented with 4 mM β-mercaptoethanol, 1 mM PMSF and 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A using HisTrap columns. For His-Imp2x3, 50 mM Tris pH7.5, 600 mM NaCl, 0.2% Tween-20 supplemented with 4 mM β-mercaptoethanol, 1 mM PMSF and 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A was used. The protein on the column was washed with the respective lysis buffer lacking Tween-20 supplemented with increasing imidazole concentrations (10 mM, 12 mM, 15 mM) before elution using buffer containing 600 mM imidazole. Finally, size exclusion chromatography (HiLoad 16/600 Superdex 200 pg, GE Healthcare) was performed in 50 mM Tris pH7.5, 250 mM NaCl, 0.8 mM PMSF, 2 mM DTT, 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A (Imp2x1) or 50 mM Tris pH7.5, 150 mM NaCl, 1 mM PMSF, 4 mM β-mercaptoethanol, 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A (Imp2x3). If required, the protein was concentrated to ≥ 100 µM.

CRM1

His10-ZZ-CRM1 was induced in BL21-DE3 Rosetta2 overnight at 18°C using 0.5 mM IPTG. Cells were lysed in 50 mM Tris pH7.4, 500 mM NaCl, 1 mM EDTA, 2 mM MgCl2, 2 mM imidazole supplemented with 4 mM β-mercaptoethanol, 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A and 0.1 mg/ml RNase A using lysozyme and sonication. His10-ZZ-CRM1 was purified using Ni-NTA agarose (QIAGEN). After several washes with CRM1 buffer A (50 mM Tris pH7.4, 500 mM NaCl, 2 mM MgCl2, 2 mM imidazole, 4 mM β-mercaptoethanol, 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A), His10-ZZ-CRM1 was eluted by CRM1 buffer A with 300 mM imidazole. The His-ZZ-tag was cleaved off during overnight dialysis against 20 mM Na2HPO4/NaH2PO4 pH7.4, 75 mM NaCl, 5% (v/v) glycerol, 2 mM DTT using His-Tev protease. Cleaved CRM1 was separated from both His-ZZ tag and protease using size exclusion chromatography (HiLoad 16/600 Superdex 200 pg, GE Healthcare) in dialysis buffer and subsequently concentrated to ≥ 70 µM.

TDP-43-MPB-His6

TDP-43-MPB-His6 was purified with minor amendments according to Wang et al. (2018). In brief, protein expression was performed in E. coli BL21-DE3 Rosetta 2 or BL21-codonPlus (DE3)- RIL cells (Agilent) using 0.5 mM or 0.1 mM IPTG, respectively, overnight at 16°C.

For visualization of TDP-43 phase separation by microscopy or sedimentation analysis, cells were lysed in purification buffer (20 mM Tris pH 8, 1 M NaCl, 10 mM imidazole, 10% (v/v) glycerol, 4 mM β-mercaptoethanol and 1 µg/ml each of aprotinin, leupeptin hemisulfate and pepstatin A) supplemented with 0.1 mg/ml RNase A using lysozyme and sonication. For turbidity assays, cells were resuspended in purification buffer (20 mM Tris pH 8.0, 1 M NaCl, 10 mM imidazole, 10% (v/v) glycerol, 2 mM β-mercaptoethanol supplemented with complete EDTA-free protease inhibitor cocktail) and lysed using lysozyme and sonication. Protein was purified by Ni-NTA agarose (QIAGEN) and eluted using 300 mM imidazole in purification buffer. For all microscopy-based assays or sedimentation analysis, full length TDP-43-MPB-His6 was separated from protein aggregates and contaminants by size exclusion chromatography (HiLoad 16/600 Superdex 200 pg, GE Healthcare) in 20 mM Tris pH 8, 300 mM NaCl, 10% (v/v) glycerol supplemented with...
2 mM DTT. For turbidity measurements, TDP-43-MBP-His<sub>6</sub> was further purified over amylose resin (NEB) and eluted with 20 mM Tris-HCl, pH 8.0, 1 M NaCl, 10 mM imidazole, 10 mM maltose, 10% (v/v) glycerol, and 1 mM DTT. Purified protein was concentrated, flash frozen and stored at −80°C.

