Self-tuned mirror descent schemes for smooth and nonsmooth high-dimensional stochastic optimization

Nahidsadat Majlesinasab, Farzad Yousefian, Arash Pourhabib

Abstract

We consider randomized block coordinate stochastic mirror descent (RBSMD) methods for solving high-dimensional stochastic optimization problems with strongly convex objective functions. Our goal is to develop RBSMD schemes that achieve a rate of convergence with a minimum constant factor with respect to the choice of the stepsize sequence. To this end, we consider both subgradient and gradient RBSMD methods addressing nonsmooth and smooth problems, respectively. For each scheme, (i) we develop self-tuned stepsize rules characterized in terms of problem parameters and algorithm settings; (ii) we show that the non-averaging iterate generated by the underlying RBSMD method converges to the optimal solution both in an almost sure and a mean sense; (iii) we show that the mean squared error is minimized. When problem parameters are unknown, we develop a unifying self-tuned update rule that can be applied in both subgradient and gradient SMD methods, and show that for any arbitrary and small enough initial stepsize, a suitably defined error bound is minimized. We provide constant factor comparisons with standard SMD and RBSMD methods. Our numerical experiments performed on an SVM model display that the self-tuned schemes are significantly robust with respect to the choice of problem parameters, and the initial stepsize.

I. INTRODUCTION

In this work, we consider the canonical stochastic optimization problem given by

\[ \min_{\beta \in \mathcal{B}} F(\beta) := \mathbb{E}[f(\beta, \xi)], \tag{SO} \]

where \( \mathcal{B} \triangleq \prod_{i=1}^l \mathcal{B}_i \subset \mathbb{R}^n \) with \( \mathcal{B}_i \subset \mathbb{R}^{n_i} \) being nonempty, closed, and convex sets, \( n \triangleq \sum_{i=1}^l n_i \), and the function \( f : \mathcal{B} \times \Omega \to \mathbb{R} \) is a stochastic function. The vector \( \xi : \Omega \to \mathbb{R}^d \)

arXiv:1709.08308v2 [math.OC] 7 Aug 2018
is a random vector associated with a probability space represented by $(\Omega, \mathcal{F}, \mathbb{P})$. A wide range of problems in machine learning and signal processing can be formulated as problem (SO). In addressing problem (SO), challenges arise in the development of efficient solution methods mainly due to: (i) presence of uncertainty: in many applications arising in statistical learning, the probability distribution $\mathbb{P}$ is unknown. Even when $\mathbb{P}$ is known, the evaluation of the expectation of $f$ becomes costly, especially when $d > 5$; (ii) high-dimensionality of the solution space: another difficulty arises when $n$ is huge. In such applications the computational complexity of first-order methods significantly increases, which makes them impractical for large values of $n$ (e.g., $10^{12}$ or more). In addressing uncertainty, the stochastic approximation (SA) method was first developed by Robbins and Monro [1]. Since then, the SA method and its variants have been vastly employed in addressing stochastic optimization ([2]–[4]). Averaging techniques first introduced by Polyak and Juditsky [5] proved successful in increasing the robustness of the SA method. In vector spaces equipped with non-Euclidean norms, prox generalizations of deterministic gradient method ([6], [7]) were introduced and applied in smooth and nonsmooth regimes. Also, in the stochastic regime, Nemirovski et al. [8] developed the stochastic mirror descent (SMD) method for solving problem (SO) when $F$ is nonsmooth and convex. Under a window-based averaging scheme, the rate of $O \left( \frac{1}{\sqrt{t}} \right)$ is established. When the dimension of the solution space is huge, to reduce the computational burden, coordinate descent (CD) methods have been developed in recent decades (cf. [9]–[11]). Recently, Dang and Lan [12] developed the stochastic block mirror descent (SBMD) method. They showed that under averaging the convergence rate of $O \left( \frac{l}{\sqrt{t}} \right)$ and $O \left( \frac{l}{t} \right)$ can be established for the case when $F$ is merely convex, and strongly convex, respectively. Some recent works have considered SMD on a class of non-convex problems called variationally coherent that includes pseudo-/quasiconvex, and star-convex optimization problems and provided convergence rate of $O \left( \frac{1}{\sqrt{t}} \right)$ for strongly coherent problems [13], [14]. While these non-asymptotic convergence orders are known to be optimal for the SMD method, the performance of this method can be significantly sensitive with respect to problem parameters and the uncertainty. Much of the interest in the literature has focused on establishing the optimal convergence rates, and there is little guidance on development of stepsize update rules for the SMD method in order to minimize the constant factor of the associated error bounds. Motivated by this gap, our goal in this work lies in improvement of the finite-time behavior of the SMD methods and their block variants through development self-tuned stepsizes. Several efforts have
been done in development of efficient stepsize rules for SA schemes (e.g., see [15], [16]). Spall [17] discusses a harmonic stepsize of the form $\eta_t = \frac{a}{(t+1+A)^\alpha}$ where $a > 0$ is a tuning parameter, and $A \geq 0$ is the stability constant. George and Powell [18] propose a class of harmonic stepsizes which minimizes the mean squared estimation error (see also [19], [20], [21], [22]). Self-tuned stepsizes were first introduced in [23] where a recursive update rule is developed for the stochastic (sub)gradient methods. It is shown that using such update rules, the mean squared error of the method is minimized w.r.t. the stepsize choice. Motivated by that work, we develop self-tuned stepsize rules for SMD methods and their randomized block variants (RBSMD) to solve problem (SO) where the objective function $F$ is strongly convex. We consider two cases where (i) $F$ is nondifferentiable, (ii) $F$ is differentiable and has Lipschitz gradients. In the following, we present the main contributions and explain the distinctions with the earlier works [23], [24]:

(1) Convergence and complexity analysis: For each variant of the RBSMD methods, we develop new recursive error bounds. These error bounds are given by Lemma 2 and 5 for cases (i) and (ii), respectively. In each case, we then develop self-tuned stepsizes that are characterized in terms of problem parameters and algorithm settings. We show that under such update rules, the error function of the underlying RBSMD method converges to zero in an almost sure and a mean sense. Importantly, we show that the expected value of the error is minimized under the self-tuned stepsizes within a specified range. We also derive bounds on the probability of error of the RBSMD schemes in terms of problem parameters, algorithm settings, and the iteration number (see Propositions 1 and 2 for cases (i) and (ii), respectively). Our results in this work extend the previous findings on self-tuned stepsizes in [23], [24] to a broader class of algorithms, i.e., SMD methods and their randomized block variants. Moreover, our approach in addressing nonsmoothness is different from that considered in [23], [24]. Here we develop subgradient variants of the RBSMD method allowing us to prove convergence to the true optimal solution to problem (SO), while in [23], [24] a convolution-based smoothing scheme is applied where the nondifferentiable function $F$ is approximated by a smooth function defined on an expansion of the feasible set $\mathcal{B}$. Consequently, in addressing nonsmooth problems, the convergence in [23], [24] is established to the optimal solution of an approximate smooth problem.

(2) Unifying self-tuned stepsizes: Another improvement to [23], [24] in deriving self-tuned schemes is addressing the case where some of problem parameters are unknown. In this case, we develop unifying self-tuned stepsizes and show convergence in both an almost sure and a mean
sense. Importantly, we show that for any arbitrary and small enough initial stepsize, a suitably defined error bound of the SMD scheme is minimized (see Theorem 1). This indeed implies robustness of the proposed schemes w.r.t. the choice of initial stepsize and addresses a common challenge associated with the harmonic choice of stepsizes.

(3) Constant factor comparison: While we prove the superiority of the constant factor of the error bounds associated with the self-tuned RBSMD schemes, we also provide two sets of comparisons: (i) with a widely used harmonic stepsizes (e.g., in [8], [17]), and also (ii) with an averaging RBSMD scheme developed in [12]. In case (ii), our comparison implies the constant factor for the class of stochastic subgradient methods can be improved up to four times under non-averaging schemes versus using the averaging scheme in [12].

The rest of the technical note is organized as follows. In Section II, we describe the randomized block coordinate SMD methods, then develop a self-tuned stepsize scheme for smooth and nonsmooth problems and provide the convergence rate analysis. We present the experimental results in Section III and conclude with some remarks in Section IV.

Notation. Throughout, we abbreviate “almost surely” as a.s., while $\text{Prob}(Z)$ and $E[z]$ are used to denote the probability of an event $Z$, and the expectation of a random variable $z$, respectively. We let $\beta^i \in \mathbb{R}^{n_i}$ denote the $i$th block coordinate of vector $\beta \in \mathbb{R}^n$, and the subscript $i$ represents the $i$th block of a mapping in $\mathbb{R}^n$. For any $i = 1, \ldots, l$, we use $\|\cdot\|_i$ to denote the general norm on $\mathbb{R}^{n_i}$ and $\|\cdot\|_{**i}$ to denote its dual norm. The inner product of vectors $u, v \in \mathbb{R}^n$ is defined by $\langle u, v \rangle \triangleq \sum_{i=1}^l \langle u^i, v^i \rangle$. We define norm $\|\cdot\|$ as $\|x\|^2 \triangleq \sum_{i=1}^d \|x^i\|^2_i$ for any $x \in \mathbb{R}^n$, and denote its dual norm by $\|\cdot\|_*$. Throughout, $p_i$ denotes the probability associated with choosing the $i$th block coordinate. We use the notation $p_\wedge \triangleq \min_{1 \leq i \leq l} p_i$, $p_\vee \triangleq \max_{1 \leq i \leq l} p_i$, $L_{max} \triangleq \max_{1 \leq i \leq l} L_i$, and $\mu_{min} \triangleq \min_{1 \leq i \leq l} \mu_{\omega_i}$.

