The properties of quasispecies dynamics in molecular evolution

V. V. Gafiychuk * and A. K. Prykarpatsky†

February 2, 2008

Abstract

We consider the general properties of the quasispecies dynamical system from the standpoint of its evolution and stability. Vector field analysis as well as spectral properties of such system has been studied. Mathematical modelling of the system under consideration has been performed. 

Keywords: quasispecies dynamics, Hamiltonian systems, gradient dynamical system, biological evolution, complex system.

1 Introduction

This article is devoted to the theoretical study of a self-organization problem of an ensemble of interacting species and to developing a model of a naturally fitted coevolving ecosystem. It is well known since Eigen’s work on replicating molecules [1] that the quasispecies approach is very fruitful for modeling the fundamental behavior of evolution (See, for example [2, 4, 5, 6, 7]). Despite a huge amount of papers devoted to this problem biological evolution is too complex that we are still far from understanding real biological processes of self-organization. The matter is that real experiments and obtained data on the evolution of primitive systems need a comprehensive theoretical description that would allow to explain these data and put them into a proper context. In this case the central place is put to the investigation of intrinsic properties of a nonlinear system which describe the system evolution. We put our attention to Eigen’s approach and will establish some new but very important mathematical properties of the system which could be useful for modeling many co-evolving ecosystem. In part we will use an approach devised in [8] for describing similar systems of evolution.

†Dept. of Applied Mathematics at the AGH University of Science and Technology, Cracow, Poland and Institute for Applied Problems of Mechanics and Mathematics at the National Academy of Sciences Mailling address: Institute for Applied Problems of Mechanics and Mathematics at the National Academy of Sciences, Naukova St, 9-b, Lviv 79601, Ukraine
We start our analysis of quasispecies dynamics in molecular evolution with discussion of background of modeling aspects which appear to be very important for further. The first principle of modeling such types of dynamics we accept here is based on probability consideration of molecular replicator processes and which are well described by resulting quasispecies concentration vector \( x \in [0, 1]^n \), where \( n \in \mathbb{Z}_+ \) is a number of species, being normalized by the full probability condition \( \sum_{j=1}^{n} x_j = 1 \). The latter condition is fundamental ensuring the full molecular number concentration and will play, in what will follow, an important role. Moreover, the set of such vectors \( x \in \mathbb{R}^n \) in the Euclidian space \( \mathbb{R}^n \) forms the algebraic simplicial submanifold \( S_{n-1} \subset \mathbb{R}^n \) on which in reality the studied dynamics holds. For it to be described analytically, it is naturally to consider a representative symmetric matrix \( P \in \text{End}\mathbb{R}^n \), such that \( P = f \otimes f, \langle f, f \rangle = 1 \), for same vector \( f \in \mathbb{R}^n \) modeling the resulting replicator dynamics simultaneously ensuring two constraints: life on the simplex \( S_{n-1} \) and conservation of the initial molecular system information during its replicator evolution. In general, such a dynamics can be represented in the following form:

\[
P(t) = U(t)P(0)V^{-1}(t),
\]

with evolution parameter \( t \in \mathbb{R} \), for some invertible mappings \( V, U : \mathbb{R} \to \text{GL}(\mathbb{R}^n) \), where \( P(0) \in \text{End}\mathbb{R}^n \) is an initial molecular dynamics state. Below we consider the symmetric replicator dynamics, whose the inverse replicator process matrix \( V \in \text{GL}(\mathbb{R}^n) \) has to coincide with the forward replicator process matrix \( U \in \text{GL}(\mathbb{R}^n) \), that is the equality \( U = V \) holds. As a result, our dynamics is representable as

\[
P(t) = U(t)P(0)U^{-1}(t) \tag{1}
\]

for all moments of time \( t \in \mathbb{R} \). Assuming smooth dependence of \( \mathbb{R}^n \) on \( t \in \mathbb{R} \), one easily derives that the following Lax type dynamics

\[
dP/dt = [\Lambda, P] \tag{2}
\]

holds, where by definition, the matrix \( \Lambda := dU/dtU^{-1} \). For the matrix \( P \in \text{End}\mathbb{R}^n \) to conserve its symmetricity, the matrix \( \Lambda \in \text{End}\mathbb{R}^n \) must be evidently skew-symmetric, that is \( \Lambda = -\Lambda^* \) in \( \mathbb{R}^n \).