**MBP- Tev-TDP-43-GFP-Tev-His<sub>6</sub>**

Expression was induced in BL21-DE3 Rosetta2 using 1 mM IPTG overnight at 15°C. The protein was purified by tandem-affinity purification using Ni-NTA agarose (QIAGEN) and amylose resin (NEB). First, cells were lysed in resuspension buffer (50 mM Na<sub>2</sub>PO<sub>4</sub>/NaH<sub>2</sub>PO<sub>4</sub> pH 8.0, 300 mM NaCl, 10 μM ZnCl<sub>2</sub>, 10% (v/v) glycerol, 40 mM imidazole, 4 mM β-mercaptoethanol and protease inhibitor cocktail (Sigma)) using sonication. The protein was bound to Ni-NTA agarose, washed with resuspension buffer lacking glycerol and eventually eluted in resuspension buffer including 250 mM imidazole. For binding to amylose beads, the eluate was diluted to 150 mM NaCl and after several washes with binding buffer eluted in 40 mM HEPES pH 7.5, 300 mM NaCl, 5% (v/v) glycerol, 1 mM DTT and protease inhibitors containing 20 mM maltose. MBP-TDP-43-GFP-His<sub>6</sub> was stored in 40 mM HEPES pH 7.5, 300 mM NaCl, 5% (v/v) glycerol, 1 mM DTT and protease inhibitors.

**His<sub>6</sub>-Tev**

Expression and purification was performed as described in Hofweber et al. (2018). In brief, expression was induced in BL21-DE3 Rosetta-LysS overnight at 20°C using 1 mM IPTG. Cells were lysed in 50 mM Tris pH8, 200 mM NaCl, 20 mM imidazole, 10% (v/v) glycerol, 4 mM β-mercaptoethanol and 1 μg/ml each aprotinin, leupeptin and pepstatin in presence of 0.1 mg/ml RNase A using lysozyme and sonication. His-Tev was purified using Ni-NTA agarose (QIAGEN), washed using lysis buffer containing 1 M NaCl and eluted in lysis buffer at pH 8.5 supplemented with 800 mM imidazole. His<sub>6</sub>-Tev was dialyzed against storage buffer (50 mM Tris, 150 mM NaCl, 20% glycerol, 2 mM DTT).

**Biotin-DPR Pulldowns**

For pulldowns (PDs) using biotin-labeled DPR peptides as bait, Streptavidin Sepharose HP (GE Healthcare) was blocked with 20 mg/ml chicken ovalbumin in B-buffer (50 mM Tris pH 7.5, 200 mM NaCl, 20% glycerol, 2 mM DTT and protease inhibitors), before biotin-labeled DPRs were immobilized overnight in presence of 2 mg/ml ovalbumin in B-buffer (5 μg peptide per reaction on 10 μl bead volume). For the actual pulldown, 5 μg of prey protein per reaction was added to immobilized biotin-DPRs in B-buffer with 2 mg/ml BSA (50 mM Tris pH 7.5, 200 mM NaCl, 1 M MgCl<sub>2</sub>, 5% (v/v) glycerol supplemented with 2 mM DTT and protease inhibitors). After several washes in B-buffer lacking BSA, bound proteins were eluted from the beads using two-fold concentrated protein loading buffer (125 mM Tris pH 6.8, 20% (v/v) glycerol, 4% (w/v) SDS, 0.05% (w/v) bromophenolblue, 2% (v/v) β-mercaptoethanol) and visualized by SDS-PAGE and Sypro-Ruby (Sigma) stain. PDs were performed ≥2 times as independent replicates.

