Abstract

Background: Regulatory B cells (Bregs), which protect from autoimmunity, are deficient in multiple sclerosis (MS). Novel regulatory B cell subsets CD19+CD24hiCD38hi cells and CD19+PD-L1hi cells, with disparate regulatory mechanisms have been defined. Alemtuzumab provides a long-lasting suppression of disease activity in MS. In contrast to its documented efficacy, alemtuzumab’s mechanism of action is not fully understood and information about the composition of repopulating B cell pool is scarce.

Aim: To characterize repopulated B cell subsets and elucidate alemtuzumab’s mechanism of action in B cell perspective.

Methods: The frequency and the absolute number of Bregs were studied in peripheral blood mononuclear cells (PBMC) of 37 MS patients and 11 healthy controls (HC). Longitudinal analysis of the frequency and the absolute number of Bregs in PBMC of 11 MS patients was evaluated, before and at 6, 9, and 12 months post alemtuzumab.

Results: We found deficiency of CD19+CD24hiCD38hi cells during relapse compared to remission and HC (relapse vs remission: \( p = 0.0006 \), relapse vs HC: \( p = 0.0004 \)). CD19+PD-L1hi cells were deficient during relapse than remission and HC (relapse vs remission: \( p = 0.0113 \), relapse vs HC: \( p = 0.0007 \)). Following alemtuzumab, the distribution of B cells shifts towards naïve phenotype and Breg deficiency is restored. The frequency of CD19+CD24hiCD38hi cells was significantly increased at 6 M and 9 M compared to 0 M (6 M vs 0 M: \( p = 0.0004 \), 9 M vs 0 M: \( p = 0.0079 \)). At 9 M, the frequency of CD19+CD24hiCD38hi cells started to decrease and by 12 M the frequency was reduced compared to 6 M, although it was significantly higher than baseline level (12 M vs 0 M: \( p = 0.0257 \)). The absolute number was significantly increased at 6 M and 9 M post-alemtuzumab (6 M vs 0 M: \( p = 0.0063 \), 9 M vs 0 M: \( p = 0.02 \)). The frequency of CD19+PD-L1hi cells significantly increased until 12 M (6 M vs 0 M: \( p = 0.0004 \), 12 M vs 0 M: \( p = 0.0036 \)). The frequency of CD19+PD-L1hi cells at 12 M was significantly higher than 9 M (\( p = 0.0311 \)). We further pinpoint that CD19+CD24hiCD38hi cells were deficient at severe relapses following alemtuzumab infusion and restored during recovery.

Conclusions: Our results highlight the preferential reconstitution of Bregs as a possible mechanism of action of alemtuzumab and CD19+CD24hiCD38hi cells as a potential biomarker for disease activity.

Background

The concept that multiple sclerosis (MS) is a T-cell-mediated disease has been changed and it is now widely accepted that B cells play a part in the pathogenesis of MS. [1–3] Multiple roles of B cells have been elucidated emphasizing that B cells have dual contribution to autoimmunity [1, 4–6]. Hence, the concept of regulatory B cells (Breg) has emerged, proving that B cell subset distribution is far more complex than the original concept. A novel Breg subset that was originally known as immature transitional B cells (CD19+CD24hiCD38hi) has been described to have regulatory capacity through interleukin-10 production [7]. Another study has found B cells highly expressing programmed death ligand-1 (CD19+PD-L1hi cells) that exert regulatory function through cell-to-cell contact via interaction of CD19+PD-L1hi cells with PD-1 on T cells, resulting in suppression of T follicular helper (Tfh) cell differentiation and expansion, which are the cell type known to be involved in the relapse of MS patients [8, 9].

Alemtuzumab is a highly effective treatment in relapsing MS. It provides a long-lasting suppression of disease activity by altering the proportion of lymphocyte subsets with preferential increase of regulatory T cells (Treg) [10, 11]. In contrast to alemtuzumab’s documented efficacy, alemtuzumab’s mechanism of action is not fully understood and information about the composition of the repopulating B cell pool, especially Breg, is scarce.

Here, we pinpoint deficiency of CD19+CD24hiCD38hi and CD19+PD-L1hi cells during relapse and subsequent expansion following alemtuzumab infusion. We also highlight the possible clinical implication of CD19+CD24hiCD38hi cells.

