ARITHMETIC ANALOGUES OF SOME BASIC CONCEPTS
FROM RIEMANNIAN GEOMETRY

ALEXANDRU BUIUM

Abstract. Following recent work of the author, partly in collaboration with
T. Dupuy and M. Barrett, we describe arithmetic analogues of some key con-
cepts from Riemannian geometry such as: metrics, Chern connections, curva-
ture, etc. Theorems are stated to the effect that the spectrum of the integers
has a non-vanishing curvature.

1. Introduction

In previous work (initiated in [4] and partly summarized in [5, 6]) the author
has developed an arithmetic analogue of differential calculus and, in particular, of
differential equations. As explained in [3,13], this theory can be viewed as an alter-
native approach to “absolute geometry” (or the “geometry over the field with one
element, \( F_1 \)”) and led to a series of diophantine applications [6]. Once an arithmetic
analogue of differential calculus is available one can ask for arithmetic analogues
of the basic concepts of differential geometry and, in particular, of Riemannian
geometry. Such analogues were recently proposed in [8, 9, 10, 11, 2] and led to the
somewhat surprising conclusion that the spectrum of the integers, \( \text{Spec} \, \mathbb{Z} \), can be
viewed as an (infinite dimensional) manifold which is naturally “curved” (although,
as we shall see, only “mildly” curved). The aim of this note is to present, in a self
contained manner, some of the ideas and results of this “arithmetic Riemannian”
theory. For the details of the theory we refer to the papers cited above.

Acknowledgement. The author would like to acknowledge partial support from
the Simons Foundation (award 311773) and from the Romanian National Authority
for Scientific Research (CNCS - UEFISCDI, project number PN-II-ID-PCE-2012-
4-0201).

2. Main concepts and results

The best way to present our material is by analogy with classical differential ge-
ometry. In classical differential geometry one starts with an \( m \)-dimensional smooth
manifold \( M \) and its ring of smooth functions \( C^\infty(M) \). For our purposes it is enough
to think of \( M \) as being the Euclidean space \( M = \mathbb{R}^m \). Also we would like to think
of the dimension \( m \) as going to infinity, \( m \to \infty \). In this paper the arithmetic
analogue of \( \mathbb{R}^m \), with \( m \to \infty \), will be the scheme \( \text{Spec} \, \mathbb{Z} \); hence the arithmetic
analogue of the ring

\[
A := C^\infty(\mathbb{R}^m)
\]

will be the ring of integers \( \mathbb{Z} \) or, more generally, the ring

\[
A := \mathbb{Z}[1/N_0, \zeta_N]
\]
where \( N_0 \) is an even integer, \( N \) is an integer, and \( \zeta_N \) is a primitive \( N \)-th root of unity. Let

\[
(2.3) \quad x_1, x_2, \ldots, x_m
\]

be the coordinates on \( \mathbb{R}^m \); then the arithmetic analogues of these coordinates will be a sequence of primes

\[
(2.4) \quad \mathcal{P} = \{ p_1, p_2, p_3, \ldots \}.
\]

One can take all primes or, better, all primes not dividing \( N_0N \). Next one considers the partial derivative operators

\[
(2.5) \quad \frac{\partial}{\partial x_i} : C^\infty(\mathbb{R}^\infty) \to C^\infty(\mathbb{R}^\infty), \quad i \in \{ 1, \ldots, m \}.
\]

Following [4] we propose to take, as an analogue of (2.5), the operators

\[
(2.6) \quad \delta_p : A \to A, \quad \delta_p(a) = \frac{\phi_p(a) - a^p}{p}, \quad p \in \mathcal{P},
\]

where \( \phi_p : A \to A \) is the unique ring automorphism of \( A \) sending \( \zeta_N \) into \( \zeta_N^p \). More generally the concept of derivation on a ring \( B \) (by which we mean an additive map \( B \to B \) that satisfies the Leibniz rule) has, as an arithmetic analogue, the concept of p-derivation on a ring \( B \) (by which we mean a set theoretic map \( \delta_p : B \to B \) with the property that the map \( \phi_p : B \to B \) defined by \( \phi_p(b) = b^p + p\delta_p b \) is a ring homomorphism; we will always denote by \( \phi_p \) the ring homomorphism attached to a p-derivation \( \delta_p \) and we shall refer to \( \phi_p \) as the Frobenius lift attached to \( \delta_p \)).

