We study the propagation of surface waves on a current in the presence of an electromagnetic field. A horizontal (vertical) field strengthens (weakens) the counter-current which blocks the waves. We compute the phase space diagrams (blocking velocities versus period of the waves) with and without surface tension. Three new dimensionless numbers are introduced to compare the relative strengths of gravity, surface tension and field effects. This work shows the importance of an electromagnetic field in order to design wave-breakers or in microfluidics applications.

PACS numbers: 47.35.Bb, 47.35.-i, 47.35.Pq, 47.35.Tv, 47.65.-d, 68.03.Cd

\[\omega^2 \simeq \left( gk + \frac{(\epsilon - \epsilon_0)^2 E_x^2}{\rho (\epsilon_0 + \epsilon)} k^2 + \frac{\gamma k^3}{\rho} \right)\]  

(3)

\[\omega^2 \simeq \left( gk + \frac{(\mu - \mu_0)^2 B_z^2}{\rho (\mu_0 + \mu) k^2} + \frac{\gamma k^3}{\rho} \right),\]  

(4)

where \(g\) denotes the gravitational acceleration of the Earth at the water surface, \(\rho\) the fluid density, \(\gamma\) its surface tension, \(\mu\) its permeability, \(\epsilon\) its permittivity, \(E\) (\(B\)) an external electric (magnetic) field. All the preceding dispersion relations are valid if the fluid depth \(h\) is such that \(|k|h \gg 1\) (thick case). This hypothesis will be used in the rest of the paper.

Besides, the presence of a uniform current induces a Doppler shift of the pulsation \(\omega \approx \frac{\omega}{k}\),

\[\left(\omega - U k\right)^2 = F(k),\]  

(5)

where \(U\) is the constant velocity of the background flow. We will assume that \(k = k_x\) and \(U = U_x\) for simplicity. The dispersion relation features the following symmetry: \(U \rightarrow -U\) and \(k \rightarrow -k\); hence, negative energy waves \((k < 0\) and \(\omega - U k < 0\)) are also described using this symmetry \((6)\). For the quadratic term, the symmetry is hidden by the deep water approximation \(|k|h \gg 1\) where a \(\text{coth}(kh) \approx -1\) term introduces a negative sign for negative wavenumbers \((14)\).

Hence, the universal dispersion relation for water waves propagating on a counter-current in presence of an horizontal \((+v_f^2)\) or vertical \((-v_f^2)\) field writes

\[\left(\omega - U k\right)^2 \simeq |s| \left( gk + |s|(\pm v_f^2) k^2 + \frac{\gamma k^3}{\rho} \right),\]  

(6)

where \(|s| = \pm 1\) is the sign of \(k\). \(v_f\) can be seen as the effective velocity resulting from the Maxwell electromagnetic tensions \(\sigma_{\text{Maxwell}} \approx \epsilon E^2\) or \(\frac{B^2}{\mu} = \rho v_f^2\).

First, we study the influence of a field on the propagation of gravity waves on a counter-current \((U < 0)\). Then, we include the effect of capillarity. The examples shown on the figures correspond to the case of an electric...
field \( E \) (horizontal and/or vertical).

Following our dynamical system approach \[8, 11\], wave blocking can be seen as a saddle-node bifurcation for the wave-number. Indeed, the usual condition \[13, 18\] for blocking –group velocity vanishes, \( \frac{\partial \omega}{\partial k} = 0 \) – is equivalent to the appearance of a double root in the dispersion relation \( P(k)(k - k_2)^2 = 0 \) where \( P(k) \) is a polynomial.

First, we neglect surface tension and from (6) the dispersion relation leads to a quadratic polynomial in \( k \) \( (U_\ast \) is a blocking velocity)

\[
k^2 - \left( |s|g + 2\omega U_\ast \right) \left( \frac{\omega}{U_\ast^2 - (\pm v_f^2)} \right) k + \frac{\omega^2}{U_\ast^2 - (\pm v_f^2)} = 0, \tag{7}
\]

with \( |U_\ast| \neq v_f \) in the horizontal field case.

Close to the bifurcation, we have:

\[
(k - k_2)^2 = (k - 2k_2 + k_2^2) = 0. \tag{8}
\]

From \( \textbf{4} \) and \( \textbf{5} \), we get two expressions for a blocking wave-number with the constraint \( |U_\ast| > v_f \) in the horizontal field case:

\[
k_2 = \left( |s|g + 2\omega U_\ast \right) \left( \frac{\omega}{2(U_\ast^2 - (\pm v_f^2))} \right) = \left[ s \right] \frac{\omega}{\sqrt{(U_\ast^2 - (\pm v_f^2))}} \tag{9}
\]

so that, with \( \omega = 2\pi/T \), a blocking velocity writes:

\[
U_\ast = \left[ s \right] \left( \frac{gT}{8\pi} + \frac{2\pi(\pm v_f^2)}{gT} \right) \tag{10}
\]

and the associated blocking wave-number becomes:

\[
k_2 = \left[ s \right] \frac{2\pi}{T} \left( \frac{\sqrt{4\pi^2v_f^2 - (\pm v_f^2)}}{gT} + \frac{gT}{4\pi^2} \right) \tag{11}
\]