Return now back to analyzing the intrinsic structure of our matrix \( P \in \text{End}\mathbb{R}^n \), modeling replicator dynamics under regard. From the general form \( \mathbb{R}^n \) one sees that our dynamics possesses a priori so called trace-invariants, namely, all quantities \( SpP^m \) are such for any \( m \in \mathbb{Z}_+ \), where \( Sp : \text{End}\mathbb{R}^n \to \mathbb{R} \) is the standard matrix trace operator. This fact may be naturally used within our modeling approach. Really, consider a representative vector \( f \in \mathbb{R}^n \) in the following form: \( f = \{ \sqrt{x_i} \in \mathbb{R} : i = \frac{1}{n}, n \} \). Then, the condition \( \langle f, f \rangle = \sum_{j=1}^{n} x_j = 1 \) is satisfied due to the equality \( SpP = \sum_{j=1}^{n} x_j \) and the fact that the latter quantity
is conserved! Since $P^2 = P$, all of the other invariants are the same, introducing into the dynamics no additional constraint. Thus, we have naturally imbedded our molecular replicator dynamics initially in the space of concentration vectors $x \in S_{n-1} \subset E^n$ into the matrix phase space $P \ni P$ of symmetric projector mappings of co-dimension one, that is $P = P^*$ and $\dim(\text{Im} P) = 1$. The latter phase space $P$ is still called a Grassmann manifold possessing a lot of important intrinsic mathematical properties, which we shall use further for deeper analyzing our molecular replicator dynamics under regard.

Consider an evolution equation modeling our molecule replicator dynamics in the general matrix Lax type form (2), where $\Lambda(x) = \{ \Lambda_{jk} : j, k = 1, n \}$ is a certain matrix depending on variables $x = \{ x_i \in \mathbb{R}_+ : i = 1, n \}$ and $P = \{ \sqrt{x_j x_k} : j, k = 1, n \}$. In this case as the matrix $P$ symmetric, it is evident that the matrix $\Lambda$ must be skew-symmetric. Below we will put the main attention to processes similar to quasispecies dynamics considered in [1, 2]. Since we will consider $x \in [0,1]^n$ as a concentration vector of quasispecies, it has to be nonnegative for all time, so the system (1) now is defined on the nonnegative orthant $\mathbb{R}^+_n = \{ x \in \mathbb{R}^n : x_i \geq 0 \}$.

Let us now suppose a system evolves due to the Eigen positive feedback associated with the terms corresponding to the increase of concentrations $x_j, j = 1, n$:

$$\frac{dx_j}{dt} = \sum_{k=1}^n a_{jk} x_k R_k(x) - F_j(x), \quad (3)$$

where an element $a_{jk}$ expresses the probability that a molecule $k$ copies into a molecule $j$ and $F_j(x)$ denotes the corresponding inverse sink term. In turn the element $a_{jj}$ gives the probability that a molecule $j$ replicates faithfully, $R_k(x)$ is the fitness of the molecules of $k$ type and characterizes their replication rate.

We have to determine the sink term $F_j(x), j = 1, n$, in order to fulfill the governing condition on the dynamic determined on the $(n-1)$ dimensional simplex

$$S_{n-1} = \left\{ x \in \mathbb{R}^+_n : \sum_{i=1}^n x_i = 1 \right\}. \quad (4)$$

In order to get the corresponding source term in the equation (3) let us determine elements $\Lambda_{jk}, j, k = 1, n$ of the skew symmetric matrix $\Lambda$ in (1) as

$$\Lambda_{jk} = \frac{1}{2} \left[ a_{jk} \sqrt{x_k / x_j} R_k(x) - a_{kj} \sqrt{x_j / x_k} R_j(x) \right], \quad (5)$$