**Fluorescence Polarization Measurements**

For this assay, N-terminally fluorescein isothiocyanate (FITC)-labeled GR<sub>25</sub> and PR<sub>25</sub> peptides were used at 250 nM. All protein samples were equilibrated in 50 mM Tris (pH 7.5), 200 mM NaCl, 2 mM TCEP, 1 mM MgCl<sub>2</sub>, 5% (v/v) glycerol. Measurements were taken at room temperature in black 384-well plates using a ClarioStar Plus (BMG labtech) spectrophotometer. Filters were selected as a function of FITC optical characteristics (λ<sub>ex</sub> = 495 nm, and λ<sub>em</sub> = 530 nm). 250 nM FITC-GR<sub>25</sub> and FITC-PR<sub>25</sub>, respectively, was incubated with increasing concentration of purified TNPO1 in a final volume of 35 μl. The polarization data were fitted using CLARIOstar - Data Analysis (MARS) to the following equation:

\[
P = P_0 + (P_{\text{max}} - P_0) \frac{L}{(L + K_D)}
\]

Here, \(P_0\) represents the polarization of FITC-GR<sub>25</sub> and FITC-PR<sub>25</sub> in absence of TNPO1, and \(P_{\text{max}}\) to the highest polarization of the binding curve corresponding to the saturation of the interaction. \(L\) corresponds to the concentration of TNPO1 protein and \(K_D\) is the dissociation constant.

**SAXS**

For this assay, N-terminally fluorescein isothiocyanate (FITC)-labeled GR<sub>25</sub> and PR<sub>25</sub> peptides were used. All samples were equilibrated in 50 mM Tris (pH 7.5), 200 mM NaCl, 2 mM TCEP, 1 mM MgCl<sub>2</sub>, 5% (v/v) glycerol. SAXS data for solution of the TNPO1-[GR]<sub>25</sub> and TNPO1-[PR]<sub>25</sub> complexes were recorded with an in-house SAXS instrument (SAXSspace, Anton Paar, Graz, Austria) equipped with a sealed X-ray tube source and a one-dimensional Mythen2 R 1k hybrid photon coupling detector (Dectris, Baden-Daettwil, Switzerland). The scattering patterns were measured with a 90-minutes exposure time (90 frames, each 1 minute) with a solute concentration of 50 μM (TNPO1) at 4°C. Radiation damage was excluded on the basis of a comparison of individual frames of the 90-minutes exposures, wherein no changes were detected. A range of momentum transfer of 0.010 < q < 0.63 Å<sup>−1</sup> was covered (s = 4π sin(θ)/λ, where 2θ is the scattering angle, and λ is the X-ray wavelength, in this case 1.5 Å).

All SAXS data were analyzed and processed using the SAXS analysis package (Anton Paar, version 3.0). The data were desmeared using GIFT (PCG-Software). The interatomic distance distribution function (P(r)) were computed with GIFT (PCG-Software).
In vitro phase separation assays
For all assays, the investigated protein or cytosol was centrifuged for 5-10 min at 4°C and 21,000 g to remove any preformed protein precipitates.

Sedimentation assay
For sedimentation analysis of NTRs, 1 μM purified NTR (or 500 nM Imp2 with 500 nM Imp3) was incubated in the absence or presence of indicated amounts of TMR-labeled DPRs in 50 μL condensation buffer (50 mM Tris pH 7.5, 200 mM NaCl, 2 mM DTT) for 15 min at 4°C, followed by centrifugation for 15 min at 21,000 g at 4°C. For quantitative sedimentation analysis of TDP-43, 1 μM of purified TDP-43-MBP-His was cleaved in the absence or presence of equimolar amounts of GST-tagged DPRs and/or NTRs using 20 μg/ml His-Tev for 60 min at 30°C, followed by centrifugation for 15 min at 21,000 g at 4°C. Equal volumes of supernatant and pellet fraction were analyzed by SDS-PAGE and proteins visualized by Sypro-Ruby stain or western blot.

For sedimentation analysis of proteins from HeLa cytosol, cytosol was used at 1 mg/ml in TPB (20 mM HEPES pH 7.3-7.4, 110 mM K-Ac, 2 mM Mg(Ac)_2, 1 mM EGTA supplemented with protease inhibitors and 2 mM DTT). Indicated concentrations of TMR-labeled DPRs were added and reactions incubated for 15 min at 4°C before centrifugation at 21,000 g for 15 min. Equal volumes of pellet and supernatant were analyzed by western blot analysis.