Methods

Study population

For cross-sectional study, 20 MS patients during relapse (MS-relapse) and 17 MS patients in remission (MS-remission) and 11 healthy controls (HC) were included. For longitudinal analysis, 11 patients who were treated with alemtuzumab were included. All MS patients fulfilled the 2010 McDonald’s criteria [12]. Current study was approved by the Institutional Review Board, and informed consent was obtained from each subject. Demographic and clinical characteristics of participants are summarized in Table 1.

Flow cytometry

For cross-sectional study, fresh peripheral blood mononuclear cells (PBMCs) were surface stained with monoclonal antibodies against CD19-APC-cy7, CD27-FITC, CD24-BV421, CD38-BV510, and PD-L1(CD274)-PE-cy7 (BD Biosciences). For longitudinal study, frozen PBMCs, collected from 11 RRMS patients undergoing alemtuzumab at baseline and 6, 9, and 12 months, were surface stained with monoclonal antibodies as stated above.

Table 1 Demographic and clinical characteristics of MS patients in relapse and remission

| Characteristic               | MS relapse | MS remission |
|------------------------------|------------|--------------|
| Age (years, mean ± SD)       | 34.5 ± 9.4 | 36.9 ± 5.2   |
| Women:men (n)                | 16:4       | 10:7         |
| Onset age (years, mean ± SD) | 30.4 ± 22.0| 29.8 ± 7.3   |
| Disease duration (years, mean ± SD) | 12 ± 24.9 | 6 ± 5.9     |
| EDSS (mean ± SD)             | 2.9 ± 1.9  | 1.8 ± 1.9    |

Statistical analysis

We performed analysis of significance in Prism (GraphPad, La Jolla, USA). For cross-sectional data, one-way ANOVA analysis with Tukey’s multiple comparison post hoc analysis was performed to compare the frequency of Bregs between HC, MS-relapse, and MS-remission. Unpaired t test was used to compare the absolute number of Bregs between MS-relapse and MS-remission. Repeated measures ANOVA with Tukey’s multiple comparison post hoc analysis was performed for longitudinal analysis. A p value of < 0.05 was considered statistically significant. All values show mean ± SEM.

Result

Regulatory B cells are deficient in MS patients during relapse

In order to evaluate the relationship between the frequency of CD19+CD24hiCD38hi cells and CD19+PD-L1hi cells with disease activity of MS, the frequency and the absolute number were measured in total CD19+ B cells in MS-relapse and MS-remission and HC. The frequency of both CD19+CD24hiCD38hi cells (Fig. 1a, b) and CD19+PD-L1hi cells (Fig. 2a, b) was significantly reduced in MS-relapse compared to MS-remission and HC. The average frequency of Bregs in MS-remission was lower than those of HC, but no statistical difference was observed. The absolute number of CD19+CD24hiCD38hi cells was significantly reduced in MS-relapse compared to MS-remission (Fig. 1c). Although no significant difference was observed, the absolute number of CD19+PD-L1hi cells was reduced in MS-relapse compared to MS-remission (Fig. 2c).

Preferential reconstitution of naïve B cells following alemtuzumab

As expected, the frequency and absolute number of total lymphocytes was decreased at 6 months and gradually increased up to 12 months post alemtuzumab (Fig. 3a). The frequency and the absolute number of memory B cells and plasmablasts were significantly decreased compared to pre-treatment level, and naïve B cells comprised the majority of repopulated CD19+ B cells (Fig. 3b).
MS patients show deficiency of CD19⁺CD24⁺⁰CD38⁺² cells during relapse. The percentage and the absolute number of CD19⁺CD24⁺⁰CD38⁺² B cells were measured in MS patients undergoing relapse (n = 15) and patients in remission (n = 15) and healthy controls (n = 8). PBMC was isolated from fresh peripheral blood and surface stained for flow cytometry. a Representative flow cytometry dot plot of CD24 and CD38 expression in total CD19⁺ B cells. b Scatter plots showing the percentage of CD19⁺CD24⁺⁰CD38⁺² B cells in MS-relapse, MS-remission, and HC. A significant reduction in the frequency of CD19⁺CD24⁺⁰CD38⁺² B cells was observed in MS-relapse compared to MS-remission and HC (relapse vs remission: $p = 0.0006$, relapse vs healthy: $p = 0.0004$). All values show mean ± SEM. Data were analyzed by one-way analysis of variance (ANOVA) with Tukey’s multiple comparison post hoc analysis. ***$p < 0.001$. c The absolute number of CD19⁺CD24⁺⁰CD38⁺² B cells in MS-relapse was significantly reduced compared to MS-remission ($p = 0.009$). All values show mean ± SEM. Data were analyzed by unpaired t test. **$p < 0.01$. Ex vivo data were collected from peripheral blood samples taken during the time course of this study.
Breg deficiency in MS is restored following alemtuzumab

