Abstract

Background: The management of Guillain-Barré Syndrome is very crucial for the outcome of the patient. 

Objective: The aim of the study was to compare efficacy of IvIg(Intravenous Immunoglobulin) versus PE(Plasma Exchange) in treatment of mechanically ventilation adults with GBS in neuro-intensive care unit of Bangladesh. 

Methodology: This was a prospective, observational cohort study, in a Neuro-ICU from 2017 to 2018. We included all patients with GBS who required mechanical ventilation (MV). We defined two groups: group 1 (treated by IvIg: 0.4 g/kg/day for 5 days) and group 2 (treated by PE: 5 PE during 10 days, every alternate day). We collected clinical and therapeutic aspects and outcome. 

Results: A total number of 49 patients (34 in group 1 and 15 in group 2) were enrolled. The mean age was 37.4 ± 9.2 years, with a male predominance (65.3%). In electrophysiological findings, in 4(32.7%) patients had acute inflammatory demyelinating polyradiculoneuropathy (AIDP) and acute motor axonal neuropathy (AMAN) in 26 (53.1%) patients and acute motor-sensory axonal neuropathy (AMSAN) was 3(6.1%) and NCS was not done in 4(8.2%) cases. The mean length of ICU stay was 20±19.10 days and 46.6±30.02 days in IVIG and PE group respectively. The ICU stay was significantly shorter (p=0.001) in the IVIg group than PE group. Patients receiving IvIg were early weaned of MV (p=0.002) compared to those receiving PE with a statistical significance. Also, duration of MV (P=0.002), Need of tracheostomy (p=0.005) and over all survival rate (p=0.007) was significantly in favoue of IvIg group than PE group. Out of 49 patients, total 3 patients were died and they all were AMAN variety.

Conclusion: Our work reveals a meaningful difference for the MV duration, ICU stay, weaning and excellent outcome in IvIg group compared to PE group in terms of less complications.

Keywords: Guillain-Barré syndrome (GBS), IVIG(Intravenous Immunoglobulin), PE(Plasma Exchange), Nerve conduction study (NCS)
Introduction
Guillain-Barré syndrome (GBS) is a demyelinating polyradiculoneuropathy with an acute paralysing disorder, typically symmetric and ascending and areflexia. Incidence varies between 0.66 and 1.79 cases per 100,000 persons in general population. About pathogenesis, the aetiologies of GBS remain unclear; however, several findings suggest that causes such as an infection of the respiratory or gastrointestinal tract, vaccinations, surgery and pregnancy generate an abnormal immune response which leads to a destruction of myelin sheaths and/or axons. The treatment is based on two mainstays: supportive care and immunomodulatory treatment. Supportive care prevents complications such as deep vein thrombosis, digestive bleeding and infections especially and physiotherapy. Both plasma exchange (PE) and intravenous immunoglobulins (IVIg) are the two immunomodulatory treatment. Several studies demonstrated that IVIg and PE are efficacious treatment for GBS. Collective data on five trials and 582 patients do not reveal a significant improvement in outcome, either improving faster or more completely with the combination of IVIg and plasmapheresis. The combination exposes the patients to the risks of adverse events from both modalities. There is no evidence to support the use of both IVIg and plasmapheresis therapies.

The aim was to compare efficacy of IVIg versus PE in treatment of mechanically ventilation adults with GBS in a medical intensive care unit.

Methodology
This was a prospective, observational study, realized in a neuro-ICU in National Institute of Neurosciences & Hospital of Bangladesh which is a tertiary referring Neuro centre, during 1 year. We included all patients with GBS who required mechanical ventilation (MV). Data collected included age, sex, antecedent infection, the need for mechanical ventilation, length of stay in the neuro-intensive care unit, clinical outcome of cases during stay in ICU and HDU and investigation performed. Investigations included lumbar puncture and electrophysiological studies for AIDP and axonal forms of GBS, which include AMSAN, AMAN. The diagnosis of acute GBS was based on the criteria of an acute progressive symmetric weakness of the extremities with areflexia or hyporeflexia; the cerebral spinal fluid (CSF) showing albumin-cytological dissociation; and electrophysiological studies revealing features of demyelinating/axonal neuropathy.

