INTRODUCTION

Manufactured or domestic chemicals, fertilizers, heavy metals are considered environmental pollutants. Many of them can induce oxidative stress. Particularly, cadmium, lead, arsenic and mercury are heavy metals that constitute severe dangers to human wellbeing health (Ognjanović et al., 2010; Liu et al., 2016; Tahir et al., 2017). Cadmium is a poisonous environmental pollutant. Cadmium is classified as a human carcinogen (Group1 [IARC], Group 2a [EPA], and 1B Carcinogen [ECHA]). However, cadmium is widely used in batteries, plastics, colors, and electroplated. The main way for smokers or professional workers to ingest cadmium is through inhalation (Siu et al., 2009). Industrial workers as well as people in general, are exposed to cadmium given its increased production and usage. Cadmium can induce various severe pathological conditions such as hepatic and renal dysfunctions, testicular harm, and nervous system issue.

Long-term exposure to low doses of cadmium has become a growing public health concern, which can invade into an individual’s or animal’s body mainly by the following ways: ingestion of cadmium-contaminated foods (e.g., irrigation water and fertilizers) and/or cadmium bioconcentration in aquatic and plant organisms through food chains intake of polluted water, or inhalation of polluted air. Ingestion of cadmium affects the functions of the kidney, liver, bones and other tissues (Butt et al., 2018). Furthermore, cadmium induces free-radical production, leading to the oxidative stress of lipids, proteins and DNA.

The health benefits of plant-derived polyphenolic compounds have been extensively studied. Baicalein is the main active constituent in the roots of the medicinal herb Scutellaria baicalensis Georgi (Lamiaceae family) (Sahu et al., 2015). The roots of S. baicalensis have been utilized for the treatment of bacterial and chronic hepatitis, thrombotic stroke in China (Hsieh et al., 2007). Baicalein can improve myocardial ischemic/reperfusion injury and show remedial impact in endotoxin-induced myocardial dysfunction in rats (Song et al., 2014). Baicalein decreases doxorubicin-induced cardiotoxicity suppressing myocardial oxidative stress, apoptosis, and JNK activation.

ABSTRACT

This study explored the protective effects of baicalein on cadmium induced oxidative stress and morphological changes in rat testes. Twenty-four male Sprague–Dawley rats were assigned into four groups: control group, CdCl2-treated group (2 mg/kg.b.w), Baicalein-treated group (100 mg/kg.b.w), CdCl2+Baicalein-treated group (2 mg/kg.b.w CdCl2 and 100 mg/kg.b.w of baicalein). They were treated accordingly for 4 weeks. Body weight, relative weight of the testes, and morphological changes of the testes were assessed. The levels of superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GSH-Px), glutathione (GSH), and malondialdehyde (MDA) were measured. Results showed that cadmium decreased the body weight, and relative weight of the testes. In cadmium-treated rats, the spermatogenic cells in the testicular seminiferous tubule showed disordered arrangement and structure, and their levels were unclear. Furthermore, cadmium increased the activities of antioxidant enzymes, SOD, CAT and GSH-Px, decreased GSH levels, and increased MDA content in the testes, indicating cadmium-induced oxidative stress. However, baicalein treatment increased the body weight and relative weight of the testes and prevented cadmium-induced testicular damage. Treatment with baicalein reversed the cadmium-induced changes of the antioxidant defense system. Therefore, as an effective antioxidant, baicalein protects testes from cadmium-induced oxidative stress and injury.
(Sahu et al., 2016). Many in vitro studies of baicalein have been carried out. However, no study has clarified the mechanism and valuable impact of baicalein on testes in cadmium-induced injury in vivo study. Hence, this study investigated the mechanisms to understand the protective effects of baicalein on rat testes.

In this study, the body weight, relative weight of the testes, and morphological changes of the testes of male Sprague–Dawley (SD) rats were examined. Cadmium-induced biochemical aspects were investigated by measuring the levels of superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GSH-Px), glutathione (GSH), and malondialdehyde (MDA). In addition, the protective effects of baicalein on cadmium-induced injury in rat testes were studied.