The frequency and the absolute number of CD19⁺CD24hiCD38hi cells were markedly increased at 6 and 9 months following alemtuzumab treatment compared to pre-treatment level. By the end of the cycle (12 M), both the frequency and number were decreased, although did not reach pre-treatment level. The frequency and absolute number of CD19⁺CD24intCD38int mature naïve B cells were increased at 6 and 9 months post-alemtuzumab, and at 12 months post-alemtuzumab, the frequency of CD19⁺CD24intCD38int cells was lower than baseline level. A significant decrease in the frequency and absolute number of CD19⁺CD24hiCD38⁻ memory B cells was observed following alemtuzumab treatment (Fig. 4a–c).

The frequency and absolute number of CD19⁺PD-L1hi cells were increased at 6 and 9 months and maintained until the end of the cycle. The frequency of CD19⁺PD-L1int cells was significantly decreased at 6, 9, and 12 months following alemtuzumab. The absolute number of CD19⁺PD-L1int cells showed no significant difference. The frequency and absolute number of CD19⁺PD-L1low cells showed no significant difference (Fig. 5a–c).
Clinical implications
Among 11 patients treated with alemtuzumab, one patient experienced two severe relapses within 2 cycles of alemtuzumab infusion (Fig. 6a, b). During his first attack, overshoot of total B cells was observed while the frequency of CD19⁺CD24hiCD38hi cells was remarkably decreased to 0.45% compared to previous follow-up (6 M: 11.1%). 4 months later, the frequency of CD19⁺CD24hiCD38hi cells increased to 6.5%. 3 months post second alemtuzumab infusion, the frequency of CD19⁺CD24hiCD38hi cells was 10.5%. However, at his second attack, 10 M after second cycle infusion, the frequency of CD19⁺CD24hiCD38hi cells was again markedly decreased to 1.93% accompanied by overshooting B cell response. Interestingly, the reduction in the frequency of CD19⁺CD24hiCD38hi cells (3.98%) 20 days preceding second attack was observed, which is an immense reduction from previous follow-up (15 M: 10.5%). In contrast to CD19⁺CD24hiCD38hi cells, no change in the frequency of CD19⁺PD-L1hi cells was observed during both relapses. The absolute number of CD19⁺CD24hiCD38hi cells was also reduced during relapses.
Fig. 4 Alemtuzumab treatment restores CD19⁺CD24⁺⁺⁺CD38⁺⁺⁺ cells. In order to evaluate the B cell subset distribution post-alemtuzumab, thawed PBMCs of alemtuzumab-treated patients (n = 11) were evaluated up to 12 months after induction. A. Representative flow-cytometry dot plot of CD24 and CD38 in total CD19⁺ B cells. B. Cumulative data for the frequency of CD19⁺CD24⁺⁺⁺CD38⁺⁺⁺ B cells. The frequency of CD19⁺CD24⁺⁺⁺CD38⁺⁺⁺ cells were significantly increased at 6 M and 9 M compared to pre-treatment level (6 M vs 0 M: p = 0.0004, 9 M vs 0 M: p = 0.0079). At 9 M, the frequency of CD19⁺CD24⁺⁺⁺CD38⁺⁺⁺ cells started to decrease and by 12 M, the frequency was reduced compared to 6 M, although it was significantly increased than baseline level (12 M vs 0 M: p = 0.0257). C. The absolute number was significantly increased at 6 M and 9 M post-alemtuzumab (6 M vs 0 M: p = 0.0063, 9 M vs 0 M: p = 0.02). All values show mean ± SEM. Data were analyzed by repeated measures ANOVA with Tukey's multiple comparison post-hoc analysis. *p < 0.05; **p < 0.01; ***p < 0.001.
Discussion

Little is known about the repopulating B cell pool following alemtuzumab. Cases of severely exacerbated central nervous system inflammation in alemtuzumab-treated MS patients have reported B-cell driven pathology, further emphasizing the importance of B cell study in alemtuzumab-treated patients [13–15]. We show that deficiency of CD19+CD24hiCD38hi cells and CD19+PD-L1hi cells in the peripheral blood of relapsing MS patients are restored following alemtuzumab and that B cell distribution shifts towards naïve phenotype. In fact, the frequency of Bregs with disparate regulatory mechanisms exceeded baseline level, which may underlie the long-lasting suppression of disease activity.

