Chiral crystals in strong-coupling lattice QCD
at nonzero chemical potential

Abstract

We study the effective action for strong-coupling lattice QCD with one-component staggered
fermions in the case of nonzero chemical potential and zero temperature. The structure of this
action suggests that at large chemical potentials its ground state is a crystalline ‘chiral density
wave’ that spontaneously breaks chiral symmetry and translation invariance. In mean-field theory,
on the other hand, we find that this state is unstable. We show that lattice artifacts are partly
responsible for this, and suggest that if this phase exists in QCD, then finding it in Monte-Carlo
simulations would require simulating on relatively fine lattices. In particular, the baryon mass in
lattice units, $m_B$, should be considerably smaller than its strong-coupling limit of $m_B \sim 3$.

I. INTRODUCTION

The idea that the ground state of QCD at zero temperature and nonzero chemical potential can spontaneously break translation invariance was first suggested by Deryagin, Grigoriev and Rubakov (DRG) \[1\]. They studied large-$N$ QCD at weak coupling, and showed that the four-quark interaction, that is generated by a single gluon exchange, causes an instability in the quark Fermi sea toward the creation of a condensate of the form

\[
\langle \bar{\psi}(x)\psi(x) \rangle \sim \cos(2 \vec{Q} \cdot \vec{x}).
\]  

(1.1)

Here the wave vector $\vec{Q}$ has an arbitrary direction but its modulus is given by the Fermi momentum of the quarks

\[ Q = p_F. \]  

(1.2)

This phenomenon is often referred to as chiral density waves, and has famous solid-state counterparts like the one-dimensional Peierls instability \[2\], and the spin density wave of the Overhauser effect \[3\].

The large-$N$ result of \[1\] was consequently found to be misleading \[4, 5\], and Shust er and Son showed in \[4\] that if $N$ is decreased from infinity to $N < O(1000)$, then color-superconductivity becomes preferable over the DGR state. Nonetheless, the authors in \[6\] studied what may happen at lower densities (for $N = 3$), where weak coupling treatments are less reliable \[7\]. The conclusion of \[6\] was that chiral density waves may still be competitive with superconductivity, especially when one uses an instanton vertex to couple the quarks.

Recently, there has been related progress in the Gross-Neveu model. This 1+1 model can be studied in large-$N$, and its phase structure in the temperature-density plane was known to have a line of first order transitions that separate a low density phase with spontaneously broken chiral symmetry, and a high density phase, where this symmetry is intact. This structure arises when one restricts to an $x$-independent ansatz for $\langle \bar{\psi}(x)\psi(x) \rangle$ and was recently revisited in \[8\] (and later with a lattice regularisation in \[9\]), where the condensate was allowed to depend on the spatial coordinate of $x$. The study in \[8\] discovered a new phase at low temperatures and high densities, which is separated by a second order phase transition from the low density phase, and where the chiral condensate has a crystalline structure. This crystal structure was also seen in the ‘t Hooft model \[10\], and is reminiscent of results from older work in the Skyrme model \[11\].
In this paper we look for a phase with chiral density waves using an effective action that is derived from the strong-coupling expansion of lattice QCD. Apart from a phenomenological interest in this model, and in the way it may expose the phase we are after, we are also motivated by the following, more practical, reason. Future Monte-Carlo simulations of QCD at low temperatures and large chemical potentials, that will manage to control the sign problem, will presumably start by simulating relatively coarse lattices with strong couplings. This makes the knowledge on the phase diagram of the strong-coupling limit important, and in our context it is desirable to know whether one should expect a crystal phase, and if so, at which values of the chemical potential $\mu$.

Indeed, numerous authors have analytically investigated the phase diagram of the strong-coupling limit (for reviews see [12, 13]), but the possibility to have chiral density waves was never considered, and these works were always restricted to homogeneous field configurations.

Here we relax this constraint for the first time. To do so, we choose to work with one-component staggered fermions. In four dimensions, these lattice fermions describe four degenerate continuum Dirac fermions, commonly referred to as tastes. The continuum theory has an $SU(4) \times SU(4)$ chiral symmetry, that explicitly breaks on the lattice to the following axial taste non-singlet $U(1)$

$$\psi \rightarrow \exp (i \theta \gamma_5 \otimes \xi_5) \psi, \quad \bar{\psi} \rightarrow \bar{\psi} \exp (i \theta \gamma_5 \otimes \xi_5).$$

(1.3)

Here $\xi_5$ is a $4 \times 4$ traceless matrix that operates in taste space, and that can be chosen to have the same matrix elements of $\gamma_5$. The ground state that we study in this paper is characterised by the helical condensates

$$\langle \bar{\psi}(x) \psi(x) \rangle \sim \cos \left(2\vec{Q} \cdot \vec{x}\right),$$

(1.4)

$$\langle \bar{\psi}(x) (i \gamma_5 \otimes \xi_5) \psi(x) \rangle \sim \sin \left(2\vec{Q} \cdot \vec{x}\right),$$

(1.5)

that spontaneously break the chiral symmetry of Eq. (1.3) as well as translation invariance. Note that Eqs. (1.4)–(1.5) cannot be rotated by a global transformation to have $\langle \bar{\psi}(x) (\gamma_5 \otimes \xi_5) \psi(x) \rangle = 0$. This means that if we regard the continuum limit as a theory of four degenerate light quarks, then our chiral waves break $SU(4)$ flavor. As a result, we are studying a ground state which is closer to the one studied in [14] than to the original DGR state, which is a flavor singlet.
The reason we choose this particular type of lattice fermions is that, in the strong-coupling limit, they give rise to a very simple effective action in terms of hadrons. This action was derived some time ago by Hoek, Kawamoto, and Smit [15], and in the next section we re-derive it for self-completeness. After discussing why it is natural to expect chiral density waves in the ground state of this action (at nonzero $\mu$), we formulate in Section III a mean-field theory that is general enough to allow for such chiral waves to emerge. The mean-field equations are solved in Section IV where we also investigate how the mean-field ground state evolves when we increase $\mu$. We conclude in Section V with a few remarks on the implications of this work and on future prospects. Appendix A includes technical details related to the calculation of the mean-field equations and the mean-field free energy.

II. THE EFFECTIVE ACTION

In this section we follow the work of Hoek, Kawamoto, and Smit (HKS) [15], and re-derive their effective action. Readers who are familiar with [15] can proceed to Section II B, where we discuss the structure of the effective action, and why it is natural to expect a chiral density wave in its ground state at nonzero $\mu$.

A. Deriving the Hoek-Kawamoto-Smit action for hadrons

The starting point is the strong-coupling limit of an $SU(N)$ lattice gauge theory with one-component staggered fermions. The action in this case is

$$S = -\frac{1}{2} \sum_{n,\nu} \left[ \bar{\chi}_n \eta_{\nu\nu} U_{\nu\nu} \chi_{n+\hat{\nu}} - \bar{\chi}_{n+\hat{\nu}} \eta_{\nu\nu}^{1/2} U_{\nu\nu} \chi_n \right] + \sum_n \left[ NJ_n M_n + \bar{c}_n B_n + B_n c_n \right], \quad (2.1)$$

where $n = (n_0, n_1, \ldots, n_d)$ is an Euclidean lattice index and $\nu = 0, 1, 2, \ldots, d$ is the direction index ($d$ is the number of spatial dimensions). The fields $\chi$ and $\bar{\chi}$ are independent Grassmann variables and $U_{\nu\nu}$ is an $SU(N)$ matrix that represents the gauge fields. The factors $\eta_{\nu\nu}$ are the Kogut-Susskind factors that give the fermions their Dirac structure

$$\eta_{\nu\nu} = \begin{cases} e^\mu & \nu = 0, \\ (-1)^{n_0+n_1+\ldots+n_{\nu-1}} & \nu \in [1, d], \end{cases} \quad (2.2)$$
and here $\mu \geq 0$ is the quark chemical potential in units of the lattice spacing $a$. The source terms $J, c,$ and $\bar{c}$ couple to the following meson and baryon fields

$$M_n = \frac{1}{N} \sum_{a=1}^{N} \chi_{n,a} \bar{\chi}_{n,a},$$
$$B_n = \chi_{n,1} \chi_{n,2} \cdots \chi_{n,N},$$
$$\bar{B}_n = \bar{\chi}_{n,N} \bar{\chi}_{n,N-1} \cdots \bar{\chi}_{n,1},$$

and as indicated here, the only internal index that $\chi_n$ and $\bar{\chi}_n$ carry, is the color index $a = 1, \ldots, N$. This leads to significant simplifications compared to the flavoured case, because it means that $(M_n)^k = 0$ for $k > N$, and $(B_n)^k = (\bar{B}_n)^k = 0$ for $k > 1$.