MATERIALS AND METHODS

Chemicals: SOD, CAT, GSH-Px, MDA and GSH kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China). CdCl₂ was obtained from Aladdin Industrial Corporation. Furthermore, baicalein (purity: >98%) was purchased from Mianyang Oriental Source Technology Co., Ltd (Mianyang, China).

Animals: Adult male SD rats weighing 180-200 g were used and kept on 12 h light: 12 h dark cycles with controlled temperature (24±2°C). They were fed with a commercial standard diet with free access to drinking water under standard laboratory conditions.

Experimental design: After acclimatization to the laboratory conditions for 2 weeks, the rats were randomly divided into four experimental groups with 6 rats each. They were treated everyday as follows: control group (received redistilled water and 0.9% NaCl by oral gavage); CdCl₂-treated group (received 2 mg/kg.b.w of CdCl₂ intraperitoneally); baicalein-treated group (received 100 mg/kg.b.w of baicalein daily by oral gavage) and CdCl₂+baicalein-treated group (received 2 mg/kg.b.w of CdCl₂ intraperitoneally and 100 mg/kg.b.w of baicalein intragastrically).

Every weekend, the rats’ body weight was recorded. The experiment lasted for 4 weeks. After the treatments, the rats were anesthetized with ether anesthesia. Then, all rats were sacrificed, and the testes were removed and washed using cold PBS solution. The relative weight of the testes was calculated. Tissues were minced, homogenized (10%, w/v) in PBS solution (pH 7.4), and centrifuged (3000 rpm for 10 min). The clear supernatant was stored at -80°C and used for different enzymatic and nonenzymatic biochemical measures. Moreover, some testes were preserved in 10% neutral buffered formalin for microscopic analysis.

Biochemical assays: The lipid peroxidation (LP) content was exhibited by the MDA level with thiobarbituric acid reaction. The testicular SOD, CAT, GSH-Px, GSH and MDA levels were analyzed using commercial kits (Wang et al., 2012).

Histopathological analyzes: The testicular tissues were fixed in 10% neutral buffered formalin for 48 h, dehydrated with different concentrations of ethanol, cleared with xylene and embedded in paraffin. Then, 4 μm-thick sections were prepared and stained with hematoxylin and eosin (Sahu et al., 2016). The structural changes of the testes were assessed by optical microscopy.

Statistical analyses: The results obtained were expressed as the mean ± standard deviation. All statistical analyses were performed using SPSS 15.0 statistical software. Comparison of means was subjected to one-way analysis of variance and Duncan’s multiple range test. Values were considered significant when P<0.05.

RESULTS

Effect of baicalein on cadmium-induced body weight and relative weight of the testes: As shown in Table 1, in rats treated with cadmium alone, the body weight significantly (P<0.05) decreased compared with that of the control group after cadmium exposure for 1-4 weeks. However, treatment with baicalein (100 mg/kg) alongside cadmium significantly decreased the reduction in body weight (P<0.05) after exposure for 3 and 4 weeks compared with the control group.

Effect of baicalein on cadmium-induced relative weight of the testes in rats: As shown in Table 2, in rats treated with cadmium alone, the relative weight of the testes significantly decreased (P<0.05) compared with that of the control group. Treatment with baicalein (100 mg/kg/day) alongside cadmium increased the relative weight of the testes. However, no significant difference was found compared with the cadmium group (P>0.05).