II. SELF-TUNED RANDOMIZED BLOCK COORDINATE SMD

In this section, our goal is to develop self-tuned randomized block coordinate SMD methods. We start with the case where the objective function is non-differentiable. Later, in Section II-B, we discuss the case of differentiable objective functions with Lipschitz gradients. In Section II-C, we provide unifying self-tuned update rules addressing both cases in absence of problem parameters. Let the distance generating function $\omega_i : \mathbb{R}^{n_i} \to \mathbb{R}$ be a continuously differentiable function. The
Bregman divergence $D_{\omega_i} : \mathbb{R}^m \times \mathbb{R}^m \rightarrow \mathbb{R}$ associated with $\omega_i$ is given for $\beta_1, \beta_2 \in \mathcal{B}_i$ as

$$D_{\omega_i}(\beta_1, \beta_2) = \omega_i(\beta_2) - \omega_i(\beta_1) - \langle \nabla \omega_i(\beta_1), \beta_2 - \beta_1 \rangle.$$ 

Let $\nabla_{\beta_2} D_{\omega_i}(\cdot, \cdot)$ denote the partial derivative of $D_{\omega_i}(\beta_1, \beta_2)$ with respect to $\beta_2$. Then,

$$\nabla_{\beta_2} D_{\omega_i}(\beta_1, \beta_2) = \nabla \omega_i(\beta_2) - \nabla \omega_i(\beta_1), \quad \text{for all} \quad \beta_1, \beta_2 \in \mathcal{B}_i. \quad (1)$$

The Bregman divergence has the following property for all $\beta_1, \beta_2, \beta_3 \in \mathcal{B}_i$

$$D_{\omega_i}(\beta_1, \beta_2) - D_{\omega_i}(\beta_3, \beta_2) = D_{\omega_i}(\beta_1, \beta_3) + \langle \nabla \omega_i(\beta_3) - \nabla \omega_i(\beta_1), \beta_2 - \beta_3 \rangle. \quad (2)$$

We assume the distance generating function $\omega_i$ has Lipschitz gradients with parameter $L_{\omega_i}$ and is strongly convex with parameter $\mu_{\omega_i}$, i.e., for all $\beta_1, \beta_2, \beta_3 \in \mathcal{B}_i$

$$\frac{\mu_{\omega_i}}{2} \| \beta_2 - \beta_1 \|^2 \leq D_{\omega_i}(\beta_1, \beta_2) \leq \frac{L_{\omega_i}}{2} \| \beta_2 - \beta_1 \|^2. \quad (3)$$

**Remark 1.** Lipschitzian property of $\omega_i$ is a standard assumption in the literature of SMD methods; the convergence rate analysis provided in [25] and [12] relies on this property. Also note that for the stochastic gradient descent (SGD) method, we have $\mu_{\omega} = L_{\omega} = 1$.

The prox mapping $P_{i} : \mathcal{B}_i \times \mathbb{R}^{n_i} \rightarrow \mathcal{B}_i$ is defined by

$$P_{i}(\beta_1, \beta_2) = \text{argmin}_{z \in \mathcal{B}} \{ \langle \beta_2, z \rangle + D_i(\beta_1, z) \}, \quad (4)$$

for all $\beta_1 \in \mathcal{B}_i$ and $\beta_2 \in \mathbb{R}^{n_i}$. In the analysis, we use the following error function $\mathcal{L} : \mathcal{B} \times \mathcal{B} \rightarrow \mathbb{R}$ defined as

$$\mathcal{L}(\beta, z) \triangleq \sum_{i=1}^{l} p_i^{-1} D_i(\beta^i, z^i), \quad \text{for all} \quad \beta, z \in \mathcal{B}. \quad (5)$$

**A. Self-tuned randomized block subgradient SMD method**

Consider problem (SO) where $F$ is a non-differentiable convex function of $\beta$. Let $g_i \in \partial F(\beta_i)$ denote a subgradient of function $F$ at point $\beta_i \in \mathcal{B}$, i.e., there exists $g_i$ such that

$$F(\beta_i) + \langle g_i, \beta - \beta_i \rangle \leq F(\beta), \quad \text{for all} \quad \beta \in \mathcal{B}. \quad (6)$$

Similarly, for any $\xi \in \Omega$, we let $\tilde{g}_i \in \partial f(\beta_i, \xi)$ denote a subgradient of function $f(\cdot, \xi)$ at point $\beta_i$. Throughout, we assume that $F$ is strongly convex with parameter $\mu_F > 0$ over the set $\mathcal{B}$ with respect to the underlying norm $\| \cdot \|$, i.e., for all $\beta_1, \beta_2 \in \mathcal{B}$ and $g \in \partial F(\beta_2)$

$$F(\beta_1) \geq F(\beta_2) + \langle g, \beta_1 - \beta_2 \rangle + \frac{\mu_F}{2} \| \beta_1 - \beta_2 \|^2. \quad (6)$$

In our analysis, we make use of the following result. The proof can be found in [26].

**Lemma 1.** Consider problem (SO). Let $F$ be strongly convex with parameter $\mu_F > 0$. Then,
there exists a unique optimal solution \( \beta^* \in \mathcal{B} \). Moreover, we have
\[
F(\beta) - F(\beta^*) \geq \frac{\mu_F}{2} \| \beta - \beta^* \|^2, \quad \text{for all } \beta \in \mathcal{B}.
\]

Next we present the outline of the randomized block coordinate SMD method. Let \( P_b \) be a discrete probability distribution with probabilities \( p_i > 0 \) for \( i = 1, \ldots, l \), where \( \sum_{i=1}^l p_i = 1 \). Given an initial vector \( \beta_0 \in \mathcal{B} \), at iteration \( t \geq 1 \), random variable \( i_t \) is generated from the probability distribution \( P_b \) independently from random variable \( \xi \). Then, only the \( i_t \)th block of \( \beta_t \), i.e. \( \beta_t^{i_t} \), is updated as follows:
\[
\beta_{t+1}^{i_t} = \begin{cases} 
\mathcal{P}_{i_t}(\beta_t^{i_t}, \eta_t \tilde{g}_{i_t}(\beta_t)) & \text{if } i = i_t, \\
\beta_t^{i_t} & \text{if } i \neq i_t,
\end{cases}
\]
(RB-SSMD)
where \( \tilde{g}_{i_t}(\beta_t) \) is the \( i_t \)th block of the subgradient of \( f(\beta_t, \xi_t) \) and \( \eta_t \) is the stepsize. Throughout, let \( \mathcal{F}_t = \{i_0, \xi_0, \ldots, i_{t-1}, \xi_{t-1}\} \). Next, we state the main assumptions.

**Assumption 1.** Let the stochastic subgradient \( \tilde{g}(\beta) \in \partial f(\beta, \xi) \) be such that a.s. for all \( \beta \in \mathcal{B} \), we have \( \mathbb{E}[\tilde{g}(\beta) | \beta] = g(\beta) \in \partial F(\beta) \). Moreover, for all \( i = 1, \ldots, l \) and \( \beta \in \mathcal{B} \), there exists a scalar \( C_i > 0 \) such that \( \mathbb{E}[\| g_i(\beta) \|^2] \leq C_i^2 \).

Next, we develop a recursive inequality in terms of the error of the (RB-SSMD) scheme. Such a recursive inequality will be employed to develop a self-tuned stepsize rule.

**Lemma 2.** Let Assumption 7 hold and \( \beta_t \) be generated by the (RB-SSMD) scheme. Then for all \( t \geq 0 \),
\[
\mathbb{E}[\mathcal{L}(\beta_{t+1}, \beta^*) | \mathcal{F}_t] \leq (1 - \eta_t 2 \mu_F \Sigma_{\max}^{-1}) \mathcal{L}(\beta_t, \beta^*) + \eta_t^2 \sum_{i=1}^l C_i^2 (2 \mu_{\omega_i})^{-1}.
\]
(7)

**Proof.** At iteration \( t \), we have \( \beta_{t+1}^{i_t} = \mathcal{P}_{i_t}(\beta_t^{i_t}, \eta_t \tilde{g}_{i_t}(\beta_t)) \). Consider the definition of \( \mathcal{P}_{i_t} \) given by (4). Writing the optimality condition, we have
\[
\langle \eta_t \tilde{g}_{i_t} + \nabla D_{i_t} (\beta_t^{i_t}, \beta_t^{i_t}), \beta_t^{i_t} - \beta_{t+1}^{i_t} \rangle \geq 0, \quad \text{for all } \beta \in \mathcal{B}.
\]
Using relations (1) and (2), and from the preceding relation,
\[
D_{i_t} (\beta_t^{i_t}, \beta_t^{i_t}) - D_{i_t} (\beta_t^{i_t}, \beta_t^{i_t}) - D_{i_t} (\beta_t^{i_t}, \beta_t^{i_t}) \geq \eta_t \langle \tilde{g}_{i_t}, \beta_t^{i_t} - \beta_{t+1}^{i_t} \rangle, \quad \text{for all } \beta \in \mathcal{B}.
\]
From the strong convexity of \( \omega_{i_t} \) and relation (3), we have
\[
D_{i_t} (\beta_t^{i_t}, \beta_t^{i_t}) - D_{i_t} (\beta_t^{i_t}, \beta_t^{i_t}) - 0.5 \mu_{\omega_{i_t}} \| \beta_t^{i_t} - \beta_{t+1}^{i_t} \|^2 \geq \eta_t \langle \tilde{g}_{i_t}, \beta_t^{i_t} - \beta_{t+1}^{i_t} \rangle.
\]
(8)
By adding and subtracting \( \eta_t \langle \tilde{g}_{i_t}, \beta_t^{i_t} \rangle \) in the right-hand side, and using Fenchel’s inequality, we
have
\[ \eta_t \langle \tilde{g}_{it}, \beta_{i+1}^t - \beta_i^t \rangle + \eta_t \langle \tilde{g}_{it}, \beta_i^t - \beta^t \rangle \geq -0.5 \eta_t^2 \mu_{\omega_t}^{-1} \| \tilde{g}_{it} \|_{\star_t}^2 - 0.5 \mu_{\omega_t} \| \beta_{i+1}^t - \beta_i^t \|_{\star_t}^2 + \eta_t \langle \tilde{g}_{it}, \beta_i^t - \beta^t \rangle. \] (9)

Combining (8) and (9) yields for all \( \beta \in \mathcal{B} \)
\[ D_{it}(\beta_{i+1}^t, \beta^t) \leq D_{it}(\beta_i^t, \beta^t) + \eta_t \langle \tilde{g}_{it}, \beta_i^t - \beta^t \rangle + 0.5 \eta_t^2 \mu_{\omega_t}^{-1} \| \tilde{g}_{it} \|_{\star_t}^2. \]