Since the plaquette term is absent in Eq. (2.1), one can readily integrate over the $SU(N)$ link matrices. This is performed by link and the result is

$$Z(J, c, \bar{c}) = \int D\bar{\chi} D\chi DU \exp S = \int D\bar{\chi} D\chi \exp S_1(M, B, \bar{B}),$$
$$S_1 = \sum_n \left\{ NF_N(M_n M_{n+\hat{\nu}}) - \frac{2^{-N+1}}{2} \left[ \bar{B}_n(\eta_{n\nu})^N B_{n+\hat{\nu}} - B_{n+\hat{\nu}}(\eta_{n\nu})^{-N} B_n \right] \right\} + \sum_n \left\{ NJ_n M_n + \bar{c}_n B_n + \bar{B}_n c_n \right\}. \quad (2.4)$$

Here the function $F_N$ is known for several values of $N$, and in particular, for $SU(3)$, it is

$$F_3(u) = \frac{1}{4} u + \frac{3}{64} u^2 - \frac{15}{256} u^3. \quad (2.5)$$

The next step is to write $Z$ as a path integral over color-singlet fields. This is accomplished by first writing

$$Z = \exp \left[ S_1(\frac{1}{N} \partial_J, -\partial_c, \partial_{\bar{c}}) \right] Z_0, \quad \text{(2.6)}$$
$$Z_0 = \int D\bar{\chi} D\chi \exp \left\{ \sum_n \left[ NJ_n M_n + \bar{B}_n c_n + \bar{c}_n B_n \right] \right\}. \quad \text{(2.7)}$$

Performing the integral over $\chi$ and $\bar{\chi}$ results in (here we assume that $N$ is odd)

$$Z_0 = \prod_n \left[ J_n^N + \bar{c}_n c_n \right], \quad \text{(2.8)}$$

that can be written as

$$Z_0 = \int D\bar{b} Db Dm \exp \left\{ \sum_n \left[ -d_N \bar{b}_n m_n^{-N} b_n + NJ_n m_n + \bar{c}_n b_n + \bar{b}_n c_n \right] \right\}, \quad \text{(2.9)}$$
with $d_N = N! / N^N$. Here $b_n$ and $\bar{b}_n$ are Grassmann variables, and the field $m_n = e^{i\theta_n}$ takes values on the unit circle and has the measure

$$
\int dm_n \equiv \oint \frac{dm_n}{2\pi i m_n} = \int_{-\pi}^{\pi} \frac{d\theta_n}{2\pi}.
$$

We are now ready to apply Eq. (2.6) and doing so one obtains (setting $J = c = \bar{c} = 0$, and replacing $b \rightarrow -2^{N-1}b$)

$$
Z = \int D\bar{b} Db Dm \exp(S_{\text{HKS}}),
$$

$$
S_{\text{HKS}} = S_{\text{Meson}} + S_{\text{Baryon}} + S_I,
$$

$$
S_{\text{Meson}} = \sum_{n} N F_N (m_n m_{n+\hat{\nu}}),
$$

$$
S_{\text{Baryon}} = \sum_{nm} \bar{b}_n D_{nm} b_m,
$$

$$
S_I = \sum_{n} \bar{b}_n b_n \left(2^{N-1} d_N m_n^{-N}\right).
$$

Here $D$ is the massless Dirac operator of a free one-component staggered fermion whose chemical potential is equal to $N\mu$,

$$
D_{n,m} = \frac{1}{2} \left\{ \left[ \delta_{m,n+\hat{0}} e^{N\mu} - \delta_{m,n-\hat{0}} e^{-N\mu} \right] + \sum_{\nu} \eta_{n\nu} \left[ \delta_{m,n+\hat{\nu}} - \delta_{m,n-\hat{\nu}} \right] \right\}.
$$

Since the composite fields $M_n$, $B_n$, and $\bar{B}_n$ in Eq. (2.1) couple to the same currents as $m_n$, $b_n$, and $\bar{b}_n$ of $S_{\text{HKS}}$ (see Eq. (2.9)), then their correlation functions are the same. This means that the fields $b_n$ and $m_n$ represent the baryons and mesons respectively. Their hopping on the lattice is described by $S_{\text{Baryon}}$ and $S_{\text{Meson}}$, while the latter also describes meson-meson interactions. Interactions between mesons and baryons are described by the Yukawa-like vertex $S_I$, which in terms of quarks, represents a rearrangement of $N$ quark-antiquark pairs into a single baryon-antibaryon pair.

### B. Chiral density waves from $S_{\text{HKS}}$?

The purpose of this section it is to show why it is natural to expect that chiral density waves emerge from $S_{\text{HKS}}$ (Eq. (2.12)). We begin with Section II B 1 by formulating the chiral wave ansatz of Eqs. (1.4)-(1.5) in terms of the fields that appear in $S_{\text{HKS}}$, and proceed to Section II B 2 where we explain the mechanism by which these waves can arise.
1. The chiral density wave ansatz with staggered fermions

We begin with constructing the condensates in Eqs. (1.4)–(1.5). To do so we define a new lattice with spacing \(a = 2\) that has \(2^{d+1}\) sites in its unit cell (This is the lattice of hyper-cubes used to define the taste basis \([19]\)). The original lattice coordinate \(n\) is related to the new one \(X\) by
\[
n = 2X + \rho, \tag{2.17}
\]
where the \((d + 1)\)-dimensional vector \(\rho\) has \(\rho_\nu = 0, 1\), and denotes the internal sites in the unit cell. The mean-field ansatz that we study in this paper is
\[
\langle \left( \frac{\bar{\chi}_n \chi_n}{N} \right)^q \rangle = \langle (m_n)^q \rangle = V_q e^{iq\vec{Q} \cdot \vec{\epsilon}_n}, \quad q = 1, 2, \ldots, N. \tag{2.18}
\]
where the sign factor \(\epsilon_n\) is given by
\[
\epsilon_n = (-1)^{\sum_{\nu=0}^{d} \rho_\nu} = \begin{cases} +1 & \text{even site} \\ -1 & \text{odd site} \end{cases}. \tag{2.19}
\]
The appearance of this sign factor in the phases of the condensates realises the helical structure of Eqs. (1.4)–(1.5) in the staggered formalism. To see this, we transform to taste basis with the unitary transformation \(U\) \([19]\)
\[
\bar{\chi}_\rho(X) \equiv \sum_{\alpha=1}^{2^{d/2}} \sum_{f=1}^{2^{d/2}} (U^\dagger)_{\rho,(\alpha,f)} \psi_{\alpha,f}(X), \tag{2.20}
\]
\[
\bar{\chi}_\rho(X) \equiv \sum_{\alpha=1}^{2^{d/2}} \sum_{f=1}^{2^{d/2}} \bar{\psi}_{\alpha,f}(X)U_{(\alpha,f),\rho}, \tag{2.21}
\]
\[
U_{(\alpha,f),\rho} = N_0 \left( D \prod_{\nu=1}^{D/2} \gamma^{\rho_\nu}_{\nu} \right)_{\alpha,f}. \tag{2.22}
\]
Here \(D = d + 1\) is the number of spacetime dimensions, which we restrict to \(D = 1 + 1\) or \(D = 3 + 1\). The indices \(\alpha\) and \(f\) are identified with the Dirac and taste indices respectively, and \((\alpha, f)\) is a composite index that takes \(2^D\) values. The normalisation \(N_0\) is a chosen to have \(U^\dagger U = 1\), and the matrices \(\gamma_\mu\) are the Euclidean Dirac matrices.\(^1\) Using Eqs. (2.20)–(2.22) and the fact that the sign factor \(\epsilon_n\) depends only on \(\rho\),
\[
\epsilon_n = \epsilon_{2X+\rho} = (-1)^{\sum_\nu \rho_\nu} \equiv \epsilon_\rho. \tag{2.23}
\]
\(^1\) In \(d = 1\) we choose \((\gamma_0, \gamma_1, \gamma_3)\) to be the Pauli matrices \((\sigma_z, \sigma_y, \sigma_x)\), and in \(d = 3\) we use the convention of \([19]\).
we can write
\[\sum_{\rho} \langle \bar{\chi}_\rho (X) \chi_\rho (X) \rangle = \sum_{\alpha,f} \langle \bar{\psi}_{\alpha,f} (X) \psi_{\alpha,f} (X) \rangle \equiv \langle \bar{\psi} (X) \psi (X) \rangle, \quad (2.24)\]
\[\sum_{\rho} \langle \bar{\chi}_\rho (X) i \epsilon_\rho \chi_\rho (X) \rangle = i \sum_{\alpha',f'} \langle \bar{\psi}_{\alpha,f} (X) (\gamma_5)_{\alpha\alpha'} (\xi_5)_{f'f} \psi_{\alpha',f'} (X) \rangle \equiv \langle \bar{\psi} (X) i (\gamma_5 \otimes \xi_5) \psi (X) \rangle. \quad (2.25)\]

Here \(\gamma_5\) and \(\xi_5\) have the same matrix elements, and act in Dirac and taste space respectively. Substituting Eq. (2.18) in the left hand side of Eqs. (2.24)–(2.25) and using Eq. (2.23) gives
\[\langle \bar{\psi} (X) \psi (X) \rangle = A \cos \left( 2 \vec{Q} \cdot \vec{X} + \phi \right), \quad (2.26)\]
\[\langle \bar{\psi} (X) (i \gamma_5 \otimes \xi_5) \psi (X) \rangle = -A \sin \left( 2 \vec{Q} \cdot \vec{X} + \phi \right), \quad (2.27)\]
with
\[\phi \equiv \frac{1}{2} \sum_{\nu=1}^{d} Q_\nu, \quad (2.28)\]
\[A \equiv 2V_1 \left\{ \begin{array}{ll}
\cos \left( \frac{1}{2} Q_1 \right) & d = 1 \\
\cos \phi + \sum_{\nu=1}^{3} \cos \left( \frac{1}{2} Q_\nu - \frac{1}{2} \sum_{\mu \neq \nu} Q_\mu \right) & d = 3
\end{array} \right., \quad (2.29)\]
By performing the chiral rotation of Eq. (1.3) with \(\theta = \phi/2\) we get rid of the angle \(\phi\) in the arguments of the sine and cosine functions in Eqs. (2.26)–(2.27), and obtain the assured helical structure of Eqs. (1.4)–(1.5).

2. The mechanism of the chiral density wave instability

We now proceed to show that the Yukawa-like interaction, \(S_I\), can make the state characterised by Eq. (2.18) become the ground state of \(S_{\text{HKS}}\) (Eq. (2.12)) at \(\mu > 0\). For simplicity, we consider the \(d = 1\) case only.

