UNIFORM STABILITY OF THE DIRICHLET SPECTRUM FOR ROUGH OUTER PERTURBATIONS

BRUNO COLBOIS, ALEXANDRE GIROUARD, AND METTE IVERSEN

Abstract. The goal of this paper is to study the Dirichlet eigenvalues of bounded domains \( \Omega \subset \Omega' \). With a local spectral stability requirement on \( \Omega \), we show that the difference of the Dirichlet eigenvalues of \( \Omega' \) and \( \Omega \) is explicitly controlled from above in terms of the first eigenvalue of \( \Omega' \setminus \overline{\Omega} \) and of geometric constants depending on the inner domain \( \Omega \). In particular, \( \Omega' \) can be an arbitrary bounded domain.

1. Introduction and results

Let \( M \) be a complete smooth Riemannian manifold. The Dirichlet eigenvalues of a bounded domain \( \Omega \subset M \) are denoted
\[
\lambda_1(\Omega) < \lambda_2(\Omega) \leq \lambda_3(\Omega) \leq \cdots \uparrow \infty.
\]
In the Euclidean case, there is a vast literature on spectral stability of the Dirichlet spectrum under perturbation of the domain. The aim is to show that if \( \Omega' \) is another domain which is, in some sense, geometrically close to \( \Omega \), then its Dirichlet eigenvalues are close to those of \( \Omega \). See for instance the papers [5, 9] and the references therein, where spectral stability is studied in particular from the point of view of \( \gamma \)-convergence. Explicit control of the spectrum has been studied for example in [3, 11].

In this paper, we are interested in obtaining explicit estimates in the situation where the two domains \( \Omega \) and \( \Omega' \) might not be geometrically close. For domains \( \Omega \subset \Omega' \), the difference of eigenvalues \( |\lambda_k(\Omega) - \lambda_k(\Omega')| \) will be controlled in terms of the fundamental tone \( \lambda_1(\Omega' \setminus \overline{\Omega}) \). In particular, the domains \( \Omega' \) and \( \Omega \) can have very different shapes, and the volume of \( \Omega' \) can be large compared to that of \( \Omega \). Some natural conditions on the inner domain \( \Omega \) need to be assumed, but \( \Omega' \) can be any bounded open set. We will do this by combining local estimates based on the work of E.B. Davies [7], with global estimates based on the work of the first author and J. Bertrand [2]. Note that in this paper constants will depend only on the stated parameters.

1.1. Statement of results. Our goal is to estimate \( |\lambda_k(\Omega) - \lambda_k(\Omega')| \) in the situation where \( \Omega \subset \Omega' \) are bounded domains. Throughout we will use the notation
\[
\Omega^\varepsilon = \{ x \in M : d(x, \Omega) < \varepsilon \}, \quad \Omega_\varepsilon = \{ x \in \Omega : d(x, \Omega^\varepsilon) > \varepsilon \},
\]
and
\[
\mu = \lambda_1(\Omega' \setminus \overline{\Omega}), \quad \lambda = \lambda_k(\Omega'),
\]

\[\text{[A domain is a connected open set.]}
\]
with the convention $\lambda_1(\emptyset) = \infty$. Observe that because $\Omega \subset \Omega^c \cap \Omega' \subset \Omega'$, it follows from monotonicity of the Dirichlet eigenvalues that
\begin{equation}
0 \leq \lambda_k(\Omega^c) - \lambda_k(\Omega') = (\lambda_k(\Omega^c \cap \Omega') - \lambda_k(\Omega')) + (\lambda_k(\Omega) - \lambda_k(\Omega^c \cap \Omega')),
\end{equation}
where the two terms on the right hand side are non-negative. We estimate these two terms separately, and call them the global and the local term respectively.

Global estimates. In Section 2, we prove the following theorem allowing control of the first term in the right hand side of (1.1) when $\mu = \lambda_1(\Omega' \setminus \Omega)$ is large.

**Theorem 1.2.** There are constants $a_k, b_k \geq 1$ defined by the recurrence relations (2.2) and (2.3), with the following property: For each $\alpha \in (0, \frac{1}{4})$, if
\begin{equation}
32 \left( \frac{\lambda}{\mu} \right)^{\frac{1}{2}-2\alpha} a_k \leq 1
\end{equation}
then
\begin{equation}
|\lambda_k(\Omega^c \cap \Omega') - \lambda_k(\Omega')| \leq b_k \left( \frac{\lambda}{\mu} \right)^{\frac{1}{2}-2\alpha} \lambda,
\end{equation}
for the choice
\begin{equation}
\epsilon = 2 \left( \frac{\lambda}{\mu} \right)^\alpha \frac{1}{\sqrt{\lambda}}.
\end{equation}

**Remark 1.5.**
- Monotonicity implies that the eigenvalue $\lambda = \lambda_k(\Omega')$ is bounded above by $\lambda_k(\Omega)$, so that the numerator of the right hand side of (1.4) is bounded above in terms of $\Omega$ and $k$ only.
- Inequality (1.3) is invariant under homothetic scaling of the domains. Of course, the value of $\epsilon$ must also be modified in accordance with its definition.

The strategy consists in a geometrical approach inspired by a special case of the proof of Theorem 3.3 in [2].

Local estimates. In Section 3, we describe classes of domains $\Omega \subset \mathbb{R}^n$ for which we have uniform control of the second term in the right hand side of (1.1) for each $k \in \mathbb{N}$. They consist of domains $\Omega$ with thickenings $\Omega^c$ satisfying a weak Hardy inequality.

**Definition 1.6.** A domain $\Omega$ satisfies a weak Hardy inequality with constants $a, b$ if for each $u \in C^\infty_0(\Omega)$,
\begin{equation}
\int_{\Omega} \frac{u^2}{\delta^2} \leq a \int_{\Omega} \left( |\nabla u|^2 + bu^2 \right),
\end{equation}
where $\delta$ denotes the distance function to the boundary of $\Omega$.

The following illustrates our use of the Hardy inequality for a particular class of domains. (See Section 3.4 for the definition of the uniform external rolling ball condition.)

**Lemma 1.7.** Let $\varepsilon_0 > 0, r_0 > 0$. Let $\mathcal{A} = \mathcal{A}(\varepsilon_0, r_0, n)$ be the family of open, bounded sets $\Omega$ in $\mathbb{R}^n$, $n \geq 2$, with inradius bounded below by $r_0$ satisfying a uniform external rolling ball condition with parameter $\varepsilon_0$. Then there exist positive constants...
\[ \gamma = \gamma(n), \ C_k = C_k(n, \varepsilon_0, r_0) \text{ and } \varepsilon_k = \varepsilon_k(n, \varepsilon_0, r_0) \] such that for any \( \Omega \in A \) and any \( \varepsilon \leq \min(\varepsilon_0/2, \varepsilon_k) \),

\[ 0 < \lambda_k(\Omega) - \lambda_k(\Omega') \leq C_k \varepsilon^\gamma. \]  

Remark 1.9. In contrast to the global estimate of Theorem 1.2, this local estimate is not scaling invariant. Indeed, the proof of Lemma 1.7 is based on the fact that the geometric hypotheses imply uniform control of the constants \( a \) and \( b \) appearing in the Hardy inequalities for the thickenings \( \Omega' \). This control allows the application of a result of E.B. Davies from [7], which is inherently non-homogeneous. However, for convex domains, we were able to obtain invariant local bounds (see Proposition 3.1).

**Corollary 1.10.** Under the hypotheses of Lemma 1.7, there exist constants \( a_k, b_k, \gamma = \gamma(n), C_k = C_k(n, \varepsilon_0, r_0) \) and \( \varepsilon_k = \varepsilon_k(n, \varepsilon_0, r_0) \) such that for each domain \( \Omega \in A \) the following holds. Let \( \alpha \in (0, \frac{1}{4}) \), and suppose that \( \lambda, \mu \) satisfy \((\lambda \mu)^{1/2} - 2 \alpha \leq \min(\varepsilon_0, \varepsilon_k) \). Then

\[ |\lambda_k(\Omega) - \lambda_k(\Omega')| \leq b_k \left( \frac{\lambda}{\mu} \right)^{\frac{1}{2} - 2\alpha} \lambda + C_k \left( \frac{\lambda}{\mu} \right)^{\gamma \alpha}. \]  

Taking for example \( \alpha = \frac{1}{2(2 + \gamma)} \) gives

\[ |\lambda_k(\Omega) - \lambda_k(\Omega')| \leq \left( b_k \lambda^{\frac{4 + 3\gamma}{2(2 + \gamma)}} + C_k \lambda^{-\frac{2(1 + \gamma)}{2(2 + \gamma)}} \right) \mu^{\frac{1}{2(2 + \gamma)}}. \]

In Section 3, similar results will be proved for families defined in terms of a cone condition and a capacity density condition. In Section 3.1, we give two simple examples to illustrate the necessity of two of the geometric conditions imposed in Section 3.4. Our goal for this section is to give some simple criteria implying local stability.

