Abstract. Due to the growing use of brick masonry for the construction of buildings in Pakistan, huge quantities of Brick Kiln Waste (BKW) are generated which can not only create disposal problems but are hazardous to the environment. In order to resolve such problems, it is necessary to investigate the suitability of the BKW as a stabilizer for the clayey soils. For this purpose, an experimental program was carried out to stabilize clayey soil with the BKW ranging from 5 to 40%. Basic geotechnical tests were performed on the clayey soil blended with the BKW. The results showed that the clayey soil became coarser and more suitable as a subgrade material with the addition of the BKW. There was a negligible reduction in dry density up to 7% when the BKW added was 40%. As expected, the cohesion and friction angle of the blended soils decreased and increased, respectively, with the inclusion of the BKW. As compared to the clayey soil, the ultimate bearing capacity of the blended soil, characterized by 40% of the BKW, increased by 21%. This study showed that clayey soils stabilized with BKW could be used as a partial fill material for highway embankments and foundations of buildings.

1. Introduction

Presently, fired bricks are widely used for constructing buildings. Due to a constant increase in the population of Pakistan, there is more demand for houses. To meet demand for houses, bricks are manufactured on a large scale. In Pakistan, approximately 18000 kilns are in operation which fire about 45 billion bricks annually [1]. The fuel used for firing bricks in kilns consists of wood and agricultural by-products such as rice husk, sugarcane bagasse, old pieces of clothes, etc. As a result, a huge quantity of waste consisting of ash and small pieces of bricks is generated on sites where kilns are located. The Brick Kiln Waste (BKW) is not disposed of properly, which is a current practice in Pakistan. The BKW gradually accumulates on the sites of the kilns. The accumulated BKW may create not only disposal but environmental problems. To alleviate these problems, it is necessary to investigate whether the BKW can be used as a stabilizer for clayey soils, which are considered as poor material for various civil engineering works.

Highway embankments and foundations of buildings require massive quantities of fill materials. The

clayey soils may exhibit low bearing capacity, high compressibility, and settlement. As a result, the pavements of roads may experience cracks and buildings may suffer from differential settlement, which may reduce their service life. Under these conditions, the clayey soils may be stabilized with granular soils to achieve satisfactory performance. The use of the BKW as a partial fill material with clayey soils in highway embankments and foundations of buildings could be a better option than disposal, which is costly.

Throughout the world, billions of tons of solid waste are generated annually. Efforts are being made to implement waste management practices to reduce the environmental problems of solid wastes [2–4]. Nowadays, solid wastes are utilized in various civil engineering domains such as soil stabilization [5–8] and landfills [9,10]. Fly ash has been utilized as a partial fill material in highway embankments [11–14]. Rice husk ash is also used as a partial construction material in highways [15–17]. Waste ceramic dust [18], marble dust [19], and brick dust [20] have also been utilized for soil stabilization. The authors are of the view that no study has been published on the suitability of BKW as a stabilizer for civil engineering construction projects. The purpose of this study is to assess the viability of the BKW as a partial fill material for the construction of highway embankments and foundations of buildings. For this purpose, index properties, compaction, shear strength parameters, and ultimate bearing capacity of the clayey soil partially blended with the BKW are determined.

2. Materials and methods
   2.1. Materials
   Clayey soil samples were excavated from areas close to Nawabshah city. The BKW was obtained from a local brick kiln in the surrounding area of Nawabshah city (Figure 1). The BKW consists of ash of rice husk and wood and small pieces of broken bricks, which were finer than Sieve 4. The larger pieces of the bricks were broken and made finer than Sieve 4. The BKW was mixed with the clayey soil with an increment of 5% by weight. This mixing process of the BKW with clayey soil increased up to 40%.

2.2. Testing program
   The particle-size distribution curves of the soils were evaluated using ASTM D422 [21]. Liquid and plastic limits were determined with ASTM D-4318 [22]. The soils were classified according to AASHTO classification system [23]. Moisture density relationship and shear strength parameters of the soils were evaluated using references ASTM D1557-12 [24] and ASTM D3080/D3080M-11 [25], respectively. Free swell ratio of the soils was determined using a procedure described by Prakash and Sridharan [26].

3. Results and discussion
   3.1. Liquid limit, plastic limit, and plasticity index of the soils
   Table 1 shows the values of plastic limit, liquid limit, and plasticity index of all soil samples. As expected, the values of the above-mentioned parameters of the blended soils decreased with an increase in content of the BKW. As compared to the clayey soil, the values of the liquid limit, plastic limit, and plasticity index of the blended soil having 40% BKW were reduced by 27%, 28%, and 11%, respectively. The decrease of consistency values of blended soils results from an increase in coarse particles of the BKW.

3.2. Classification
   The particle-size distribution curves of the clayey soil mixtures blended with various proportions of the BKW are presented in Figure 2. It can be observed that particle sizes of clay and the BKW range from 2 mm to 0.01 mm and from 4.75 mm to 0.01 mm, respectively. For all mixes, the soils are well graded. The original soil is classified as A-7-5 group (clayey soil), which is considered as a poor soil. The blended soil was improved into A-4 (silty soil) and A-2-4 (silty or clayey gravel and sand) groups, when the BKW was increased.

![Figure 1](image1.png) A view of brick kiln waste generated by a local brick manufacturing work.

![Figure 2](image2.png) Particle size distribution curves of soils blended with 5 to 40% Brick Kiln Waste (BKW).
from 10% to 30% and 35% to 40%. This implies that the blended soil became coarser with an increase in the BKW than the clayey material. According to AASHTO classification system, the A-7-5 and A-2-4 groups represent the poor- and good-quality subgrade soils, respectively. A-2-4 soils are appropriate material for the construction of embankments. Soils belonging to A-4 group can also be used as a fill material for low-height embankments in those locations where moisture is not expected to increase above the placement water content (see, e.g., [27]).