In the absence of \(S_I\), the baryons behave like free massless fermions, and it is straightforward to show that the poles of the propagator \(D^{-1}\) of Eq. (2.14) are determined in momentum space by
\[0 = \left[ \sin^2 (p_0/2 - i\mu N) + \sin^2 (p_1/2) \right]^2 \; ; \; -\pi \leq p_{0,1} \leq +\pi. \quad (2.30)\]
Eq. (2.30) tells us that \(S_{\text{Baryon}}\) describes the four energy bands
\[\sinh E_0^{(1),(2)} (p_1) = +|\sin (p_1/2)|, \quad (2.31)\]
\[\sinh E_0^{(3),(4)} (p_1) = -|\sin (p_1/2)|, \quad (2.32)\]
with $p_1 \in [-\pi, +\pi]$, and that the Fermi energy and Fermi momentum of the baryons are

$$E_F = \mu N,$$

$$\sin p_F/2 = \sinh N\mu.$$  \hfill (2.33)

To take $S_I(b, \bar{b}, m)$ into account we use mean-field theory, and replace the meson fields by their condensates. In the next section we find that with the mean-field ansatz of Eq. (2.18) we should replace $S_I$ with

$$S_I^{\text{mean-field}} \equiv \sum_n \bar{b}_n b_n \left( \Sigma e^{-iNQ n_1 \epsilon_n} \right),$$  \hfill (2.35)

where the amplitude $\Sigma$ is a complicated function of the amplitudes $V_1, 2, \ldots, N$ from Eq. (2.18). In terms of the lattice coordinates of the new lattice Eq. (2.35) becomes

$$S_I^{\text{mean-field}} = \sum_{X\rho} \bar{b}_\rho(X) b_\rho(X) \left( \Sigma e^{-iNQ(2X_1 + \rho_1)\epsilon_\rho} \right),$$  \hfill (2.36)

where we defined $b_n = b_{2X+\rho} \equiv b_\rho(X)$ and similarly for $\bar{b}$.

Clearly, $S_I^{\text{mean-field}}$ mixes baryons whose momenta differ by the amount $\delta p_1 = 2NQ$. The strongest effect will occur between baryons that in the absence of $S_I$ are degenerate in energy, and in particular, this mixing can occur between the bands $E^{(1)}$ and $E^{(2)}$ of Eq. (2.31). This will lead to level repulsion, and to the opening of a gap in the spectrum. To see this explicitly we move to momentum space with

$$b_\rho(X) = \sqrt{\frac{4}{N_s}} e^{-i\epsilon_\rho NQ(2X_1 + \rho_1)/2} \sum_p e^{+ipX} b_\rho(p),$$  \hfill (2.37)

$$\bar{b}_\rho(X) = \sqrt{\frac{4}{N_s}} e^{-i\epsilon_\rho NQ(2X_1 + \rho_1)/2} \sum_p e^{-ipX} \bar{b}_\rho(p).$$  \hfill (2.38)

Note that Eqs. (2.37)–(2.38) are not a usual Fourier transform, because they give the field $b_\rho(p)$ a momentum that differs from the momentum of $\bar{b}_\rho(p)$ by an amount $\delta p_1 = 2NQ\epsilon_\rho$. This makes $S_I^{\text{mean-field}}$ diagonal in $p$ space, and we find that the contributions of the baryons to $S_{\text{HKSy}}$ are given by

$$S_{\text{Baryon}} + S_I^{\text{mean-field}} \equiv \sum_{p\rho\rho'} \bar{b}_\rho(p) K_{\rho\rho'}(p) b_{\rho'}(p),$$  \hfill (2.39)

Note that Eqs. (2.37)–(2.38) are not a usual Fourier transform, because they give the field $b_\rho(p)$ a momentum that differs from the momentum of $\bar{b}_\rho(p)$ by an amount $\delta p_1 = 2NQ\epsilon_\rho$. This makes $S_I^{\text{mean-field}}$ diagonal in $p$ space, and we find that the contributions of the baryons to $S_{\text{HKSy}}$ are given by

$$S_{\text{Baryon}} + S_I^{\text{mean-field}} \equiv \sum_{p\rho\rho'} \bar{b}_\rho(p) K_{\rho\rho'}(p) b_{\rho'}(p),$$  \hfill (2.39)

2 Although we insert identical phases of $\epsilon_\rho NQ(2X_1 + \rho_1)/2$ into Eq. (2.37) and Eq. (2.38), the transform between $X$-space and $p$-space still has a unit determinant due to the sign factor $\epsilon_\rho$. (On a lattice with an even number of sites in each direction).
where the Dirac operator $K$ is

$$K_{\rho \rho'}(p) = \left[ \Gamma_0 \sin \left( p_0 / 2 - i \mu N \right) + \Gamma_1 \sin \left( p_1 / 2 + \hat{\epsilon} Q N / 2 \right) + \Sigma 1 \right]_{\rho \rho'} .$$

(2.40)

Here

$$\langle \epsilon \rangle_{\rho \rho'} \equiv \epsilon_\rho \delta_{\rho \rho'},$$

(2.41)

$$\langle \Gamma_\nu \rangle_{\rho \rho'} \equiv \tilde{\eta}_\nu \left( \delta_{\rho \rho'} + \delta_{\rho' \rho} + \hat{\nu} \frac{p_1}{2} \right) e^{i p (\rho - \rho') / 2},$$

(2.42)

with $\tilde{\eta}_0 = 1$ and $\tilde{\eta}_1 = (-1)^{\rho_0}$. Using the methods of Appendix A it is easy to calculate the determinant of $K(p)$, extract its roots, and find that the four energy levels in Eqs. (2.31)–(2.32) are modified to two positive energies,

$$\sinh E_\pm = \pm \left| \sqrt{\Sigma^2 + \sin^2(p_1 / 2) \cos(NQ / 2)} \pm \cos(p_1 / 2) \sin(NQ / 2) \right|,$$

(2.43)

and two negative energies $\bar{E}_\pm = -E_\pm$. We plot $E_\pm$ in Fig. 1, where we choose $\Sigma = Q = 0$ (black solid lines), $\Sigma = 0.1$ and $NQ = \pi/4$ (dashed blue lines), and $\Sigma = 0.1$ and $Q = 0$ (dotted green lines). Note that the case with $\Sigma = 0$ corresponds to the absence of $S_I$ and the band structure should not depend on $Q$. Indeed, from Eq. (2.43) we see that if $\Sigma = 0$ the energies $E_\pm$ reduce to $E^{(1)/(2)}$ (up to a shift of $\pm NQ$ from the origin, that can be removed by redefining the Brillouin Zone).

Next, consider the following choice of the wave-vector $Q$

$$NQ = p_F.$$  

(2.44)

Together with Eq. (2.34) and Eq. (2.31), this identifies the dashed-dotted horizontal line of Fig. 1 with the Fermi level Eq. (2.33), in which case the effect of the level repulsion is to lower all the energies in the Fermi sea (see dashed blue line in Fig. 1). This decreases the baryon contribution to the free energy of the system with respect to the $\Sigma = 0$ case. In contrast, if we choose $Q = 0$ then $S_I$ is a simple mass term that makes

$$\sinh E_\pm = \sqrt{\Sigma^2 + \sin^2(p_1 / 2)},$$

(2.45)

and increases the energy of the Fermi sea (see dotted green line in Fig. 1). As a result, if we denote the contribution of the baryons to the free energy by $\mathcal{E}_B(\Sigma, Q)$ then

$$\mathcal{E}_B(\Sigma, p_F/N) < \mathcal{E}_B(0, 0) < \mathcal{E}_B(\Sigma, 0),$$

(2.46)
FIG. 1: Dispersion relations $E_{\pm} : \Sigma = Q = 0$ (black solid lines), $\Sigma = 0.1$ and $NQ = \pi/4$ (dashed blue lines), and $\Sigma = 0.1$, and $Q = 0$ (dotted green lines). Note that the solid and dotted lines have been shifted $\pm QN$ from the origin, so that they have the same abscissa as the dashed lines. With these shifts the level repulsion occurs at $p_1 = 0$, where the $\Sigma = 0$ energy bands are degenerate with $E_+ = E_- = \sin(QN/2)$.

and so, for $\mu > 0$, the Fermi sea energetically prefers that the condensates in Eqs. (2.18) carry a nonzero momentum $Q$.

In the discussion above we have ignored many details. Firstly, we addressed only $d = 1$, where both the Fermi sphere and the gap occur at single points that can always be made to coincide. For $d > 1$, the Fermi sphere is a curved surface, and it is not assured that one can find a wave $\vec{Q}$ that will change the energy bands such that all the energies in the Fermi sea are pushed down. Indeed, it is known in condensed matter physics that similar inhomogeneous instabilities take place for $d > 1$ only for sufficiently strong interactions [2, 3]. Secondly, we discussed only the contribution of the Fermi sea to the free energy. The remaining contributions are the anti-baryons energy (coming in the form of the negative energy bands $\bar{E}_{\pm}$ of the Dirac sea) and the meson self-energy coming from $S_{\text{Meson}}$. In fact, as we find in the next sections, both these contributions depend on $Q$, and can prefer $Q = 0$ for all values of $\mu \geq 0$. Thirdly, $\Sigma$ may also depend on $Q$, while in the discussion above we have treated it as being fixed.
Finally, note that our discussion relies on the level repulsion presented in Fig. 1, where we choose $\Sigma = 0.1$. Since $S_I$ also gives mass to the baryons (see Eq. (2.45)), this means that we have, so far, had in mind small baryon masses. It is a priori unclear whether the chiral wave instability occurs for large values of $\Sigma$ and very massive baryons, but what is clear is that if the energy bands of the baryons in the crystalline phase look qualitatively like what we present in Fig. 1, then it is natural to expect this instability when $NQ \simeq p_F$.

More precisely, by comparing the solid black lines and the dashed blue lines in Fig. 1, we see that what allows the crystalline phase (that has nonzero $\Sigma$ and $Q$) to compete with the massless phase (that has $\Sigma = 0$) is the fact that it has gapless excitations.

To study the effects of the issues we mention above on the viability of the chiral density waves, we develop a mean-field analysis for inhomogeneous vacua in the next Section.