**Proximity of eigenspaces.** In Section 4, we control the proximity of the eigenspaces on \( \Omega' \) and \( \Omega \) in terms of \( \mu = \lambda_1(\Omega' \setminus \Omega) \). Stability of eigenfunctions for the Dirichlet problem is well known, so our contribution is to provide an explicit control in terms of \( \mu \).

1.2. **Discussion of results.** Stability of the Dirichlet spectrum is closely related to the stability of the corresponding Dirichlet problem

\[ -\Delta u = f \text{ in } \Omega, \quad u = 0 \text{ on } \partial \Omega. \]

Indeed, it is well known that estimates for the associated resolvent operator \( R_\Omega \) translate into corresponding bounds for the eigenvalues. This has been studied from the point of view of various interrelated notions of convergence of domains. See [10] Chapter 2.3 for an enlightening discussion. In [5] it is proved, under rather weak assumptions on \( \Omega \), that if a sequence \( \Omega_n \) of domains containing \( \Omega \) is such that

\[ \lim_{n \to \infty} \lambda_1(\Omega_n \setminus \Omega) = \infty, \]

then \( \Omega_n \) \( \gamma \)-converges to \( \Omega \), which implies

\[ \lim_{n \to \infty} \lambda_k(\Omega_n) = \lambda_k(\Omega). \]
In this situation, our results provide explicit control of the difference $|\lambda_k(\Omega) - \lambda_k(\Omega_n)|$ in terms of $\mu$, and so control of the rate of convergence.

As mentioned, explicit estimates of the difference $|\lambda_k(\Omega) - \lambda_k(\Omega')|$ in terms of for example the measure of the symmetric difference $\Omega' \Delta \Omega$ in $[3]$ have also been given previously. Our estimate in terms of $\mu = \lambda_1(\Omega' \setminus \Omega)$ allows control in addition when the measure of $\Omega' \setminus \Omega$ is large. The results of $[3]$ are valid for classes of Lipschitz domains described in $[3$, Section 2.3]. Our results complement this by providing a selection of geometric conditions under which we have control of the spectrum.

**Acknowledgements.** We would like to thank Yuri Netrusov, Dorin Bucur, Michiel van den Berg, Iosif Polterovich and Antoine Lemenant for valuable discussions. Part of this work was accomplished during the conference Shape optimization problems and spectral theory which was held at CIRM (Marseille) from May 28 to June 2, 2012. We would like to thank the organizers as well as CIRM for this great opportunity.

### 2. Global estimates

The goal of this section is to prove Theorem 1.2. Let $\Omega \subset \Omega'$ be bounded domains in the complete smooth Riemannian manifold $M$. Let $(f_i)_{i \in \mathbb{N}}$ be an orthonormal basis of $L^2(\Omega')$ corresponding to the Dirichlet eigenvalues $\lambda_i(\Omega')$. Fix $\epsilon > 0$ and let $\eta : M \to \mathbb{R}$ be a cutoff function such that

$$0 \leq \eta \leq 1, \quad |\nabla \eta| \leq \frac{1}{\epsilon},$$

$$\eta \equiv \begin{cases} 1 & \text{in } \Omega^\epsilon, \\ 0 & \text{in } M \setminus \Omega^{2\epsilon}. \end{cases}$$

For each $k \in \mathbb{N}$, the function

$$\psi_k := \eta f_k \in H^1_0(\Omega^{2\epsilon} \cap \Omega')$$

will be used as test function in the variational characterization of $\lambda_k(\Omega^{2\epsilon})$ thanks to a result of the first author and J. Bertrand [2, Lemma 3.13]. This result is stated here in a slightly modified version for convenience.

**Lemma 2.1.** Let $a_1 = 1$ and for $k > 1$, recursively define

$$a_k = 1 + \sum_{i=1}^{k-1} a_i^2. \tag{2.2}$$

Let $\rho$ be a positive number such that $4\rho a_k \leq 1$. Let $b_1 = 4$ and for $k > 1$, recursively define

$$b_k = (1 + 8a_k)((1 + \rho b_{k-1})(1 + 8a_k) + 1). \tag{2.3}$$

For each $\lambda > 0$, the following holds: Let $q$ be a quadratic form on an Euclidean space $E$ of dimension $k$. Let $\psi_1, \cdots, \psi_k \in E$ be such that for each $i, j \leq k$,

$$|\langle \psi_i, \psi_j \rangle - \delta_{ij}| \leq \rho \quad \text{and} \quad q(\psi_i) \leq \lambda(1 + \rho). \tag{2.4}$$

Then there exists an orthonormal basis $(F_i)_{1 \leq i \leq k}$ of $E$ such that for each $i \in \{1, 2, \cdots, k\}$

$$q(F_i) \leq \lambda(1 + \rho b_k).$$
The proof of Lemma 2.5 differ only slightly of the original proof, and the modifications will be presented in Section 5. In our situation, the quadratic form is the Dirichlet energy defined on the space $E = \text{span}(\psi_1, \cdots, \psi_k)$ in $L^2(\Omega^2)$. 

**Lemma 2.5.** For each $j \in \{1, 2, \cdots, k\}$, the Dirichlet energy of the test function $\psi_j = \eta f_j$ satisfies

$$\|\nabla \psi_j\|^2 \leq \lambda + \Lambda + 2\Lambda^{1/2}\lambda^{1/2},$$

where $\Lambda = 2 \left(1 + \frac{\epsilon^2}{\epsilon^2} \mu\right)$.

**Proof of Lemma 2.5.** Writing $f = f_j$ and $\psi = \eta f$ to simplify notations, direct computation using the definition of $\psi$ and of the cutoff function $\eta$ leads to

$$\int_{\Omega^2} |\nabla \psi|^2 = \int_{\Omega^2 \setminus \Omega'} |\nabla \eta|^2 f^2 + 2 \int_{\Omega^2 \setminus \Omega'} \eta f \nabla \eta \cdot \nabla f + \int_{\Omega^2} \eta^2 |\nabla f|^2$$

$$\leq \frac{1}{\epsilon^2} \int_{\Omega^2} f^2 + \frac{2}{\epsilon} \int_{\Omega^2 \setminus \Omega'} |\nabla \eta| |\nabla f| + \int_{\Omega^2} |\nabla f|^2$$

$$\leq \frac{1}{\epsilon^2} A + \frac{2}{\epsilon} A^{1/2} \left(\int_{\Omega^2 \setminus \Omega'} |\nabla f|^2\right)^{1/2} + \int_{\Omega^2} |\nabla f|^2$$

$$\leq \frac{1}{\epsilon^2} A + \frac{2}{\epsilon} A^{1/2} \lambda^{1/2} + \lambda.$$  

In order to give an upper bound for

$$A = \int_{\Omega^2 \setminus \Omega'} f^2,$$

an auxiliary cutoff function $\chi : M \to \mathbb{R}$ is introduced, satisfying

$$0 \leq \chi \leq 1, \quad |\nabla \chi| \leq \frac{1}{\epsilon},$$

$$\chi \equiv \begin{cases} 1 & \text{in } M \setminus \Omega', \\ 0 & \text{in } \Omega. \end{cases}$$

(2.8)

It follows that

$$A = \int_{\Omega^2 \setminus \Omega'} \chi^2 f^2 \leq \int_{M \setminus \Omega} \chi^2 f^2 = \|\chi f\|^2.$$

The function $\chi f$ is then used in the variational characterization of $\mu$:

$$\mu \|\chi f\|^2 \leq \int_{\Omega \setminus \Pi} |\nabla (\chi f)|^2 \leq 2 \int_{\Omega \setminus \Pi} (|\nabla f|^2 + \chi^2 |\nabla f|^2)$$

$$\leq \frac{2}{\epsilon^2} \int_{\Omega \setminus \Pi} f^2 + 2 \int_{\Omega \setminus \Pi} |\nabla f|^2$$

$$\leq 2 \left(1 + \frac{\epsilon^2}{\epsilon^2} \lambda\right).$$

It follows that

$$A \leq \|\chi f\|^2 \leq 2 \left(1 + \frac{\epsilon^2 \lambda}{\epsilon^2 \mu}\right),$$

which is substituted back into inequality (2.7) to complete the proof. \(\square\)
The following lemma shows that the test functions $\psi_i$ form an almost orthonormal family in $L^2$.