Histological assessment of seminiferous tubules: The testicular seminiferous tubules of rats in the control group (Fig. 1A and B) and the baicalein-treated group (Fig. 1E and F) were arranged in order, interstitial clear, seminiferous tubules seen in all stages of spermatogenic cells. Examination of tissue sections affirmed the extreme morphological changes in the testes of cadmium-treated rats. In cadmium-treated rats, the spermatogenic cells in the testicular seminiferous tubule showed disordered arrangement and structure, and their levels were unclear; meanwhile, the sperm chromatinn structure of the testes in the cavity of the spermatogenic small tubule could not be observed (Fig. 1C and D). In the CdCl₂+baicalein group (Fig. 1G and H), the atrophy and degeneration of rat testicular tissue structure were significantly improved, and germ cells levels of in the tubule of rats were basically in order.

**Histological assessment of seminiferous tubules:** The testicular seminiferous tubules of rats in the control group (Fig. 1A and B) and the baicalein-treated group (Fig. 1E and F) were arranged in order, interstitial clear, seminiferous tubules seen in all stages of spermatogenic cells. Examination of tissue sections affirmed the extreme morphological changes in the testes of cadmium-treated rats. In cadmium-treated rats, the spermatogenic cells in the testicular seminiferous tubule showed disordered arrangement and structure, and their levels were unclear; meanwhile, the sperm chromatin structure of the testes in the cavity of the spermatogenic small tube could not be observed (Fig. 1C and D). In the CdCl₂+baicalein group (Fig. 1 G and H), the atrophy and degeneration of rat testicular tissue structure were significantly improved, and germ cells levels of in the tubule of rats were basically in order.

**Effect of baicalein on testicular oxidative stress:** Changes in oxidative status were assessed by enzymatic and nonenzymatic measures. Cadmium administration significantly increased the levels of SOD, CAT and GSH-Px (P<0.05) and decreased the GSH content (P<0.05) in the testicular tissue compared with the control group. Baicalein treatment significantly (P<0.05) recovered the levels of these antioxidants to nearly normal values when compared with the cadmium-treated rats.

In rats treated with cadmium alone the MDA level significantly increased (Table 3) compared with the control group. Baicalein treatment attenuated the cadmium-induced elevation of MDA in the testicular tissue.

**DISCUSSION**

Cadmium is one of the highly toxic environmental pollutants. It can induce oxidative damage by disturbing the oxidant/antioxidant balance in the tissue, as observed in previous study (Adi et al., 2016). The male reproductive system is particularly sensitive to cadmium (Doaa et al., 2014). However, the mechanisms of cadmium-induced male reproductive system toxicity have not been established (Spiauzzi et al., 2013). Whether baicalein has the ability of protective effects against cadmium-induced toxicity has not been clarified. In this study, the body weight loss, relative testicular mass, morphological changes, and oxidative stress of the testes in rats exposed to cadmium were investigated to elucidate its molecular toxicity mechanisms.

We demonstrated that intraperitoneal injection of 2 mg CdCl₂/kg for 28 days induced weight loss and reduced relative testicular mass and macroscopic changes in rats. Weight gain is related to the availability and absorption of nutrients (Asagba and Eriyamremu, 2007). Our results showed that cadmium can inhibit the growth of rats. Cadmium-induced decreased nutrient digestion and absorption has also been shown (Eriyamremu et al., 2005). The current study is consistent with the results of Horiguchi et al. (1996), who found that the effect of cadmium can induce body weight loss. Yousef et al. (2008) indicated that body weight reduction can be used as an important indicator for the deterioration of rat general health status. Cadmium has inhibitory action on digestive and absorption enzymes (Asagba, 2010). This finding may explain the weight loss of rats as observed in this experiment. Reduced relative testicular mass is consistent with recent studies that cadmium decreases testicular volume, sperm count and motility (Ekhoye et al., 2013; Djuric et al., 2015). Szuster-Ciesielska et al. (2000)
reported that the decrease in the quality of male sex organs is a major indicator of the changes in the status of androgen, which can lead to apoptosis and necrosis of testicular tissue.