It is easy to observe here that there exists the matrix $\overline{\Lambda} = \{ \frac{1}{2} a_{jk} \sqrt{x_k / x_j} R_k(x) : j, k = 1, n \}$, such that $\Lambda = \overline{\Lambda} - \overline{\Lambda}$. Substituting expression (5) into (1) we get that $F_j(x) = x_j R_j(x) \sum_{k=1}^n a_{kj}, j = 1, n$. As a result the governing equation for the quasispecies dynamics takes the form:
\[ \frac{dx_j}{dt} = \sum_{k=1}^{n} a_{jk} x_k R_k(x) - \sum_{k=1}^{n} \sqrt{x_j x_k} a_{kj} \sqrt{x_j / x_k} R_j(x) \]

\[ = \sum_{k=1}^{n} a_{jk} x_k R_k(x) - x_j R_j(x) \sum_{k=1}^{n} a_{kj} \]

\[ = \sum_{k \neq j} (a_{jk} x_k R_k(x) - x_j R_j(x)) a_{kj} \]  

(6)

It is easy to see after summing up equations (6) that

\[ \sum_{j}^{n} \frac{dx_j}{dt} = 0, \]

meaning in this case that the evolution dynamics is determined really on the simplex \([11]\).

It should be mentioned that the system (6) is a little bit diverse from systems considered in a set of papers \([2, 3, 4, 5, 6, 7]\) mainly by sink terms. But namely only such a form of the sink term ensures the important simplex condition \(\sum_{j}^{n} x_j = 1\) for all \(t \in \mathbb{R}\), without additional constraints involved in the model.

Note here that, the system (6) is really representable in the evolution form (1) that can be checked easily, and the matrix \(P \in \text{End}\mathbb{R}^n\) is a one dimensional symmetric projector, that is \(P^2 = P, P^* = P\) for \(t \in \mathbb{R}\), being important for our further studying the structure of vector field (11) on the corresponding projector matrix manifold \(P\) \([10, 11]\). The component vector form of the system (6) can be also represented as

\[ \frac{dx}{dt} = AX - BR(x)x. \]  

(7)

with \(A = \{a_{jk} : j, k = 1, n\}\), \(B = \text{diag} \left\{ \sum_{k=1}^{n} a_{kj} : j = 1, n \right\}\), and \(R(x), x \in S_{n-1}\) being a fitness matrix expression. If the fitness matrix \(R(x), x \in S_{n-1}\) is diagonal one that is \(R = \bar{R} = \text{diag} \left\{ \bar{R}_j : j = 1, n \right\}\) and does not depend on \(x \in S_{n-1}\), the system (7) evidently will be linear. Thereby the solution of such a system can be obviously represented as

\[ x(t) = x(0) \exp((A - B)\bar{R})t, \]

where \(x(0) \in S_{n-1}\) is a concentration of population of each type at initial time.

2 Vector field analysis: imbedding into gradient structure

Since our system dynamic flow (2) in reality lives on the projector matrix of Grassmann manifold \(P \in \text{End}\mathbb{R}^n\) \([12]\), all its properties can be naturally extracted
from deeper analysis of its structure on this manifold. In particular, it is important to know where the vector field \( \delta \) admits the structure of gradient type endowed with some Lyapunov function, ensuring the existence of stable states on the compact Grassmann manifold \( \mathcal{P} \). In order to study the gradient field structure of the flow \( \mathbf{1} \) if any on the projector matrix manifold \( \mathcal{P} \) let us consider a smooth functional \( \Psi : \mathcal{P} \rightarrow \mathbb{R} \), whose usual variation is given as

\[
\delta \Psi(P) := \text{Sp}(D\delta P)
\]