**III. MEAN-FIELD THEORY**

We start from Eq. (2.12) and introduce auxiliary fields for the expectation values of $m_n, (m_n)^2, \ldots, (m_n)^N$ by writing

$$\exp \left[ N \sum_{n\nu} F_N(m_n m_{n+\nu}) \right] = \exp \left[ N \sum_{q=1}^{N} \sum_{n\nu} a_q m_n^q m_{n+\nu}^q \right]$$

$$= \int D V \exp \left[ N \sum_{q=1}^{N} \sum_{n\nu} a_q V_{q,n} V_{q,n+\nu} \right] \delta (V_{q,n} - m_n^q)$$

$$= \int D V D h \exp \left[ N \sum_{q=1}^{N} \sum_{n\nu} a_q V_{q,n} V_{q,n+\nu} - N h_{q,n} (V_{q,n} - m_n^q) \right].$$

Here $\int dV \equiv \prod_q \int_{-\infty}^{\infty} dV_R^{(q)} \int_{-\infty}^{\infty} dV_I^{(q)}$, and $V_R^{(q)}, V_I^{(q)}$ are the real and imaginary parts of $V_q$, while $\int dh \equiv \prod_q \int_{-i\infty}^{i\infty} dh_{q}^{(1)} \int_{-i\infty}^{i\infty} dh_{q}^{(2)}$. Also, $h_{q} V_q$ means $h_{q}^{(1)} V_R^{(q)} + h_{q}^{(2)} V_I^{(q)}$, and similarly for $h_{q}(m)^q$. Proceeding from Eq. (3.1), the action for the scalar fields $V$ and $h$ becomes

$$S_{\text{eff}}(V, h) = N \sum_{q=1}^{N} a_q \sum_{n\nu} V_{q,n} V_{q,n+\nu} - N \sum_{n,q} h_{q,n} V_{q,n} + S_0,$$

$$\exp (S_0) \equiv \int D h D V D m \exp \left\{ b \cdot \left[ 2^{N-1} d_N m^{-N} \mathbf{1} + D \right] \cdot b + N \sum_{n,q} h_{q,n} m_n^q \right\}. (3.3)$$

The starting point of Mean field theory is to write the path integral for the action in Eq. (3.2) as

$$Z(\lambda) \equiv \int D h D V e^{\frac{i}{\lambda} S_{\text{eff}}}$$

12
and to approach the physical point, \( \lambda = 1 \), by expanding around \( \lambda = 0 \) \( \lambda \). Calculating \( O(\lambda) \) corrections is, however, outside the scope of the work we present here, and we study only the \( O(\lambda^0) \) level. In this case, the tree-level mean-field equations are

\[
\frac{\partial S_{\text{eff}}}{\partial V_{q,n}} = 0, \quad \text{and} \quad \frac{\partial S_{\text{eff}}}{\partial h_{q,n}^{(1,2)}} = 0,
\]

which give

\[
\begin{align*}
  h_{q,n}^{(1)} &= a_q \sum_{\nu=\pm 0} \pm d V_{q,n+\nu}, \\
  h_{q,n}^{(2)} &= ia_q \sum_{\nu=\pm 0} V_{q,n+\nu}, \\
  V_{q,n} &= \langle m_q^n \rangle.
\end{align*}
\]

Here the average \( \langle \cdot \rangle \) in Eq. (3.8) is with respect to the path integral in Eq. (3.3).

Equations (3.6)-(3.7) tell us to try an ansatz with \( h_{q,n}^{(2)} = ih_{q,n}^{(1)} \equiv ih \), in which case the \( hV \) and \( hm \) terms in Eq. (3.2) and Eq. (3.3) have the meaning of a simple complex multiplication. Restricting to this type of ansatz we use

\[
\oint \frac{dm}{2\pi i m} m^k = \delta_{k,0},
\]

which gives

\[
\begin{align*}
  Z(1) \text{ of Eq. (3.4)} = & \int DV D\bar{b} D\bar{c} \exp S_{\text{eff}}, \\
  S_{\text{eff}} = & N \sum_{q=1}^N a_q \sum_{n,\nu} V_{q,n} V_{q,n+\nu} - N \sum_{q,n} h_{q,n} V_{q,n} + \sum_{n,m} \bar{b}_n [\Sigma_n 1 + D]_{nm} b_m, \\
  \Sigma_n = & 4 \left( h_{1,n}^3 + 2h_{1,n} h_{2,n} + \frac{2}{3} h_{3,n} \right).
\end{align*}
\]

The next step is to assume an ansatz for the spatial behaviour of \( V_{q,n} \) and \( h_{q,n} \). Here we allow for the possibility of the broken translation invariance, and write

\[
\begin{align*}
  V_{q,n} &= V_q \exp \left( +i q \epsilon_n \bar{Q} \bar{n} \right), \\
  h_{q,n} &= h_q \exp \left( -i q \epsilon_n \bar{Q} \bar{n} \right).
\end{align*}
\]
with real $h_q$ and $V_q$. This ansatz breaks the symmetry of spatial translations as well as the $U(1)_c$ chiral rotations

$$V_{q,n} \rightarrow V'_{q,n} = e^{i\epsilon_n q \theta} V_{q,n}, \quad h_{q,n} \rightarrow h'_{q,n} = e^{-i\epsilon_n q \theta} h_{q,n},$$  \hspace{1cm} (3.15)$$

and, as we discuss in Section II B, implies a helical structure for the chiral condensate.

A substitution of Eq. (3.14) in Eq. (3.6) gives

$$h_q = 2(d+1)a_q V_q \gamma_q(Q),$$  \hspace{1cm} (3.16)$$

where

$$\gamma_q(Q) = \frac{1}{d+1} \left[ 1 + \sum_{i=1}^{d} \cos(qQ_i) \right],$$  \hspace{1cm} (3.17)$$

and a subsequent substitution of that into Eq. (3.8), with a use of

$$\frac{\partial \Sigma_n}{\partial h_{nq}} = 4 \times \begin{cases} 3h_{1,n}^2 + 2h_{2,n} & q = 1 \\ 2h_{1,n} & q = 2 \\ \frac{2}{3} & q = 3 \end{cases},$$  \hspace{1cm} (3.18)$$

gives the final form of the mean-field equations

$$h_1 = \frac{9a_1 \gamma_1}{2a_3 \gamma_3} \left( h_1^2 + \frac{2a_2 \gamma_2}{a_3 \gamma_3} h_1 h_3 \right) h_3,$$  \hspace{1cm} (3.19)$$

$$h_2 = \frac{3a_2 \gamma_2}{a_3 \gamma_3} h_1 h_3,$$  \hspace{1cm} (3.20)$$

$$h_3 = \frac{16(d+1)a_3 \gamma_3}{9} \times A(h_q, Q; \mu).$$  \hspace{1cm} (3.21)$$

Also, $a_{1,2,3} = \frac{1}{7}, \frac{3}{84}, -\frac{15}{256}$, are the coefficients in $F_3$ (see Eq. (2.5)), and $\gamma_{1,2,3}$ are given in Eq. (3.17) (Here, for brevity, we write $\gamma_q$ to denote $\gamma_q(Q)$). The function $A(h_q, Q; \mu)$ is defined as

$$A(h_q, Q; \mu) \equiv \langle \hat{b}_n \hat{b}_n \rangle \cdot e^{-3iQ_n \theta} = \frac{\partial \text{tr} \log [\Sigma_n 1 + D]}{\partial \left( \Sigma_n e^{3iQ_n} \right)},$$  \hspace{1cm} (3.22)$$

and the derivative here is evaluated at

$$\Sigma_n = \Sigma e^{-3iQ_n \theta},$$  \hspace{1cm} (3.23)$$

$$\Sigma = 4 \left( h_1^3 + 2h_1 h_2 + \frac{2}{3} h_3 \right).$$  \hspace{1cm} (3.24)$$

14
To determine which of the solutions of the mean-field equations is the true vacuum we calculate the mean-field free energy. Using Eq. (3.16), the energy per number of sites \( N_s \) is given by can be expressed in terms of the fields \( h_q \) alone, and we find

\[
\mathcal{E} \equiv -\mathcal{E}_{\text{mean-field eff}}^\text{mean}/N_s = \frac{3}{4} \sum_q \frac{h_q^2}{(d + 1)a_q\gamma(Q)} + \mathcal{E}_{\text{matter}},
\]

(3.25)

where the contribution of the \( b \) fields is

\[
\mathcal{E}_{\text{matter}} = -\frac{1}{N_s} \text{tr} \log [\Sigma_n 1 + D].
\]

(3.26)

We calculate \( A(h_q, Q; \mu) \) and \( \mathcal{E}_{\text{matter}} \) in Appendix A, where we also show that the right hand side of Eq. (3.22) is indeed independent of the lattice site index \( n \). The result for \( \mathcal{E}_{\text{matter}} \) is

\[
\mathcal{E}_{\text{matter}} = \frac{1}{2} \sum_{b=\pm} \int \left( \frac{dp}{2\pi} \right)^d \left( E_b - 3\mu \right) \theta \left( E_b - 3\mu \right),
\]

(3.27)

where \( \theta(x) \) is the step function. The momentum integrals are from \(-\pi\) to \(\pi\), and \( E_{\pm} \), that replace \( E^{(1),(2)} \) of Eq. (2.31), are the band energies of the baryons. In this paper we focus on \( d = 3 \) and \( \vec{Q} = Q\hat{z} \), for which the dispersions are

\[
\sinh^2 E_{\pm} = \sin^2(p_x/2) + \sin^2(p_y/2) + \left( \sqrt{\Sigma^2 + s_z^2 \pm |c_z|} \right)^2,
\]

(3.28)

\[
s_z \equiv \sin(p_z/2) \cos 3Q/2,
\]

(3.29)

\[
c_z \equiv \cos(p_z/2) \sin 3Q/2.
\]

(3.30)

(For the general dispersions with \( \vec{Q} = (Q_x, Q_y, Q_z) \) see Appendix A). \( \Sigma \) is related to the expectation values \( V_q = \langle m_q^n \rangle \) through Eqs (3.6)–(3.8) and for \( Q = 0 \) it is the spectral gap that defines the baryon mass \( m_B \) (see Eq. (3.28))

\[
\sinh m_B = \Sigma.
\]

(3.31)

From here on we refer to energy bands of Eq. (3.28) with \( \Sigma > 0 \) as massive bands, and to energy bands with \( \Sigma = 0 \) as massless bands.

