Is Your Perspective Also My Perspective? Enriching Prediction with Subjectivity

Abstract

Although argumentation can be highly subjective, the common practice with supervised machine learning is to construct and learn from an aggregated ground truth formed from individual judgments by majority voting, averaging, or adjudication. This approach leads to a neglect of individual, but potentially important perspectives and in many cases cannot do justice to the subjective character of the tasks. One solution to this shortcoming are multi-perspective approaches, which have received very little attention in the field of argument mining so far.

In this work we present PerspectifyMe, a method to incorporate perspectivism by enriching a task with subjectivity information from the data annotation process. We exemplify our approach with the use case of classifying argument concreteness, and provide first promising results for the recently published CIMT PartEval Argument Concreteness Corpus.

1 Introduction

The analysis of arguments and especially their properties is challenging and often subjective, which renders the creation of suitable language resources for argument mining difficult (Stab and Gurevych, 2014; Lindahl et al., 2019). Uniform annotation often requires intensive training, and this costly approach has been shown to regularly result in at most moderate agreement among annotators (Aharoni et al., 2014; Rinott et al., 2015; Habernal and Gurevych, 2017; Shnarch et al., 2018). Alternative approaches such as crowd-sourcing share this problem, especially for demanding tasks like argument quality (Toledo et al., 2019).

Although the lack of consensus might clearly indicate that the annotation task is either ambiguous (Artstein and Poesio, 2008), too complex (Aroyo and Welty, 2015), or influenced by variables such as demographics and individual bias (Sap et al., 2022; Biester et al., 2022), the established procedure is to aggregate the individual judgments into a single ground truth at the end of the annotation process (by majority vote, averaging, or adjudication).

Learning from aggregated ground truth has several drawbacks. Minority voices are ignored, however valuable they may be, and only those in line with the mainstream are heeded (Noble, 2012). This rises also a fairness concern, as certain socio-demographic groups and their perspectives may be underrepresented (Prabhakaran et al., 2021). Finally, it is questionable whether the assumption of a single truth, i.e., that there is only one correct label for an example, holds at all for subjective tasks (Ovesdotter Alm, 2011; Aroyo and Welty, 2015).

Therefore, the question of multi-perspective approaches arises (Abercrombie et al., 2022). Basile et al. (2021) introduced the paradigm of data perspectivism in order to “integrate the opinions and perspectives of the human subjects involved in the knowledge representation step of ML processes”. One example for perspectivist data is argumentation (Hautli-Janisz et al., 2022; Romberg et al., 2022b).

However, many popular algorithms require a single ground truth to which the model can adapt. In this paper, (i) we thus introduce a method that combines collaborative and subjective viewpoints by complementing an aggregated label with a subjectivity score. More specifically, PerspectifyMe proposes to add the prediction of how perspectivist an input is as an additional sub-task. Providing this information can for example help a human decide when to rely on their own perspective. (ii) To exemplify our approach, we draw on a recently published perspectivist dataset for argument concreteness in public participation processes (Romberg et al., 2022b). We provide several baselines based on our proposed method for this subjective task. While these are certainly extendable, they already show promising results for automatic classification by concreteness. (iii) To the best of our knowledge, we are the first to automatically classify arguments...
in an explicitly perspectivist manner.

2 Related Work

Basile et al. (2021) provide a nice summarization of the previous work towards perspectivist machine learning, dividing the field in two groups.

The first aims at building unified ground labels that involve perspectivism by either only keeping instances on which a statistically significant majority agrees (Cabitza et al., 2020), by computing a weighting according to annotator reliability (Heinecke and Reyzin, 2019; Cabitza et al., 2020; Hovy et al., 2013), by replicating or weighting instances using provided labels or disagreement measures (Plank et al., 2014; Akhtar et al., 2019), or by participatory consensus building (Chang et al., 2017; Schaekermann et al., 2018).