with a symmetric matrix \( D \in \text{End}E^n \) and \( \text{Sp} : \text{End}E^n \rightarrow \mathbb{R}^1 \) being as before the standard matrix trace. Taking into account the natural metrics on \( \mathcal{P} \), we consider the projection \( \nabla_{\varphi} \Psi \) of the usual gradient vector field \( \nabla \Psi \) upon the tangent space \( T(\mathcal{P}) \) under the following conditions:

\[
\varphi(X; P) := \text{Sp}(P^2 - P, X) = 0, \quad \text{Sp}(\nabla_{\varphi}, \nabla_{\varphi} \Psi)|_P = 0,
\]

holding on \( \mathcal{P} \) for all \( X \in \text{End}\mathbb{R}^n \). The first condition is evidently equivalent to \( P^2 - P = 0 \), that is \( P \in \mathcal{P} \). Thereby we can formulate such a Statement.

**Statement 1.** The functional gradient \( \nabla_{\varphi} \Psi(P), P \in \mathcal{P} \) under the condition \( \mathbf{9} \) admits the following commutator Lax type representation:

\[
\nabla_{\varphi} \Psi(P) = [\Lambda, P]
\]

with \( \Lambda \in \text{end}E^n \) being a skew-symmetric matrix satisfying the commutator equation

\[
\Lambda = [D, P],
\]

where \( D \) is a symmetric matrix. Really, consider the projection of the usual gradient \( \nabla \Psi(P) \) upon the tangent space \( T(\mathcal{P}) \) of the Grassmann manifold \( \mathcal{P} \) with \( P \in \mathcal{P} \) imbedded into \( \text{End}E^n \):

\[
\nabla_{\varphi} \Psi(P) = \nabla \Psi(P) - \nabla_{\varphi}(Q; P),
\]

where \( Q \in \text{End}E^n \) is some still unknown matrix. Taking into account the conditions \( \mathbf{9} \), we find that

\[
\nabla_{\varphi} \Psi(P) = D - Q - P(D - Q) - (D - Q)P + PD + DP = PD + DP + 2PQP,
\]

where we made use of the relationships

\[
\nabla_{\varphi} \Psi(P) = D - Q + PQ + QP)
\]

and

\[
P(D - Q) + (D - Q)P + 2PQP = D - Q.
\]

Now one can easily see from \( \mathbf{11} \) and the second condition in \( \mathbf{10} \), that

\[
PQP = -PD P\quad (12)
\]
for all $P \in \mathcal{P}$, giving rise to the final result

$$\nabla_\varphi \Psi(P) = PD + DP - 2PDP,$$

(13)

coinciding exactly with the commutator $[[D, P], P]$. Since the matrix admits the representation

$$\Lambda = \tilde{\Lambda} - \tilde{\Lambda}^* = DP - PD$$

one gets right away that

$$\tilde{\Lambda} = DP + S$$

(14)

with $S = S^* \in \text{End}E^n$. If there exists such symmetric matrices $D$ and $S \in \text{End}E^n$ that (14) is satisfied, then our model will be evidently of gradient type. In particular, the matrix $D \in \text{End}E^n$ found from (14) must enjoy the Volterra criteria

$$D'(P) = D^n(P)$$

for any $P \in \mathcal{P}$ imbedded into $\text{End}E^n$.

It should be noted here that the Grassmann manifold $\mathcal{P}$ is also a symplectic manifold [10, 11] whose canonical symplectic structure is given by the expression:

$$\omega^{(2)}(P) := \text{Sp}(PdP \wedge dPP),$$

(15)

where $d\omega^{(2)}(P) = 0$ for all $P \in \mathcal{P}$, and the 2-differential form (15) is non-degenerate [10, 12] upon the tangent space $T(\mathcal{P})$.