In Fig. 2 we plot \( E_{\pm} \) for \( \vec{p} = (0, 0, p_z) \). In the upper panel we choose \( m_B = 3 \) (or \( \Sigma \sim 10 \)), which is close to the value that solves the mean-field equations in \( d = 3 \) and \( \mu = 0 \) (see next section). We present the cases of \( Q = 0 \), where \( E_{\pm} \) are degenerate, and \( Q = \pi/3 \), where this degeneracy is removed. In the lower panel we show the case of \( m_B = 0 \) (or \( \Sigma = 0 \)), where \( E_{\pm} \) are again degenerate and also independent of \( Q \).
FIG. 2: The energy bands $E_\pm$ of Eq. (3.28) for $p = (0, 0, p_z)$. Upper panel: Massive bands with $m_B = 3$ and $Q = \pi/3$ (highest and lowest curves), and $Q = 0$ (middle curve). The bands $E_\pm(Q = 0)$ are degenerate and very flat, ranging between $E = 3$ and $E = \sqrt{\sinh^2(3) + \max \left( \sum_{i=1}^3 \sin^2(p_i/2) \right)} \approx 3.0147$. Lower panel: The massless band with $\Sigma = 0$.

Finally, to make a connection with the discussion in Section II B leading to Eq. (2.46), we write Eq. (3.27) as

$$\mathcal{E}_{\text{matter}} = -|\mathcal{E}_B| + \mathcal{E}_B - 3\mu n_B, \quad (3.32)$$

where the anti-baryon and baryon energies, $-|\mathcal{E}_B|$ and $\mathcal{E}_B$, are given by

$$-|\mathcal{E}_B| = +3\mu - \frac{1}{2} \sum_{b = \pm} \int \left( \frac{dp}{2\pi} \right)^d E_b, \quad (3.33)$$

$$\mathcal{E}_B = \frac{1}{2} \sum_{b = \pm} \int \left( \frac{dp}{2\pi} \right)^d (E_b - 3\mu) \theta (3\mu - E_b), \quad (3.34)$$

and the baryon number density $n_B$ is

$$n_B = \frac{1}{2} \sum_{b = \pm} \int \left( \frac{dp}{2\pi} \right)^d \theta (3\mu - E_b). \quad (3.35)$$
IV. THE MEAN-FIELD GROUND STATE

In this section we present the solutions for the mean-field equations Eqs. (3.19)–(3.21), and their corresponding energy densities. To understand the results we then study a formal limit of Eq. (2.12) where one takes $N \to 1$.

A. Physical case: $N = 3$ and $d = 3$

We begin by describing the solution to the mean-field equation that leaves chiral symmetry intact in Section IV A 1, and proceed to discuss the chiral broken phase in Section IV A 2. Finally, in Section IV A 3 we discuss how the ground state evolves with increasing values of $\mu$.

1. Solution I : Intact chiral symmetry

The first solution to the mean-field equations is obtained by taking $h_1 = h_2 = h_3 = 0$. This corresponds to a phase with intact chiral symmetry, $V_1 = V_2 = V_3 = 0$, and zero baryon mass $\Sigma = \sinh(m_B) = 0$. In this case the energy bands are trivially independent of $Q$ (since $S^\text{mean-field}_I = 0$), and $E_\pm$ are degenerate

$$E_\pm = \sinh^{-1} \sqrt{\sum_{\nu=1}^{d} \sin^2(p_\nu/2)} \equiv E_{\text{massless}}. \quad (4.1)$$

The energy and baryon number densities of this solution are independent of $Q$ as well, and are given by

$$E_I = -\int \left(\frac{dp}{2\pi}\right)^3 (E_{\text{massless}} - 3\mu) \theta (E_{\text{massless}} - 3\mu), \quad (4.2)$$

$$n_{B,I} = \int \left(\frac{dp}{2\pi}\right)^3 \theta (3\mu - E_{\text{massless}}). \quad (4.3)$$

In Fig. 3 we plot $E_I$ as a function of $\mu$, where one can see that for $\mu = 0$, we get $E_I \simeq -1$. As we increase $\mu$, the energy density increases, and saturates when $\mu = \mu_s \simeq 0.439$, where it reaches zero. Looking at the form of $E_{\text{massless}}$ from Fig. 2, we can understand why. The maximum energy to which $E_{\text{massless}}$ of Eq. (4.1) can reach is $\sinh^{-1} \sqrt{\max \sum_{i=1}^{3} \sin^2(p_i/2)} \simeq 1.317$. This means that when $\mu > \mu_s$, where the baryon chemical potential $3\mu$ is already
larger than $3 \times 0.439 \simeq 1.317$, the band $E_{\text{massless}}$ is already saturated. This saturation can be seen also in the plot of the baryon number density, $n_{B,I}$ which reaches $n_{B,I} = 1$ at $\mu_s$.

![Graph showing energy density and baryon number density](image)

**FIG. 3:** The energy density, $E_I$, (solid line) and baryon number density, $n_{B,I}$, for the massless energy bands of solution type I, as a function of the chemical potential $\mu$.

### 2. Solution II: Spontaneously broken chiral symmetry

In this case $h_{1,2,3}$ are nonzero, and we divide Eq. (3.19) with $h_1$ to obtain

$$h_1 = \frac{2a_3\gamma_3}{9a_1\gamma_1} \frac{1}{h_3} - \frac{2a_2\gamma_2}{a_3\gamma_3} h_3. \quad (4.4)$$

Substituting this in Eq. (3.20) and Eq. (3.24) we get $\Sigma$ as a function of $h_3$, which we then substitute into Eq. (3.21) and obtain a single equation for $h_3$, that we solve for all values of $Q$ and $\mu$.

The results are presented in Fig. 4 where we show $m_B \equiv \sinh^{-1}(\Sigma)$ as a function of $Q$, for $\mu = 0, 0.5, 0.75, 0.9$. In Fig. 5 we show the energy densities of these solutions. There are two branches in both figures that correspond to two solutions of type II that we find. From Figs. 4-5 we see that at $\mu = 0$ the minima of both branches (referred to as branches no. 1-2 below) is at $Q = 0$ and have

$$m_B^{(1)}/3 \simeq 1.0347, \quad \text{with} \quad \mathcal{E}_{II}^{(1)} \simeq -1.6826, \quad (4.5)$$
FIG. 4: The values of $\frac{1}{3} m_B(Q; \mu)$ that solve the mean-field equations. Note the two branches of the solution, and that one of them (branch no.1, ending at $Q = 0$, and $m_B/3 = 1.0347$) hardly changes with $\mu$. We find that this branch has a lower energy and therefore corresponds to the ground state (see text).

$$m_B^{(2)}/3 \simeq 0.1309, \quad \text{with} \quad \mathcal{E}_{II}^{(2)} \simeq -0.8981.$$ (4.6)

Consequently, the ground state of Solution II at $\mu = 0$ is given by the minimum of branch no. 1 (Eq. (4.5)).

To see whether the chiral wave instability takes place, we consider Fig. 5 and find that the minima of $\mathcal{E}_{II}$ is at $Q = 0$ for all values of $\mu$. This is not in contradiction with the discussion of Section II B because, there, we only showed that the baryon contribution to the free energy, $\mathcal{E}_B(\Sigma, Q)$, has a minimum at $Q \neq 0$. What we see here is that the remaining contributions to $\mathcal{E}$ offset this minimum and lead to a ground state with $Q = 0$.

It is important to note that even if the minimum of $\mathcal{E}_B$ was deeper, such that $\mathcal{E}_{II}$ itself had a minimum at $Q \neq 0$, it is still unlikely that the chiral density wave would become the ground state. To understand why, recall that in Section II B we showed that what allows the crystalline phase to compete with the $\Sigma = 0$ phase of Solution I are the gapless excitations in the baryon spectrum. From Eq. (3.28) we see that the momentum of these excitations is given by

$$\vec{p} = (0, 0, p_z),$$ (4.7)
FIG. 5: The energy density $E_{II}$ as a function of $Q$ and $\mu$ for solution II. The lower branch (branch no.1) for each $\mu$ is the one that ends at $Q = 0$ and $m_B/3 = 1.0347$ (see Fig. 4).

\[
\sin^2 \frac{p_z}{2} = \sin^2 \left( NQ/2 \right) - \Sigma^2,
\]

which has a solution only if

\[
\Sigma \leq 1.
\]

Unfortunately, with the baryon mass of our ground state \[^3\] we have $\Sigma = \sinh m_B \sim 11$. This prohibits gapless excitations, and makes the appearance of the chiral waves improbable.\[^3\]

3. Evolution of mean-field ground state as a function of $\mu$

Here we discuss the way the ground state evolves with increasing chemical potential $\mu$. Given the conclusions of the previous sections, we restrict to states with $Q = 0$ only.