Albumino-cytological dissociation was defined as CSF with a raised protein and total cell count of ≤10 per cubic mm. Nerve conduction velocity and electromyography were performed at the end of 1st weeks of admission. We defined two groups: group 1 (group treated by IVIg: 0.4 g/kg/day) and group 2 (group treated by PE: 4 PE during 10 days, every alternate day). The choice of treatment depends on the economic level of the patient and the presence or not of a contraindication to any of the treatments. We recorded data age, sex of the patient, comorbidities, results of CSF study, Varieties of GBS by NCS, the mean length of ICU stay, duration of ventilation, need of tracheostomy, complications, and specific treatments including plasma Exchange and IVIg. We also registered the findings Survival status by subdividing to survived and non-survived. All patients were ventilated using endotracheal mechanical ventilation then tracheotomised. Patients were intubated if they had SpO2 less than 90% in room air requiring increasing FiO2, or showed clinical symptoms of CO2 retention, laboured breathing and aspiration. When patients were able to trigger spontaneous breathing, they were changed to a pressure-support spontaneous ventilation mode. Pressure support was gradually decreased to 10 cmH2O. If secretions were manageable with good airway reflexes, a daily spontaneous breathing trial (SBT) was performed using a T-piece for 12 to 24 hours. Patients were extubated if SBT was successful. SBT was declared successful if there was no increased work of breathing or apnea, symptoms of hypercapnia, tachycardia and if SpO2 remained well compared to pre-SBT value. Tracheostomy was done usually after second week when patient still have poor airway reflexes, excessive secretions, and SBT was unsuccessful.

Statistical analysis: Statistical analysis was performed with SPSS version 22.0 for Windows. Frequencies, percentages, means and standard deviation (SD) were calculated. The Chi-square test and Fisher’s exact test were used for comparison between independent groups of categorical data. The unpaired t-test was used for numerical data and one-way analysis of variance (ANOVA) was used to compare more than two groups. For all statistical tests, values of p<0.05 (two-tailed) were considered statistically significant.

Results
Between January 2017 and December 2018, 74 patients were enrolled, 58 in group 1 (IVIg group) and 16 in group 2 (PE group). The mean age was 30.94 ± 14.96...
years, with a masculine predominance (65.3%). There was no significant difference of age, sex, antecedent events, cranial nerve affection, pattern of weakness, MRC scale, comorbidities and NCS between the two groups, representing that two groups are equally distributed best cohort not influencing outcome. Symptoms preceding the onset of GBS were gastro-intestinal infections in 36(79.59%) patients, RTI 13(26.53%) and 1(2.04%) chicken pox. There was no involvement of the cranial nerves in 10 patients (Table 1).

*Chi-Square Tests * corrected by Fisher's Exact Test

The reason for admission in the ICU was respiratory impairment. Most of the patients were transferred from the department of neurology. CSF study was performed on all patients without increasing CSF cell count.

*Chi-Square Tests * corrected by Fisher's Exact Test

Based on electrophysiological findings, in 4(32.7%) patients had acute inflammatory demyelinating polyradiculoneuropathy with an acute paralyzing disorder, typically symmetric and ascending and ameliorated within hours to days. This present study showed favourable outcome than PE in terms of shorter ICU stay, early starting weaning from MV, shorter duration of MV, less complications and reduced the cost of hospitalization and intensive care costs.
polyradiculoneuropathy (AIDP) and acute motor axonal neuropathy (AMAN) in 26 (53.1%) patients and acute motor-sensory axonal neuropathy (AMSAN) was 3(6.1%)and NCS was not done in 4(8.2%) cases (Table 3).

The mean length of ICU stay was 20±19.10 days and 46.60±30.02 days in IVIG and PE group respectively. The ICU stay was significantly shorter (p=0.001) in the IVlg group than PE group. Patients receiving IVlg were early weaned of MV (p=0.002) compared to those receiving PE with a statistical significance. Also, duration of M/V (P=0.002), Need of tracheostomy (p=.005) and over all survial rate (p=0.007) was significantly in favour of IVlg group than PE group (Table 5).

Table 5: Comparison of Outcome between Two Groups

| Variables                  | IVIG group | PE        | P value |

Discussion

In this study, mean age was 30.94 ± 14.96 years, females were affected more than males and this is against most of the previous reports which mention that GBS demonstrates a slight male predominance, with a male/female ratio of approximately 1.2–1.5:115.13. Other researchers in Hong Kong reported a similar predilection between the sexes14. Symptoms preceding the onset of GBS were gastro-intestinal infections in 36 (79.59%) patients, RTI 13(26.53%) and 1 (2.04%) chicken pox. It was reported that respiratory infections are the commonest antecedent infection, occurring in about 40–70% of cases, while 7–20% are gastrointestinal infections3.15. The findings of this present study have showed that AMAN is the most common diagnosed subtype by electrophysiological studies which is 46(50.0%) patients followed by AIDP (34.78%), AMASN (6.52%) and no MPS. AMAN pattern was the predominant underlying subtype in China, Japan, and Central and South America15. Other studies from North America and Europe as most GBS was AIDP variety13.15. This different figure supports the large variations in the incidence of different types of GBS which may be related to seasonal or genetic factors with no support studies explaining this difference until now15.