Let us assume now that $\xi : \mathcal{P} \to \mathbb{R}$ is an arbitrary smooth function on $\mathcal{P}$. Then the Hamiltonian vector field $X_\xi : \mathcal{P} \to T(\mathcal{P})$ on $\mathcal{P}$ generated by this function subject to the symplectic structure (14) is given as follows:

$$X_\xi = [[D_\xi, P], P],$$

(16)

where $D_\xi \in \text{End}E^n$ is a certain symmetric matrix. The vector field $X_\xi : \mathcal{P} \to T(\mathcal{P})$ generates on the compact manifold $\mathcal{P}$ the flow

$$dP/dt = X_\xi(P),$$

(17)

being defined globally for all $t \in \mathbb{R}$. This flow by construction is evidently compatible with the projector condition $P^2 = P$. This means in particular that the condition

$$-X_\xi + PX_\xi + X_\xi P = 0$$

(18)

holds on $\mathcal{P}$. Thus, we stated that dynamical system (2) being considered on the Grassmann manifold $\mathcal{P}$ can be Hamiltonian that makes it possible to formulate the following statement.

**Statement 2.** A gradient vector field of the form (14) on the Grassmann manifold $\mathcal{P}$ is Hamiltonian with respect to the canonical symplectic structure (15) and a certain Hamiltonian function $\xi : \mathcal{P} \subset \text{End}E^n \to \mathbb{R}$, satisfying conditions
\[ \nabla \xi(P) = [D\xi, P] - Z + PZ + ZP, \]
\[ \nabla \xi'(P) = \nabla \xi'^*(P), \]
\[ D\xi = D \]

for some matrix \( Z \in \text{End} E^n \) for all \( P \in P \subset E^n \).

Consider now the \((n-1)\)-dimensional simplex \( S_{n-1} \) as a Riemannian space \( M^{n-1}_g = S_{n-1} \) with the metrics

\[ ds^2(x) := d^2\Psi \big|_P (x) = \sum_{i,j=1}^n g_{ij}(x) dx_i dx_j \big|_P, \]

where for \( i, j = 1, n, g_{ij}(x) = \frac{\partial^2 \Psi(x)}{\partial x_i \partial x_j}, \sum_{i=1}^n x_i = 1. \)

Relative to the metrics on \( M^{n-1}_g \) we can calculate the gradient \( \nabla_g \Psi \) of the function \( \Psi : P \to \mathbb{R} \) and set on \( M^{n-1}_g \) the gradient vector field

\[ dx/dt = \nabla_g \Psi(x), \tag{19} \]

with \( x \in M^{n-1}_g \), that is the condition \( \sum_{i=1}^n x_i = 1 \) is satisfied a priori. Having calculated (19), we can formulate the next statement.

**Statement 3.** The gradient vector fields \( \nabla \varphi \Psi \) on \( P \) and \( \nabla_g \Psi \) on \( M^{n-1}_g \) are equivalent, or in another words, vector fields

\[ dx/dt = \nabla \Psi(x) \tag{20} \]

and

\[ dP(x)/dt = [[D(x), P(x)], P(x)] \tag{21} \]

generate the same flow on \( M^{n-1}_g \).

As a result from the Hamiltonian property of the vector field \( \nabla \varphi \Psi \) on the Grassmann manifold \( P \) we get such a new statement.

**Statement 4.** The gradient vector field \( \nabla_g \Psi \) on the metric space \( M^{n-1}_g \) where \( n = 2m + 1 \) is Hamiltonian subject to the non-degenerate symplectic structure

\[ \omega_g^{(2)}(x) := \omega^{(2)}(P) \big|_{M^{n-1}_g} \tag{22} \]

for all \( x \in M^{2m}_g \) with a Hamiltonian function \( \xi_\psi : M^{2m}_g \to \mathbb{R}, \) where \( \xi_\psi := \xi \big|_{M^{n-1}_g} \), \( \xi : \mathbb{R} \to \mathbb{R} \) is the Hamiltonian function of the vector field \( X_\xi \) on \( P. \) Otherwise, if \( n \in \mathbb{Z}_+ \) is arbitrary our two flows (20) and (21) are on \( P \) only Poissonian.
3 Spectral properties

Consider the eigenvalue problem for a matrix $P \in \mathcal{P}$, depending on the evolution parameter $t \in \mathbb{R}$:

$$P(t)f = \lambda f,$$

(23)

where $f \in \mathbb{R}^n$ is an eigenfunction, $\lambda \in \mathbb{R}$ is a real eigenvalue since $P^* = P$, i.e. matrix $P \in \mathcal{P}$ is symmetric. It is seen from the expression $P^2 = P$ that $\text{spec}(P(t)) = \{0, 1\}$ for all $t \in \mathbb{R}$. Moreover, taking into account the invariance of $\text{Sp}P = 1$ we can conclude that only one eigenvalue of the projector matrix $P(t), t \in \mathbb{R}$, is equal to 1, all others being equal to zero.