From the preceding relation, relation (5), and that \( \beta_{i+1}^t = \beta_i^t \) for all \( i \neq i_t \), we have
\[ \mathcal{L}(\beta_{i+1}, \beta) \leq \sum_{i \neq i_t} p_i^{-1} D_i(\beta_i^t, \beta^t) + p_{i_t}^{-1} \left( D_{i_t}(\beta_{i_t}^t, \beta^t) + \eta_t \langle \tilde{g}_{i_t}, \beta_{i_t}^t - \beta^t \rangle + 0.5 \eta_t^2 \mu_{\omega_t}^{-1} \| \tilde{g}_{i_t} \|_{\star_t}^2 \right) \]
\[ = \mathcal{L}(\beta_i, \beta) + p_{i_t}^{-1} \left( \eta_t \langle \tilde{g}_{i_t}, \beta_{i_t}^t - \beta^t \rangle + 0.5 \eta_t^2 \mu_{\omega_t}^{-1} \| \tilde{g}_{i_t} \|_{\star_t}^2 \right). \]

Taking conditional expectations from both sides of the preceding relation on \( \mathcal{F}_t \cup \{i_t\} \), we get
\[ \mathbb{E}[\mathcal{L}(\beta_{i+1}, \beta) | \mathcal{F}_t \cup \{i_t\}] \leq \mathcal{L}(\beta_i, \beta) + 0.5 \eta_t^2 \mu_{\omega_t}^{-1} \mathbb{E}\left[ \| \tilde{g}_{i_t} \|_{\star_t}^2 | \mathcal{F}_t \cup \{i_t\} \right] \]
\[ + \frac{\eta_t}{p_{i_t}} \mathbb{E}[\langle \tilde{g}_{i_t} | \mathcal{F}_t \cup \{i_t\} \rangle, \beta_{i_t}^t - \beta^t] \]
\[ \leq \mathcal{L}(\beta_i, \beta) + p_{i_t}^{-1} \eta_t \langle \tilde{g}_{i_t}, \beta_{i_t}^t - \beta^t \rangle + p_{i_t}^{-1} \eta_t^2 \frac{C_i^2}{2 \mu_{\omega_t}}, \]
where we used Assumption [1]. Taking expectations from previous inequality with respect to \( i_t \) and setting \( \beta := \beta^* \),
\[ \mathbb{E}[\mathcal{L}(\beta_{i+1}, \beta^*) | \mathcal{F}_t] \leq \mathcal{L}(\beta_i, \beta^*) + \sum_{i=1}^l \frac{p_i}{p_i} \left( \eta_t \langle \tilde{g}_i, \beta^* - \beta_i \rangle + \eta_t^2 \frac{C_i^2}{2 \mu_{\omega_i}} \right) \]
\[ = \mathcal{L}(\beta_i, \beta^*) + \eta_t \langle \tilde{g}_i, \beta^* - \beta_i \rangle + \eta_t^2 \sum_{i=1}^l \frac{C_i^2}{2 \mu_{\omega_i}}, \]
where we use the definition of \( \langle \cdot, \cdot \rangle \) given in the notation. From strong convexity of function \( F \), we have \( \langle g_t - g^*, \beta_t - \beta^* \rangle \geq \mu_F \| \beta_t - \beta^* \|^2 \). By optimality of \( \beta^* \), we have \( \langle g^*, \beta_t - \beta^* \rangle \geq 0 \).

From the two preceding relations and the definition of norm,
\[ \langle g_t, \beta_t - \beta^* \rangle \geq \mu_F \sum_{i=1}^l \| \beta_i^t - \beta^* \|_i^2 \geq 2 \mu_F \sum_{i=1}^l \frac{D_i(\beta_i^t, \beta^*)}{\Sigma_{i_t}} \]
\[ \geq 2 \mu_F p_n \Sigma_{n=1}^{-1} \sum_{i=1}^l p_i^{-1} D_i(\beta_i^t, \beta^*) = 2 \mu_F p_n \Sigma_{n=1}^{-1} \mathcal{L}(\beta_t, \beta^*), \]
where in the second inequality we used relation (3), and in the last relation we used the definition of function \( \mathcal{L} \). From the preceding two relations, we obtain the desired inequality. \( \square \)

Next, we present some important properties of the self-tuned sequences. Some of them can
Proposition 1. Let $\beta_i$ be generated by the (RB-SSMD) method. Let the sets $\mathcal{B}_i$ be convex and closed such that $\|\beta_i\| \leq M_i$ for all $\beta_i \in \mathcal{B}_i$ and some $M_i > 0$, for all $i$. Let Assumption 1 hold for some $C_i$ large enough such that $C_i^2 \mathbb{E}_{\omega_i} \geq 8M_i^2 \mathbb{E}_{\mu_\omega_i} \mu_i^2$ for all $i$. Let the stepsize $\eta_t$ be given by

$$
(\eta_t^*) := (1 - \theta \eta_t) \eta_t + \delta \eta_t^2
$$

for all $t \geq 1$. Let $\epsilon_0 \leq \frac{2\delta}{\theta^2}$ and let the self-tuned sequence $\{\eta_t^*\}$ be given by $\eta_t^* = \eta_{t-1}^*(1 - \frac{\theta}{2} \eta_{t-1}^*)$ for any $t \geq 1$, where $\eta_0^* = \frac{\theta}{2\delta} \epsilon_0$. Then the following properties hold:

(a) For any fixed $t \geq 1$, the vector $(\eta_0^*, \ldots, \eta_{t-1}^*)$ minimizes the function $e_t(\eta_0, \ldots, \eta_{t-1})$ over the set $U_t := \{\gamma \in \mathbb{R}^t : 0 < \gamma_j \leq 1/\theta \text{ for } j = 1, \ldots, t\}$. More precisely, for $t \geq 1$, and any $(\eta_0, \ldots, \eta_{t-1}) \in U_t$,

$$
e_t(\eta_0, \ldots, \eta_{t-1}) - e_t(\eta_0^*, \ldots, \eta_{t-1}^*) \geq \delta(\eta_{t-1} - \eta_{t-1}^*)^2.
$$

(b) For all $t \geq 1$, we have $\eta_t^* \leq \frac{2}{\theta} (\frac{1}{t})$. Moreover, under the choice of $\eta_t := \eta_t^*$, the term $e_t$ is bounded by $O(1/t)$:

$$
e_t(\eta_0^*, \ldots, \eta_{t-1}^*) \leq \frac{4\delta}{\theta^2} \left(\frac{1}{t}\right), \text{ for all } t \geq 1.
$$

(c) We have $\sum_{t=0}^{\infty} \eta_t^* = \infty$ and $\sum_{t=0}^{\infty} \eta_t^*^2 < \infty$.

We use the following lemma in the convergence analysis.

Lemma 4. [27, page 49] Let $\{v_t\}$ be a sequence of non-negative random variables where $\mathbb{E}[v_0] < \infty$, let $\{\alpha_t\}$ and $\{\lambda_t\}$ be deterministic scalar sequences such that

$$
\mathbb{E}[v_{t+1}|v_0, \ldots, v_t] \leq (1 - \alpha_t)v_t + \lambda_t, \text{ a.s. for all } t \geq 0,
$$

$$0 \leq \alpha_t \leq 1, \quad \lambda_t \geq 0, \quad \sum_{t=0}^{\infty} \alpha_t = \infty, \quad \sum_{t=0}^{\infty} \lambda_t < \infty, \quad \frac{\lambda_t}{\alpha_t} \to 0.
$$

Then, $v_t \to 0$ a.s., $\mathbb{E}[v_t] \to 0$, and for any $\epsilon > 0$ and $t > 0$

$$
\text{Prob}(v_j \leq \epsilon \text{ for all } j \geq t) \geq 1 - \frac{1}{\epsilon} \left(\mathbb{E}[v_t] + \sum_{i=t}^{\infty} \lambda_i\right).
$$

Next, we present self-tuned stepsizes and their properties for the (RB-SSMD) method.

Lemma 3. Let $\theta, \delta > 0$ be scalars, and $\{e_t\} \geq 0$ be a sequence for $t \geq 0$, such that for an arbitrary non-negative sequence $\{\eta_t\}$

$$
e_{t+1} := (1 - \theta \eta_t) e_t + \delta \eta_t^2, \text{ for all } t \geq 1.
$$

Let $\epsilon_0 \leq \frac{2\delta}{\theta^2}$ and let the self-tuned sequence $\{\eta_t^*\}$ be found in [23] and [24]. The proof of the next lemma is presented in the Appendix.
by

\[ \eta_0^* = \frac{4\mu_F^2 \sum_{i=1}^l p_i^{-1} \Sigma_{\omega_i} M_i^2}{2 \sum_{i=1}^l \mu_i^{-1} C_i^2}, \]

\[ \eta_t^* = \eta_{t-1}^* \left( 1 - \frac{\mu_F^2 \Sigma_{\max}^2 \eta_{t-1}^*}{2 \sum_{i=1}^l \mu_i^{-1} C_i^2} \right), \quad \text{for all } t \geq 1. \]

Then, the following hold:

(a) The sequence \( \{\beta_t\} \) converges a.s. to the unique optimal solution \( \beta^* \) of problem \( \text{(SO)} \).

(b) For any \( t \geq 1 \), the vector \( (\eta_0^*, \ldots, \eta_{t-1}^*) \) minimizes the upper bound of the error \( E[\mathcal{L}(\beta_t, \beta^*)] \) given in Lemma 2 for all \( (\eta_0, \ldots, \eta_{t-1}) \in \left(0, \frac{\Sigma_{\max}}{2p_i, \mu_F}\right)^l \).