At $\mu = 0$, solution of type I has $E_I \approx -1$, while the solution of type II that has the lowest energy is given in Eq. (4.5). Comparing $E_I$ and the energy in Eq. (4.5) we see that the latter is the ground state of the system, and so, the baryon mass is $m_B/3 \approx 1.0347$. The

\[^3\] The true relevant value of $\Sigma$ that should be tested against Eq. (4.9) is $\Sigma(Q; \mu) \equiv \sinh m_B(Q; \mu)$, but from Fig. 4 we see that $\Sigma(Q; \mu) \geq \Sigma(\pi; 0) \approx 4$, for which Eq. (4.9) is still not satisfied.
condensates $V_q$ (Eq. (2.18)) that we find for this ground state are

$$
\langle \frac{\chi^3}{3} \rangle = V_1 \simeq 0.67685,
$$

(4.10)

$$
\langle \left( \frac{\chi^3}{3} \right)^2 \rangle = V_2 \simeq 0.31947,
$$

(4.11)

$$
\langle \left( \frac{\chi^3}{3} \right)^3 \rangle = V_3 \simeq 0.07872.
$$

(4.12)

Comparing these results to the literature, we see that our mass is $0.22\% - 0.54\%$ lower than other tree level results (see, for example, the summary in [22]), and that our condensates are close to the analytical and numerical results of [15, 17, 21, 22, 23] (discrepancies are on the level of $2\% - 5\%$).

When $\mu$ increases, the energy densities of both type of solutions grow. As explained in Section IV A 1, the energy of solution I stops increasing at $\mu_s$ where it reaches $E_I = 0$. Nothing special happens to solution II at this point, and its energy is still negative and continues to grow monotonically. In Fig. 6 we replot $E_I(\mu)$ of Fig. 3 together with the ground state value of $E_{II}(\mu)$ (i.e. for given $\mu$, we extract the minima of the curves in Fig. 5).

![Fig. 6: The energy densities $E_I$ and $E_{II}$ as a function of $\mu$.](image)

From Fig. 6 we see that a transition occurs at $\mu = \mu_t$ where

$$
E_{II}(\mu_t) = 0.
$$

(4.13)
Substituting Eq. (3.25) and Eq. (3.16) in Eq. (4.13) gives (for $Q = 0$)
\[ 3(d + 1) \sum_{q=1}^{3} a_q V_q^2 = \int \left( \frac{dp}{2\pi} \right)^3 \frac{1}{3} (E - 3\mu_t) \right. \theta (E - 3\mu_t). \] (4.14)

From Fig. 4 we see that, for $Q = 0$, the mass $m_B$ does not change as a function of $\mu$ up to $\mu \simeq m_B/3$, at which point solution II disappears. This reflects the fact that the condensates $V_q$ are independent of $\mu$ as well, and allows us to use the $\mu = 0$ values of $m_B$ and $V_q$ in Eq. (4.14). This is a consistent procedure provided that the resulting $\mu_t$ obeys $\mu_t < m_B/3$.

Indeed, solving Eq. (4.14) for $\mu_t$ gives
\[
\mu_t = \left( \frac{1}{3} \int \left( \frac{dp}{2\pi} \right)^3 E(p) \right) - 4 \left( a_1 V_1^2 + a_2 V_2^2 + a_3 V_3^2 \right)
\simeq 1.0367 - (0.45813 + 0.01914 - 0.001452) = 0.5609,
\] (4.15)

which is lower than $m_B/3 \simeq 1.0347$. Consequently this means that the chiral symmetry of Eq. (1.3) is restored in a first order transition at $\mu_t \simeq 0.5609$ that separates a low density phase characterised by the baryon mass of Eq. (4.5) and the chiral condensates in Eqs. (4.10)-(4.12), and a high density phase where this symmetry is intact and the baryons are massless.

Let us emphasise that the way chiral symmetry is restored here is largely influenced by lattice artifacts of the infinite coupling limit. In particular, we cannot observe the crystalline phase partly because the mass of the baryons in lattice units, $m_B$, is around $\sim 3$. This prevents the baryons spectrum from having gapless excitations, and makes their contribution to the free energy $\mathcal{E}_B(m_B, Q)$ higher compared to what it would be with $m_B = Q = 0$. This is in contrast to the ‘continuum-like’ scenario that we discussed in Section II B, where $m_B$ was small, and $\mathcal{E}_B(m_B, Q) < \mathcal{E}_B(0, 0)$. In the next section we study such a continuum-like case by taking a formal limit of $S_{HKS}$, in which the mass of the $b$ fields is significantly smaller than discussed above.

B. The formal limit of $N \to 1$

In this section we study a formal limit of Eq. (2.12), where one takes $N = 1$ and $F_N(u) = u/4$. In this case Eq. (2.12) cannot be obtained from an underlying lattice gauge theory, but nevertheless seems to be useful to understand, since it shows chiral restoration with less
lattice artifacts. In their original preprint, the authors of [15] have considered this limit as an example for a case where the baryonic terms in Eq. (2.12) are important at \( \mu = 0 \). Here we approach this limit at nonzero \( \mu \) and seek for signs of a crystalline solution for the mean-field equations. We first do so for \( d = 1 \), where it is known that crystalline instabilities are robust [2, 3]. (The physical significance of the result in this case is, however, unclear since the continuous \( U(1) \) symmetry cannot break in \( 1 + 1 \) dimensions.)

We begin the analysis by noting that for \( N = 1 \), Eq. (2.12) depends only linearly on \( m_n m_{n+\phi} \). This allows us to take \( h_2 = h_3 = V_2 = V_3 = 0 \), and to call \( h_1 = h, V_1 = V \). The mean-field equations become (we keep \( d \) general at this stage)

\[
\begin{align*}
    h &= 2(d + 1)a_1 V \gamma_1(Q), \\
    V &= A(h, Q; \mu),
\end{align*}
\]

(4.16) (4.17)

and the free energy is now given by

\[
\mathcal{E} = \frac{h^2}{4(d + 1)a_1 \gamma_1(Q)} + \mathcal{E}_{\text{matter}}.
\]

(4.18)

Both \( A(h, Q; \mu) \) and \( \mathcal{E}_{\text{matter}} \) are still defined in Eqs. (3.22), and (3.26), with the difference that the dependence of \( \Sigma_n \) on \( h_n \) is now

\[
\Sigma_n = h_n = h e^{-i\pi Q n}. 
\]

(4.19)

Again, it is easy to see that there are two type of solutions which are the analogues of the type I and II solutions in the \( SU(3) \) case. In Fig. 7 we present the energy bands for \( m_B = \sinh^{-1}(\Sigma) = 0.5 \), which is close to the value that solves the mean-field equations for \( N = 1 \) and \( d = 1 \). With this value of \( m_B \) the effect of the lattice coarseness is smaller compared to the \( N = 3 \) case: the massive and massless bands of solutions I and II overlap, and there exists momenta where the energy of solution II is zero.

As a result, a crystalline ground state is stable. In Fig. 8 we present the dependence of \( V \) and \( Q \) on \( \mu \). We also plot the following analytic expectation for \( Q(\mu) \) that arises from our discussion in Section II B (adjusted to \( N = 1 \))

\[
Q(\mu) = p_F(\mu) = 2 \sin^{-1} (\sinh \mu).
\]

(4.20)

It is clear that Eq. (4.20) works well, especially for \( \Sigma \ll 1 \), which means that the mechanism described in Section II B is indeed the one generating the chiral density wave instability here.
FIG. 7: The energy bands $E_{\pm}$ of the baryons for $p = (0, 0, p_z)$. The dashed line is the gapless band with $m_B = 0$, and the solid lines are have $m_B = 0.5$, and $Q = 0, \pi$.

When we move from $d = 1$ to $d = 2$ the crystalline phase disappears. We find that the reason is that the meson self energy described by the first term in Eq. (4.18) prefers $Q = 0$, and ‘wins’ the instability generated in $E_{\text{matter}}$. This effect comes from the function $\gamma_1(Q)$ in Eq. (5.17), and can be considered as a lattice artifact as well, since in the continuum limit the lattice quantities $\Sigma, \mu$, and $Q$ vanish, and so $\gamma_1(Q) \to 1$. Indeed, in continuum treatments of the Nambu-Jona-Lasinio model such as [24], the contribution to the free energy that is the analog of the first term in Eq. (4.18), does not depend on $Q$.

When we move to $d = 3$ it appears that even without the $Q$ dependence in $\gamma_1(Q)$, the crystalline phase is unstable. This changes if one makes the meson self-interaction $F_1(u) = \frac{1}{4} u$ stronger by changing it to $F_1(u) = a_1 u$ with $a_1 > 1/4$. 

24
V. CONCLUSIONS

Our aim in this paper was to see whether the phase diagram of strongly-coupled lattice QCD at zero temperature and nonzero density includes an incommensurate crystalline phase with chiral density waves. To do so we followed Hoek, Kawamoto, and Smit (HKS), and used the effective hadronic action, $S_{\text{HKS}}$, that they derived in [15] for one-component staggered fermions. We formulated a mean-field theory for $S_{\text{HKS}}$ which is novel in the following ways. Firstly, we do not neglect the terms in $S_{\text{HKS}}$ that have four and six powers of the meson fields, and treat the baryon contribution in full. Secondly, our mean-field analysis is free of any undetermined parameters and we fix all vacuum expectation values by minimising the free-energy. Lastly, we do not assume a homogeneous ansatz, which is imperative in order to look for the crystalline phase. This leads us to introduce auxiliary fields without the usual Hubbard-Stratonovich transformation, that can become ill-defined for inhomogeneous
vacua.

Despite the fact that the generic structure of $S_{\text{HKS}}$ can give rise to a crystal phase (see discussion in Section [II.B]), we find that this does not happen with our mean-field ansatz. This is partly due to lattice artifacts that come in the form of a large lattice baryon mass $m_B \sim 3$. The latter prohibits any possibility to have a gapless baryonic spectrum in the presence of the chiral density waves, which would allow the crystalline vacuum to compete with the massless homogeneous vacuum. To check this explanation, we take a formal limit of $S_{\text{HKS}}$, where $m_B \simeq 0.5$, and indeed find that this lower mass can stabilise the crystal.

More precisely, when we study this formal limit in the $1 + 1$ system, we see a crystal structure at intermediate densities, with a wave vector given by the Fermi momentum of the system. However, this result is not robust; when we move to $2 + 1$ and $3 + 1$ dimensions we see that the crystalline instability is too weak to survive. The reasons for that include an additional lattice artifact, that does not go away when $m_B$ decreases, and a too weak interaction between the fermions.