The second group incorporates the perspectivism into the core machine learning workflow by either training an ensemble of models that rely on different ground truths (Akhtar et al., 2020; Campagner et al., 2021), by soft loss learning (Plank et al., 2014; Uma et al., 2020; Campagner et al., 2021), or by utilizing multi-task learning (Cohn and Specia, 2013; Guan et al., 2018; Sudre et al., 2019; Fornaciari et al., 2021; Davani et al., 2022).

Our approach ties into the latter idea by transforming the original problem into multiple sub-tasks. However, multi-task learning approaches for multi-perspectivist tasks have primarily aimed at improving model performance. To do so, the aggregated ground truth is learned along with the distribution of individual labels. Instead, we focus on outputting an indication of how perspectivist the model predictions are (namely, by adding a subjectivity score) to help interpret the results.

The only previous studies that specifically address argument mining are, to the best of our knowledge, two recently published non-aggregated datasets: QT30nonaggr (Hautli-Janisz et al., 2022) and the CIMT PartEval Argument Concreteness Corpus (Romberg et al., 2022a).

3 Use Case: Argument Concreteness in Public Participation

Public participation is a means regularly used by democratic authorities to involve citizens in policy-making processes (Dryzek et al., 2019). The manual evaluation workflow often includes reading the contributions, detecting duplicates, identifying arguments and opinions, and thematically clustering content before drawing conclusions from the input (Romberg and Escher, 2022).

One solution to reduce the workload of human evaluators is machine learning (OECD, 2003). Although there is a general consensus that such important democratic processes cannot be fully automated, automating sub-tasks such as topic classification or argument detection and analysis can support the evaluation.

Argument Mining for public participation has received considerable attention (Kwon et al., 2007; Liebeck et al., 2016; Lawrence et al., 2017; Park and Cardie, 2018; Romberg and Conrad, 2021). While works such as Park and Cardie (2014) and Niculae et al. (2017) have already addressed the evidence and verifiability of propositions, there has been no attempt to automatically classify their concreteness. Predicting the concreteness of propositions can assist a human analyst to speed up the evaluation by ranking them, since less concrete ideas tend to be more laborious to evaluate (Romberg et al., 2022b).

The CIMT PartEval Argument Concreteness Corpus (Romberg et al., 2022a) provides argumentative text units (ATU) in German extracted from mobility-related public participation processes. Each ATU consists of one to several sentences, consecutive in the original document, and a tag that describes the argumentative function (major positions: proposed courses of action and policy options or premises: attacking/supporting reasons). In total, the dataset contains 1,127 ATUs, 614 of which are major positions and 513 are premises.

These ATUs have been categorised into three different degrees of concreteness:

- ATUs of high concreteness contain comprehensive details that describe the “what”, “how”, and “where”.
- ATUs of intermediate concreteness contain only partial specification of the “what”, “how” and “where”. There is room for interpretation in inferring specific actions (major positions) or in evaluating the actual reasons (premises).
- ATUs of low concreteness contain no detailed information of the “what”, “how” and “where”. A variety of measures could be derived and reasons remain vague.

Table 1 illustrates the three types to provide a better understanding of the dataset. Example A is a major position unit of high concreteness: it is clear what action is desired (protective cycle lanes next
to the rails), where it is to be implemented (along Friedrich-Breuer-Straße) and how (free space by parking space removal). The premise unit in example B is of intermediate concreteness: it is clear, what the issue is and where (connection through Obere Wilhelmstraße not very pleasant to drive).

However, it remains unclear what makes driving through unpleasant. Example C shows a major position unit of low concreteness: the claim is very general and does not refer to specific locations, nor is it more specific about what rules are required.

The annotation of the data was performed by five coders. While finalizing the annotation guidelines, the coders annotated a selection of contributions, and inconsistencies were discussed in a group with the coders and two process supervisors. The guidelines were adjusted and the coders trained to the point where it became apparent that the divergent annotations were different perspectives rather than incorrect coding: In the discussion, the different coders were able to argue convincingly for their stance. Krippendorff’s αw (Krippendorff, 2013) of 0.46 confirms that the codings, although subjective, are not arbitrary.