(c) The \( \text{(RB-SSMD)} \) method attains the convergence rate \( \mathcal{O}(1/t) \), i.e., for all \( t \geq 1 \)

\[ E[\|\beta_t - \beta^*\|^2] \leq \frac{p_\lambda^2}{\mu_{\min}} \sum_{i=1}^l \frac{C_i^2}{\mu_i} \left( \frac{\Sigma_{\max}}{p_i, \mu_F} \right)^2 \frac{1}{t}. \]

(d) Let \( \epsilon \) and \( \rho \) be arbitrary positive scalars and \( T \triangleq 1.5 \left( \frac{\Sigma_{\max}}{p_i, \mu_F} \right)^2 \sum_{i=1}^l \frac{\mu_i^2}{C_i^2} \frac{1}{\epsilon \rho} \)

we have for all \( t \geq T \)

\[ \text{Prob}(\mathcal{L}(\beta_j, \beta^*) \leq \epsilon \text{ for all } j \geq t) \geq 1 - \rho. \]

Proof. (a) To show a.s. convergence, we apply Lemma 4. Consider the inequality (7) given by Lemma 2. Let us define

\[ v_t \triangleq \mathcal{L}(\beta_t, \beta^*), \quad \alpha_t \triangleq \frac{2\mu_F^2 \lambda \eta_t^*}{\Sigma_{\max}^2}, \quad \lambda_t \triangleq \sum_{i=1}^l \frac{C_i^2}{\mu_i} \eta_t^2. \] (12)

From definition of \( \eta_t^* \) and \( C_i^2 \Sigma_{\omega_i} \geq 8M_i^2 \mu_i \mu_F^2 \), we have

\[ \alpha_0 = \frac{8\mu_F^2 \lambda \sum_{i=1}^l \frac{\Sigma_{\omega_i} M_i^2}{p_i}}{\Sigma_{\max}^2 \sum_{i=1}^l \frac{C_i^2}{\mu_i}} \leq \frac{p_\lambda \sum_{i=1}^l \frac{\Sigma_{\omega_i} C_i^2}{p_i \mu_i^2}}{\Sigma_{\max} \sum_{i=1}^l \frac{C_i^2}{\mu_i}} \leq p_\lambda < 1. \] (13)

Therefore, since \( \{\eta_t^*\} \) is non-increasing, we have \( 0 \leq \alpha_t \leq 1 \) for all \( t \geq 0 \). Moreover, from Lemma 3(c), we have that \( \sum_{t=0}^\infty \alpha_t = \infty \) and \( \sum_{t=0}^\infty \lambda_t < \infty \). Also, the definition of \( \alpha_t \) and \( \lambda_t \) and that the self-tuned stepsize \( \eta_t^* \) has a limit of zero (see proof of Lemma 3, part (c) in the Appendix) imply that \( \frac{\lambda_t}{\alpha_t} \to 0 \). Therefore, all conditions of Lemma 4 are met and so \( \mathcal{L}(\beta_t, \beta^*) \to 0 \) a.s.

The definition of \( \mathcal{L} \) and that \( p_i > 0 \) for all \( i \) imply that \( D_i(\beta_i^*, \beta^*) \to 0 \) for all \( i \). Using the strong convexity of \( \omega_i \) (cf. (3)), we have \( \frac{\mu_i}{2} \|\beta^* - \beta^*\|^2 \leq D_i(\beta_i^*, \beta^*) \) for all \( i \). We conclude that \( \beta_t \to \beta^* \) a.s..

(b) For any \( t \geq 1 \), let us define the function \( e_t(\eta_0, \ldots, \eta_{t-1}) \) given by the recursion (10) where

\[ \theta \triangleq \frac{2p_i, \mu_F}{\Sigma_{\max}^2}, \quad \delta \triangleq \sum_{i=1}^l \frac{C_i^2}{2p_i \mu_i}. \]

Also, let \( e_0 \triangleq 2 \sum_{i=1}^l p_i^{-1} \Sigma_{\omega_i} M_i^2 \). Next, we show that \( \mathcal{L}(\beta_0, \beta^*) \leq
conditions of Lemma 3 hold. First we show that

\[ \mathcal{L}(\beta_0, \beta^*) = \sum_{i=1}^{l} \frac{D_i(\beta_0^i, \beta^*)}{p_i} \leq \sum_{i=1}^{l} \frac{\delta_{\omega_i}}{2p_i} \| \beta_0^i - \beta^* \|^2 \leq \sum_{i=1}^{l} \frac{\delta_{\omega_i}}{2p_i} (2\| \beta_0^i \|^2 + 2\| \beta^* \|^2) \]

\[ \leq \sum_{i=1}^{l} \frac{2\delta_{\omega_i} M_i^2}{p_i} = e_0. \]

From \( \mathcal{L}(\beta_0, \beta^*) \leq e_0 \), relations (10), (7) and using induction, it can be seen that \( \mathbb{E}[\mathcal{L}(\beta_t, \beta^*)] \leq e_t(\eta_0, \ldots, \eta_{t-1}) \) for all \( t \geq 0 \) and any arbitrary \( (\eta_0, \ldots, \eta_{t-1}) \) \( \in \left( 0, \frac{\delta_{\max}}{2p_{\max}^\mu_F} \right]^t \). Therefore, \( e_t \) is a well-defined upper bound for the algorithm. To complete the proof, it suffices to show that the conditions of Lemma 3 hold. First we show that \( e_0 \leq \frac{2\delta}{\theta^2} \). From the values of \( e_0 \), \( \eta_0 \), \( \theta \), and \( \delta \), we have \( \eta_0^* = \frac{\theta}{\delta^2} e_0 \). From the definition of \( \alpha_0 \) in (12) and (13), we have \( \alpha_0 = \theta \eta_0^* < 1 \). By two preceding relations we obtain \( e_0 \leq \frac{2\delta}{\theta^2} \). Hence, conditions of Lemma 3 hold. From Lemma 3(a), we conclude the desired result.

(c) Following the proof of part (b), from Lemma 3(b) and definitions of \( \delta \) and \( \theta \) in part (b), we obtain for all \( t \geq 1 \)

\[ \mathbb{E}[\mathcal{L}(\beta_t, \beta^*)] \leq e_t \leq \left( \frac{\delta_{\max}}{p_{\max}^\mu_F} \right)^2 \sum_{i=1}^{l} \frac{C_i^2}{2\mu_{\omega_i}} \frac{1}{t}. \] (14)

Note that from strong convexity of \( \omega_i \) we have

\[ \mathcal{L}(\beta_t, \beta^*) = \sum_{i=1}^{l} p_i^{-1} D_i(\beta_t^i, \beta^*) \geq \sum_{i=1}^{l} p_i^{-1} 0.5\mu_{\omega_i} \| \beta_t^i - \beta^* \|^2 \geq \mu_{\min}(2p_{\min})^{-1} \| \beta_t - \beta^* \|^2. \]

Combining the two preceding relations completes the proof.

(d) We use the probabilistic bound given in Lemma 4. First we estimate the term \( \sum_{i=t}^{\infty} \lambda_i \) where \( \lambda_i \) is given by (12). Note that Lemma 3(b) implies \( \eta_i^* \leq \frac{1}{2\theta} \). Therefore, we can write

\[ \sum_{i=t}^{\infty} \lambda_i \leq \sum_{i=t}^{\infty} \sum_{j=1}^{l} \frac{C_j^2}{2\mu_{\omega_j}} \eta_i^2 \leq \sum_{j=1}^{l} C_j^2 \sum_{i=t}^{\infty} \left( \frac{\delta_{\max}}{p_{\max}^\mu_F} \right)^2 \sum_{i=1}^{l} \frac{C_j^2}{2\mu_{\omega_j}} \left( \frac{1}{t} + \int_{t}^{\infty} \frac{1}{x^2} \, dx \right) \]

\[ = \left( \delta_{\max}(p_{\max}^\mu_F)^{-1} \right)^2 \sum_{j=1}^{l} C_j^2 \mu_{\omega_j}^{-1} (1/t). \] (15)

By (15), (14), and Lemma 4 we obtain the desired relation.

Under a uniform distribution, i.e., \( p_i = \frac{1}{l} \) for \( i = 1, \ldots, l \), Proposition 1 indicates that \( \mathbb{E}[\| \beta_t - \beta^* \|^2] \to 0 \) with the order of \( O \left( \frac{1}{t} \right) \). This is similar to the error bound derived in [12] for stochastic block mirror descent (SBMD) method (cf. Corollary 2.5 in [12]). Next, we compare the constant factor of the error bound derived in [12] with that of the (RB-SSMD) method.

**Comparison 1.** Let Assumption 7 hold for some unknown \( C_i > 0 \) for all \( i \). Let \( \beta_t \) be generated
by algorithm (RB-SSMD) where \( \Sigma_\omega = \Sigma_\omega \) and \( \mu_\omega = \mu_\omega \) for all \( 1 \leq i \leq l \) and \( \bar{\beta}_t \) be generated by SBMD method in [12]. Then, By Lemma 1 we have \( E[\|\bar{\beta}_t - \beta^*\|^2] \leq \frac{2}{\mu_\omega} E[(\bar{\beta}_t - \beta^*)] \) and by Corollary 2.5 in [12], we have \( E[F(\bar{\beta}_t) - F(\beta^*)] \leq \frac{2\nu_\omega}{\mu_F} \sum_{i=1}^l C_i^2 \left( \frac{1}{t+1} \right) \). Combining the preceding inequalities, we obtain for all \( t \geq 1 \)

\[
E[\|\bar{\beta}_t - \beta^*\|^2] \leq \frac{4l\omega_\omega}{\mu_F^2 \mu_\omega} \sum_{i=1}^l C_i^2 \left( \frac{1}{t+1} \right).
\]

(16)

On the other hand, by Proposition 1 we have for all \( t \geq 1 \)

\[
E[\|\beta_t - \beta^*\|^2] \leq \frac{4l\omega_\omega}{\mu_\omega^2 \mu_F^2} \sum_{i=1}^l C_i^2 \left( \frac{1}{t+1} \right).
\]

(17)

Comparing (16) and (17), we note that the constant factor of the error bound of (RB-SSMD) method is smaller when \( \frac{\omega_\omega}{\mu_\omega} < 4 \). In particular, for SGD method where \( \omega_\omega = \mu_\omega = 1 \), it can be four times better than the constant factor of SBMD in [12].