Our results stress that to get continuum physics from Monte-Carlo simulations at nonzero $\mu$ and low temperature, one will have to simulate on relatively fine lattices, with weak couplings. In particular, the baryon mass in lattice units, $m_B$, should be much smaller than its strong-coupling limit of $m_B \sim 3$. Only when this happens will the structure of the baryon energy bands be 'continuum-like'. For stronger couplings, the energy bands are qualitatively different than the continuum ones, and physical phenomena that are sensitive to their structure will also be qualitatively different than it is in the continuum. Chiral crystals is an good example for such a phenomenon, that simply goes away at strong couplings.

There are several ways in which one could extend this study. First, recall that we have focused on an ansatz that breaks translation invariance only in one direction. This direction was chosen to be along one of the lattice axes, but a further study can generalise this easily (we have already derived the free energy for a general $\vec{Q} = (Q_1, Q_2, Q_3)$) and check whether this makes the crystalline phase more robust. Second, as the authors in [4] point out, one can lower the energy of the crystalline phase by considering an ansatz which is a linear combination of waves, that will break translation invariance in all directions. Third, it will be useful (but also hard) to see how do the sub-leading terms in the strong-coupling expansion influence the results. These were obtained in [25] for the fermions we consider here, and give rise to more complicated interactions between the hadrons. Finally, it can be interesting to
numerically study the possibility of chiral density waves in the Nambu-Jona-Lasinio model, where Monte-Carlo simulations are free from the sign-problem.

Acknowledgments

I thank J. Burkardt for help on using his numerical integration routines, J. Chalker and F. Essler for useful discussions, and Y. Shamir and B. Svetitsky for their remarks on this manuscript. I was supported by PPARC.

APPENDIX A: THE BARYONIC DETERMINANT

In this section we calculate the baryonic determinant Eq. (3.26) and its variation $A(h_q, Q; \mu)$ of Eq. (3.22). We begin by showing that $A$, which, for the general $SU(N)$ case, is defined by

$$A(h_q, Q; \mu) \equiv \langle \bar{b}_n b_n \rangle e^{-N_i \vec{Q} \vec{n} \epsilon_n},$$

$$\langle \bar{b}_n b_n \rangle = \frac{\int D\bar{b} Db e^{S_0} \bar{b}_n b_n}{\int D\bar{b} Db e^{S_0}}$$

$$S_0 = \sum_{n,m} \bar{b}_n [\Sigma_n \mathbf{1} + D_{nm}] b_m,$$

is independent of the lattice site index $n$. To see this we use the symmetries of the action $S_0$

$$S_0 \equiv \bar{b} K b = \sum_n \bar{b}_n \Sigma e^{-iN\vec{Q}\vec{n} \epsilon_n} b_n + \frac{1}{2} \sum_{n\nu} \bar{b}_n \left( \eta_{\mu\nu} b_{n+\nu} - \eta_{\mu\nu}^{-1} b_{n-\nu} \right) \equiv S_\Sigma + S_{\text{kinetic}},$$

where $\epsilon_n = \pm$ is the parity of the site. In particular, $S_{\text{kinetic}}$ is invariant under spatial translations

$$T_{\vec{R}} : n \to n + \vec{R}$$

and chiral symmetry

$$U(1)_\epsilon : b_n \to e^{iNQ\epsilon_n} b_n, \quad \bar{b}_n \to \bar{b}_n e^{iNQ\epsilon_n}.$$
Although $S_0$ is invariant under these correlated transformations, $(b_n b_n)$ is not, and transforms as follows

$$
\begin{align*}
\text{For } \epsilon_n = \epsilon_{n+\vec{R}} : & \quad \langle b_n b_n \rangle \xrightarrow{T_{\vec{R}}} \langle b_{n+\vec{R}} b_{n+\vec{R}} \rangle \xrightarrow{U(1)} \langle b_{n+\vec{R}} b_{n+\vec{R}} \rangle e^{-Ni\vec{Q}\vec{R} \epsilon_n} \\
\text{For } \epsilon_n = -\epsilon_{n+\vec{R}} & \quad \langle b_n b_n \rangle \xrightarrow{\text{reflection}} \langle \tilde{b}_{-(n+\vec{R})} \tilde{b}_{-(n+\vec{R})} \rangle e^{-Ni\vec{Q}\vec{R} \epsilon_n} = \langle \tilde{b}_{-(n+\vec{R})} \tilde{b}_{-(n+\vec{R})} \rangle e^{+Ni\vec{Q}\vec{R} \epsilon_{-(n+\vec{R})}}. \quad (A8)
\end{align*}
$$

Putting $n = 0$ gives $(\tilde{b}_0 \tilde{b}_0) = (\tilde{b}_{\vec{R}} \tilde{b}_{\vec{R}}) e^{-Ni\vec{Q}\vec{R} \epsilon_{\vec{R}}}$ for $\epsilon_{\vec{R}} = +1$ from Eq. (A7), and for $\epsilon_{\vec{R}} = -1$ from Eq. (A8). This proves that

$$
\langle \tilde{b}_n b_n \rangle e^{-Ni\vec{Q}\vec{R} \epsilon_n} = \text{independent of } n,
$$

and therefore that\footnote{This is different from Eq. (3.22) since here we evaluate the determinant for the helical ansatz, and then take the derivative with respect to $\Sigma$.}

$$
A(h_q, Q; \mu) = \frac{1}{N_s} \left( \frac{\partial \log \det \left[ \Sigma e^{-Ni\vec{Q}\vec{x}_n} (1 + D) \right]}{\partial \Sigma} \right). \quad (A10)
$$

We now turn to calculate the determinant itself. It will be convenient to note that

$$
\log \det K \equiv \log \det \left[ \Sigma e^{-iQ\vec{x}_n} (1 + D) \right] = \log \det \left[ 1 + \Sigma^{-1} e^{iQ\vec{x}_n} D \right] + \sum_n \log \Sigma - Ni \sum_n \vec{Q} \vec{x}_n, \quad (A11)
$$

and to calculate $\det \tilde{K} \equiv \det \left[ 1 + \Sigma^{-1} e^{iQ\vec{x}_n} D \right]$ instead. (Note that the last term in Eq. (A11) drops out for a lattice with an even number of sites in each direction). To proceed, we use coordinates defined on a new lattice with spacing $a = 2$, and write $n = 2X + \rho$, with $\rho_1, \ldots, d = 0$ or 1 and $X$ taking values in the new lattice \footnote{Note that the last term in Eq. (A11) drops out for a lattice with an even number of sites in each direction}. In these coordinates we use the following definitions

$$
\begin{align*}
b_n & \equiv b_{\rho}(X), \\
b_{n+\rho} & \equiv \sum_{\rho'} (\delta_{\rho', \rho+\rho} b_{\rho'}(X) + \delta_{\rho', \rho-\rho} b_{\rho'}(X + \vec{\nu})) , \\
b_{n-\rho} & \equiv \sum_{\rho'} (\delta_{\rho', \rho-\rho} b_{\rho'}(X) + \delta_{\rho', \rho+\rho} b_{\rho'}(X - \vec{\nu})).
\end{align*}
$$

(A12) (A13) (A14)

Moving to momentum space with

$$
\begin{align*}
b_{\rho}(X) & = \sqrt{\frac{2^d}{N_s}} \sum_p e^{i(pX + \epsilon_{\nu}Q(2X+\rho)/2)} b_{\rho}(p), \\
\tilde{b}_{\rho}(X) & = \sqrt{\frac{2^d}{N_s}} \sum_p e^{-i(pX + \epsilon_{\nu}Q(2X+\rho)/2)} \tilde{b}_{\rho}(p),
\end{align*}
$$

(A15) (A16)

\footnote{This is different from Eq. (3.22) since here we evaluate the determinant for the helical ansatz, and then take the derivative with respect to $\Sigma$.}
we get

\[ \tilde{S}_0 \equiv \tilde{b} \tilde{K} \tilde{b} = \sum_{\rho, \rho'} \tilde{b}_\rho(p) \tilde{K}_{\rho \rho'}(p) \tilde{b}_{\rho'}(p), \]  
(A17)

\[ \tilde{K}_{\rho \rho'}(p) = \delta_{\rho \rho'} + \Sigma^{-1} \sum_\rho \left( \eta_\rho e^{i p' \nu / 2} - \eta_\rho^{-1} e^{-i p' \nu / 2} \right) (\delta_{\rho + \tilde{\nu}, \rho'} + \delta_{\rho - \tilde{\nu}, \rho'}) e^{i p(p' - \rho') / 2}, \]  
(A18)

\[ p' = p - N Q \epsilon_\rho, \]  
(A19)

where we used \( \epsilon_\rho = -\epsilon_{\rho'} \). Eq. (A18) can be brought to the form

\[ \tilde{K}(p) = 1 + i \Sigma^{-1} \sum_{\nu = 0}^d \Gamma_\nu(p) \sin \left( p_\nu / 2 - i N \mu \eta_\nu,0 + N Q \epsilon / 2 \right) \]  

\[ = 1 + i \Sigma^{-1} \left[ \Gamma_0(\omega) \sin \left( \omega / 2 - i N \mu \right) + \sum_{\nu = 1}^d \Gamma_\nu(p) \sin(p_\nu / 2) \cos(N Q \nu / 2) + \Gamma_\nu(p) \hat{\epsilon} \cos(p_\nu / 2) \sin(N Q \nu / 2) \right] \]  
(A20)