Visualization of condensates by microscopy
To visualize condensation of GFP-TNPO1 by R-rich DPRs, 1 μM purified His-GFP-TNPO1 or GFP-Imp3 (in absence or presence of equimolar amounts of unlabeled His-Imp3x3) was incubated with indicated concentration of TMR-labeled DPRs in droplet buffer A (20 mM Na3HPO4/NaH2PO4, pH 7.5, 200 mM NaCl, 2.5% (v/v) glycerol, 1 mM DTT). To follow TDP-43 condensate formation, 2 μM TDP-43-MBP-His mixed with substoichiometric amounts of MBP-TDP-43-GFP-His (ratio 1:4-1:5) was cleaved in the absence or presence of TMR-labeled DPRs at indicated concentrations using 100 μg/ml His-Tev in condensation buffer (50 mM Tris pH 7.5, 200 mM NaCl, 2 mM DTT). For shielding by NTRs, TDP-43-Tev-MBP/MBP-Tev-TDP-43-GFP was mixed with equimolar concentration of TMR-GR25b in absence or presence of NTRs before Tev-cleavage. Condensates were imaged in 384 well plates using a laser scanning confocal microscope. For RNA-induced condensate formation of TMR-GR25b, total RNA was heated for 1 min at 65°C and chilled on ice before adding it to a final concentration of 20 ng/μl to 20 μM TMR-GR25b in the absence or presence of equimolar concentrations of NTRs in 20 mM Na3HPO4/NaH2PO4 pH7.5, 200 mM NaCl, 2.5% (v/v) glycerol and 2 mM DTT.

For analysis of GR-induced GFP-TNPO1 condensates by FRAP, 2 μM GFP-TNPO1 were incubated with 20 μM TMR-GR25 for 1-2 h at RT in a microscopic chamber before FRAP analysis.

Analysis of oligomer formation by SDD-AGE
Samples were prepared in protein low binding tubes (Eppendorf) using 2 μM importin and 20 μM TMR-DPR in 50 mM Tris pH 7.5, 200 mM NaCl supplemented with 1× protease inhibitor mix (Sigma) and 1 mM TCEP. After 1 h incubation at RT, samples were analyzed by SDD-AGE (modified protocol according to French et al. [2019] and Halfmann and Lindquist [2008]) in SDD-AGE buffer (40 mM Tris-HCl pH 6.8, 5% Glycerol, 0.5% SDS, 0.1% bromphenol blue) on a horizontal 1.5% agarose gel in running buffer (60 mM Tris, 20 mM Acetate, 200 mM glycine, 1 mM EDTA and 0.1% SDS) for 5-6 h at low voltage. Proteins are transferred on nitrocellulose membrane using capillary transfer in TBS (50 mM Tris pH 7.6, 150 mM NaCl) overnight at 4°C and subsequently processed according to western blot standard protocol.

Turbidity assay
Purified TDP-43-MBP-His and TNPO1 were first thawed and buffer exchanged into 20 mM HEPES-NaOH, pH 7.4, 150 mM NaCl and 1 mM DTT, using a Micro Bio-Spin™ P-6 Gel Column (Bio-Rad). TDP-43-MBP-His was then diluted to a final concentration of 5 μM, with addition of either 2 μM GR25 (or equivalent volume of 1× PBS as a control), 5 μM TNPO1, or addition of both. Phase separation was initiated by addition of 1 μg/ml Tev protease and measured over 16 h at an absorbance of 395 nm using a TECAN M1000 plate reader. Values were normalized to TDP-43 + Tev protease alone to determine the relative extent of phase separation.