This present study showed favourable outcome than PE in terms of shorter ICU stay, early starting weaning from MV, shorter duration of MV, less complications and less mortality. It has been found that the mean duration of ICU stay and duration of mechanical ventilation in patients treated with plasmapheresis are significantly lower than in cases treated with IVIG; this reduced the cost of hospitalization and intensive care unit (ICU) care in these patients.

The results of this present study are supported by some previous studies that recorded a significant decrease in duration of ICU stay and shorter mechanical ventilation duration which compensate for the cost of plasmapheresis; better secondary outcomes were also achieved11.15. However, some studies suggested that patients who received IVIG treatment had more improvement than those with plasmapheresis16-17. Some other researchers showed no significant difference between the two treatment groups16-19. However, some other studies suggest that patients had IVlg treatment had more improvement than those had PE. Indeed, Koul and Alfutaisi17 and Van der Meché et al16 showed that IVlg group had a significant fast evolution than PE group.

There are some limitations of this study. The small number of cases has also made the comparison statistics not valuable enough as significant results.

Conclusion

Although our results are not conclusive, our work reveals that there are positive recovery of ICU stay, duration of MV, weaning from MV in IVlg group compared to the PE group. IVIG group reduce the duration of hospital stay and hasten the recovery of patients with GBS. These encouraging results would merit to be confirmed by controlled and randomized works.

The aim was to compare efficacy of IvIg versus PE in mechanically ventilated adults with GBS. Intravenous immunoglobulins (IvIg) are the two most commonly used immunomodulatory treatment. Supportive care prevents complications such as deep vein thrombosis, pneumonia, and infections. The goal of this study was to compare the efficacy of IvIg versus PE in mechanically ventilated patients with GBS. The study was conducted at the National Institute of Neurosciences & Hospital of Bangladesh, a tertiary referral center.

Introduction

Guillain-Barré syndrome (GBS) is a demyelinating/axonal neuropathy. Table 1 shows the number of cases classified by electrophysiological findings. Most GBS cases were AIDP (34.78%), AMAPS (6.52%) and no MFS. AMAN (53.1%) cases were the most common in this study.

In this study, mean age was 30.94 ± 14.96 years, male/female ratio of approximately 1.2–1.5:1. Other researchers in Hong Kong reported a similar male predominance (65.3%). There were gastrointestinal infections 13,15. The findings of this study showed that 46 (50.0%) patients followed by AIDP (34.78%), AMAPS (6.52%) and no MFS. AMAN (53.1%) cases were the most common in this study.

Methodology

GBS diagnosis was based on the criteria of an acute onset of weakness within 4 weeks. Albumino-cytological dissociation was defined as CSF protein >100 mg/dl with a raised protein and total cell count of <5 cells/µl. Nerve conduction velocity and electromyography were performed at the end of 1st week of admission. Demographic characteristics and outcome measures were collected from the medical records. The Statistical Package for Social Science (SPSS) version 20 was used for all statistical analysis. Data was presented as mean ± standard deviation (SD). *P* < 0.05 was considered statistically significant.

Results

Forty-six patients treated by IvIg and 46 treated by PE were included in this study. The mean age was 30.94 ± 14.96 years in each group. The number of cases with gastrointestinal infections in 36 (79.59%) patients, RTI 13 (26.53%) and ocular involvement of the cranial nerves in 10 patients. There were no significant differences in sex distribution between the two groups (Table 1). The choice of treatment depends on the clinician’s judgement considering the severity of the disease and associated complications.

Conclusion

This present study showed favorable outcome than PE in terms of shorter ICU stay, early starting weaning, duration of ICU stay and shorter mechanical ventilation duration which compensate for the cost of PE. However, some studies suggested that patients had IvIg treatment had more improvement than those had PE. The comparison is not statistically not valuable enough as significant results. Further studies are required to evaluate the cost-effectiveness of IvIg and PE in the treatment of GBS.