Interestingly, both frequency and absolute number of CD19+CD24hiCD38hi cells are reduced during and prior to relapse in an alemtuzumab-treated patient. CD19+CD24hiCD38hi cells are known to maintain Tregs and limit the differentiation of T helper 1 (Th1) and T helper 17 (Th17) cells [16]. The deficiency of CD19+CD24hiCD38hi cells could have a significant impact on the regulation of pathology. Indeed, recent studies have found that transitional B cells are impaired in various immune-related disorders [7, 16–18], although conflicting results were observed in MS. [19, 20] In the early phase of alemtuzumab therapy, CD19+ B cells repopulate earlier than CD4+ T cells and immature B cells dominate the repopulated CD19+ B cells [21]; the

Fig. 5 Alemtuzumab treatment restores CD19+PD-L1hi cells. In order to evaluate the B cell subset distribution post-alemtuzumab, thawed PBMCs of alemtuzumab-treated patients (n = 11) were evaluated up to 12 months after induction. a Representative flow-cytometry dot plot of PD-L1 in total CD19+ B cells. b Cumulative data for the frequency of CD19+PD-L1hi cells. The frequency of CD19+PD-L1hi cells increased significantly until 12 M (6 M vs 0 M; p = 0.0004, 12 M vs 0 M; p = 0.0036). c Cumulative data for the absolute number of CD19+PD-L1hi cells. No significant difference was observed in the absolute number of CD19+PD-L1hi, CD19+PD-L1int, and CD19+PD-L1low cells. All values show mean ± SEM. All values show mean ± SEM. extensive repopulation of CD19^+CD24^hiCD38^hi cells following alemtuzumab may contribute to the expansion of Tregs while suppressing differentiation of naïve CD4^+ T cells into Th1 and Th17 cells and hence, contributing to the efficacy of alemtuzumab.

A recent study described that CD19^+PD-L1^hi cells are capable of suppressing Tfh cell differentiation and expansion through interaction with PD-1 on activated T cells [8]. Interaction causes an increase in signal transducer and activator of transcription 5 expression, a known suppressor of Tfh-cell development and expansion. Since Tfh cells aid germinal center formation and hence, involved in the formation of memory B cells and plasma cells, Tfh cells were thought to have pathogenic role in the B-cell-mediated autoimmune diseases. There has been several reports on Tfh cell involvement in MS. [22–25] Most of all, there has been report that CCR7^+ ICOS^+ circulating memory Tfh cells are increased in MS patients during relapse, but decreased in patients during remission [9]. This finding is in line with our results, where CD19^+PD-L1^hi cells are decreased in MS patients during relapse, but restored during remission. Hence, suppression of Tfh cell differentiation and proliferation by CD19^+PD-L1^hi cells may be impaired due to CD19^+PD-L1^hi cell deficiency, contributing to enhancement of disease activity.

This study is limited by its small sample size. In addition, we report that the marked reduction of CD19^+CD24^hiCD38^hi cells during relapse in an alemtuzumab-treated patient was observed in only 2 relapses of a single case. Therefore, in order to decipher the critical role of CD19^+CD24^hiCD38^hi cells in the long-term disease suppression of MS and in the mechanism of action of alemtuzumab, further longitudinal study with larger number of patients on how CD19^+CD24^hiCD38^hi cells and other lymphocytes (including Tregs) change during relapse, is required. The extensive expansion of CD19^+CD24^hiCD38^hi cells was maintained until 9 months post-alemtuzumab, whereas CD19^+PD-L1^hi cells were maintained until the end of the cycle. Further work needs to be established to explain the difference in the results. In addition, a recent

study has reported that hyperrepopulation of immature B cells post-alemtuzumab in the absence of adequate regulation by T cells increases the risk of secondary autoimmunity [21]. Due to vast composition of immature B cells and lack of understanding of their function, it remains to be further elucidated which specific immature B cell subset would be responsible for the secondary autoimmunity. Lastly, further functional study on the CD19+CD24hiCD38hi cells would clarify the mechanism of action of alemtuzumab.

Conclusion
Our results highlight the preferential reconstitution of Bregs as a possible mechanism of action of alemtuzumab and CD19+CD24hiCD38hi cells as a potential biomarker for disease activity.