The next step in the classical theory is to consider a vector bundle \( \pi : E \to M \) of rank \( n \) over the manifold \( M \) and to consider the frame bundle \( F(E) \) of \( E \); a point of \( F(E) \) is a point \( P \) of \( M \) together with a basis of \( \pi^{-1}(P) \). The frame bundle \( F(E) \) is a principal homogeneous space for the group \( GL_n \); and if \( E \) is a trivial vector bundle (which we shall assume from now on) then \( F(E) \) is identified with \( M \times GL_n \). (Note that the rank \( n \) of \( E \) and the dimension \( m \) of \( M \) in this picture are unrelated.) We want to review the classical concept of connection in \( F(E) \); we shall do it in a somewhat non-standard way so that the transition to arithmetic becomes more transparent. Indeed consider an \( n \times n \) matrix \( x = (x_{ij}) \) of indeterminates and consider the ring of polynomials over \( A \), with the determinant inverted,

\[
(2.7) \quad B = A[x, \det(x)^{-1}].
\]

Note that \( B \) is naturally a subring of the ring \( C^\infty(M \times GL_n) \). Then by a connection on \( F(E) = M \times GL_n \) we will understand a tuple \( \delta = (\delta_i) \) of derivations

\[
(2.8) \quad \delta_i : B \to B, \quad i \in \{ 1, \ldots, m \},
\]

lifting the derivations (2.5). We say the connection is linear if \( \delta_i x = A_i x \) for some \( n \times n \) matrix \( A_i \) with coefficients in \( A \); linearity corresponds to the concept of invariance of classical connections under the right action of \( GL_n \) on the frame bundle \( F(E) \). For a linear connection \( \delta \) as above one can define the curvature as the matrix \( (\varphi_{ij}) \) of commutators

\[
(2.9) \quad \varphi_{ij} := [\delta_i, \delta_j] : B \to B, \quad i, j \in \{ 1, \ldots, m \}.
\]

One has then \( \varphi_{ij}(x) = F_{ij} x \) where \( F_{ij} \) is the matrix given by the classical formula

\[
(2.10) \quad F_{ij} := \delta_i A_j - \delta_j A_i - [A_i, A_j].
\]
We would like to introduce now an arithmetic analogue of connection and curvature. The first step is clear: we consider a ring $B$ defined as in 2.7 but where $A$ is given now by 2.2 rather than by 2.1. A first attempt to define arithmetic connections would be to consider families of $p$-derivations $\delta_p : B \to B$, $p \in \mathcal{P}$, lifting the $p$-derivations 2.6; one would then proceed by considering their commutators on $B$ (or, if necessary, expressions derived from these commutators). But the point is that the examples of “arithmetic connections” we will encounter in practice (when we develop arithmetic analogues of the Chern connections of classical differential geometry) will never lead to $p$-derivations $B \to B$! What we shall be led to is, rather, a concept we next introduce. For each $p \in \mathcal{P}$ we consider the $p$-adic completion of $B$:

\[ B^\hat{p} := \lim_{\leftarrow} B/p^n B. \]