**Comparison 2.** Proposition 1 states that the self-tuned stepsizes not only guarantee the convergence of the (RB-SSMD) method, but also the constant factor provided in part (c) is the minimum for any arbitrary stepsize rule within a given range. For example, compare this constant factor with that of the stochastic subgradient method under harmonic stepsize rules in [8]. In that work (see relations (2.9)-(2.10)), under the harmonic update rule for stepsizes given by \( \eta_t = \gamma/t \) for some constant \( \gamma > 1/(2\mu_F) \), it is shown that

\[
E[\|\beta_t - \beta^*\|^2] \leq \max \left\{ \frac{\gamma^2 C^2}{2\mu_F \gamma - 1}, \|\beta_0 - \beta^*\|^2 \right\} \frac{1}{t}.
\]

(18)

Let \( l = 1 \). Here we show that for any arbitrary \( \gamma > \frac{1}{2\mu_F} \), the term \( \frac{\gamma^2 C^2}{2\mu_F \gamma - 1} \) is larger than the constant factor of the self-tuned stepsizes that is \( \frac{\omega(\beta)}{\mu_\omega \mu_F} \). Note that in the stochastic subgradient method \( \omega(\beta) := \frac{\|\beta\|^2}{2} \). This implies \( \mu_\omega = \omega_\omega = 1 \). Then,

\[
\frac{\text{Harmonic constant factor}}{\text{Self-tuned constant factor}} = \frac{\gamma^2 C^2 \mu_F^2}{(2\mu_F \gamma - 1) C^2} = \frac{\gamma^2 \mu_F^2}{2\mu_F \gamma - 1}.
\]

Note that \( \gamma^2 \mu_F^2 - 2\mu_F \gamma + 1 = (\gamma \mu_F - 1)^2 > 0 \) for all \( \gamma > \frac{1}{2\mu_F} \). Therefore, the preceding relation implies that the harmonic constant factor in [8] is larger than the self-tuned constant factor for any arbitrary \( \gamma > \frac{1}{2\mu_F} \).

**B. Self-tuned randomized block gradient SMD method**

In this section, we assume the objective function in problem (SO) is differentiable and has Lipschitz gradients. Our goal is to utilize this property and develop a self-tuned scheme that is
characterized with the problem parameters and algorithm settings. To solve problem (SO), we consider the randomized block gradient SMD method as follows

\[
\beta_{t+1}^i = \begin{cases} \mathcal{P}_{s_t}(\beta_t^i, \eta_t g_{t}(\beta_t^i)) & \text{if } i = i_t, \\ \beta_t^i & \text{if } i \neq i_t, \end{cases} \tag{RB-GSMD}
\]

for all \( t \geq 0 \), where \( g_{t}(\beta_t^i) \) is the \( i_t \)th block of the gradient of the stochastic function \( f(\cdot, \xi_t) \) at \( \beta_t \). Throughout this section, we let \( F \) have Lipschitz gradients with parameter \( \mathcal{L}_F > 0 \). We also define the stochastic errors \( z_t \) as follows

\[
z_t \triangleq g(\beta_t) - \nabla F(\beta_t). \tag{19}
\]

Next, we state the main assumptions on stochastic gradients.

**Assumption 2.** The errors \( z_t \) are such that a.s. we have \( \mathbb{E}[z_t \mid F_t] = 0 \) for all \( t \geq 0 \). Moreover, there exists some \( \nu_i > 0 \) for all \( i \) such that \( \mathbb{E}[\|z_t^i\|_2^2 \mid F_t] \leq \nu_i^2 \), for all \( t \geq 0 \).

Next, we have the lemma that provides a recursive bound on the error of the algorithm.

**Lemma 5.** Let Assumption 2 hold and \( \beta_t \) be generated by the (RB-GSMD) method. We have a.s. for all \( t \geq 0 \)

\[
\mathbb{E}[\mathcal{L}(\beta_{t+1}, \beta^*) \mid F_t] \leq (1 - \eta_t 2\mu_F p \mathcal{L}_t^{-1} + \eta_t^2 \mathcal{L}_F^2 p \nu \mu_{\min}^{-2}) \mathcal{L}(\beta_t, \beta^*) + \eta_t^2 \sum_{i=1}^I \nu_i^2 \mu_{\min}^{-1}. \tag{20}
\]

**Proof.** Consider the update rule (RB-GSMD). Writing the first-order optimality condition, we have for all \( \beta \in \mathcal{B} \)

\[
\langle \eta_t g_{t_i} + \nabla D_{t_i}(\beta_{t_i}^i, \beta_t^i), \beta^* - \beta_{t+1} \rangle \geq 0, \tag{21}
\]

Using equation 1, from (21) we obtain for all \( \beta \in \mathcal{B} \)

\[
\langle \nabla \omega_{t_i}(\beta_{t+1}^i) - \nabla \omega_{t_i}(\beta_t^i), \beta^* - \beta_{t+1} \rangle \geq \eta_t \langle g_{t_i} + \nabla D_{t_i}(\beta_{t+1}^i, \beta_{t+1}^i), \beta^* - \beta_{t+1} \rangle. \tag{22}
\]

Let \( \beta := \beta^* \) in relation (22). Adding and subtracting the term \( \eta_t \langle \nabla F_{t_i}(\beta^*), \beta_{t_i} - \beta_{t+1} \rangle \), we get

\[
\langle \nabla \omega_{t_i}(\beta_{t+1}^i) - \nabla \omega_{t_i}(\beta_t^i), \beta^* - \beta_{t+1} \rangle \geq \eta_t \langle g_{t_i} - \nabla F(\beta^*), \beta_{t_i} - \beta_{t+1} \rangle + \eta_t \langle \nabla F_{t_i}(\beta^*), \beta_{t_i} - \beta_{t+1} \rangle \tag{23}
\]

From relation (2), we get

\[
\langle \nabla \omega_{t_i}(\beta_{t+1}^i) - \nabla \omega_{t_i}(\beta_t^i), \beta^* - \beta_{t+1} \rangle = D_{t_i}(\beta_{t+1}^i, \beta^*) - D_{t_i}(\beta_{t+1}^i, \beta_{t+1}^*) - D_{t_i}(\beta_t^i, \beta_{t+1}^i). \]
Therefore, from the preceding relation, (23), and relation (3),

\[
D_{t_i}(\beta_{t_i}^{i}, \beta^{*i}) - D_{t_i}(\beta_{t+1}^{i}, \beta^{*i}) - \frac{\mu_{\omega_{t_i}}}{2} \|\beta_{t_i}^{i} - \beta_{t+1}^{i}\|_{t_i}^2 - \eta_t (\nabla F_{t_i}(\beta^*), \beta_{t+1}^{i} - \beta^{*i}) \geq \eta_t \langle g_{t_i} - \nabla F_{t_i}(\beta^*), \beta_{t+1}^{i} - \beta^{*i} \rangle
\]  

(24)

Next, we find a lower bound for the right-hand side term. By adding and subtracting \( \eta_t \langle g_{t_i} - \nabla F_{t_i}(\beta^*), \beta_{t+1}^{i} - \beta^{*i} \rangle \), we get

\[
\eta_t \langle g_{t_i} - \nabla F_{t_i}(\beta^*), \beta_{t+1}^{i} - \beta^{*i} \rangle + \eta_t \langle g_{t_i} - \nabla F_{t_i}(\beta^*), \beta_{t_i}^{i} - \beta^{*i} \rangle \geq \frac{-\eta_t^2}{2\mu_{\omega_{t_i}}} \|g_{t_i} - \nabla F_{t_i}(\beta^*)\|_{t_i}^2
\]

\[
- \frac{\mu_{\omega_{t_i}}}{2} \|\beta_{t+1}^{i} - \beta_{t_i}^{i}\|_{t_i}^2 + \eta_t \langle g_{t_i} - \nabla F_{t_i}(\beta^*), \beta_{t_i}^{i} - \beta^{*i} \rangle,
\]

(25)

where the last inequality follows from Fenchel’s inequality, i.e., \( |\langle x, y \rangle| \leq \frac{1}{2} \|x\|^2 + \frac{1}{2} \|y\|^2 \). Combining (24) and (25) yields

\[
D_{t_i}(\beta_{t+1}^{i}, \beta^{*i}) \leq D_{t_i}(\beta_{t_i}^{i}, \beta^{*i}) - \eta_t \langle \nabla F_{t_i}(\beta^*), \beta_{t+1}^{i} - \beta^{*i} \rangle + \eta_t^2 \mu_{\omega_{t_i}}^{-1} \|g_{t_i} - \nabla F_{t_i}(\beta^*)\|_{t_i}^2
\]

Using relation (19), and invoking the triangle inequality and relation \((a + b)^2 \leq 2a^2 + 2b^2\) for any \(a, b \in \mathbb{R}\), we obtain

\[
D_{t_i}(\beta_{t+1}^{i}, \beta^{*i}) \leq D_{t_i}(\beta_{t_i}^{i}, \beta^{*i}) - \eta_t \langle \nabla F_{t_i}(\beta^*), \beta_{t+1}^{i} - \beta^{*i} \rangle
\]

\[
- \eta_t \langle \nabla F_{t_i}(\beta) - \nabla F_{t_i}(\beta^*) + z_{t_i}^{i*}, \beta_{t+1}^{i} - \beta^{*i} \rangle + \eta_t^2 \mu_{\omega_{t_i}}^{-1} \|\nabla F_{t_i}(\beta) - \nabla F_{t_i}(\beta^*)\|_{t_i}^2
\]

\[
+ \eta_t^2 \mu_{\omega_{t_i}}^{-1} \|z_{t_i}^{i*}\|_{t_i}^2.
\]