In general case the image $\text{Im}P \subset \mathbb{R}^n$ of the matrix $P(t) \in \mathcal{P}$ for all $t \in \mathbb{R}$ is $k$-dimensional, $k = \text{rank}P$, and the kernel $\text{Ker}P \subset \mathbb{R}^n$ is $(n - k)$-dimensional, where $k \in \mathbb{Z}_+$ is constant, not depending on $t \in \mathbb{R}$. As a consequence we establish that at $k = 1$ there exists a unique vector $f_0 \in \mathbb{R}^n / (\text{Ker}P)$ for which

$$Pf_0 = f_0,$$

(24)

Due to the statement above for a projector $P \in \text{End}E^n$ we can write down the following expansion in the direct sum of mutually orthogonal subspaces:

$$E^n = \text{Ker}P \oplus \text{Im}P.$$

Take now $f_0 \in \mathbb{R}^n$ satisfying the condition (24). Then in accordance with the next statement holds.

**Statement 5.** The vector $f_0 \in E^n$ satisfies the following evolution equation:

$$\frac{df_0}{dt} = [D(x), P(x)] f_0 + C_0(t) f_0,$$

(25)

where $C_0 : \mathbb{R} \rightarrow \mathbb{R}$ is a certain function depending on the choice of the vector $f_0 \in \text{Im}P$. At some value of the vector $f_0 \in \text{Im}P$ we can evidently ensure the condition $C_0 \equiv 0$ for all $t \in \mathbb{R}$. Moreover one easily observes that for the matrix $P(t) \in \mathcal{P}$ one has the representation $P(t) = f_0 \otimes f_0$, giving rise to the system if $f_0 := \{\sqrt{a_j} \in \mathbb{R}_+: j = 1, n\} \in E^n$.

4 Discussion of the quasispecies dynamics

Quasispecies dynamics is very interesting for researchers and there are a lot of papers devoted to computer simulation of it \[2, 4, 5, 6, 7\]. In order to single out the characteristic features of the model stated above let us write down the model typically used for quasispecies dynamics. In vector form such a model can be written as

$$dx/dt = (AR - < R >)x$$

(26)

where $R = \text{diag} \{R_j : j = 1, n\}$ is the diagonal matrix with the Malthusian fitness values, $< R > := \sum_{i=1}^n R_i x_i$. The diagonal elements $a_{jj}, j = 1, n$, of
the matrix $A = \{a_{jk} : j, k = 1, n\}$. In correspond to the self-replication process and nondiagonal - to mutation. In order to fulfill the simplex condition we have to put \cite{2, 3, 4, 5} for each column $a_{jj} = 1 - \sum_{k=1}^{n} a_{kj}$, $j = 1, n$ and hence the column sum will give rise to unity. In contrast to \cite{26} in our model \cite{6} we do not require such a constraint in order to satisfy the simplex condition.