Then we define an arithmetic connection on $GL_n$ to be a family $(\delta_p)$ of $p$-derivations

\[ \delta_p : B^\hat{p} \to B^\hat{p}, \quad p \in \mathcal{P}, \]

lifting the $p$-derivations in 2.6. We do not impose any condition analogous to linearity; instead, what happens is that our arithmetic connections of interest turn out to enjoy a certain invariance property with respect to right translations by the elements of the normalizer of the maximal (diagonal) torus of $GL_n$. This invariance can be viewed as a substitute for linearity and will not be discussed here further. Leaving the linearity issue aside we are facing, at this point, a more severe dilemma: our $p$-derivations $\delta_p$ in 2.12 do not act on the same ring, so there is no a priori way of considering their commutators and, hence, it does not seem possible to define, in this way, the notion of curvature. It will turn out, however, that our arithmetic connections of interest will satisfy an interesting property which we call “being global along the identity,” and which will allow us to define curvature via commutators. Here is the definition of this property. Consider the matrix $T = x - 1$, where $1$ is the identity matrix. We say that an arithmetic connection $(\delta_p)$ on $GL_n$, with attached family of Frobenius lifts $(\phi_p)$, is global along 1 if, for all $p$, $\phi_p$ sends the ideal of 1 into itself and, moreover, the induced homomorphism $\phi_p : A[[T]] \to A[[T]]$ sends the ring $A[[T]]$ into itself. If the above holds then one can consider the commutator $[\phi_p, \phi_{p'}] : A[[T]] \to A[[T]]$ for all $p, p' \in \mathcal{P}$; this commutator is divisible by $pp'$ and one can define the curvature of $(\delta_p)$ as the matrix $(\varphi_{pp'})$ with entries

\[ \varphi_{pp'} := \frac{1}{pp'}[\phi_p, \phi_{p'}] : A[[T]] \to A[[T]], \quad p, p' \in \mathcal{P}. \]

The idea of comparing $p$-adic phenomena for different $p$’s by “moving along the identity section” is borrowed from [7] where it was referred to as “analytic continuation along primes.” Of course, in order for the above definitions to be interesting, we will need to:

1) find natural “metric” arithmetic connections on $GL_n$,
2) show that these connections are global along 1, and
3) compute and interpret the curvatures of these connections.

We embark now on explaining how this program can be achieved. First we go back to classical differential geometry and we “recall” the definition of the Chern connection [12]. We shall present this definition in the “real setting” only, where the Chern connections should be more appropriately referred to as Duistermaat connections [11]; for the “complex setting” we refer to [9 1]. So let us consider...
the ring \( A = C^\infty(\mathbb{R}^m) \) and let \( q \) be an \( n \times n \) invertible matrix with coefficients in \( A \) which is either symmetric \((q^t = q)\) or antisymmetric \((q^t = -q)\), where the \( t \) superscript means transposition. Of course, a symmetric \( q \) as above is viewed as a “metric” while an antisymmetric \( q \) is viewed as a “2-form.” Set \( G = GL_n \) and consider the maps of schemes over \( A \), \( \mathcal{H}_q : G \to G \), \( \mathcal{B}_q : G \times G \to G \) defined by \( \mathcal{H}_q(x) = x'q x \) and \( \mathcal{B}_q(x, y) = x'yqy \). We continue to denote by the same letters the corresponding maps of rings \( B \to B \) and \( B \to B \otimes_A B \). Consider the trivial (linear) connection \( \delta_0 = (\delta_{0i}) \) on \( G \) defined by \( \delta_{0i}x = 0 \). Then one can easily check (see below) that there is a unique linear connection \((\delta_i)\) on \( G \) such that the following diagrams are commutative:

\[
\begin{array}{ccc}
B & \xrightarrow{\delta} & B \\
\mathcal{H}_q \uparrow & & \uparrow \mathcal{H}_q \\
B & \xleftarrow{\delta_{0i}} & B \\
& \mathcal{B}_q \uparrow 1 + 1 \otimes \delta_i \uparrow & B \\
& B \otimes_A B & \xleftarrow{\mathcal{B}_q} B
\end{array}
\]