From the preceding relation, the definition of the function \( L \), and that \( \beta_{t+1}^{i} = \beta_{t_i}^{i} \) for all \( i \neq i_t \), we have

\[
L(\beta_{t+1}, \beta^*) = \sum_{i \neq i_t} p_{i_t}^{-1} D_{t_i}(\beta_{t+1}^{i}, \beta^{*i}) + p_{i_t}^{-1} D_{t_i}(\beta_{t+1}^{i}, \beta^{*i})
\]

\[
\leq L(\beta, \beta^*) + p_{i_t}^{-1} \left(- \eta_t \langle \nabla F_{t_i}(\beta) - \nabla F_{t_i}(\beta^*) + z_{t_i}^{i*}, \beta_{t+1}^{i} - \beta^{*i} \rangle
\]

\[
- \eta_t \langle \nabla F_{t_i}(\beta^*), \beta_{t+1}^{i} - \beta^{*i} \rangle + \eta_t^2 \mu_{\omega_{t_i}}^{-1} \|\nabla F_{t_i}(\beta) - \nabla F_{t_i}(\beta^*)\|_{t_i}^2
\]

\[
+ \eta_t^2 \mu_{\omega_{t_i}}^{-1} \|z_{t_i}^{i*}\|_{t_i}^2 \right).
\]
Taking conditional expectations from both sides of the preceding relation on $\mathcal{F}_t \cup \{i_t\}$, we get
\[
E[\mathcal{L}(\beta_{t+1}, \beta^*) \mid \mathcal{F}_t \cup \{i_t\}] \leq \mathcal{L}(\beta_t, \beta^*) + p_t^{-1} \eta_t( - \langle \nabla F_{i_t}(\beta^*), \beta_{t+1}^* - \beta_{i_t}^* \rangle \\
+ \langle E[z_t^i \mid \mathcal{F}_t \cup \{i_t\}], \beta_{i_t+1}^* - \beta_{i_t}^* \rangle \\
+ p_t^{-1} \eta_t \langle \nabla F_{i_t}(\beta_t) - \nabla F_{i_t}(\beta^*), \beta_{i_t+1}^* - \beta_{i_t}^* \rangle \\
+ p_t^{-1} \eta_t^2 \mu_{\omega_i}^{-1} \langle \| \nabla F_{i_t}(\beta_t) - \nabla F_{i_t}(\beta^*) \|_{2 i_t}^2 + \nu_{i_t}^2 \rangle.
\]
Assumption 2 implies that $E[z_t^i \mid \mathcal{F}_t] = 0$. Using that and the bound provided in Assumption 2, we obtain
\[
E[\mathcal{L}(\beta_{t+1}, \beta^*) \mid \mathcal{F}_t \cup \{i_t\}] \leq \mathcal{L}(\beta_t, \beta^*) - p_t^{-1} \eta_t( - \langle \nabla F_{i_t}(\beta^*), \beta_{t+1}^* - \beta_{i_t}^* \rangle \\
+ \langle \nabla F_{i_t}(\beta_t) - \nabla F_{i_t}(\beta^*), \beta_{i_t+1}^* - \beta_{i_t}^* \rangle \\
+ p_t^{-1} \eta_t^2 \mu_{\omega_i}^{-1} \langle \| \nabla F_{i_t}(\beta_t) - \nabla F_{i_t}(\beta^*) \|_{2 i_t}^2 + \nu_{i_t}^2 \rangle.
\]

Next, taking expectations with respect to $i_t$, we obtain
\[
E[\mathcal{L}(\beta_{t+1}, \beta^*) \mid \mathcal{F}_t] \leq \mathcal{L}(\beta_t, \beta^*) + \eta_t( - \langle \nabla F(\beta^*), \beta_{t+1} - \beta_t \rangle - \langle \nabla F(\beta^*), \beta_{t+1} - \beta_t \rangle) \\
+ \eta_t^2 \mu_{\omega_i}^{-1} \langle \| \nabla F(\beta_t) - \nabla F(\beta^*) \|_{2 i_t}^2 + \nu_{i_t}^2 \rangle,
\]
where we use the definition of $\langle \cdot, \cdot \rangle$ given in the notation. Using the optimality condition for problem (SO) and under the Lipschitzian property of $\nabla F$ and strong convexity of $F$,
\[
E[\mathcal{L}(\beta_{t+1}, \beta^*) \mid \mathcal{F}_t] \leq \mathcal{L}(\beta_t, \beta^*) - \eta_t \mu_{F} \| \beta_t - \beta^* \|^2 + \eta_t^2 \Omega_{F}^2 \mu_{\omega_i}^{-1} \| \beta_t - \beta^* \|^2 \\
+ \eta_t^2 \sum_{i=1}^t \nu_{i} \mu_{\omega_i}^{-1}.
\]
From the definition of norm $\| \cdot \|$, we can write
\[
\| \beta_t - \beta^* \|^2 = \sum_{i=1}^t \| \beta_t^i - \beta^* \|^2 \geq 2 \sum_{i=1}^t D_i(\beta_t^i, \beta^*) \Omega_{\omega_i}^{-1} \geq 2 \rho_{\lambda} \sum_{i=1}^t p_t D_i(\beta_t^i, \beta^*) \\
= 2 p_{\lambda} \sum_{i=1}^t D_i(\beta_t^i, \beta^*) \Omega_{\omega_i}^{-1} \mu_{\omega_i} \mathcal{L}(\beta_t, \beta^*),
\]
where in the first inequality we used relation (3), and in the last relation we used the definition of function $\mathcal{L}$. Similarly,
\[
\| \beta_t - \beta^* \|^2 \leq 2 \sum_{i=1}^t D_i(\beta_t^i, \beta^*) \mu_{\omega_i} \leq \frac{2 \rho_{\lambda}}{\mu_{\omega_i}} \mathcal{L}(\beta_t, \beta^*),
\]
From the last three relations, we obtain the desired inequality. \qed

Next, we present self-tuned stepsizes for the (RB-GSMD) method and show their properties.

**Proposition 2.** Let $\{\beta_t\}$ be generated by the (RB-GSMD) method. Let the set $\mathcal{B}_i$ be convex and
closed such that \( \|\beta^i\| \leq M_i \) for all \( \beta_i \in \mathcal{B}_i \) and some \( M_i > 0 \). Let Assumption 2 hold for some \( \nu_i > 0 \), and the stepsize \( \eta_t \) be given by

\[
\eta_t^* := \frac{4 \mu F p \lambda L}{\sum_{i=1}^{l} p_i^{-1} \mathcal{L}_{\omega_i} M_i^2},
\]

\[
\eta_t^* := \eta_{t-1} (1 - p \mu F \mathcal{L}_{\max}^{-1} \eta_{t-1}^*), \quad \text{for all } t \geq 1.
\]

Then, the following hold:

(a) The sequence \( \{\beta_t\} \) generated by the (RB-GSMD) method converges a.s. to the unique optimal solution \( \beta^* \) of problem (SO).

(b) For any \( t \geq 1 \), the vector \( (\eta_0^*, \eta_1^*, \ldots, \eta_{t-1}^*) \) minimizes the upper bound of the error \( \mathbb{E}[D_\omega(\beta_t, \beta^*)] \) given in Lemma 5 for all \( (\eta_0, \eta_1, \ldots, \eta_{t-1}) \in \left( 0, \frac{\mathcal{L}_{\max}}{2 \mu F p \lambda} \right) \).

(c) The (RB-GSMD) method attains the convergence rate \( \mathcal{O}(1/t) \), i.e., for all \( t \geq 1 \)

\[
\mathbb{E}[\|\beta_t - \beta^*\|^2] \leq 2 \left( \frac{\mathcal{L}_{\max}}{p \mu F} \right)^2 \left( 4 \frac{\mathcal{L} F_{\omega}^2 p \nu}{\mu_{\min}^2} \sum_{i=1}^{l} p_i^{-1} \mathcal{L}_{\omega_i} M_i^2 + \sum_{i=1}^{l} \frac{2 \nu_i^2}{\mu_{\omega_i}} \right) \frac{1}{t^2}.
\]

(d) Let \( \epsilon \) and \( \rho \) be arbitrary positive scalars and \( T \triangleq \frac{1.5}{\epsilon \rho} \left( \frac{\mathcal{L}_{\max}}{p \mu F} \right)^2 \times \)

\[
\left( \frac{8 \mu F^2 p \nu}{\mu_{\min}^2} \sum_{j=1}^{l} p_j^{-1} \mathcal{L}_{\omega_j} M_j^2 + \sum_{j=1}^{l} \frac{2 \nu_j^2}{\mu_{\omega_j}} \right)
\]

we have for all \( t \geq T \)

\[
\text{Prob}(\mathcal{L}(\beta_j, \beta^*) \leq \epsilon \text{ for all } j \geq t) \geq 1 - \rho.
\]

Proof. Consider relation (20). Taking expectations from both sides and rearranging the terms, we can write

\[
\mathbb{E}[\mathcal{L}(\beta_{t+1}, \beta^*)] \leq (1 - \eta_t 2 \mu F \lambda \mathcal{L}_{\max}^{-1}) \mathbb{E}[\mathcal{L}(\beta_t, \beta^*)] + 2 \eta_t^2 \mathcal{L} F^2 p \nu \mu_{\min}^{-2} \mathbb{E}[\mathcal{L}(\beta_t, \beta^*)]
\]

\[
+ \eta_t^2 \sum_{i=1}^{l} \nu_i^2 \mu_{\omega_i}^{-1}.
\]

From relation (3), and the triangle inequality, we have

\[
\mathcal{L}(\beta_t, \beta^*) \leq \sum_{i=1}^{l} p_i^{-1} \mathcal{L}_{\omega_i} M_i^2 \leq 2 \sum_{i=1}^{l} p_i^{-1} \mathcal{L}_{\omega_i} M_i^2.
\]

From the preceding inequalities, we obtain

\[
\mathbb{E}[\mathcal{L}(\beta_{t+1}, \beta^*)] \leq (1 - \eta_t 2 \mu F \lambda \mathcal{L}_{\max}^{-1}) \mathbb{E}[\mathcal{L}(\beta_t, \beta^*)] + \left( \frac{8 \mu F^2 p \nu}{\mu_{\min}^2} \sum_{i=1}^{l} p_i^{-1} \mathcal{L}_{\omega_i} M_i^2 + \sum_{i=1}^{l} \frac{2 \nu_i^2}{\mu_{\omega_i}} \right) \frac{1}{2} \eta_t^2.
\]

Let us define \( C^2 \triangleq \sum_{i=1}^{l} \mu_{\omega_i}^{-1} C_i^2 \) and \( \bar{C}^2 \) such that \( \bar{C}^2 \triangleq \sum_{i=1}^{l} \mu_{\omega_i}^{-1} C_i^2 \).