4 PerspectifyMe

Previous work has incorporated perspectivism through distributions over individual labels. However, such distributions may be of limited use when provided to a human as a direct output, e.g. in human-machine interactions. In particular, providing such a diversity of perspectives that might apply (from the annotators’ point of view - not necessarily from the point of view of the particular user) can be too complex and potentially confusing.

For items that trigger a subjective perception, it might make more sense (e.g., in a use case like ours) to inform the user about this and let them decide whether to make their own assessment or to go along with the collaborative opinion.

Therefore, we propose to enrich model predic-

Table 1: Examples of argumentative text units with argument types and concreteness ratings from the CIMT PartEval Argument Concreteness Corpus. To assist readers understand the content, the texts have been translated into English. (The examples presented here are cases in which the annotators were in complete agreement on the coding of concreteness.)

| Ex. | Unit text                                                                 | Unit type     | Concreteness |
|-----|---------------------------------------------------------------------------|---------------|--------------|
| A   | If the parking spaces along Friedrich-Breuer-Straße were removed, there would be enough space for protective cycle lanes next to the rails. | major position | high         |
| B   | The connection to the centre of Beuel through Obere Wilhelmstraße is also not very pleasant to drive. | premise       | intermediate |
| C   | Rules for cycle paths                                                    | major position | low          |

Table 2: Overview of the label distributions for the tasks.

| Task   | Label  | Support |
|--------|--------|---------|
|        | High   | 709 (62.9%) |
|        | Intermediate | 336 (29.8%) |
|        | Low    | 82 (7.3%) |
| Sub-Task T_H: Concreteness         | Objective | 478 (42.4%) |
| Sub-Task T_S: Subjectivity         | Rather objective | 244 (21.7%) |
|        | Rather subjective | 275 (24.4%) |
|        | Subjective | 130 (11.5%) |

4.1 General Description

Given a task T, we assume that there are both objective and subjective items in a corresponding dataset. This means that part of the dataset is annotated in a very consistent way, while the rest has elicited different views among coders. Our goal is then to predict a so-called hard label (aggregated by some method), and jointly inform on items for which there might be multiple correct outputs, depending on the perspective. We thus propose PerspectifyMe, a method to introduce perspectivism into the machine learning workflow by translating T into two sub-tasks T_H and T_S. T_H refers to the original prediction task using hard-labels as ground truth. T_S refers to an artificial task of predicting the subjectivity of the input using a subjectivity score.

4.2 Application to Our Use Case

The perspectivity of judging argument concreteness is reflected in the CIMT PartEval Argument Concreteness Corpus through five single annotations. Following the previously introduced method, we conducted two transformation steps to yield the target variables for T_H and T_S.

Concreteness Score We first built an aggregated ground truth by calculating the average concreteness per unit. For this, we mapped the categorical labels to numerical values (high: 3, intermediate: 2, low: 1) and averaged them. To retain the origi-
We translated the resulting distances into a four-category scheme of concreteness and subjectivity. At the same time, low concreteness is rare. Over sixty percent of the units elicited a fairly objective perception, a large proportion of which were even coded in a completely consistent manner. At the same time, there is a notable proportion of perspectivist ATUs.

Table 3: Excerpt from the results for the classification of ATUs according to concreteness and subjectivity.

| Model | Macro-F1 | Accuracy | Macro-F1 | Accuracy |
|-------|----------|----------|----------|----------|
| Majority Baseline | 0.26 | 0.66 | 0.15 | 0.42 |
| LR (length) | 0.31 ± 0.06 | 0.71 ± 0.03 | 0.32 ± 0.03 | 0.68 ± 0.03 |
| LR (bow) | 0.53 ± 0.04 | 0.75 ± 0.02 | 0.50 ± 0.03 | 0.71 ± 0.03 |
| LR (length+bow) | 0.54 ± 0.04 | 0.74 ± 0.03 | 0.50 ± 0.04 | 0.72 ± 0.03 |
| SVM (length) | 0.35 ± 0.04 | 0.71 ± 0.03 | 0.35 ± 0.03 | 0.70 ± 0.02 |
| SVM (bow) | 0.59 ± 0.04 | 0.74 ± 0.03 | 0.49 ± 0.04 | 0.71 ± 0.03 |
| SVM (length+bow) | 0.62 ± 0.05 | 0.75 ± 0.03 | 0.50 ± 0.03 | 0.72 ± 0.02 |
| BERT | 0.67 ± 0.06 | 0.70 ± 0.03 | 0.62 ± 0.03 | 0.72 ± 0.02 |