This \( \delta \) can be referred to as the Chern connection attached to \( q \). The definition just given may look non-standard. It turns out that the Chern connection we just defined is a real analogue \([11]\) of the usual Chern connection in differential geometry \([12]\) (in which \( \delta_0 \) is an analogue of a complex structure). To see this set \( \Gamma_i = -A_i^t \), let \( \Gamma_{ij}^k \) be the \((j, k)\)-entry of \( \Gamma_i \) (the Cristoffel symbols), and set \( \Gamma_{ijk} := \Gamma_{ij}^l q_lk \) (Einstein notation). Assume we are in the symmetric case, \( q^t = q \). Then the commutativity of the left diagram in (2.14) is equivalent to the condition

\[
\delta_i q_{jk} = \Gamma_{ijk} + \Gamma_{ikj},
\]

and the commutativity of the right diagram in (2.14) is equivalent to the condition

\[
\Gamma_{ijk} = \Gamma_{ikj};
\]

so the Chern connection attached to \( q \) is given by

\[
\Gamma_{ijk} = \frac{1}{2} \delta_i q_{jk}.
\]

The Chern connection will have an arithmetic analogue to be explained presently. The condition (2.15) expresses the fact that \( q \) is parallel with respect to the connection \( \delta \). It is important to note, however, that, in our setting, the torsion is not defined and, in particular, the symmetry in (2.16) has nothing to do with the vanishing of the torsion. On the other hand, if one takes \( E \) to be the tangent bundle of \( M \) (so in particular \( n = m \)), then the condition that the torsion of \( \delta \) vanishes is given by:

\[
\Gamma_{ijk} = \Gamma_{jik}
\]

which is a symmetry condition rather different from (2.16). By the way there is a unique connection \( \delta \) such that conditions (2.15) and (2.18) are satisfied; this connection is referred to as the Levi-Civita connection and is given by the formula

\[
\Gamma_{ijk} = \frac{1}{2} \left( \delta_k q_{ij} + \delta_i q_{jk} - \delta_j q_{ki} \right).
\]

The Levi-Civita connection does not seem to have an arithmetic analogue in our theory.

Now we move to the arithmetic situation. So let \( A = \mathbb{Z}[1/N_0, \zeta_N] \). Let \( q \in GL_n(A) \) with \( q^t = \pm q \). Set \( G = GL_n = \text{Spec} \, B \), viewed as a group scheme over \( A \). Attached to \( q \) we have, again, maps \( \mathcal{H}_q : G \to G \) and \( \mathcal{B}_q : G \times G \to G \) defined by \( \mathcal{H}_q(x) = x'q x \) and \( \mathcal{B}_q(x, y) = x'yqy \). We continue to denote by \( \mathcal{H}_q, \mathcal{B}_q \)
the maps induced on the $p$-adic completions $G\hat{p}$ and $G\hat{p} \times G\hat{p}$. Consider the unique arithmetic connection $\delta_0 = (\delta_{0,p})$ on $G$ with $\delta_{0,p} x = 0$ and denote by $(\phi_p)$ and $(\phi_{0,p})$ the families of lifts of Frobenius attached to $\delta$ and $\delta_0$ respectively. Then one has the following:

**Theorem 2.1.** [9] For any $q \in GL_n(A)$ with $q^4 = \pm q$ there exists a unique arithmetic connection $\delta$ such that the following diagrams are commutative:

$$
\begin{align*}
G\hat{p} & \xrightarrow{\phi_p} G\hat{p} \\
H_q \downarrow & \quad \quad \quad \downarrow H_q \\
G\hat{p} & \xrightarrow{\phi_{0,p} \times \phi_p} G\hat{p} \times G\hat{p}
\end{align*}
$$

Then it turns out that $\phi_p : G\hat{p} \to G\hat{p}$ is defined by $\phi_p : \mathbb{Z}_p[x,x^{-1}] \to \mathbb{Z}_p[x,x^{-1}]\hat{p}$,

$$(2.20) \quad \phi_p(x) = q^{(p-1)/2} \left( \frac{q}{p} \right) x^p,$$

where $\left( \frac{q}{p} \right)$ is the Legendre symbol of $q \in A^\times \subset \mathbb{Z}(p)$.