**Lemma 2.10.** For each $i,j \leq k$,

$$|\langle \psi_i, \psi_j \rangle - \delta_{ij}| \leq 8\epsilon^2 \Lambda,$$

where $\Lambda = 2 \left( \frac{1+\epsilon^2 \lambda}{\epsilon^2 \mu} \right)$.

**Proof of Lemma 2.10.** For the case $i = j$, the inequality (2.9) implies

$$\|\psi_i\|^2 \geq \int_{\Omega^*} f_i^2 = 1 - \int_{M \setminus \Omega^*} \chi^2 f_i^2 \geq 1 - 2 \left( \frac{1+\epsilon^2 \lambda}{\epsilon^2 \mu} \right),$$

where the cutoff function $\chi$ has been defined in (2). Since $\|\psi_i\|^2 \leq \|f_i\|^2 = 1$, this implies

$$|\langle \psi_i, \psi_i \rangle - 1| \leq 2 \left( \frac{1+\epsilon^2 \lambda}{\epsilon^2 \mu} \right) = \epsilon^2 \Lambda.$$

For $i \neq j$,

$$|\langle \psi_i, \psi_j \rangle| = |\int_{\Omega^*} \eta^2 f_i f_j| = |\int_{\Omega^*} (\eta^2 - 1) f_i f_j + \int_{\Omega^*} f_i f_j|.$$

As $f_i$ and $f_j$ are orthogonal on $\Omega'$,

$$\left| \int_{\Omega^*} f_i f_j \right| \leq 2 \int_{\Omega' \setminus \Omega^*} (f_i^2 + f_j^2) \leq 2(\|f_i\|^2 + \|f_j\|^2),$$

which together with $1 - \eta^2 \leq \chi^2$ implies

$$\left| \int_{\Omega^*} (\eta^2 - 1) f_i f_j \right| \leq 2(\|f_i\|^2 + \|f_j\|^2).$$

Combining this with inequality (2.9) and noting that $\max(\lambda_i, \lambda_j) \leq \lambda_k(\Omega')$, then gives

$$\left| \int_{\Omega^*} \psi_i \psi_j \right| \leq 16 \left( \frac{1+\epsilon^2 \lambda}{\epsilon^2 \mu} \right).$$

\[\square\]

**Proof of Theorem 1.2.** Given $\alpha \in (0, \frac{1}{4})$, let

$$\epsilon = \left( \frac{\lambda}{\mu} \right)^\alpha \frac{1}{\sqrt{\lambda}}.$$

Note that by condition (1.3), $\epsilon < 1/\sqrt{\lambda}$, which implies $\Lambda \leq \frac{4}{\epsilon^2 \mu}$. Thus

$$\Lambda + 2\sqrt{\lambda} \sqrt{\lambda} \leq \frac{4}{\epsilon^2 \mu} + \frac{4\sqrt{\lambda}}{\epsilon^2 \sqrt{\mu}} = 4 \left( \frac{\lambda}{\mu} \right)^{1-4\alpha} \lambda + 4 \left( \frac{\lambda}{\mu} \right)^{\frac{1}{2}-2\alpha} \lambda \leq 8 \left( \frac{\lambda}{\mu} \right)^{\frac{1}{2}-2\alpha} \lambda.$$

Moreover

$$\epsilon^2 \Lambda \leq \frac{4}{\epsilon^2 \mu} = 4 \left( \frac{\lambda}{\mu} \right)^{1-2\alpha} \leq 8 \left( \frac{\lambda}{\mu} \right)^{\frac{1}{2}-2\alpha}.$$

The hypotheses of Lemma 2.11 then holds with

$$\rho = 8 \left( \frac{\lambda}{\mu} \right)^{\frac{1}{2}-2\alpha}.$$
3. Uniform local stability

A family \( A \) of domains \( \Omega \subset M \) is \textit{uniformly locally stable} if there exists \( \epsilon_0 > 0 \) such that for each \( \Omega \in A \), a uniform upper bound for \( |\lambda_k(\Omega) - \lambda_k(\Omega^\epsilon)| \) holds, in terms of \( \epsilon \leq \epsilon_0 \), \( k \in \mathbb{N} \), and some geometric quantities depending only on \( \Omega \). The family \( A \) described in the introduction (see Lemma 1.7) is a prototypical example of uniform local stability. Other examples of such families will be given in Section 3.4.

3.1. Motivating examples. The goal of the present section is to give two simple examples to illustrate the necessity of the geometric conditions imposed in the construction of the families in Section 3.4. The first illustrates the need for a lower bound on the inradius, while the second for a condition of the form \( (\Omega^\epsilon)_{N^\epsilon} \subset \Omega \) for all \( \epsilon \leq \epsilon_0 \), as required in Lemma 1.7.

Example 1. The Dirichlet eigenvalues of the ball \( \Omega = B(0, r) \subset \mathbb{R}^n \) are

\[
\lambda_k(\Omega) = \frac{c(n, k)}{r^2}, \quad k \in \mathbb{N},
\]

where \( c(n, k) \) is the \( k \)-th eigenvalue of a ball of radius one in \( \mathbb{R}^n \). It follows that

\[
\lambda_k(\Omega) - \lambda_k(\Omega^\epsilon) = c(n, k)\epsilon \left( \frac{2r + \epsilon}{r^2(\epsilon + r)^2} \right).
\]

In order to have a uniform upper bound on \( \lambda_k(\Omega) - \lambda_k(\Omega^\epsilon) \), it is necessary to consider balls \( B(0, r) \) of radius \( r \) bounded below, say by \( r_0 > 0 \). Consider the family

\[
A = A(n, r_0) = \{ B(p, r) : p \in \mathbb{R}^n, r \geq r_0 \}.
\]

For any ball \( \Omega \in A \), and for any \( \epsilon \leq \epsilon_0 := r_0 \), one easily sees that

\[
\lambda_k(\Omega) - \lambda_k(\Omega^\epsilon) \leq \frac{3c(n, k)}{r_0} \frac{\epsilon}{r_0}.
\]

In the more general context of Section 3.4, this will translate into lower bounds on the inradius.

Example 2. Consider the family \( A = \{ \Omega_t : t \in (0, 1) \} \) described in Figure 1. Some

![Figure 1](image_url)

Figure 1. The domains \( \Omega_t, 0 < t < 1 \).
The inradius of $\Omega_t$ is uniformly bounded.
(2) The boundary $\partial \Omega_t$ is smooth and its curvature is uniformly bounded.

In spite of these two properties, this family is not uniformly locally stable. Indeed, for each $\epsilon_0 > 0$, choosing $t \leq \epsilon_0$ leads to discontinuous variations of $\lambda_k$ as $\epsilon$ varies from 0 to $\epsilon_0$. This follows from the fact that $\Omega_{\epsilon_0}^t$ is completely different from $\Omega_t$ since at $\epsilon = \epsilon_0/2$, the domain $\Omega_{\epsilon_0}^t$ becomes doubly connected.

In Lemma 1.7, this situation was avoided by requiring $(\Omega_{\epsilon_0}^t)^{N_{\epsilon_0}} \subset \Omega$ for all $\epsilon \leq \epsilon_0$, and we will need a condition of this type to be satisfied throughout.

3.2. Convex domains. Local spectral stability is particularly simple for convex domains. Given $r_0 > 0$, consider the family

$$A = A(n, r_0) = \{ \Omega \subset \mathbb{R}^n : \Omega \text{ is convex, inradius}(\Omega) \geq r_0 \}.$$

Proposition 3.1. For any domain $\Omega \in A$,

$$\lambda_k(\Omega) - \lambda_k(\Omega') \leq \frac{c(n, k)}{r_0^2} \left( \frac{2\epsilon}{r_0} + \frac{\epsilon^2}{r_0^2} \right).$$

Lemma 3.2. Let $\Omega$ be a convex domain. Then $(\Omega')_{\epsilon} = \Omega$.

Proof of Lemma 3.2. A point $x \in \mathbb{R}^n$ lies in $(\Omega')_{\epsilon}$ if and only if $B(x, \epsilon) \subset \Omega'$. Suppose that $x \notin \Omega$. Then there exists a hyperplane separating $x$ from $\Omega$. This implies the existence of $y \in B(x, \epsilon)$ such that $d(y, \Omega) \geq \epsilon$, which contradicts $B(x, \epsilon) \subset \Omega'$. □

Lemma 3.3. Let $r_0 > 0$. Let $\Omega \subset \mathbb{R}^n$ be a bounded convex Euclidean domain such that $B(x, r_0) \subset \Omega$. Then

$$\Omega' \subset H(\Omega)$$

where $H$ is an homothety of factor $1 + \epsilon/r_0$ with center $x$.