Table 3: Excerpt from the results for the classification of ATUs according to concreteness and subjectivity. The rounded average scores for each model were combined with text length (in tokens) and a bag-of-words as features. The language model BERT was initialized with a case-sensitive base model for German (110M parameters). We fitted separate classifiers for the two sub-tasks.

5.2 Experimental Setup

We evaluated model performance on the dataset with and without respect to the types of arguments (major position/premise vs. joint) to see whether there are differences in predicting concreteness and subjectivity. To obtain reliable results, we used a repeated 5-fold cross-validation setup (Krastajic et al., 2014) (10 repetitions) and kept 10% for validation (i.e. splitting the dataset each time in 70/10/20 for train/val/test). The hyperparameters were tuned with a grid search in each fold (an overview of the search space is given in Appendix A.2). F1 and accuracy are the evaluation scores.

5.3 Results

Table 3 shows a selection of the results for the classification of ATUs. A complete overview, including class scores, can be found in Appendix A.3.

When predicting degrees of concreteness, BERT achieved the best results (F1 as well as accuracy). Looking at the other models, it turned out that simple length was already a good indicator for concreteness. When analyzing correlation effects with Spearman’s rank correlation coefficient this finding was supported by a strong correlation of the target variables with the text length (concreteness: $\rho = 0.657$, subjectivity: $\rho = -0.525$). Adding

We introduced PerspectifyMe, a simple method to include perspectivism in machine learning workflows. Using argument concreteness as an example, we have shown that our baseline approaches can assess the subjective perception of ATUs.

In future work, we plan to apply advanced multi-task learning models as previous work has shown that they can lead to an increase in performance (Davani et al., 2022). Furthermore, we have tailored the transformation of the spectrum of annotations into a subjectivity score specific to the use case at hand. It would be of great interest to develop a more general (task-independent) algorithm.

Table 5: Overview of the different combinations of individual annotations, their occurrence, the overall L1 distance and the mappings to subjectivity categories for both the 4-class and the 2-class schema. (O: Objective, RO: Rather Objective, RS: Rather Subjective, S: Subjective)

A.2 Hyperparameter-Tuning

For LR we tested the L1 and L2 norms for the penalty and set the regularization parameter $C$ to take a value from $[0.001, 0.1, 1, 10, 100]$. Furthermore the classes were either weighted to simulate a balanced distribution or not weighted at all. We used an SVM with RBF kernel and a balanced class weighting. The regularization parameter $C$ was set to be from $[0.001, 0.1, 1, 10, 100]$ and the kernel coefficient to be from $[1, 0.1, 0.01, 0.001]$. In RF
the split quality was either measured with the Gini index or the Shannon information gain. Regarding the imbalance of the classes, we tested balancing weights and none.

For fine-tuning BERT we used the AdamW optimizer with beta coefficients of 0.9 and 0.999, and an epsilon of $1e^{-8}$, and set the maximum sequence length to 128. We further trained for 5 epochs with a batch size from $[16, 32]$ and a learning rate from $[5e^{-5}, 4e^{-5}, 3e^{-5}]$. For reproducibility of the experiments, we fixed the random seeds.

### A.3 Full Overview of the Results

Table 6 and Table 7 list the full overview of results from the experiments.
Table 6: Complete overview of all experiment results for sub-task $F_4$: Concreteness.

| Model           | low     | intermediate | high    | macro-$F_1$ | accuracy |
|-----------------|---------|--------------|---------|-------------|----------|
| **Baseline Majority** | 0.00    | 0.00         | 0.75    | **0.25**    | 0.60     |