Next one can ask which of these arithmetic connections admit curvatures. One has:

**Theorem 2.2.** [1] If all the entries of $q$ are roots of unity or $0$ then the Chern connection $\delta$ attached to $q$ is global along $1$. In particular $\delta$ has a well defined curvature.

Next we address the question of computing the curvature of Chern connections. Let us say that a matrix $q \in GL_n(A)$ is split if it is one of the following:

$$(2.21) \quad \begin{pmatrix} 0 & 1_r \\ -1_r & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1_r \\ 1_r & 0 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1_r & 0 \\ 0 & 0 & 1_r \end{pmatrix},$$

where $1_r$ is the $r \times r$ identity matrix and $n = 2r, 2r, 2r + 1$ respectively. These are matrices that define the classical split groups $Sp_{2r}, SO_{2r}, SO_{2r+1}$, respectively. One has the following:

**Theorem 2.3.** [1] Let $q$ be split and let $(\varphi_{pp'})$ be the curvature of the Chern connection on $G$ attached to $q$.

1) Assume $n \geq 4$. Then for all $p \neq p'$ we have $\varphi_{pp'} \neq 0$.
2) Assume $n$ even. Then for all $p, p'$ we have $\varphi_{pp'}(T) \equiv 0 \mod (T)^3$.
3) Assume $n = 2$ and $q^4 = -q$. Then for all $p, p'$ we have $\varphi_{pp'} = 0$.
4) Assume $n = 1$. Then for all $p, p'$ we have $\varphi_{pp'} = 0$.

In assertion 2) we denoted by $(T)^3$ the cube of the ideal in $A[[T]]$ generated by the entries of the matrix $T$. Assertion 1) morally says that $\text{Spec } \mathbb{Z}$ is “curved,” while assertion 2) morally says that $\text{Spec } \mathbb{Z}$ is only “mildly curved.” Note that the theorem says nothing about the vanishing of the curvature $\varphi_{pp'}$ in case $n = 2, 3$ and $q^4 = q$; our method of proof does not seem to apply to these cases.
The theory explained above has a “complex analogue” (or, rather, a (1,1)-analogue) for which we refer to \cite{[1]}. This theory (that largely follows \cite{[1]}) was based on what we called “analytic continuation between primes”; this was the key to making Frobenius lifts corresponding to different primes act on a same ring. There is a different approach towards making Frobenius lifts comparable; this approach was developed in \cite{[2]}. The idea in \cite{[2]} was to show that if \( \delta = (\delta_p) \) is the Chern connection attached to a matrix \( q \in GL_n(A) \) with \( q^t = \pm q \), then one can find correspondences \( \Gamma_p = (Y_p, \pi_p, \varphi_p) \) on \( G = GL_n \), i.e. maps of \( A \)-schemes

\[
(2.22) \quad \pi_p : Y_p \to G, \quad \varphi_p : Y_p \to G,
\]

such that:

i) \( \pi_p \) are affine and étale,

ii) \( \pi^\ast_p : Y_p^\ast \to G^\ast \) are isomorphisms, and

iii) \( \varphi^\ast_p = \phi_p \circ \pi^\ast_p : Y_p^\ast \to G^\ast \).

In other words the correspondences \( \Gamma_p \) are “algebraizations” of our Frobenius lifts \( \phi_p \); the system \( \Gamma_p \) is referred to as a correspondence structure \( \delta_p \); it is not unique but does have some “uniqueness features” (cf. \cite{[2]}). On the other hand any correspondence \( \Gamma_p \) as in \( \delta \) acts on the field \( E \) of rational functions of \( G \) by the formula \( \Gamma_p^\ast : E \to E \),

\[
(2.23) \quad \Gamma_p^\ast(z) = \text{Tr}_{\pi_p}(\varphi_p^\ast(z)), \quad z \in E,
\]

