Abstract

In this paper, we study the degraded compound multi-receiver wiretap channel. The degraded compound multi-receiver wiretap channel consists of two groups of users and a group of eavesdroppers, where, if we pick an arbitrary user from each group of users and an arbitrary eavesdropper, they satisfy a certain Markov chain. We study two different communication scenarios for this channel. In the first scenario, the transmitter wants to send a confidential message to users in the first (stronger) group and a different confidential message to users in the second (weaker) group, where both messages need to be kept confidential from the eavesdroppers. For this scenario, we assume that there is only one eavesdropper. We obtain the secrecy capacity region for the general discrete memoryless channel model, the parallel channel model, and the Gaussian parallel channel model. For the Gaussian multiple-input multiple-output (MIMO) channel model, we obtain the secrecy capacity region when there is only one user in the second group. In the second scenario we study, the transmitter sends a confidential message to users in the first group which needs to be kept confidential from the second group of users and the eavesdroppers. Furthermore, the transmitter sends a different confidential message to users in the second group which needs to be kept confidential only from the eavesdroppers. For this scenario, we do not put any restriction on the number of eavesdroppers. As in the first scenario, we obtain the secrecy capacity region for the general discrete memoryless channel model, the parallel channel model, and the Gaussian parallel channel model. For the Gaussian MIMO channel model, we establish the secrecy capacity region when there is only one user in the second group.

1 Introduction

Information theoretic secrecy was initiated by Wyner in his seminal work [1], where he considered the degraded wiretap channel and established the capacity-equivocation rate region of this degraded channel model. Later, Csiszar and Korner generalized his result to arbitrary, not necessarily degraded, wiretap channels in [2]. In recent years, multi-user versions of the wiretap channel have attracted a considerable amount of research interest; see for example references [3-21] in [3]. Among all these extensions, two natural extensions of the wiretap channel to the multi-user setting are particularly of interest here: secure broadcasting and compound wiretap channels.

Secure broadcasting refers to the situation where a transmitter wants to communicate with several legitimate receivers confidentially in the presence of an external eavesdropper. We call this channel model the multi-receiver wiretap channel. Since the underlying channel model without an eavesdropper is the broadcast channel, which is not understood to the full extent even for the two-user case, most works on secure broadcasting have focused on some special classes of multi-receiver wiretap channels, where these classes are identified by certain degradation orders [4–8]. In particular, [5–7] consider the degraded multi-receiver wiretap channel, where observations of all users and the eavesdropper satisfy a certain Markov chain. In [5], the secrecy capacity region is derived for the two-user case, and in [6, 7], the secrecy capacity region is established for an arbitrary number of legitimate users. The importance of this result lies in the facts that the Gaussian multi-receiver wiretap channel belongs to this class, and the secrecy capacity region of the degraded multi-receiver wiretap channel serves as a crucial step in establishing the secrecy capacity region of the Gaussian multiple-input multiple-output (MIMO) multi-receiver wiretap channel [3], though the latter channel is not necessarily degraded. In [3], besides proving the secrecy capacity region of the Gaussian MIMO multi-receiver wiretap channel, we also present new optimization results regarding extremal properties of Gaussian random vectors, which we generalize here.

Another extension of the wiretap channel that we are particularly interested in here, is the compound wiretap channel. In compound wiretap channels, there are a finite number of channel states determining the channel transition probability. The channel takes a certain fixed state for the entire duration of the transmission, and the transmitter does not have any knowledge about the channel state realization. Thus, the aim of the transmitter is to ensure the secrecy of messages irrespective of the channel state realization. In addition to this definition, the compound wiretap channel admits another interpretation. Consider the multi-receiver wiretap channel with several legitimate users and many eavesdroppers, where the transmitter wants to transmit a common confidential message to legitimate users while keeping all of the eavesdroppers totally ignorant of the message. Since each eavesdropper and legitimate user pair can be regarded as a different channel state realization, this channel is equivalent to a compound wiretap channel. Therefore, one can interpret a compound wiretap channel as multicasting a common confidential message to several legitimate receivers in the
presence of one or more eavesdroppers [9]. In this work, we mostly refer to this interpretation, which is also the reason why we classify the compound wiretap channel as an extension of the wiretap channel to a multi-user setting.