Note that the preceding inequality is similar to the relation (7), where \( C^2 \) is replaced by the term \( \bar{C}^2 \). Therefore, the desired results here follow by only substituting \( C^2 \) by \( \bar{C}^2 \) in Proposition 1. It only remains to show that: (i) \( \eta_t^* = \frac{4 \mu F p \lambda \mathcal{L}_{\max}^{-1} \eta_{t-1}^*}{\sum_{i=1}^{l} p_i^{-1} \mathcal{L}_{\omega_i} M_i^2} \), and (ii) the conditions of Proposition 1.
also hold for $\alpha_0$. The relation (i) holds directly from definition of $\eta_0^*$ given by Proposition 2 and the definition of $C$. To show (ii), we need to verify that $\alpha_0 < 1$. From definition of $\alpha_0$ given by (12), we have

$$
\alpha_0 = 2\mu_F p_n \xi_{\max}^{-1} \eta_0^* = 2\mu_F p_n \xi_{\max}^{-1} \times \frac{4\mu_F p_n \sum_{i=1}^l p_i^{-1} \xi_\omega M_i^2}{\xi_{\max} \left( \frac{8\xi_F^2 p_n}{\mu_{\min}} \sum_{i=1}^l p_i^{-1} \xi_\omega M_i^2 + \sum_{i=1}^l \frac{2\xi_\omega^2}{\mu_{\min}} \right)}
$$

$$
= \frac{\mu_F^2 p_n^2}{\xi_{\max}^2} \times \frac{\sum_{i=1}^l p_i^{-1} \xi_\omega M_i^2}{\left( \frac{\xi_F^2 p_n}{\mu_{\min}} \sum_{i=1}^l p_i^{-1} \xi_\omega M_i^2 \right)} = \frac{\mu_F^2 p_n^2 \mu_{\min}^2}{\xi_F^2 p_n \xi_{\max}^2} < 1,
$$

where the last relation follows since $\mu_F \leq \xi_F$ and $\mu_{\omega_i} \leq \xi_\omega$. Therefore, the conditions of Proposition 1 hold for $\alpha_0$ and the desired results follow.

C. Unifying self-tuned stepsizes

Recall that Propositions 1 and 2 provide self-tuned stepsize rules for the case where problem (SO) is nonsmooth and smooth, respectively. These update rules are characterized in terms of problem parameters such as $C_i, \nu_i, \mu_F$ and algorithm settings such as $\mu_{\omega_i}, \xi_\omega$. An important question is how we may employ such self-tuned stepsize rules when some of the problem parameters are not known in advance, or are challenging to estimate? Here, our goal is to develop a unifying class of self-tuned stepsize rules that can be employed in both smooth and nonsmooth cases when some of the problem parameters are unavailable. Assume that $l = 1$.

Let us compare the stepsize rules in Propositions 1 and 2. We observe that although the initial stepsize $\eta_0^*$ is different, both schemes share the same tuning rule. We also observe that the only problem parameter that is needed to be known for the tuning update rule is $\mu_F$. This parameter is known in advance in many applications such as SVM. Note that $\xi_\omega$ is the Lipschitzian parameter associated with the prox mapping and depends on the choice of the distance generating function $\omega$. This function is user-specified. In practice, when problem parameters such as $M, C$, or $\xi_F$ are unavailable or difficult to estimate, the initial stepsize $\eta_0^*$ cannot be evaluated. In such cases one may choose $\eta_0^*$ arbitrarily and still use the update rule $\eta_t^* := \eta_{t-1}^* \left( 1 - (\mu_F / \xi_\omega) \eta_{t-1}^* \right)$. We show that even under this relaxation, some of the main properties of the self-tuned stepsizes are preserved by the following result.

**Theorem 1.** [Unifying self-tuned stepsize rules] Consider problem (SO) with $l = 1$. Let the set $B$ be convex, closed, and bounded. Suppose either of the following cases holds:

- **case (1):** $F$ is non-differentiable and Assumption 1 holds for some unknown $C > 0$. 

case (2): $F$ is continuously differentiable over $B$ for all $\xi$, but $\nabla F$ is not Lipschitz over $B$ and Assumption 2 holds.

case (3): $F$ is differentiable over $B$, it has Lipschitz gradients with an unknown parameter $\Sigma_F$, and Assumption 2 holds.

In cases (1) and (2), let $\{\beta_t\}$ be generated by algorithm (RB-SSMD). In case (3), let $\{\beta_t\}$ be generated by algorithm (RB-GSMD). In all cases, let the stepsize $\eta_t$ be given by $\eta_t = \eta_{t-1} \left(1 - (\mu_F / \Sigma_\omega)\eta_{t-1}\right)$ for all $t \geq 1$, where $0 < \eta_0 \leq \Sigma_\omega / 2\mu_F$ is an arbitrary constant. Then: (i) $\{\beta_t\}$ converges to $\beta^*$ a.s., and (ii) there exists a threshold $\bar{\eta} \leq \Sigma_\omega / 2\mu_F$ such that for any $\eta_0 \leq \bar{\eta}$, an upper bound of the error $E[D_\omega(\beta_t, \beta^*)]$ is minimized for all $(\eta_0, \ldots, \eta_{t-1}) \in (0, \Sigma_\omega / 2\mu_F]^t$.

Proof. First, we show (i) and (ii) hold in case (1). Let $C_{\text{min}}$ denote the minimum of all constants $C > 0$ that satisfy Assumption 1 (note that such a constant always exists). Let $\bar{C} = \max \left\{ C_{\text{min}}, \sqrt{8M^2\mu_\omega\mu_F^2 / \Sigma_\omega} \right\}$ and define $\bar{\eta} = 4\mu_F\mu_\omega M^2 / \bar{C}^2$. Note that $\bar{\eta} \leq \frac{\Sigma_\omega}{2\mu_F}$ from definition of $\bar{C}$. Let $0 < \eta_0 \leq \bar{\eta}$ be an arbitrary scalar and define $C_0 = \bar{C}\sqrt{\bar{\eta}/\eta_0}$. Note that since $C_0 \geq \bar{C} \geq C_{\text{min}}$, $C_0$ satisfies Assumption 1. Also, $C_0^2\Sigma_\omega \geq 8M^2\mu_\omega\mu_F^2$. Therefore, for $\eta_0 = 4\mu_F\mu_\omega M^2 / C_0^2$, we found a $C_0$ such that all conditions of Proposition 1 are met. Then we can apply Proposition 1 which implies that (i) and (ii) hold. Next, consider case (2). Note that since $f$ is continuously differentiable, the set $\partial f(\beta, \xi)$ is a singleton, i.e., $\partial f(\beta, \xi) = \{\nabla f(\beta, \xi)\}$. From compactness of $B$ and continuity of $\nabla f(\cdot, \xi)$, we conclude that Assumption 1 holds for some $C > 0$. Next, in a similar fashion to the proof of case (1), we can conclude that (i) and (ii) hold in case (2). The proof for case (3) can be done by invoking Proposition 2 similar to the proof for case (1). \qed

Remark 2. The unifying stepsize rule minimizes the mean squared error even when problem parameters are unknown. This suggests that self-tuned stepsizes are robust with respect to the choice of the initial stepsize. We will demonstrate this property of the self-tuned stepsizes in our numerical experiments in Section III. This can be seen as an important advantage in contrast with the classical harmonic stepsizes of the form $\left(\frac{a}{t+c}\right)^c$ that have been seen very sensitive to the choice of three parameters $a, b$ and $c$ (cf. [17], Ch. 4).
III. EXPERIMENTAL RESULTS

In this section, we analyze the performance of the self-tuned RBSMD schemes for solving the following soft-margin linear support vector machine problem:

$$\min F(\beta) \triangleq \frac{1}{m} \sum_{i=1}^{m} L(\langle \beta, x_i \rangle, y_i) + \frac{\lambda}{2} \| \beta \|_2^2,$$  (27)

where $L(\langle \beta, x_i \rangle, y_i) \triangleq \max \{0, 1 - y_i \langle \beta, x_i \rangle\}$. SVM is known as an effective classification framework and is applied to real-world applications such as text categorization, image classification, etc. [28]. We use two binary classification data sets namely RCV1 and Skin. The Reuters Corpus Volume I (RCV1) data set [29] is a collection of news-wire stories produced by Reuters journalists from 1996-1997. The articles are categorized into four different classes including Industrial, Economics, Social, and Markets. Here, the samples are documents and the features represent the existence/nonexistence of a given token in an article. We use a subset of the original data set with 199,328 samples and 138,921 features. The goal is to predict whether an article belongs to Markets class or not. Skin segmentation data set classifies each pixel of scan photographs as skin or non-skin texture and is used in face and human detection applications. The goal is identifying the skin-like regions. It consists of 3 features, and 245,057 samples out of which 50,859 are the skin samples and 194,198 are non-skin samples. Note that (27) is a nonsmooth problem

| $\lambda$ | $\eta_0[1]$ | $\eta_0[2] = \frac{\epsilon_0}{\mu_0 F}$ | $\eta_0[3] = \frac{\epsilon_0}{4\mu_0 F}$ |
|-----------|------------|----------------|----------------|
| 0.001     | 0.9        | 100            | 250            |
| 0.01      | 0.9        | 10             | 25             |
| 1         | 0.01       | 0.1            | 0.25           |

and $F$ is strongly convex with parameter $\lambda$. We compare the unifying self-tuned stepsize rule given by Theorem 1 with harmonic stepsizes of the form $\eta_t = \frac{a}{(t+b)}$ where $a$ and $b$ are scalars [17]. Our goal is to compare the sensitivity of the harmonic stepsize rule with different choices of parameters $a$ and $b$, with that of the unifying self-tuned stepsize rule with different initial stepsizes. Let $l = 1$, we set $\omega = \frac{1}{2} \| \beta \|_2^2$ where $\mu_\omega = \Sigma_\omega = 1$. For any fixed value of $\lambda$, we use three different choices of $\eta_0$, all within the interval $(0, \Sigma_\omega / 2\mu_F]$ as assumed in Theorem 1. Initial stepsizes are denoted by $\eta_0[1], \eta_0[2], \text{and } \eta_0[3]$ and are selected according to Table I. For each experiment, the algorithm is run for $T = 10^4$ iterations. Spall [17], pg. 113] considers using $b$
that is about $5 - 10\%$ of the total number of iterations. Accordingly, we choose $b = 0.1T$ and also $b = 0.2T$ which is observed to be a better selection in some of the preliminary experiments. We select $a = \eta_0 b$ in order to start from the same initial stepsize as the self-tuned stepsize. In addition, we compare our proposed scheme with the harmonic stepsize $\eta_0/t$. Figures 1 and 2 demonstrate the performance of these stepsize schemes in terms of logarithm of the averaged objective function $F$. In these plots, the blue and red curves correspond to the harmonic stepsize with parameter $b = 1000$ and $b = 2000$ respectively, and the green curves denote the stepsize $\eta_0/t$. The black curves represent the self-tuned stepsize rule.