The mutation matrix $A$ in our model has to be nondiagonal. The choice of matrix $A$ specifies the generation and recombination rates among different molecules in chemistry. A very interesting application of the model stated in the papers \cite{2, 4, 5} is for describing quasispecies evolution. In framework of this approach the bio molecules are considered as a bitstrings of length $L$. In this case we have $2^L$ different molecules. As a result the mutation matrix $A$ is of huge dimension. If we consider a bio molecules with $L >> 1$ this approach is practically out of reason and can not be treated for large bio macromolecule. In this case some simplification has been considered when certain macromolecules are grouped together in such a way that the number of independent variables is reduced to $L + 1$ \cite{9}. In the framework of this approach a certain sequence (master sequence) is chosen beforehand and other sequences are grouped all into error classes, according to their Hamming distance from the chosen one. Sequences which have the same Hamming distance from the master one compile a one error class. Such reduction of the dimensionality make it possible to get the problem acceptable for computer simulation and to reveal some features inherent to real bio world. In this case we can write down the nondiagonal elements $a_{jk}$ of mutation matrix $A$ as the probability of mutation string $k$ to string $j$

$$a_{jk} = q^{L-H_{jk}}(1-q)^{H_{jk}}$$

where $q$ is the probability that a particular locus of the chain is copied correctly into the next generation i.e. the probability of replication, $(1-q)$ is the probability of mutation), $L$ is a bit string length $H_{jk}$ is Hamming distance.
between string $j$ and $k$ and is defined as the number of positions, in which the two sequences differ. In order to note the difference between two model we simulate our model for simplest case $L = 3$. The plot of computer simulation with matrix given by formulae (27) is presented on Fig.1 (a, b). We can easily see that having the same initial conditions and matrix replication mutation matrix $A$ the results of the evolution process is quite different.

Let us find a stationary frequency distribution in the framework of derived model (6). If we make set the right hand side of the equation (6) to zero we get for constant fitnesses the next expression

$$x_j = \frac{\sum_{k \neq j}^n a_{jk} x_k \bar{R}_k}{\bar{R}_j \sum_{k \neq j}^n a_{kj}}. \quad (28)$$

Analyzing the expression (28) one can see that the values of the frequencies do not depend on diagonal elements $a_{jj}$, $j = 1, n$, and replicator process in this model is determined only by the input given by nondiagonal elements $a_{kj}$, $k \neq j = 1, n$, being natural from the biological point of view. If the fitness value of some species $\bar{R}_j$ is much greater than all of the rest fitnesses, the values of $x_j$ will be chosen less than all the others. In this case the results obtained for example for a single peak model landscape in the framework of (26), which lead to so called “phase transition” and vanishing of the corresponding species named there master ones if $a_{jj} < 1/\bar{R}_j$ be interpreted in another way [2, 4, 5].

The equation (28) can be evidently written down as a fixed point problem $x = \tilde{A}x$, where $\tilde{A} = \{a_{jk} \bar{R}_k / (\bar{R}_j \sum_{k \neq j}^n a_{kj}) : k, j = 1, n\}$ with diagonal elements $a_{jj} := 0, j = 1, n$. So, its solution exists if the matrix $\tilde{A}$ possesses the eigenvalue $\lambda = 1$, or the determinant equation $\det(1 - \tilde{A}) = 0$, where $1$ is unity matrix, is satisfied identically. But this fact is true for any matrix $A$ and arbitrary parameters $\bar{R}_j \in \mathbb{R}_+, j = 1, n$. If this equation is not satisfied, the process of reducing some amount of species from the system happens, that is some of frequencies will become exactly zero and the resulting system remains to live on a simplex of lower dimension. The latter situation can be considered as a “phase reduction” naturally related with some threshold values of frequencies found from the determinant equation written above, against the notion of “phase transition” used in cited above articles. This behavior is of great interest for diverse applications since it can be interpreted as some kind of simplex reduction $S_{n-1} \rightarrow S_{n-l}$ for $1 < l < n$, taking place in some kinds of replicator dynamics models. Taking into account this aspect of these models and their virtual importance in studying biological replicator and other models, we plan to dwell on their deeper studying soon in another place.

Acknowledgements. Authors are kindly indebted to their friends, in particular prof. Z. Peradzynski from Warsaw University, professors J. Myjak, S. Brzychczy and B. Choczewski from AGH University of Science and Technology of Krakow for fruitful and constructive discussions of the replicator dynamics.
models considered in this paper. The work of A.P. was in part financed through a local WMS_AGH grant for which he cordially thanks.