Keeping this interpretation in mind, first works about the compound wiretap channel are due to Yamamoto [10, 11]. References [10, 11] consider the parallel wiretap channel with two sub-channels where each sub-channel is wiretapped by a different eavesdropper. References [10, 11] establish capacity-equivocation rate regions for the situation where in each sub-channel, the legitimate receiver is less noisy with respect to the eavesdropper of this sub-channel. Other works which implicitly study the compound wiretap channel are [4, 6–8, 12], where [4, 6, 7] consider the transmission of a common confidential message to many legitimate receivers in the presence of a single eavesdropper, [8] focuses on two legitimate receivers one eavesdropper and one legitimate receiver two eavesdroppers scenarios, and [12] studies the fading wiretap channel with many receivers. Reference [9] considers the general discrete compound wiretap channel and provides inner and outer bounds for the secrecy capacity. In addition to these inner and outer bounds, [9] also establishes the secrecy capacity of the degraded compound wiretap channel as well as its degraded Gaussian MIMO instance. Another work on the compound wiretap channel is [13] where the secrecy capacity of a class of non-degraded Gaussian parallel compound wiretap channels is established.

In this work, we consider compound broadcast channels from a secrecy point of view, which enables us to study the secure broadcasting problem over compound channels. We note that the current literature regarding the compound wiretap channel considers the transmission of only one confidential message, whereas here, we study the transmission of multiple confidential messages, where each of these messages needs to be delivered to a different group of users in perfect secrecy. Hereafter, we call this channel model the compound multi-receiver wiretap channel to emphasize the presence of more than one confidential message. The compound multi-receiver wiretap channel we study here consists of two groups of users and a group of eavesdroppers, as shown in Figure 1. We focus on a special class of compound multi-receiver wiretap channels which exhibits a certain degradation order. If we consider an arbitrary user from each group and an arbitrary eavesdropper, they satisfy a certain Markov chain. In particular, we assume that there exist two fictitious users. The first fictitious user is degraded with respect to any user from the first group, and any user from the second group is degraded with respect to the first fictitious user. There exists a similar degradedness structure for the second fictitious user in the sense that it is degraded with respect to any user from the second group, and any eavesdropper is degraded with respect to it. Without eavesdroppers, this channel model reduces to the degraded compound broadcast channel studied in [14]. Adapting their terminology, we call our channel model the degraded compound multi-receiver wiretap channel. Here, we consider the general discrete memoryless version of the degraded compound multi-receiver wiretap channel as well as its specializations to the parallel degraded compound multi-receiver wiretap channel, the Gaus-
sian parallel degraded compound multi-receiver wiretap channel, and the Gaussian MIMO degraded compound multi-receiver wiretap channel. We study two different communication scenarios for each version of the degraded compound multi-receiver wiretap channel model.

In the first scenario, which is illustrated in Figure 2, the transmitter wants to send a confidential message to users in the first group, and a different confidential message to users in the second group, where both messages need to be kept confidential from the eavesdroppers. For this scenario, we assume that there exists only one eavesdropper and obtain the secrecy capacity region in a single-letter form. While obtaining this result, the presence of the fictitious user between the two groups of users plays a crucial role in the converse proof by providing a conditional independence structure in the channel, which enables us to define an auxiliary random variable that yields a tight outer bound. After establishing single-letter expressions for the secrecy capacity region, we consider the parallel degraded compound multi-receiver wiretap channel. For the parallel degraded compound multi-receiver wiretap channel, we obtain the secrecy capacity region in a single-letter form as well. Though the general discrete memoryless degraded compound multi-receiver wiretap channel encompasses the parallel degraded compound multi-receiver wiretap channel as a special case, we still need a converse proof to establish the optimality of independent signalling in each sub-channel. After we obtain the secrecy capacity region of the parallel degraded compound multi-receiver wiretap channel, we consider the Gaussian parallel degraded compound multi-receiver wiretap channel. In particular, we evaluate the secrecy capacity region of the parallel degraded compound multi-receiver wiretap channel for the Gaussian case, which is tantamount to finding the optimal joint distribution of auxiliary random variables and channel inputs, which is shown to be Gaussian. We accomplish this by using Costa’s entropy power inequality [15]. Finally, we consider the Gaussian MIMO degraded compound multi-receiver wiretap channel, and evaluate its secrecy capacity region when there is only one user in the second group. We show the optimality of a jointly Gaussian distribution for auxiliary random variables and channel inputs by generalizing our optimization results in [3].