We observe in Figures 1 and 2 that the self-tuned stepsize scheme outperforms the harmonic
stepsize in most of the experiments. Importantly, the self-tune stepsize is significantly more robust with respect to (i) the choice of $\lambda$; (ii) the data set; and (iii) the initial value of the stepsize.

\[
\begin{array}{c|c|c|c}
\hline
\eta_0 & \eta_0 = 0.00625 & \eta_0 = 0.0125 & \eta_0 = 0.025 \\
\hline
\hline
\lambda &= 0.001 & \lambda &= 0.01 & \lambda &= 1 \\
\hline
\end{array}
\]

IV. CONCLUDING REMARKS

We consider stochastic optimization problems with strongly convex objective functions. We develop self-tuned stepsize rules for stochastic subgradient and gradient randomized block coordinate mirror descent methods. For each scheme, we prove almost sure convergence and show that under the self-tuned stepsize rules, the error bound of the RBSMD scheme is minimized. In the case that some problem parameters are unknown, we develop a unifying self-tuned update rule for which an error bound of the scheme is minimized for any arbitrary and small enough initial stepsize.
V. APPENDIX

Proof of Lemma 3: (a) To show part (a), we first use induction on \( t \) to show that \( e_t \) satisfies
\[
e_t(\eta_0^*, \eta_1^*, \ldots, \eta_{t-1}^*) = \frac{2\delta}{\theta} \eta_t^*, \quad \text{for all} \ t \geq 0.
\] (28)

Note that it holds for \( t = 0 \) from the definition \( \eta_0^* = \frac{\theta}{2\delta} e r_0 \). Next, let us assume (28) holds for \( t \). From this and relation (10), we have
\[
e_{t+1}(\eta_0^*, \eta_1^*, \ldots, \eta_t^*) = (1 - \theta \eta_t^*)e_t(\eta_0^*, \eta_1^*, \ldots, \eta_{t-1}^*) + \delta \eta_t^{*2} = (1 - \theta \eta_t^*) \frac{2\delta}{\theta} \eta_t^* + \delta \eta_t^{*2}
\]
\[
= \frac{2\delta}{\theta} \eta_t^* \left( 1 - \theta \eta_t^* + \frac{\theta \eta_t^*}{2} \right) = \frac{2\delta}{\theta} \eta_t^* \left( 1 - \frac{\theta \eta_t^*}{2} \right) = \frac{2\delta}{\theta} \eta_{t+1}^*,
\]
where in the last equation, we used the definition of \( \eta_{t+1}^* \). This implies that relation (28) holds for \( t + 1 \) and therefore, for any \( t \geq 0 \). We now use induction on \( t \) to prove that \((\eta_0^*, \eta_1^*, \ldots, \eta_{t-1}^*)\) minimizes \( e_t \) for all \( t \geq 1 \). By the definition of \( er_1 \) and the relation \( er_1(\eta_0^*) = \frac{2\delta}{\theta} \eta_1^* \) shown previously, we have
\[
er_1(\eta_0) - er_1(\eta_0^*) = (1 - \theta \eta_0)er_0 + \delta \eta_0^2 - \frac{2\delta}{\theta} \eta_1^*.
\]

Therefore, using relation \( \eta_1^* = \eta_0^* \left( 1 - \frac{\theta}{2\delta} \eta_0^* \right) \) and \( \eta_0^* = \frac{\theta}{2\delta} e r_0 \), we can write
\[
er_1(\eta_0) - er_1(\eta_0^*) = (1 - \theta \eta_0) \frac{2\delta}{\theta} \eta_0^* + \delta \eta_0^2 - \frac{2\delta}{\theta} \eta_0^* \left( 1 - \frac{\theta \eta_0^*}{2} \right) = \delta(\eta_0 - \eta_0^*)^2.
\]

This implies that part (a) holds for \( t = 1 \). In the rest of the proof, for the sake of simplicity, we use \( e_{t+1} \) for an arbitrary vector \((\eta_0, \eta_1, \ldots, \eta_t) \in U_{t+1} \) and \( e_{t+1}^* \) for \( e_{t+1} \) evaluated at \((\eta_0^*, \eta_1^*, \ldots, \eta_t^*)\). Now suppose part (a) holds for some \( t \geq 1 \) implying that \( e_t \geq e_t^* \) holds for any \((\eta_0, \eta_1, \ldots, \eta_{t-1}) \in U_1 \). Using (10) and (28), we have
\[
e_{t+1} - e_{t+1}^* = (1 - \theta \eta_t) e_t + \delta \eta_t^2 - \frac{2\delta}{\theta} \eta_{t+1}^*.
\]

Using \( e_t \geq e_t^* \), relation (28), the definition of \( \eta_{t+1}^* \) and that \( \eta_t \leq \frac{1}{\theta} \), we get
\[
e_{t+1} - e_{t+1}^* \geq (1 - \theta \eta_t) \frac{2\delta}{\theta} \eta_t^* + \delta \eta_t^2 - \frac{2\delta}{\theta} \eta_t \left( 1 - \frac{\theta \eta_t}{2} \right) = \delta(\eta_t - \eta_t^*)^2.
\]

Therefore, part (a) holds for \( t + 1 \). We conclude that the result of part (a) is true for any \( t \geq 1 \).

(b) Using the recursive relation \( \eta_{t+1}^* = \eta_t^* \left( 1 - \frac{\theta}{2\delta} \eta_t^* \right) \), we have
\[
\frac{1}{\eta_{t+1}} = \frac{1}{\eta_t \left( 1 - \frac{\theta}{2\delta} \eta_t \right)} = \frac{1}{\eta_t} + \frac{\theta}{2} \frac{1}{1 - \frac{\theta}{2\delta} \eta_t}, \quad \text{for all} \ t \geq 0.
\]

Summing up from \( t = 0 \) to \( k \) and canceling the common terms from both sides, we obtain
\[
\frac{1}{\eta_{k+1}} = \frac{1}{\eta_0} + \frac{\theta}{2} \sum_{t=0}^{k} \frac{1}{1 - \frac{\theta}{2\delta} \eta_t} > \frac{\theta}{2} \sum_{t=0}^{k} \frac{1}{1 - \frac{\theta}{2\delta} \eta_t}.
\] (29)

Note that from the definition of \( \eta_0^* \) and \( er_0 \), we have \( 0 < \eta_0^* \leq \frac{1}{\theta} \). From relation \( \eta_t^* = \)
we have \( \eta_{t-1}^* \left(1 - \frac{\theta}{2} \eta_{t-1}^* \right) \) we have \( 0 < \eta_t^* \leq \frac{1}{\theta} \) for all \( t \geq 0 \). Consequently, the term \( 1 - \frac{\theta}{2} \eta_t^* \) is a number between zero and one. Therefore, \( \left(1 - \frac{\theta}{2} \eta_t^* \right)^{-1} > 1 \) which implies that \( \sum_{t=0}^{k} \left(1 - \frac{\theta}{2} \eta_t^* \right)^{-1} > k+1 \). Therefore, using relation (29), for all \( k \geq 1 \) we have \( \eta_k^* < \frac{2}{\theta k} \). Combining inequality (28) and the preceding inequality, we obtain the desired result.

(c) First, we show \( \sum_{t=0}^{\infty} \eta_t^* = \infty \). From \( \eta_t^* = \eta_{t-1}^* \left(1 - \frac{\theta}{2} \eta_{t-1}^* \right) \) for all \( t \geq 0 \), we obtain

\[
\eta_{t+1}^* = \eta_0^* \prod_{i=0}^{t} \left(1 - \frac{\theta}{2} \eta_i^* \right).
\]

(30)

Note that since \( \eta_0^* \in (0, \frac{1}{\theta}] \), from \( \eta_t^* = \eta_{t-1}^* \left(1 - \frac{\theta}{2} \eta_{t-1}^* \right) \) it follows that \( \{\eta_t^*\} \) is positive non-increasing sequence. Therefore, the limit \( \lim_{t \to \infty} \eta_t^* \) exists and it is less than \( \frac{2}{\theta} \). Thus, by taking the limits from both sides in \( \eta_t^* = \eta_{t-1}^* \left(1 - \frac{\theta}{2} \eta_{t-1}^* \right) \), we obtain \( \lim_{t \to \infty} \eta_t^* = 0 \). Then, by taking limits in (30), we further obtain

\[
\lim_{t \to \infty} \prod_{i=0}^{t} \left(1 - \frac{\theta}{2} \eta_i^* \right) = 0.
\]

To arrive at a contradiction, suppose that \( \sum_{t=0}^{\infty} \eta_t^* < \infty \). Then, there is an \( \epsilon \in (0, 1) \) such that for \( j \) sufficiently large, we have \( \frac{\theta}{2} \sum_{i=j}^{t} \eta_i^* \leq \epsilon, \) for all \( t \geq j \). Since \( \prod_{i=j}^{t} \left(1 - \frac{\theta}{2} \eta_i^* \right) \geq 1 - \frac{\theta}{2} \sum_{i=j}^{t} \eta_i^* \), for all \( j < t \), by letting \( t \to \infty \), we obtain for all \( j \) sufficiently large,

\[
\prod_{i=j}^{\infty} \left(1 - \frac{\theta}{2} \eta_i^* \right) \geq 1 - \frac{\theta}{2} \sum_{i=j}^{\infty} \eta_i^* \geq 1 - \epsilon > 0.
\]

This contradicts the statement \( \lim_{t \to \infty} \prod_{i=0}^{t} \left(1 - \frac{\theta}{2} \eta_i^* \right) = 0 \). Hence, we conclude that \( \sum_{t=0}^{\infty} \eta_t^* = \infty \). Next, we show that \( \sum_{t=0}^{\infty} \eta_t^{*2} < \infty \). From \( \eta_t^* = \eta_{t-1}^* \left(1 - \frac{\theta}{2} \eta_{t-1}^* \right) \) we have

\[
\eta_t^* = \eta_{t-1}^* - \frac{\theta}{2} \eta_{t-1}^{*2}, \quad \text{for all } i \geq 1.
\]

Summing the preceding relation from \( i = 0 \) to \( t \) and canceling the common terms, we obtain

\[
\eta_t^* = \eta_0^* - \frac{\theta}{2} \sum_{i=0}^{t-1} \eta_i^{*2}, \quad \text{for all } t \geq 1.
\]

By taking limits and recalling that \( \lim_{t \to \infty} \eta_t^* = 0 \), we obtain the desired result.