where \( \text{Tr}_{\pi_p} : F_p \to E \) is the trace of the extension \( \pi^\ast_p : E \to F_p := Y_p \otimes_G E \) and \( \varphi_p^\ast : E \to F_p \) is induced by \( \varphi_p \). By the way the degrees of the extensions \( \pi^\ast_p : E \to F_p \) and \( \varphi_p^\ast : E \to F_p \) will be referred to as the left degree and the right degree of \( \Gamma_p \) respectively. Also we say \( \Gamma_p \) is irreducible if \( F_p \) is a field. So one can define the \( \ast \)-curvature of the arithmetic connection \( (\delta_p) \) as the matrix \( \varphi_p^\ast \)

\[
(2.24) \quad \varphi^\ast_{pp'} := \frac{1}{pp'}[\Gamma^\ast_p, \Gamma^\ast_p] : E \to E, \quad p, p' \in \mathcal{P}.
\]

Note that, in this way, we have defined a concept of “curvature” for Chern connections attached to arbitrary \( q \)'s (that do not necessarily have entries zeroes or roots of unity). There is a (1,1)-version of the above as follows. Given one more arithmetic connection \( \overline{\delta} = (\overline{\delta}_p) =: (\overline{\varphi}_p) \) with correspondence structure \( \overline{\Gamma}_p := (\Gamma_p) \) one can define the (1,1)-\( \ast \)-curvature of \( \Gamma_p \) with respect to \( \overline{\Gamma}_p \) as the family \( \overline{\varphi}^\ast_{pp'} \) where \( \overline{\varphi}^\ast_{pp'} \) is the additive endomorphism

\[
(2.25) \quad \varphi^\ast_{pp'} := \frac{1}{pp'}[\overline{\Gamma}^\ast_p, \Gamma^\ast_p] : E \to E \quad \text{for } p \neq p', \text{ and } \quad \overline{\varphi}^\ast := \frac{1}{p}[\overline{\Gamma}^\ast_p, \overline{\Gamma}^\ast_p] : E \to E.
\]

In what follows we let \( \overline{\delta} \) be equal to \( \delta_0 = (\delta_{0,p}) \), where \( \delta_{0,p} x = 0 \); we give \( \overline{\delta} \) the correspondence structure \( \overline{\Gamma}_p = (G, \pi_p, \varphi_p) \), \( \overline{\Gamma} \) the identity, and \( \varphi_p^\ast(x) = x^{(p)} \).

**Theorem 2.4.** \( \cite{[2]} \).

1) Assume \( n = 2 \) and \( q \) is split with \( q^t = -q \). Then \( \Gamma_p \) is irreducible and has left degree 2 and right degree \( 2p^2 \). Moreover the \( \ast \)-curvature satisfies \( \varphi^\ast_{pp'} = 0 \) for all \( p, p' \) while the (1,1)-\( \ast \)-curvature satisfies \( \varphi^\ast_{pp} \neq 0 \) for all \( p, p' \).

2) Assume \( n = 2 \) and \( q \) is split with \( q^t = q \). Then \( \Gamma_p \) is irreducible and has left degree 4. Moreover the (1,1)-\( \ast \)-curvature satisfies \( \varphi^\ast_{pp} \neq 0 \) for all \( p, p' \).

Once again, the theorem says nothing about the \( \ast \)-curvature in case \( n = 2 \) and \( q^t = q \); our method of proof does not seem to apply to this case.
3. Final remarks

The theory outlined above should be viewed as a first step in a program of developing a differential geometry of Spec Z. Other types of curvature (Ricci, mean, scalar) are developed in [1] and lead to some interesting Dirichlet series. An arithmetic Maurer-Cartan connection and a Galois theory attached to it is given in [9] [10]; this Galois theory should be viewed as an arithmetic gauge theory and should be further developed. It might be possible to attach deRham cohomology classes to our curvatures and to link them to the étale cohomology of Spec Z. Links between arithmetic connections and Galois representations might exist that mimic the link between flat connections on vector bundles over manifolds and representations of the fundamental group of those manifolds. We hope to come back to these issues in future work.