Solubility assay of endogenous TDP-43 by RIPA extraction
HeLa cells (0.5×10^6) were incubated with 10 μM TMR-DPRs (in medium lacking serum) for 2h and then harvested by scraping into PBS and centrifugation at 1,200 g for 5 min. The cell pellet was resuspended in 200 μL RIPA buffer (50 mM Tris-HCl, pH 8.0, 150 mM NaCl, 1% NP-40, 0.5% deoxycholate, 0.1% SDS) supplemented with ~0.05U/μl benzonase (Sigma), 1x Sigma protease inhibitor mix and 1x phosphatase inhibitors (final concentration: 10 mM NaF, 1 mM β-glycerophosphate, 1 mM Na2VO4) and incubated on ice for 10-15 min. Cells were sonicated for 45 s using a BioRuptorPico (Diagenode) and 10% of the lysate retained for the input. The rest of the lysate was centrifuged for 30 min at 13,000 g and 4°C to separate the RIPA-soluble proteins from the insoluble proteins. The RIPA insoluble pellet was resuspended and washed once in RIPA buffer, followed by 45 s sonication in the BioRuptorPico and subsequent centrifugation at 13,000 g for 30 min at 4°C. The RIPA insoluble pellet was finally lysed in 40 μL Urea buffer (7 M urea, 2 M thiourea, 4% CHAPS, 30 mM Tris-HCl, pH 8.5) and 45 s sonication using the BioRuptorPico. Samples were analyzed by anti-TDP-43
western blot. Note that the 4.5x overrepresentation of the pellet fraction for reasons of visibility in the western blot was corrected in the quantification.

**Immunocytochemistry**

HeLa cells grown on No. 1.5 coverslips were fixed in 3.7% formaldehyde/PBS buffer for 7-10 min at RT. Permeabilization was performed using 0.5% (v/v) TX-100/PBS for 5 min at room temperature. Cells were subsequently blocked in blocking buffer (at least 10 min in 1% donkey serum in PBS/0.1% Tween-20) and incubated with primary antibodies in blocking buffer for 1-2 h at RT or overnight at 4°C. Secondary antibodies were diluted 1:1000 in blocking buffer and incubated for 30-60 min at room temperature. Three washing steps after each antibody incubation were performed using PBS/0.1% Tween-20. DNA was stained with DAPI at 0.5 μg/ml in PBS and cells mounted in ProLong Diamond Antifade.

**Nuclear transport assay (Hormone-induced import assay)**

To analyze import of GCR2-GFP tagged (MBP-)cNLS or TDP-43 reporters, HeLa cells were grown for at least 2 passages in DMEM supplemented with 10% dialyzed FBS. Cells were either left untreated (control) or pre-incubated for 2h with 10μM TMR-labeled GR25 or PR25 added once directly into the imaging medium (fluorobrite without serum). Import of the GCR2-GFP2-reporter was induced by adding dexamethasone (5 μM final concentration) in imaging medium and followed by live cell imaging using a spinning disk confocal microscope. Images were acquired for a duration of 40-50 min in 2.5 min intervals. Successful uptake of the peptide was validated before start of the experiment and only cells displaying efficient peptide uptake in form of cytoplasmic (and/or nuclear) TMR signal were subsequently quantified.

**MICROSCOPY**

**Laser scanning confocal microscopy**

Confocal microscopy of HeLa cells and condensates of recombinant proteins was performed at the Bioimaging core facility of the Biomedical Center with an inverted Leica SP8 microscope, using lasers for 405, 488, 552 and 638 nm excitation. For fixed cells, images were acquired using two-fold frame averaging with a 63x1.4 oil objective and an image pixel size of 59 nm. The following fluorescence settings were used for detection: DAPI; 419-442 nm, GFP; 498-533 nm, Alexa 555: 562-598 nm, Alexa 647: 650-700 nm. Recording was performed sequentially to avoid bleed-through using a conventional photomultiplier tube (PMT). Unless otherwise noted, images of condensates were acquired without averaging. For DPR-induced condensation of GFP-TNPO1 or TDP-43, a 63x/1.4 oil objective was used with an image pixel size of 70-71 nm. For condensates of TMR-GR25 in presence of RNA or TDP-43 with NTRs, a 100x/1.4 oil objective was used with pixel size of 80 nm and 70 nm respectively. Recording, if applicable, was performed sequentially using a PMT with the following settings: GFP; 498-520 nm, TMR: 562-615 nm. For images of condensate formation of TDP-43 in the presence of NTRs, two-fold frame averaging with the following PMT settings: GFP; 498-533.