Here we defined

\[ (\hat{\epsilon})_{\rho \rho'} \equiv \epsilon_\rho \delta_{\rho \rho'}, \]  
(A22)

and also

\[ (\Gamma_\nu)_{\rho \rho'} = \tilde{\eta}_\nu(p) \left( \delta_{\rho_\nu + \tilde{\nu}, \rho'} + \delta_{\rho_\nu - \tilde{\nu}, \rho'} \right) e^{i p(p' - \rho') / 2}, \]  
(A23)

where \( \tilde{\eta}_\nu = \eta_\nu \) for \( \nu \in [1, d] \) and \( \tilde{\eta}_0 = 1 \). The matrices \( \Gamma_\nu \) obey

\[ \{ \Gamma_\nu, \Gamma_\tau \} = 2 \delta_{\nu \tau} \mathbf{1}, \quad \{ \Gamma_\nu, \hat{\epsilon} \} = \{ \Gamma_\nu, \Gamma_5 \} = 0, \]  
(A24)

with

\[ (\Gamma_5)_{\rho \rho'} = i \tilde{\eta}_\nu(p) \left( \delta_{\rho_\nu + \tilde{\nu}, \rho'} - \delta_{\rho_\nu - \tilde{\nu}, \rho'} \right) e^{i p(p' - \rho') / 2}, \]  
(A25)

that also obey

\[ \{ \Gamma_5, \Gamma_5 \} = 2 \delta_{\nu \tau} \mathbf{1}, \quad \{ \Gamma_5, \hat{\epsilon} \} = 0. \]  
(A26)

Next we use the fact that \( \det \hat{\epsilon} \tilde{K}(p) \hat{\epsilon} \tilde{K}(p) = \det \tilde{K}^2(p) \) and that \( \{ \Gamma_\nu(p), \hat{\epsilon} \} = 0 \) to get

\[ \left( \det \tilde{K}(p) \right)^2 = \det \hat{\epsilon} \tilde{K}(p) \hat{\epsilon} \times \det \tilde{K}(p) \equiv \det \tilde{K}_2(p), \]  
(A27)

with

\[ \tilde{K}_2(p) = \left( \hat{\epsilon} \tilde{K}(p) \hat{\epsilon} \right) \tilde{K}(p) = \left[ 1 + \Sigma^{-2} \left( \sum_{\nu = 1}^d s_\nu^2 - \sum_{\nu = 1}^d c_\nu^2 \right) \right] + 2 \Sigma^{-2} \sum_{\nu \neq 0} s_\nu c_\mu \Gamma_\nu \Gamma_\mu \hat{\epsilon}, \]  
(A28)
Here we defined
\[
s_0 = \sin \left( \frac{p_0}{2} - i N \mu \right),
\] (A29)
and for \( \nu > 0 \)
\[
s_\nu = \sin \left( \frac{p_\nu}{2} \right) \cos \left( N Q_{\nu}/2 \right), \quad \] (A30)
\[
c_\nu = \cos \left( \frac{p_\nu}{2} \right) \sin \left( N Q_{\nu}/2 \right). \quad \] (A31)

To proceed we need to find a matrix that anti-commutes with \( \Gamma_\nu \hat{\Gamma}_\mu \) for all \( \nu \neq \mu \). We can choose any of the matrices \( M = \Gamma_5 \nu \) (which also obey \( M^2 = 1 \)) and we have
\[
\left( \det \tilde{K}(p) \right)^4 = \left( \det K_2(p) \right)^2 = \det M K_2(p) M \times \det K_2(p) \equiv \det K_4(p), \quad \] (A32)
with
\[
K_4(p) = (M K_2 M) K = \left[ 1 \cdot \left( 1 + \sum_{\nu=1}^{d} \left( s_{\nu}^2 - c_{\nu}^2 \right) \right)^2 - 4 \Sigma^{-4} C^2 \right],
\]
\[
C = \sum_{\mu \neq \nu, \mu \neq 0} s_{\nu} c_{\mu} \Gamma_{\nu} \Gamma_{\mu} \hat{\epsilon}.
\] (A33)

Using the anti-commutation relations of \( \Gamma_\nu \) we get \( C^2 = -B \cdot 1 \) with
\[
B = s_0^2 \sum_{\nu=1}^{d} c_{\nu}^2 + \sum_{\nu \neq \mu, \mu \geq 1} (s_{\nu} c_{\mu} - c_{\nu} s_{\mu})^2, \quad \] (A34)
and defining \( D(p) \equiv \det K_4(p) \) we obtain the following form
\[
D(p) \cdot \Sigma^4 = \left( \sin^2 \left( \frac{p_0}{2} - i N \mu \right) + \epsilon_+^2(p) \right) \times \left( \sin^2 \left( \frac{p_0}{2} - i N \mu \right) + \epsilon_-^2(p) \right). \quad \] (A35)

Here
\[
\epsilon_+^2 = |\tilde{s}|^2 \sin^2 \phi + \left( \sqrt{\Sigma^2 + |\tilde{s}|^2 \cos^2 \phi \pm |\tilde{c}|} \right)^2, \quad \] (A36)
\[
s_i \equiv \sin(p_i/2) \cos(N Q_i/2), \quad \] (A37)
\[
c_i \equiv \cos(p_i/2) \sin(N Q_i/2), \quad \] (A38)
\[
\cos \phi \equiv \hat{c} \cdot \hat{s}. \quad \] (A39)

Since \( \det \tilde{K}(-p) = \det \tilde{K}^*(p) \) then \( \det \tilde{K} \equiv \Pi_{\mu} \det \tilde{K}(p) \) is real\(^5\) and we can write \( \det \tilde{K} =

---

^5 This can be proved as follows. We have \( \tilde{K}(p, Q) = \tilde{K}^*(-p, -Q) \), but also \( \det \tilde{K}(p, Q) = \det \Gamma_5 \nu \tilde{K}(p, Q) \Gamma_5 \mu = \det \tilde{K}(p, -Q) \). This means that \( \det \tilde{K}(p, Q) \det \tilde{K}(-p, Q) = \det \tilde{K}(p, Q) \det \tilde{K}^*(p, -Q) = \det \tilde{K}(p, Q) \det \tilde{K}^*(p, Q) = |\det \tilde{K}(p, Q)|^2 \) is real.
\[(\det \tilde{K}^4)^{1/4} = \left(\Pi_p \det K_4(p)\right)^{1/4}\] or

\[\log \det \tilde{K} = \frac{1}{4} \sum_p \log(D(p)) = \frac{N_s}{4} \int_{-\pi}^{\pi} \left(\frac{dp}{2\pi}\right)^{d+1} \log D(p). \quad (A40)\]

Dropping irrelevant constants, we get

\[\frac{1}{N_s} \log \det K = \frac{1}{4} \sum_{b = \pm} \int_{-\pi}^{\pi} \left(\frac{dp}{2\pi}\right)^d \int_{-\pi}^{\pi} \frac{dp_0}{2\pi} \log \left[\sin^2(p_0/2 - iN\mu) + \epsilon_b^2\right], \quad (A41)\]

\[\frac{1}{N_s} \frac{\partial \log \det K}{\partial \Sigma} = \frac{\Sigma}{2} \sum_{b = \pm} \int_{-\pi}^{\pi} \left(\frac{dp}{2\pi}\right)^d \int_{-\pi}^{\pi} \frac{dp_0}{2\pi} \frac{\left(1 + b \frac{|\vec{c}|}{\sqrt{\Sigma^2 + s_z^2 \cos^2 \phi}}\right)}{\epsilon_b^2(1 + \epsilon_b^2)} \sqrt{\epsilon_b^2(1 + \epsilon_b^2)} \log \underbrace{\left[\sin^2(p_0/2 - iN\mu) + \epsilon_b^2\right]}_{E_b^2(p)}, \quad (A42)\]

Performing the change of variables \(z \equiv e^{ip_0 - 2N\mu}\) the integral in Eq. (A42) becomes a simple contour integral and using complex analysis one can show that

\[\int_{-\pi}^{\pi} \frac{dp_0}{2\pi} \log \left[\sin^2(p_0/2 - iN\mu) + \epsilon_b^2\right] = \int_{X_0} \frac{dX}{2\pi} \int_{-\pi}^{\pi} \frac{dp_0}{2\pi} \frac{1}{\sin^2(p_0/2 - iN\mu) + \epsilon_b^2} = 2 \left[E_b(p) - N\mu\right] \theta(E_b(p) - N\mu). \quad (A43)\]

The final result is then

\[\frac{1}{N_s} \frac{\partial \log \det K}{\partial \Sigma} = \frac{\Sigma}{2} \sum_{b = \pm} \int \left(\frac{dp}{2\pi}\right)^d \frac{\left(1 + b \frac{|\vec{c}|}{\sqrt{\Sigma^2 + s_z^2 \cos^2 \phi}}\right)}{\epsilon_b^2(1 + \epsilon_b^2)} \theta(E_b(p) - N\mu) \quad (A44)\]

\[\frac{1}{N_s} \log \det K = \frac{1}{2} \sum_{b = \pm} \int \left(\frac{dp}{2\pi}\right)^d (E_b(p) - N\mu) \theta(E_b(p) - N\mu). \quad (A45)\]

which we evaluate numerically. In particular, in the case of \(d = 3\), we present results for \(\bar{Q}||\hat{z}\), in which case

\[\epsilon_\pm^2 = |\vec{s}_\perp|^2 + \left(\sqrt{\Sigma^2 + s_z^2} \pm |c|\right)^2, \quad (A47)\]

\[s_z = \sin(p_z/2) \cos(NQ/2), \quad (A48)\]

\[c = \cos(p_z/2) \sin(NQ/2), \quad (A49)\]

\[|\vec{s}_\perp|^2 = \sin^2 p_x/2 + \sin^2 p_y/2. \quad (A50)\]
Since the transverse directions appear very simply here, we define the density of states
\[ D(s) \, ds = \left( \frac{dp}{2\pi} \right)^{d-1} \delta \left( \sum_{\nu=x,y} \sin^2(p_\nu/2) - s \right) \]
for the transverse momenta. One can show that
\[ D(s) = \frac{2}{\pi} K(s(2 - s)) \]
where \( K(x) \) is the complete elliptic integral of the first kind (for example see [20]).