In the testes of rats in the cadmium-treated group, we found histopathological alterations, including the degeneration of seminiferous tubules and germinal cells, and the absence of spermatogenesis (Fig. 1C and D). The irregular arrangement of spermatogenic cell lines showed the lack of spermatogenesis. Laskey and Phelps (1991) also observed the decreased testicular testosterone level may be due to its reduced production by Leydig cells. Baicalein treatment significantly inhibited body weight loss and testicular relative weight. In addition, optical microscopic examination of testicular tissue in CdCl₂+ baicalein (100 mg/kg) -treated rats revealed almost normal seminiferous tubules compared with rats treated with cadmium alone. Thus, our results showed baicalein reduced the cadmium-induced weight loss and exhibited testicular protective effect.

Our results showed that the activities of antioxidative enzymes SOD, CAT, and GSH-Px increased in the testes of rats exposed to cadmium. However, this finding was contrary to that in the liver and kidney (data not shown). Djuric et al. (2015) reported that SOD and CAT decreased in cadmium-treated male Wistar rats for 21 days. This difference is related to the route, dose, and duration of exposure to cadmium. The reason for this result is that cadmium stimulated testicular cells induced oxidative stress. Considering the cellular response to oxidative damage, the expression of these enzymes was enhanced to balance a large number of ROS. Thus, the activity increased. The results in testes differed from those in the liver and kidneys, possibly because the testes have a specific blood testicular barrier; in addition, cadmium cannot easily enter the testes and the organizational structure of different cells may have led to different reactions caused by cadmium. Ezedom and Asagba (2016) reported that the activities of oxidative enzymes increased after rats were exposed to cadmium for one month (P<0.05). This finding may be because the level of cadmium was still at a low accumulated state after the 1 month exposure. Treatment with baicalein significantly reduced the activities of SOD, CAT and GSH-Px. To clarify the mechanisms of baicalein exerting its effect on cadmium-induced testicular toxicity, we treated rats with baicalein and cadmium. We found that baicalein decreased the activities of SOD, CAT and GSH-Px significantly. Thus, that baicalein could reduce the oxidative injury induced by cadmium in rats.

The changes in GSH and MDA levels in the testes are shown in Table 3. Exposure to cadmium decreased the GSH level and increased the MDA level (i.e., LPO level). Cadmium exposure can produce free radicals and lead to an increase in LP levels (Varoni et al., 2016). LP inactivates cellular components by oxidative stress in free radical chain reaction, ultimately resulting in the loss of membrane integrity or oxidation. It is a sulfhydryl peptide widely found in all biological systems. GSH acts as a nonenzymatic antioxidant to defend against oxidative stress. The decrease in GSH levels may be because of its utilization in the scavenging free radicals created by cadmium, thereby interfering with the antioxidant activity (Wang et al., 2012). Cadmium also interferes with protein metal-binding sites and/or functional groups by altering essential biometal homeostasis and the activities of corresponding metal enzymes in various organs (Wang et al., 2018). The stimulation of LP observed in this study could be because of the formation of free radicals through an exhaustion of antioxidants leading to oxidative stress and ultimately, increasing the LP level. Baicalein can inhibit oxidative stress-induced cellular damage via antioxidant effects (Kang et al., 2012). Interestingly, baicalein markedly increased GSH level and decreased MDA level in cadmium-treated rat testes in our study. Our results showed that baicalein can reduce oxidative stress by reducing the LP level in cadmium-treated testes.

**Conclusions:** Cadmium administration significantly decreased the body weight and the relative weight of the testes. Furthermore, it induced serious testicular injury and elevated SOD, CAT, and GSH-Px activities. The GSH level decreased, whereas the MDA level increased when rats were treated with cadmium. Conversely, treatment with baicalein ameliorated the cadmium-induced testicular toxicity in rats. Therefore, baicalein may be useful to treat cadmium toxicity.

**Authors contribution:** WJ, ZH and YZ conceived and designed the experiment. WJ, ZH, ZC and WH performed the experiment and analyzed the data. WJ and ZH wrote the paper. All authors have contributed to, read and approved the manuscript.