![Figure 2. Proof of Lemma 3.3](image)

Proof. Fix $y \in \partial \Omega$. There is a unique point $y' \in \partial \Omega'$ such that $y \in xy'$, where $xy'$ denotes the segment connecting $x$ and $y'$. There also exists a unique point $x' \in \partial B(x, r_0)$ such that the segment $x'y$ is tangent to $\partial B(x, r_0)$. Let $z$ be the
orthogonal projection of $y'$ onto the line through $x'$ and $y$. It follows from Thales’ theorem that we can compare the lengths of the segments to get

$$\overrightarrow{zy}' = \frac{\overrightarrow{xy}'}{\overrightarrow{xy}} = \frac{r_0}{\overrightarrow{xy}}.$$ 

Together with Lemma 3.2 this implies

$$\frac{\overrightarrow{zy}'}{\overrightarrow{xy}} = \frac{\overrightarrow{xy}'}{\overrightarrow{xy}} < \frac{\epsilon}{r_0}.$$ 

Noting that $\overrightarrow{zy} = \overrightarrow{xy} - \overrightarrow{xy}'$, we then have

$$\frac{\overrightarrow{xy}'}{\overrightarrow{xy}} < 1 + \frac{\epsilon}{r_0}.$$ 

This gives $y' \in H(\Omega)$, and so completes the proof as $y \in \partial \Omega$ was arbitrary. □

3.3. A result of E. B. Davies. In studying the behaviour of the spectrum of the outer perturbation $\Omega_{\epsilon}$ we rely on a result of Davies [7] related to the stability of the inner perturbation $\Omega_{\epsilon}$. In the sequel, we will consider bounded domains $\Omega \subset M$, where $M$ is a complete Riemannian manifold with Ricci curvature bounded from below by $-1$. We will also denote by $r_0$ the inradius of $\Omega$, i.e. the radius of the largest ball included in $\Omega$.

**Theorem 3.4.** Let $\Omega \subset M$ satisfy a weak Hardy inequality with constants $a,b$ and inradius bounded below by $r_0 > 0$. Then for each $k \in \mathbb{N}$, and each $0 < \alpha < 1/\sqrt{a}$, there exists constants $\varepsilon_k$ and $C_k$ depending only on $\alpha, a, b, r_0, k$, such that

$$0 \leq \lambda_k(\Omega_{\epsilon}) - \lambda_k(\Omega) \leq C_k \varepsilon^{2\alpha},$$

for any $0 < \varepsilon < \varepsilon_k$.

The theorem is proved in [7] for more general operators, with $\Omega \subset \mathbb{R}^n$. In [8, Theorem 13] Davies extends the result to include the sharp exponent. For insight we outline Davies’ proof for the situation we are considering. The proof will make use of the following result proved in [7, Theorem 14]. The fact that $c$ depends only on $a, \alpha$ can be deduced from a careful reading of the proofs in [7] and [8].

**Theorem 3.5.** Let $\Omega$ satisfy a weak Hardy inequality with constants $a,b$ and let $0 < \alpha < 1/\sqrt{a}$. Then there exists a constant $c$ depending only on $a, \alpha$, such that for each $u \in \text{Dom}(\Delta)$,

$$\int_{\Omega} \frac{u^2}{\delta^{2+2\alpha}} \leq c \|(-\Delta + b)u\|_2 \|(-\Delta + b)^{1/2}u\|_2,$$

and

$$\int_{\Omega} \frac{|
abla u|^2}{\delta^{2\alpha}} \leq c \|(-\Delta + b)u\|_2 \|(-\Delta + b)^{1/2}u\|_2,$$

where $\delta$ again denotes the distance function to the boundary of $\Omega$.

**Proof of Theorem 3.5.** For each $k \in \mathbb{N}$, the span of the first $k$ eigenfunctions $\phi_i, i = 1, 2, \cdots, k$ of $\Omega$ is denoted $\Lambda_k$, and we write $\lambda_k = \lambda_k(\Omega)$ for the eigenvalues of $\Omega$. 
Given \( u \in \Lambda_k \) with \( \|u\|_2 = 1 \), let \( 0 < \epsilon < r_0/2 \), and write \( S = \Omega \setminus \Omega_{2\epsilon} \). Define the cut-off function \( \chi : \Omega \to \mathbb{R} \) by

\[
\chi(x) = \begin{cases} 
0 & \text{if } x \in \Omega_e^c, \\
\epsilon^{-1}\text{dist}(x, \partial \Omega_e) & \text{if } x \in \Omega_e \setminus \Omega_{2\epsilon}, \\
1 & \text{if } x \in \Omega_{2\epsilon}.
\end{cases}
\]

Using that \( \delta \leq 2\epsilon \) and \( |\nabla \chi| \leq 1/\epsilon \) on \( S \) leads to

\[
\left| \int_{\Omega} |\nabla (\chi u)|^2 - \int_{\Omega} |\nabla u|^2 \right| \leq \left| 2 \left( \int_{S} |\chi \nabla u|^2 + \int_{S} |u \nabla \chi|^2 \right) - \int_{\Omega} |\nabla u|^2 \right|
\leq 2 \int_{S} |\chi \nabla u|^2 + \int_{S} |\nabla u|^2
\leq \frac{2}{\epsilon^2} (2\epsilon)^{2+2\alpha} \int_{S} \frac{|u|^2}{\delta^{2+2\alpha}} + (2\epsilon)^{2\alpha} \int_{S} \frac{|\nabla u|^2}{\delta^{2\alpha}}.
\]

Theorem 3.5 then gives

\[
\left| \int_{\Omega} |\nabla (\chi u)|^2 - \int_{\Omega} |\nabla u|^2 \right| \leq \varepsilon^{2\alpha} (2^{3+2\alpha} a^2 c) \|(-\Delta + b)u\|_2 \|(-\Delta + b)^{1/2} u\|_2 
\leq \varepsilon^{2\alpha} a^2 c \|\lambda_k + b\|^{3/2} \|u\|_2 = \varepsilon^{2\alpha} a^2 c \|\lambda_k + b\|^{3/2}.
\]

This holds for any \( 0 < \alpha < 1/\sqrt{a} \) with \( c = c(a, \alpha) \). For the last inequality we have used that \( u \in \Lambda_k \) is of the form \( u = \sum_{i=1}^k \alpha_i \phi_i \) giving \( -\Delta u = \sum_{i=1}^k \lambda_i \alpha_i \phi_i \) for some \( \alpha_i \in \mathbb{R} \), and thereby

\[
\|(-\Delta + b)u\|_2 \leq \|\lambda_k + b\| \|u\|_2, \\
\|(-\Delta + b)^{1/2} u\|_2 \leq \|\lambda_k + b\|^{1/2} \|u\|_2.
\]

Next we estimate

\[
\int_{\Omega} u^2 - \int_{\Omega} (\chi u)^2 \leq \int_{S} u^2 \leq \varepsilon^{2+2\alpha} \int_{S} \frac{|u|^2}{\delta^{2+2\alpha}}
\leq \varepsilon^{2+2\alpha} c \|(-\Delta + b)u\|_2 \|(-\Delta + b)^{1/2} u\|_2 \quad \text{by Theorem 3.5}
\leq \varepsilon^{2+2\alpha} c \|\lambda_k + b\|^{3/2}.
\]

Combining these two estimates with the min-max principle finally gives

\[
\lambda_k(\Omega_e) \leq \sup \left\{ \frac{\|\nabla v\|^2}{\|v\|^2} : v \in \text{span} \{\chi \phi_1, \cdots, \chi \phi_k\} \right\}
= \sup \left\{ \frac{\|\nabla (\chi u)\|^2}{\|\chi u\|^2} : u \in \Lambda_k \right\} \leq \frac{\lambda_k + \varepsilon^{2\alpha} a^2 c \|\lambda_k + b\|^{3/2}}{1 - \varepsilon^{2+2\alpha} c \|\lambda_k + b\|^{3/2}}.
\]