**Spinning disc confocal live cell microscopy**

Live cell imaging was performed at 36.5°C and 5% CO2 (EMBLEM environmental chamber) using an inverted microscope (Axio Observer.Z1; Carl Zeiss, Oberkochen, Germany) equipped with a confocal spinning disc (CSU-X1; Yokogawa, Tokyo, Japan) and a 63x/1.4 oil immersion lens. Images were acquired using the 488 nm SD laser line and an EM-CCD camera (EvolveDelta; Photometrics) at bin 1x1. For photobleaching, a laser scanning device (UGA-42 Geo; Rapp OptoElectronic, Hamburg, Germany) was used, allowing for simultaneous laser illumination within hardware-defined shapes of different sizes.

**Fluorescence Recovery after Photobleaching (FRAP)**

Experiments were performed on an inverted microscope (Axio Observer.Z1; Carl Zeiss, Oberkochen, Germany) equipped with a confocal spinning disc (CSU-X1; Yokogawa, Tokyo, Japan) and a 100x/1.46/Ph3 (TNPO1 Condensates) or 63x/1.4 (live cells) oil immersion lens. For localized photobleaching, a laser scanning device (UGA-42 Geo; Rapp OptoElectronic, Hamburg, Germany) was used. The “Geo” module allowed for simultaneous laser illumination within hardware-defined shapes of different sizes. Here, a square-like shape with an illumination size of ~5 μm (TNPO1 condensates) or 10 μm (cytoplasmic FRAP) in the sample was selected. For each experiment, the initial fluorescence intensity was bleached to ≥30% of the initial intensity using a 473 nm diode laser (DL-473/75; Rapp OptoElectronic, Hamburg, Germany). For live cells, images were acquired in the streaming mode using the 488 nm SD laser line and an EM-CCD camera (EvolveDelta; Photometrics) at bin 1x1. Fluorescence recovery of ≥14 bleached condensates was recorded at RT using streaming mode for 1 min followed a block of 4 min with image acquisition in 15 s intervals in two independent experiments.

**QUANTIFICATION AND STATISTICAL ANALYSIS**

**Microscopy**

Laser scanning confocal images were acquired using LAS X (Leica), live cell images were acquired in ZEN2 (Zeiss). All images were processed using ImageJ/Fiji software applying linear enhancement for brightness and contrast. For quantification of size
of RNA/TMR-GR<sub>25</sub> condensates in absence or presence of NTRs, confocal images were analyzed using ImageJ/Fiji. Images were displayed in gray values and a median filter with radius 2 applied. A threshold providing best coverage of condensates was set identically to all images within one experiment using the default setting built into Fiji/ImageJ and allowing for detection of white objects on black background. Subsequently a particle analysis was performed excluding particles < 0.1.

 Statistical analyses were performed in GraphPad Prism 8, details are given in each figure legend.

**FRAP analysis of cytoplasmic GCR<sub>2</sub>-GFP<sub>2</sub> dynamics**

Intensities of bleached areas were corrected both for bleaching due to imaging over time and background noise. The corresponding calculations were performed with the FIJI/ImageJ macro “TimeSeries Analyzer” by calculating the fluorescence intensity over time \( I(t) \) as follows:

\[
I(t) = \frac{[\text{ROI1}(t) - \text{ROI3}(t)]}{[\text{ROI2}(t) - \text{ROI3}(t)]}
\]

with ROI1 giving the averaged gray values within the center of the bleached area, and ROI2 corresponds to the averaged gray values of the total cell. ROI3 corresponds to averaged background values. Obtained values were further normalized to the initial fluorescence by dividing \( I(t) \) by the mean gray value of the first image before bleaching \( (t = 0) \).

**Densitometry measurements (Sypro-Ruby, western blot)**

To determine the solubility of NTRs, TDP-43 or GST-GR<sub>25</sub>, by quantitative sedimentation analysis, densitometry measurements of band intensities of supernatant and pellet fractions were performed after Sypro-Ruby gel staining or western blot analysis. For this, implemented plugins in the corresponding gel detection software for Sypro-Ruby staining (Image Lab Software; Bio-Rad Laboratories) or western blot (Image Studio Software; Li-Cor) were employed. To determine the solubility of individual proteins, the relative amount of the respective protein in the supernatant was calculated as percent of the total (i.e., sum of supernatant and pellet). All statistical analyses were performed in GraphPad Prism 8 and details indicated in the respective figure legends.