We display on Figure 1 the phase space of the control parameters \( U_g \) and \( T \). If \( v_f = 0 \), we recover \( \left[ s \right] = +1 \)

\[
U_\ast = U_g = -\frac{gT}{8\pi} \quad \text{and} \quad k_2 = \frac{16\pi^2}{gT^2}. \tag{3}
\]

When \( v_f \neq 0 \) this blocking line is modified and, only for the vertical field, a new one appears for \( k_2 < 0 \) \( \left( \left[ s \right] = -1 \right) \). So that, with a vertical field, all waves with a period inferior to \( T_f = \frac{2\pi}{g v_f} \) are blocked even with no counter-flow and there is a threshold for the appearance of negative energy waves for this same range of periods. With an horizontal field, the strength of the counter-flow to reach wave blocking is strongly increased at low periods and even, blocking will not at all occur provided that \( |U_\ast| < |v_f| \).

Now, the surface tension modifies the dispersion relation and from \( \textbf{3} \), it becomes a cubic polynomial in \( k \):

\[
k^3 - \left[ s \right] \frac{\rho(U_\ast^2 - (\pm v_f^2))}{\gamma} k^2 + \frac{\rho}{\gamma}(g + \left[ s \right] 2\omega U_\ast) k - \left[ s \right] \frac{\rho \omega^2}{\gamma} = 0. \tag{12}
\]

The condition for wave-blocking becomes:

\[
(k - k_1)(k - k_2)^2 = k^3 - (2k_2 + k_1)k^2 + (k_2^2 + 2k_1k_2)k - k_1k_2^2 = 0. \tag{13}
\]

From \( \textbf{12} \) and \( \textbf{13} \), we end up with a cubic polynomial for the blocking wave-numbers \( k_2 \),

\[
3k_2^2 - \left[ s \right] \rho \frac{(U_\ast^2 - (\pm v_f^2))}{\gamma} k_2 - \frac{\rho}{\gamma}(g + \left[ s \right] 2\omega U_\ast) = 0, \tag{14}
\]

whose determinant is

\[
\Delta = 4(\rho^2(U_\ast^2 - (\pm v_f^2))^2) - \frac{12\rho^2(g + \left[ s \right] 2\omega U_\ast)}{\gamma}, \tag{15}
\]

and \( k_2 \) and \( k_1 \) write,

\[
k_2^{(a,b)} = \left[ s \right] \left( \frac{\rho(U_\ast^2 - (\pm v_f^2))}{3\gamma} \right) \left( 1 \pm \sqrt{1 - \frac{3\gamma(g + \left[ s \right] 2\omega U_\ast)}{\rho(U_\ast^2 - (\pm v_f^2))^2}} \right) \tag{16}
\]

\[
k_1^{(a,b)} = \left[ s \right] \left( \frac{\rho(U_\ast^2 - (\pm v_f^2))}{3\gamma} \right) \left( 1 \mp 2\sqrt{1 - \frac{3\gamma(g + \left[ s \right] 2\omega U_\ast)}{\rho(U_\ast^2 - (\pm v_f^2))^2}} \right) \tag{17}
\]

with the constraint,

\[
k_1k_2^2 = \left[ s \right] \frac{\rho \omega^2}{\gamma}. \tag{18}
\]

After tedious algebra, \( \textbf{18} \) leads to the following quintic in \( U_\ast \) with coefficients depending on the period and the field (in addition to the fluid characteristics and the universal constants):
The quintic can be solved numerically as in [4], but here we have used an implicit method. We computed numerically from the dispersion relation the associated wave numbers, which is independent of the field, \( U_\pm \) whose solution is the asymptotic velocity \( U_a \):

\[
\lim_{{T \to \infty}} U_* = U_a = U_\gamma \sqrt{1 + \frac{\pm v_f^2}{U_\gamma^2}}
\]

where \( U_\gamma = -\sqrt{2} \left( \frac{2a}{\rho} \right)^{1/4} \) is the asymptotic velocity when \( v_f = 0 \) (see [4]). From [10], we get the associated wave numbers, which is independent of the field, \( k_a = \frac{|s|}{(12)}^{1/2} = k_\gamma \) (4). These asymptotic behaviors can be seen in (Fig 2).

- \( U_\to \infty \): The quintic becomes:

\[
12\rho^2 g \omega U_\gamma^5 + [s] \frac{1}{4} g \omega^2 U_*^3 - \frac{15}{2} \frac{\gamma \omega}{\rho} U_*^2 - 6 \frac{g \gamma}{\rho} U_* - \frac{27 g^2 \gamma^2 \omega^3}{4 \rho^2 g} = 0
\]

In the absence of any field, we recover the quintic polynomial and the phase space (Fig 2(a)) derived recently in [4].