If we take

\[
\epsilon \leq \left( \frac{1}{2c(\lambda_k + b)^{3/2}} \right)^{1/(2+2\alpha)} := \varepsilon_k,
\]

we have

\[
\lambda_k(\Omega_e) - \lambda_k \leq \frac{\varepsilon^{2\alpha} a^2 c \|\lambda_k + b\|^{3/2}}{1 - \varepsilon^{2+2\alpha} c \|\lambda_k + b\|^{3/2}} \leq \varepsilon^{2\alpha} a^2 c (\lambda_k + b)^{3/2}.
\]
Using again that the inradius is bounded below by \( r_0 \), it follows from the proof of [4, Corollary 2.3] that there exists a constant \( \tilde{c} \) depending only on \( n \) and \( k \) such that

\[
\lambda_k \leq \frac{(n - 1)^2}{4} + \frac{\tilde{c}}{r_0^2}.
\]

Putting everything together, we have

\[
\lambda_k(\Omega_\varepsilon) - \lambda_k \leq C_k(\alpha, a, b, r_0)\varepsilon^{2\alpha},
\]

for all \( \varepsilon \leq \varepsilon_k = \varepsilon_k(\alpha, a, b, r_0) \). For the extension to the sharp exponent \( \frac{2}{\sqrt{n}} \) please see [8, Theorem 13]. □

3.4. Examples of locally stable families. In this section we construct families \( \mathcal{A} \) of domains such that for each \( k \) and each \( \varepsilon > 0 \) small enough, the difference

\[
|\lambda_k(\Omega_\varepsilon) - \lambda_k(\Omega)|
\]

is controlled in terms of \( \varepsilon \), \( k \) and some geometric hypotheses on \( \Omega \). The bounds are uniform in \( \Omega \in \mathcal{A} \).

The goal is to describe families of domains for which we can use Theorem 3.4 to get such uniform estimates. Because Theorem 3.4 relates \( \lambda_k(\Omega) \) to \( \lambda_k(\Omega_\varepsilon) \) rather than to \( \lambda_k(\Omega_\varepsilon) \), we will need the following conditions to hold for some \( \varepsilon_0 > 0 \) in addition to the lower bound \( r_0 \) on the inradius.

- There exists \( N > 0 \) such that \( (\Omega_\varepsilon)_N \) is contained in \( \Omega \) for each \( \varepsilon \leq \varepsilon_0 \).
- The sets \( \Omega_\varepsilon \) satisfy the weak Hardy inequality with constants \( a, b \) independent of \( \varepsilon \leq \varepsilon_0 \).

This allows control of \( |\lambda_k(\Omega_\varepsilon) - \lambda_k((\Omega_\varepsilon)_N)| \), and so of \( |\lambda_k(\Omega_\varepsilon) - \lambda_k(\Omega)| \) because \( (\Omega_\varepsilon)_N \subset \Omega \). In the remainder of this section, we give an exposition of the situation in Euclidean space \( \mathbb{R}^n \).

The following three definitions will be used.

**Definition 3.6.** An open set \( \Omega \subset \mathbb{R}^n \) satisfies a *uniform external cone condition* [6, p. 129] with parameters \( \alpha > 0, \beta > 0 \) if for any \( x \in \Omega^c \) we can find a cone \( C \) of height \( \beta \) and angle \( \alpha \) with \( x \in C \) and \( C \subset \Omega^c \).

**Definition 3.7.** An open set \( \Omega \subset \mathbb{R}^n \) satisfies a *uniform external ball condition* [6, p. 27] with parameters \( \alpha > 0, \beta > 0 \) if for any \( z \in \partial \Omega \) and \( 0 < r \leq \beta \) there exists \( x \in \Omega^c \) with \( d(z, x) \leq r \) such that \( B(x, \alpha r) \subset \Omega^c \). It satisfies a *uniform external rolling ball condition* with parameter \( \beta > 0 \) if this holds with \( \alpha = 1 \).

**Definition 3.8.** An open set \( \Omega \subset \mathbb{R}^n, n \geq 3 \) satisfies a *uniform capacity density condition* [1, Lemma 3] with parameter \( \alpha > 0 \) if for any \( z \in \partial \Omega \) and any \( r > 0 \)

\[
\text{cap} \left( B(z, r) \setminus \Omega \right) \geq \alpha r^{n-2}.
\]

Here \( \text{cap} \) is the capacity defined by

\[
\text{cap} (\Gamma) = \inf \left\{ \int_{\mathbb{R}^n} \left( |\nabla v|^2 + v^2 \right) : v \in C_0^\infty (\mathbb{R}^n), \ v \geq 1 \text{ on } \Gamma \right\}.
\]

**Remark 3.9.** The uniform capacity density condition is weaker than the uniform external ball condition, which again is implied by the uniform external cone condition and finally by the stronger uniform Lipschitz condition. All of these conditions imply that the set satisfies a weak Hardy inequality.
3.4.1. Uniform external rolling ball condition.

**Proposition 3.10.** Let $\varepsilon_0 > 0, r_0 > 0$. Let $\mathcal{A} = \mathcal{A}(\varepsilon_0, r_0, n)$ be a family of open, bounded sets $\Omega$ in Euclidean space $\mathbb{R}^n$, $n \geq 2$, with inradius bounded below by $r_0$. Then each $\Omega \in \mathcal{A}$ satisfies the uniform external rolling ball condition with parameter $\beta = \varepsilon_0$ if and only if $(\Omega^r)_c \subset \Omega$ for all $\varepsilon \leq \varepsilon_0$. In this case the sets $\Omega^r$, $\varepsilon \leq \varepsilon_0/2$, satisfy the uniform external rolling ball condition with parameter $\beta = \varepsilon_0/2$.

**Proof.** Suppose $(\Omega^r)_c \subset \Omega$ for all $\varepsilon \leq \varepsilon_0$. Let $z \in \partial \Omega$ and $0 < \varepsilon \leq \varepsilon_0$. Then as $(\Omega^r)_c \subset \Omega$, $z$ is not in $(\Omega^r)_c$, and so $d(z, (\Omega^r)_c) = \varepsilon$. This gives $B(z, \varepsilon) \cap (\Omega^r)_c \neq \emptyset$, and so we choose $x$ in this set. Then $x \in (\Omega^r)^c$ implies $d(x, \Omega) \geq \varepsilon$, and so we have $B(x, \varepsilon) \subset \Omega^r$ with $d(z, x) \leq \varepsilon$ as required.

Now suppose $\Omega$ satisfies the uniform external rolling ball condition with parameter $\beta = \varepsilon_0$. Let $z \in \Omega^r$ and $0 < \varepsilon \leq \varepsilon_0$. By the rolling ball condition, there exists $x$ such that $d(z, x) \leq \varepsilon_0$ and $B(x, \varepsilon_0) \subset \Omega^r$. As $\varepsilon \leq \varepsilon_0$, we have $x \in (\Omega^r)^c$ and so $d(z, (\Omega^r)^c) \leq \varepsilon$. Thus $z$ is not in $(\Omega^r)_c$, and we conclude that $(\Omega^r)_c \subset \Omega$.

Now note that if $(\Omega^r)_c \subset \Omega$ for all $\varepsilon \leq \varepsilon_0$, then the sets $\Omega^r$, $\varepsilon \leq \varepsilon_0/2$, satisfy a condition of the form $(\Omega^r)^\delta \subset \Omega^r$ for all $\delta \leq \varepsilon_0/2$. Hence they also satisfy the uniform external rolling ball condition with parameter $\beta = \varepsilon_0/2$. \(\square\)

**Lemma 3.11.** Let $\varepsilon_0 > 0, r_0 > 0$. Let $\mathcal{A} = \mathcal{A}(\varepsilon_0, r_0, n)$ be the family of open, bounded sets $\Omega$ in $\mathbb{R}^n$, $n \geq 2$, with inradius bounded below by $r_0$ satisfying a uniform external rolling ball condition with parameter $\varepsilon_0$. Then there exist constants $\gamma = \gamma(n), \varepsilon_k = \varepsilon_k(n, \varepsilon_0, r_0)$ and $C_k = C_k(n, \varepsilon_k, r_0)$ such that for any $\Omega \in \mathcal{A}$ and any $\varepsilon \leq \min(\varepsilon_0/2, \varepsilon_k)$,

\[
0 < \lambda_k(\Omega) - \lambda_k(\Omega^r) \leq C_k \varepsilon^\gamma.
\]

**Proof.** For $\varepsilon < \varepsilon_0/2$, the sets $\Omega^r$ satisfy the rolling ball condition with parameter $\varepsilon_0/2$ by Proposition 3.10. By the proof of Theorem 1.5.4 in [6], the sets satisfy the weak Hardy inequalities

\[
\int_{\Omega} \frac{u^2}{\varepsilon^2} \leq a \left( \int_{\Omega} |\nabla u|^2 + b n u^2 \right), \forall u \in C^\infty_0(\Omega),
\]

\[
\int_{\Omega^r} \frac{u^2}{\varepsilon^2} \leq a \left( \int_{\Omega^r} |\nabla u|^2 + b n u^2 \right), \forall u \in C^\infty_0(\Omega^r), \forall \varepsilon \leq \varepsilon_0/2,
\]

with constants $b = (2/\varepsilon_0)^2$ and

\[
a = \frac{n}{32} \int_0^{\pi/6} \sin^{n-2}(t) dt / \int_0^{\pi/2} \sin^{n-2}(t) dt.
\]

Here $\delta$ denotes the distance function to the boundary. Then by Theorem 3.10, (3.18) follows with $\gamma \leq \frac{2}{\sqrt{n}}$. \(\square\)

Combining Lemma 3.11 with Proposition 3.10 leads to the following corollary.