### 3.3. Effect of BKW on moisture-density relationship of soils

Modified Proctor compaction tests were carried out on soil samples that contained clay, BKW, and blended soils. The Optimum Moisture Content (OMC) and the maximum dry density values of the blended soils were evaluated (Figure 3). The values of OMC increased, and the dry density decreased with increase in the BKW (Table 2). This is because the BKW is a porous material, which absorbed more water, thus increasing the OMC and reducing the dry density. The values of dry density of the clay slightly reduced from 18.5 kN/m$^3$ to 17.9 kN/m$^3$ and 17.2 kN/m$^3$ when it blended with 5% and 40% of the BKW. The values of the dry density of the blended soils are comparable to

![Figure 3. Moisture density relationship of the soils mixed with 5 to 40% Brick Kiln Waste (BKW).](image)

**Table 2.** Optimum moisture content and maximum dry density values of the soil mixed with different proportions of the Brick Kiln Waste (BKW).

| Serial no | Soil mixture       | OMC (%) | Increase in OMC (%) as compared to clay | Dry density (kN/m$^3$) | Decrease in dry density (%) as compared to clay |
|-----------|--------------------|---------|----------------------------------------|------------------------|-----------------------------------------------|
| 1         | Clay               | 13      | —                                      | 18.5                   | —                                             |
| 2         | Brick Kiln Waste (BKW) | 20      | —                                      | 16.4                   | —                                             |
| 3         | Clay+5% BKW        | 15      | 15                                     | 17.9                   | 3                                             |
| 4         | Clay+10% BKW       | 15      | 15                                     | 17.9                   | 3                                             |
| 5         | Clay+15% BKW       | 15      | 15                                     | 17.9                   | 3                                             |
| 6         | Clay+20% BKW       | 16      | 23                                     | 17.9                   | 3                                             |
| 7         | Clay+25% BKW       | 16      | 23                                     | 17.8                   | 4                                             |
| 8         | Clay+30% BKW       | 16.5    | 26                                     | 17.7                   | 4                                             |
| 9         | Clay+35% BKW       | 16.7    | 28                                     | 17.5                   | 5                                             |
| 10        | Clay+40% BKW       | 17.6    | 35                                     | 17.2                   | 7                                             |
those of a mixture of sand and gravel and well-graded sands (see, e.g., [28]).

It is to be noted that maximum reduction in the value of dry density of the blended soil was 7% when the BKW added was 40%. This implies that if the BKW is available in large volumes, it can be utilized by as high as 40% with clayey soil without affecting dry density.

3.4. Effect of BKW on shear strength parameters of the soil

Shear strength parameters (cohesion and friction angle) of the clayey soil mixed with different percentages of the BKW were determined through shear box tests. The cohesion of the blended soils decreased (Figure 4) and the friction angle increased (Figure 5) with an increase in the BKW. The cohesion and friction angle values of the blended soils were decreased by 40% and increased by 38%, respectively, when the BKW added was 40%. This is because the blended soils contained coarse and angular particles of the BKW.

3.5. Effect of the BKW on ultimate bearing capacity of clayey soil

In order to find the potential of the clayey soils stabilized with the BKW, the bearing capacity of an isolated square footing of 2 m × 2 m and depth of 2 m was calculated through Terzaghi’s bearing capacity equation (see, e.g., [29]):

\[ q_u = cN_c + \gamma D N_q + 0.5\gamma B N_\gamma, \]

where \( q_u, c, \gamma, D, \) and \( B \) are ultimate bearing capacity, cohesion, unit weight of the soil, depth of foundation, width of footing, respectively, and \( N_c, N_q, N_\gamma \) are Terzaghi’s bearing capacity factors.

The ultimate bearing capacity of the soils blended with the BKW is presented in Figure 6. The ultimate bearing capacity of the blended soils increased with an increase in the BKW. The ultimate bearing capacity of the clayey soil mixed with 40% BKW increased by 21%. The ultimate bearing capacity of the clayey soil blended with 25% of the BKW was about 430 kPa. According to International Code Council [30], the ultimate bearing capacity of sandy gravel and/or gravel is about 430 kPa. This implies that the BKW can be utilized with clayey soil as a foundation material without compromise on bearing capacity.

3.6. Effect of BKW on the swelling properties of the clayey soil

The free swell ratio of the blended soils decreased with an increase in the BKW (Figure 7). According to the criteria suggested by Prakash and Sridharan [26], the degree of expansion of clayey soil was moderate. With the addition of the BKW in the clayey soil up to 30%, the expansion of the blended soil became low. Finally, the degree of expansion of the blended soils became negligible when mixed with 35% to 40% of the BKW.

4. Conclusions

In this study, the suitability of the Brick Kiln Waste (BKW) as a stabilizer for clayey soils was examined. The main findings of this study are summarized below:
Figure 7. Decrease in free swell ratio of the clayey soil blended with 5 to 40% Brick Kiln Waste (BKW).

1. With the addition of the BKW, the clayey soil became coarser and more appropriate as a partial fill material for highways and foundations of buildings;
2. The dry density of the blended soil slightly reduced by 3% and 7% when the 20% and 40% values of BKW were added, respectively;
3. Values of cohesion and friction angle of the clayey soil were reduced and increased by 40% and 39%, respectively, when the BKW added was 40% in value;
4. In comparison to clayey soil, the ultimate bearing capacity of the blended soils increased by 21% when the BKW mixed was 40% in value;
5. The results presented in this study suggest that the BKW could be utilized as a stabilizer for clayey soils to be used in highway embankments and foundations of buildings.