- \( \omega \to 0 \): For large period, we find a quartic polynomial in \( U_* \):

\[
\frac{1}{4} g \omega^2 U_*^4 - \frac{1}{2} \frac{\gamma \omega}{\rho} U_*^3 - \frac{3}{4} \frac{g \gamma}{\rho} U_*^2 - \frac{3}{4} \frac{g^2 \gamma^2 \omega^3}{4 \rho^2 g} = 0
\]

whose solution is the asymptotic velocity \( U_a \):

\[
U_* \simeq \sqrt{1 + \frac{\pm v_f^2}{U_\gamma^2}}
\]

Hence, the other asymptotic limit is:

\[
U_* \simeq -\frac{1}{4} \frac{g \omega}{\sigma} \left( \frac{\pm v_f^2}{\sigma} \right) = [s] U_g \left( 1 + \frac{1}{4} \frac{\pm v_f^2}{U_\gamma^2} \right)
\]

which describes how the lower red line (blocking threshold in the presence of a field) deviates from the dotted blue line (pure gravity regime) in (Fig 2).

We introduce three new dimensionless numbers \( R_{gI}, R_{\gamma f} \) and \( R_{\gamma g} \):

\[
R_{gI} = \frac{U_g}{v_f} \quad R_{\gamma f} = \frac{U_\gamma}{v_f} \quad R_{\gamma g} = \frac{R_{gI}}{R_{\gamma f}} = \frac{U_g}{U_\gamma}
\]
If \( R_{gf} \gg 1 \), then from \([24]\), \( U_a \rightarrow U_a \) \( [3] \). \( R_{gf} \) compares the effect of gravity with the field effect. If \( R_{gf} \gg 1 \), then from \([22]\), \( U_a \rightarrow U_a \) \( [4] \). \( R_{gf} \) compares the effect of surface tension with the field effect. \( R_{gf} \) compares the effect of gravity with surface tension. For example, waves will be of the capillary type if \( R_{gf} \ll 1 \).

The critical point, the cusp \([4]\), is reached when the determinant \( \Delta \) of the quadratic polynomial \([14]\) equals zero, so that, \( k_{2}^{(a,b)} = k_{3}^{(a,b)} = k_c \). From \([10]\) (or \([17]\)) and from the constraint \([18]\), we get respectively,

\[
k_c = [s] \frac{1}{3} \frac{\rho(U_c^2 - \left(\pm v_f^2\right))}{\gamma} = \left[ s \right] \frac{\rho \omega^2}{\gamma}^{1/3},
\]

so that the velocity \( U_c \) at the cusp writes,

\[
U_c = -\sqrt{\frac{3}{2} \left( \frac{\gamma \omega_c}{\rho} \right)^{2/3} + (\pm v_f^2)},
\]

and the determinant \( \Delta \) \([15]\) at the cusp leads to an equation for \( \omega_c \):

\[
3 \left( \frac{\gamma \omega_c}{\rho} \right)^{8/3} + 6 \left( \frac{\gamma g}{\rho} \right) \left( \frac{\gamma \omega_c}{\rho} \right)^{4/3} + 4(\pm v_f^2) \left( \frac{\gamma \omega_c}{\rho} \right)^2 - \left( \frac{\gamma g}{\rho} \right)^2 = 0.
\]

Using \( X = \left( \frac{\gamma \omega_c}{\rho} \right)^{2/3} \), we get a quartic in \( X \),

\[
X^4 + \frac{4}{3}(\pm v_f^2)X^3 + 2 \left( \frac{\gamma g}{\rho} \right) X^2 - \frac{1}{3} \left( \frac{\gamma g}{\rho} \right)^2 = 0, \quad (29)
\]

which can be solved numerically. An analytical but lengthy expression for \( X \) as a function of \( \left( \frac{\gamma g}{\rho} \right) \) and \( (\pm v_f^2) \) has also been found but is out of the scope of this letter. We shall come back to this point in a forthcoming paper.

Finally, \( \omega_c \), \( k_c \) and \( U_c \) respectively write as a function of \( X \):

\[
\omega_c = \left( \frac{\rho}{\gamma} \right) X^{3/2}, \quad k_c = \left[ s \right] \left( \frac{\rho}{\gamma} \right) X,
\]

\[
U_c = -\sqrt{3X + (\pm v_f^2)}.
\]

In this work, we have shown the influence of a field (electric or magnetic) on the interaction between surface waves and a current. It should be interesting to test experimentally the “damping” effect of a vertical electric field on the propagation of waves in the design of wavebreakers. For microfluidics applications, a generalization of our results encoding different fluid densities would include another dimensionless quantity, the Atwood number \( A_t = \frac{\rho_2 - \rho_1}{\rho_1 + \rho_2} \).