**Corollary 3.13.** Let $\varepsilon_0 > 0, r_0 > 0$. Let $\mathcal{A} = \mathcal{A}(\varepsilon_0, r_0, n)$ be the family of open, bounded sets $\Omega$ in $\mathbb{R}^n$, $n \geq 2$, with inradius bounded below by $r_0$ and such that for each $\Omega \in \mathcal{A}$, $(\Omega^r)_c \subset \Omega$ for all $\varepsilon \leq \varepsilon_0$. Then there exist constants $\gamma = \gamma(n), \varepsilon_k = \varepsilon_k(n, \varepsilon_0, r_0)$ and $C_k = C_k(n, \varepsilon_k, r_0)$ such that for any $\Omega \in \mathcal{A}$ and any $\varepsilon \leq \min(\varepsilon_0/2, \varepsilon_k)$,

\[
0 < \lambda_k(\Omega) - \lambda_k(\Omega^r) \leq C_k \varepsilon^\gamma.
\]
3.4.2. Capacity density condition.

**Lemma 3.15.** Let \( N, \varepsilon_0, r_0 > 0 \). Let \( \mathcal{A} = \mathcal{A}(N, \varepsilon_0, r_0, \alpha, n) \) be the family of open, bounded sets \( \Omega \) in \( \mathbb{R}^n \), \( n \geq 3 \), such that \( (\Omega^c)_{N\varepsilon} \subset \Omega \) for all \( \varepsilon \leq \varepsilon_0 \). Suppose also \( \Omega^c \) satisfies a uniform capacity density condition with parameter \( \alpha > 0 \), uniformly in \( \varepsilon \leq \varepsilon_0 \). Then there exist constants \( \gamma = \gamma(\alpha), \varepsilon_k = \varepsilon_k(n, r_0, \alpha) \) and \( C_k = C_k(n, r_0, \alpha) \) such that for any \( \Omega \in \mathcal{A} \) and any \( \varepsilon \leq \min(\varepsilon_0, \varepsilon_k) \),

\[
0 < \lambda_k(\Omega) - \lambda_k(\Omega^c) \leq C_k(\varepsilon_0^\gamma).
\]

This follows by a combination of [7, Theorem 4.2] with Proposition 1 and [11, Lemma 3], which gives a Hardy inequality for sets satisfying a uniform capacity density condition.

3.4.3. Uniform external cone condition.

**Lemma 3.17.** Let \( \varepsilon_0 > 0, r_0 > 0 \). Let \( \mathcal{A} = \mathcal{A}(\varepsilon_0, r_0, \alpha, \beta, n) \) be the family of open, bounded sets \( \Omega \) in \( \mathbb{R}^n \), \( n \geq 2 \), with inradius bounded below by \( r_0 \) and such that for each \( \Omega \in \mathcal{A} \), the sets \( \Omega, \Omega^c, \varepsilon \leq \varepsilon_0 \) satisfy a uniform external cone condition with parameters \( \alpha > 0, \beta > 0 \). Then there exist constants \( \gamma = \gamma(\alpha, \beta), \varepsilon_k = \varepsilon_k(n, \alpha, \beta, r_0) \) and \( C_k = C_k(n, \alpha, \beta, r_0) \) such that for any \( \varepsilon \leq \min(\varepsilon_0, \varepsilon_k) \), and any \( \Omega \in \mathcal{A} \),

\[
0 < \lambda_k(\Omega) - \lambda_k(\Omega^c) \leq C_k\varepsilon^\gamma.
\]

**Proof.** As mentioned [11, Lemma 3] gives a Hardy inequality for sets satisfying a uniform capacity density condition and hence also for sets satisfying the stronger uniform external cone condition. This ensures that a weak Hardy inequality exists uniformly for the sets \( \Omega, \Omega^c, \varepsilon \leq \varepsilon_0 \). We now show \( (\Omega^c)_{N\varepsilon} \subset \Omega \) for some \( N = N(\alpha) \) uniformly in \( \varepsilon \leq \frac{\beta \tan(\alpha/2)}{\tan(\alpha/2)+1} =: \varepsilon^* \) by showing that \( x \in \Omega^c \) implies \( x \in ((\Omega^c)_{N\varepsilon^*})^c \).

Take \( x \in \Omega^c \) and let \( C \subset \Omega^c \) be a cone of height \( \beta \) and angle \( \alpha \) with \( x \in C \). Such a cone contains a ball of radius \( \varepsilon^* \) centered at a point \( y \) for which we then have \( y \in ((\Omega^c)_{N\varepsilon^*})^c \) and \( d(x, y) \leq \frac{\varepsilon^*}{\tan(\alpha/2)} \). Thus \( x \in ((\Omega^c)_{N\varepsilon^*})^c \) for \( N \geq (\tan(\alpha/2))^{-1} \).

3.4.4. The case of \( \mathbb{R}^2 \).

**Lemma 3.19.** Let \( N, \varepsilon_0, r_0 > 0 \). Let \( \mathcal{A} = \mathcal{A}(N, \varepsilon_0, r_0) \) be the family of open, bounded sets \( \Omega \) in \( \mathbb{R}^2 \) such that \( \Omega^c \) is simply connected with inradius bounded below by \( r_0 \), and satisfies \( (\Omega^c)_{N\varepsilon} \subset \Omega \) for all \( \varepsilon \leq \varepsilon_0 \). Then there exist constants \( C_k = C_k(r_0) \) and \( \varepsilon_k = \varepsilon_k(r_0) \) such that for any \( \Omega \in \mathcal{A} \) and any \( \varepsilon \leq \min(\varepsilon_0, \varepsilon_k) \),

\[
0 < \lambda_k(\Omega) - \lambda_k(\Omega^c) \leq C_k\varepsilon^{1/2}.
\]

The inequality follows by Theorem 3.4 using that simply connected planar sets satisfy a Hardy inequality with \( a = 16, b = 0 \) [6, Theorem 1.5.10]. Note that the sharp exponent for Theorem 3.4 in \( \mathbb{R}^2 \) was first given in [12].

4. PROXIMITY OF EIGENSPACES

**Some notation.** Denote by \( \lambda_i = \lambda_i(\Omega) \) the eigenvalues of \( \Omega \), and by \( \lambda'_i = \lambda_i(\Omega') \) the eigenvalues of \( \Omega' \). Most of this paper has been devoted to estimation of the difference \( \lambda_i - \lambda'_i \). We write

\[
\delta_i = \max_{j=1}^i (\lambda_j - \lambda'_j).
\]
We consider an orthonormal basis \((f'_i)_{i=1}^{\infty}\) of eigenfunctions of \(\Omega'\) corresponding to the eigenvalues \(\lambda'_i\). For \(k \geq 1\), let \(E_k\) be the successive distinct eigenspaces for \(\Omega\). Let \(n_k = \dim(E_k)\) be the corresponding multiplicities and set \(N_0 = 0\) and \(N_k = n_1 + ... + n_k\). In particular, this means that for each \(k \in \mathbb{N}\),

\[
\lambda_{N_k-1} + 1 = ... = \lambda_{N_k-1+n_k} = \lambda_{N_k}.
\]

We also introduce the corresponding vector space \(E'_k\) spanned by the eigenfunctions \(f'_{N_k-1+1}, ..., f'_{N_k}\) on \(\Omega'\). The projection operator \(P_k : L^2(\Omega') \to E'_k\) is defined, for \(f = \sum_{j=1}^{\infty} a_j f'_j\), by

\[
P_k(f) = \sum_{j=N_{k-1}+1}^{N_k} a_j f'_j.
\]

The gaps between successive distinct eigenvalues of \(\Omega\) are \(\lambda_{N_k+1} - \lambda_{N_k}\), and we write

\[
\Lambda_k = \min_{j=1}^{k}(\lambda_{N_j+1} - \lambda_{N_j}).
\]

In particular, if \(i \leq k\), we have the relation \(\frac{\lambda_i}{\lambda_1} \leq \frac{\Lambda_k}{\Lambda_i}\) which will be used in the proof, and \(\frac{\Lambda_k}{\Lambda_i} \leq \frac{1}{i}\) implies \(\frac{\Lambda_k}{\Lambda_i} \leq \frac{1}{i}\) for all \(i \leq k\).

We can now express the proximity of eigenspaces.

**Proposition 4.1.** There exists a sequence of constants \((A_k)_{k=1}^{\infty}\) such that if \(\delta_{N_k+1} \leq \frac{\Lambda_k}{2A_k}\), then the following holds:

A. For each \(f \in E_k\), \(\|f\| = 1\), we have

\[
\|(I - P_k)(f)\|^2 = 1 - \|P_k\|^2 \leq \frac{2A_k \delta_{N_k+1}}{\Lambda_k}.
\]

B. For each \(f' \in E'_k\), \(\|f'\| = 1\), there exist \(f \in E_k\), \(\|f\| = 1\) with

\[
\|f - f'\|^2 \leq \frac{4A_k \delta_{N_k+1}}{\Lambda_k}.
\]

C. For each \(f \in E_{k+1}\), \(l > 0\), \(\|f\| = 1\), we have

\[
\|(P_1 + ... + P_k)(f)\|^2 \leq \frac{4(\sum_{i=1}^{k} A_i) \delta_{N_k+1}}{\Lambda_k}.
\]

Moreover, the constants are defined by the induction \(A_k = 2 + 8\lambda_{N_k+1} + \sum_{i=1}^{k-1} A_i\), and so depend on \(k\) and the spectrum of \(\Omega\).

We first show the following technical proposition.

**Proposition 4.2.** Under the condition \(\delta_{N_i+1} \leq \frac{1}{4}\Lambda_i\), we have, for \(f \in E_i\), \(\|f\| = 1\),

\[
\|f - P_i(f)\|^2 = 1 - \|P_i(f)\|^2 \leq \frac{2}{\Lambda_i} (\delta_{N_i+1} + \lambda_{N_{i+1}} \|P_i(f) + ... + P_{i-1}(f)\|^2).
\]

**Proof.** We consider \(f \in E_i\) and, applying \(q\), we get the relations

\[
\lambda_{N_{i-1}+1} - q(P_i(f)) = \sum_{j \neq i} q(P_j(f)) \geq \sum_{j \leq i} q(P_j(f)) + \lambda_{N_{i+1}}(1 - \sum_{j \leq i} \|P_j(f)\|^2),
\]

and

\[
\lambda_{N_{i-1}+1} - q(P_i(f)) = \lambda_{N_{i-1}+1} - \lambda'_{N_{i-1}+1} + (1 - \|P_i(f)\|^2)\lambda'_{N_{i-1}+1} - (q(P_i(f)) - \lambda'_{N_{i-1}+1}\|P_i(f)\|^2).
\]

Thus,
Putting this together, we get
\[\lambda_{N,-1+1} - \lambda'_{N,-1+1} + (1 - \|P_i(f)\|^2)\lambda'_{N,-1+1}\]
\[\geq \sum_{j<i} q(P_j(f)) + \lambda'_{N,+1}(1 - \sum_{j<i} \|P_j(f)\|^2) + q(P_i(f)) - \lambda'_{N,-1+1}\|P_i(f)\|^2.\]
Noticing that \(q(P_i(f)) - \lambda'_{N,-1+1}\|P_i(f)\|^2 \geq 0\), we get
\[\lambda_{N,-1+1} - \lambda'_{N,-1+1} + \lambda'_{N,+1} \sum_{j<i} \|P_j(f)\|^2 \geq (1 - \|P_i(f)\|^2)(\lambda'_{N,+1} - \lambda'_{N,-1+1}),\]
i.e.
\[(1 - \|P_i(f)\|^2) \leq \frac{(\lambda_{N,-1+1} - \lambda'_{N,-1+1}) + \lambda'_{N,+1} \sum_{j<i} \|P_j(f)\|^2}{\lambda'_{N,+1} - \lambda'_{N,-1+1}}.\]
Moreover,
\[\lambda'_{N,+1} - \lambda'_{N,-1+1} = (\lambda'_{N,+1} - \lambda_{N,+1}) + (\lambda_{N,+1} - \lambda_{N,-1+1}) \geq \Lambda_i - (\lambda_{N,+1} - \lambda'_{N,+1}).\]
So under the condition \((\lambda_{N,+1} - \lambda'_{N,+1}) \leq \frac{1}{2}\Lambda_i\), we get
\[(1 - \|P_i(f)\|^2) \leq \frac{2(\lambda_{N,-1+1} - \lambda'_{N,-1+1}) + \lambda'_{N,+1} \sum_{j<i} \|P_j(f)\|^2}{\Lambda_i}.\]
□

Before proving Proposition 4.1, we recall a fact of linear algebra which is needed for the proof.

**Lemma 4.3.** Let \((V, (.,.))\) be a prehilbert vector space, \(P\) a projector and \(v\) a vector of norm 1 such that \(P(v) \neq 0\). Then we have
\[\|v - \frac{P(v)}{\|P(v)\|}\|^2 \leq 4(1 - \|P(v)\|^2).\]

**Proof.** We have
\[\|v - \frac{P(v)}{\|P(v)\|}\| \leq \|v - P(v)\| + \|P(v) - \frac{P(v)}{\|P(v)\|}\| \leq 2\|v - P(v)\|\]
and
\[\|v - P(v)\|^2 = \langle v, v - P(v) \rangle = \langle v, v \rangle - \langle v, P(v) \rangle = 1 - \|P(v)\|^2.\]
□

**Proof of Proposition 4.1.** The proof is by induction on \(k\):
1. We show that \(A\) is true for \(k = 1\).
2. We show that if \(A\) is true for \(k\), then \(B\) is true for \(k\).
3. We show that if \(A\) and \(B\) are true for \(1, ..., k\), then \(C\) is true for \(k\).
4. We show that if \(A, B, C\) are true for \(1, ..., k - 1\), then \(A\) is true for \(k\).
So because A is true for \( k = 1 \), it follows that B and C are true for \( k = 1 \), and this implies that A is true for \( k = 2 \). Then the induction continues in the obvious way.

(1) Proof of A for \( k = 1 \): this follows directly from Proposition 4.2 with \( A_1 = 2 \).

(2) Proof of A true for \( k \) implies B for \( k \): let \( f' \in E_k', \| f'\| = 1 \). If \( \delta_{N_k,1+1} \leq \frac{A_k}{2A_k} \), the restriction of \( P_k \) to \( E_k \) is bijective and there exist \( f \in E_k, \| f\| = 1 \) with \( f' = \frac{P_k(f)}{\|P_k(f)\|} \).

It follows from Lemma 4.3 that \( \| f' - f \|^2 \leq 4\| (I-P_k)(f)\|^2 \leq 4\frac{A_k \delta_{N_k-1,1+1}}{A_k} \).

(3) Proof of A and B true for \( 1, \ldots, k \) implies C for \( k \).

Let \( f \in E_{k+1}, l \geq 1 \) and \( \| f \| = 1 \). Let \( i \leq k \). For any \( h' \in E'_i, \| h'\| = 1 \), because \( P_i \) is surjective under the hypothesis \( \delta_{N_i,1+1} \leq \frac{A_i}{2A_k} \), there exist \( h \in E_i, \| h\| = 1 \) with \( h' = \frac{P_i(h)}{\|P_i(h)\|} \). We have

\[
\langle P_i(f), h' \rangle = \langle f, h' \rangle = \langle f, h' - h \rangle + \langle f, h \rangle.
\]

As in the case \( k = 1 \), we have \( \langle f, h \rangle = 0 \), so

\[
\langle P_i(f), h' \rangle = \langle f, h' - h \rangle \leq \| f \| \| h' - h \| = \| h - \frac{P_i(h)}{\|P_i(h)\|} \|.
\]

By Lemma 4.3 we get \( \| \langle P_i(f), h' \rangle \|^2 \leq 4(1 - \| P_i(h)\|^2) \leq 4A_i \frac{\delta_{N_i,1+1}}{A_i} \) by A. Using \( \frac{\delta_{N_i,1+1}}{A_i} \leq \frac{\delta_{N_k-1,1+1}}{A_k} \), and because this is true for each \( h' \in E'_i, \| h'\| = 1 \), we have

\[
\| P_i(f)\|^2 \leq 4A_i \frac{\delta_{N_k-1,1+1}}{A_k},
\]

and we deduce that

\[
\sum_{i=1}^{k} \| P_i(f)\|^2 \leq 4(\sum_{i=1}^{k} A_i) \frac{\delta_{N_k-1,1+1}}{A_k}.
\]

(4) Proof of A, B, C true for \( 1, \ldots, k - 1 \) implies A for \( k \).

Note that, because we have \( A_i \geq 2 \), the hypothesis \( \delta_{N_k,1+1} \leq \frac{A_k}{2A_k} \) implies \( \delta_{N_k,1+1} \leq \frac{A_k}{2} \). By Proposition 4.2, we have for \( f \in E_k, \| f\| = 1 \), and under the condition \( \delta_{N_k,1+1} \leq \frac{A_k}{2} \),

\[
\| (I-P_k)(f)\| \leq \frac{2}{A_k} (\delta_{N_k-1,1+1} + \lambda_{N_k,1+1}\| P_1(f) + \ldots + P_{k-1}(f)\|^2).
\]

By induction, \( \| P_1(f) + \ldots + P_{k-1}(f)\|^2 \leq 4(\sum_{i=1}^{k-1} A_i) \frac{\delta_{N_k-2,1+1}}{A_{k-1}} \), which is by definition

\[
\leq 4\left( \sum_{i=1}^{k-1} A_i \right) \frac{\delta_{N_k-1,1+1}}{A_k}.
\]

So we choose \( A_k = 2 + 8\frac{\lambda_{N_k-1,1+1}}{A_k} \).
\[ \square \]
5. Proof of Lemma 2.1

The proof of Lemma 2.1 is very close to the proof of [2, Lemma 3.13]. Under the hypothesis
\[ |\langle \psi_i, \psi_j \rangle - \delta_{i,j}| \leq \rho; \quad q(\psi_i) \leq \lambda_i(1 + \rho), \]
for \(1 \leq i, j \leq k\), we prove that
\[ q(F_i) \leq \lambda_i(1 + \rho b_k). \]

Here the constants \(b_k\) are defined by \(b_k = (1 + 8a_k)(1 + (1 + \rho b_{k-1})(1 + 8a_k))\) (where the \(a_k\) are defined in the statement of the lemma) with \(b_1 = 4\), and \(\{F_i\}_{i=1}^{k}\) is the orthonormal basis naturally associated to the basis \(\{\psi_i\}_{i=1}^{k}\). We have
\[ F_i = \frac{h_i}{\|h_i\|} \quad \text{where} \quad h_i = \psi_i - \sum_{j=1}^{i-1} \langle F_j, \psi_i \rangle F_j. \]

In particular, \(b_k\) depends only on \(k\) (and not on \(\lambda_k\)), but in a rather complicated form. We also denote by \(p(\psi_i)\) the projection of \(\psi_i\) given by \(p(\psi_i) = \sum_{j=1}^{s-1} \langle F_j, \psi_i \rangle F_j\), so that we have the relation \(\psi_i = h_i + p(\psi_i)\).

**Proof. First part:** The beginning of the proof is verbatim the same as the proof of [2, Lemma 3.13].

We suppose the result is true for \(s < k\) and show it for \(s = k\). As a first step, note that
\[ q(F_1) = \frac{q(\psi_1)}{\|\psi_1\|^2} \leq \lambda_1 \frac{1 + \rho}{1 - \rho} = \lambda_1 (1 + \rho \frac{2}{1 - \rho}), \]
so using \(\rho < \frac{1}{2}\) we can take \(b_1 = 4\). We also use without repeating the proof the following fact proved in the first part of [2, Lemma 3.13]. For \(i = 1, ..., k - 1\) and \(s > i\), we have
\[ |\langle \psi_s, F_i \rangle| \leq \sqrt{2}a_i \rho. \]

We have for \(s < k\)
\[ q(p(\psi_s)) = \sum_{j=1}^{s-1} \sum_{l=1}^{s-1} \langle \psi_s, F_j \rangle \langle \psi_s, F_l \rangle q(F_j, F_l). \]

By the recurrence hypothesis we have
\[ q(F_j, F_l) \leq q^{1/2}(F_j)q^{1/2}(F_l) \leq (\lambda_j(1 + \rho b_j))^{1/2} \lambda_l(1 + \rho b_l))^{1/2} \leq \lambda_{s-1}(1 + \rho b_{s-1}), \]
and, using the definition of the \(a_j\) along with the Cauchy-Schwarz inequality,
\[ q(p(\psi_s)) \leq \lambda_{s-1}(1 + \rho b_{s-1}) 2\rho^2 \sum_{j,l=1}^{s-1} a_j a_l \leq 2\rho^2 a_s \lambda_{s-1}(1 + \rho b_{s-1}). \]

We will also use the fact that \(\|h_s\|^2 \geq 1 - \rho a_s\). This implies (and this is the main change)
\[ \frac{1}{\|h_s\|^2} \leq 1 + 2\rho a_s. \]

**Second part:** The following includes some new developments in comparison with [2, Lemma 3.13].
We use that for $2 \leq s \leq k$

$$q(F_s) \leq \frac{1}{\|h_s\|^2}(q(\psi_s) + q(\rho(\psi_s)) + 2 \sqrt{q(\psi_s)q(\rho(\psi_s))}$$

and get the following estimate for $q(F_k)$:

$$q(F_k) \leq (1 + 2\rho a_k)[\lambda_k(1 + \rho) + \lambda_{k-1}2\rho^2 a_k(1 + \rho b_{k-1}) + 2\lambda_k^{1/2}\lambda_{k-1}^{1/2}(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho].$$

Because $\lambda_{k-1} \leq \lambda_k$, we get

$$q(F_k) \leq \lambda_k(1 + 2\rho a_k)[(1 + \rho) + 2\rho^2 a_k(1 + \rho b_{k-1}) + 2(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho].$$

But

$$(1 + 2\rho a_k)[(1 + \rho) + 2\rho^2 a_k(1 + \rho b_{k-1}) + 2(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho] =$$

$$1 + \rho2a_k[(1 + \rho) + 2\rho^2 a_k(1 + \rho b_{k-1}) + 2(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho] +$$

$$+ \rho[(1 + 2\rho a_k(1 + \rho b_{k-1}) + 2(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho]$$

So to obtain the conclusion, we have to show that

$$b_k \geq 2a_k[(1 + \rho) + 2\rho^2 a_k(1 + \rho b_{k-1}) + 2(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho] +$$

$$+ [(1 + 2\rho a_k(1 + \rho b_{k-1}) + 2(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho].$$

We simplify this expression using inequalities implied by the definition of $\rho$ and $a_k$ such as $\rho < 1/2$, $2\rho^2 a_k < 1$, $2\rho a_k \leq 1$ along with $\sqrt{x} \leq x$ if $x \geq 1$. This gives

$$[(1 + \rho) + 2\rho^2 a_k(1 + \rho b_{k-1}) + 2(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho] \leq$$

$$\leq [(1 + \rho) + 2\rho^2 a_k(1 + \rho b_{k-1}) + 2(1 + \rho)(2a_k(1 + \rho b_{k-1}))\rho] \leq$$

$$\leq [(1 + \rho) + (1 + \rho b_{k-1})(2\rho^2 a_k + 4(1 + \rho)a_k)] \leq 2 + (1 + \rho b_{k-1})(1 + 8a_k).$$

$$[(1 + 2\rho a_k(1 + \rho b_{k-1}) + 2(1 + \rho)^{1/2}(2a_k(1 + \rho b_{k-1}))^{1/2}\rho] \leq$$

$$\leq [(1 + 2\rho a_k(1 + \rho b_{k-1}) + 2(1 + \rho)(2a_k(1 + \rho b_{k-1}))] =$$

$$= 1 + (1 + \rho b_{k-1})[2\rho a_k + 4(1 + \rho)a_k] \leq 1 + (1 + 8a_k)(1 + \rho b_{k-1}).$$

We can then finish with

$$2a_k[2 + (1 + \rho b_{k-1})(1 + 8a_k)] + [1 + (1 + 8a_k)(1 + \rho b_{k-1})] = (1 + \rho b_{k-1})(1 + 8a_k)(1 + 2a_k) + 1 + 4a_k \leq$$

$$\leq (1 + \rho b_{k-1})(1 + 8a_k)(1 + 8a_k) + 1 + 8a_k = (1 + 8a_k)(1 + (1 + \rho b_{k-1})(1 + 8a_k)) = b_k.$$