In the second scenario we study here, which is illustrated in Figure 3, the transmitter wants to send a confidential message to users in the first group which needs to be kept confidential from users in the second group and eavesdroppers. Moreover, the transmitter sends a different confidential message to users in the second group, which needs to be kept
confidential from the eavesdroppers. If there were only one user in each group and one eavesdropper, this channel model would reduce to the channel model that was studied in [16]. However, here, there are an arbitrary number of users in each group and an arbitrary number of eavesdroppers. Hence, our model can be viewed as a generalization of [16] to a compound setting. Adapting their terminology, we call this channel model the *degraded compound multi-receiver wiretap channel with layered messages*. We first obtain the secrecy capacity region in a single-letter form for a general discrete memoryless setting, where again the presence of fictitious users plays a key role in the converse proof. Next, we consider the parallel degraded compound multi-receiver wiretap channel with layered messages and establish its secrecy capacity region in a single-letter form. In this case as well, we provide the converse proof which is again necessary to show the optimality of independent signalling in each sub-channel. After we obtain the secrecy capacity region of the parallel degraded compound multi-receiver wiretap channel with layered messages, we evaluate it for the Gaussian parallel degraded compound multi-receiver wiretap channel with layered messages by showing the optimality of a jointly Gaussian distribution for auxiliary random variables and channel inputs. For that purpose, we again use Costa’s entropy power inequality [15]. Finally, we consider the Gaussian MIMO degraded compound multi-receiver wiretap channel with layered messages, and evaluate its secrecy capacity region when there is only one user in the second group. To this end, we show that jointly Gaussian auxiliary random variables and channel inputs are optimal by extending our optimization results in [3].
2 System Model

In this paper, we consider the degraded compound multi-receiver wiretap channel, see Figure 1 which consists of two groups of users and a group of eavesdroppers. There are $K_1$ users in the first group, $K_2$ users in the second group, and $K_Z$ eavesdroppers. The channel is assumed to be memoryless with a transition probability

$$p(y_1, \ldots, y_{K_1}^1, y_1^2, \ldots, y_{K_2}^2, z_1, \ldots, z_{K_Z}|x)$$

where $X \in \mathcal{X}$ is the channel input, $Y_j^1 \in \mathcal{Y}_j^1$ is the channel output of the $j$th user in the first group, $j = 1, \ldots, K_1$, $Y_k^2 \in \mathcal{Y}_k^2$ is the channel output of the $k$th user in the second group, $k = 1, \ldots, K_2$, and $Z_t \in \mathcal{Z}_t$ is the channel output of the $t$th eavesdropper, $t = 1, \ldots, K_Z$.

We assume that there exist two fictitious users with observations $Y^* \in \mathcal{Y}^*$, $Z^* \in \mathcal{Z}^*$ such that they satisfy the Markov chain

$$X \rightarrow Y_j^1 \rightarrow Y^* \rightarrow Y_k^2 \rightarrow Z^* \rightarrow Z_t, \quad \forall (j, k, t)$$

This Markov chain is the reason why we call this channel model the degraded compound multi-receiver wiretap channel. Actually, there is a slight inexactness in the terminology here because the Markov chain in (2) is more restrictive than the Markov chain

$$X \rightarrow Y_j^1 \rightarrow Y_k^2 \rightarrow Z_t, \quad \forall (j, k, t)$$

and it might be more natural to define the degradedness of the compound multi-receiver wiretap channel by the Markov chain in (3). However, in this work, we adapt the terminology of the previous work on compound broadcast channels [14], and call the channel satisfying (2) the degraded compound multi-receiver wiretap channel. Finally, we note that when there are no eavesdroppers, this channel reduces to the degraded compound broadcast channel that was studied in [14].

2.1 Parallel Degraded Compound Multi-receiver Wiretap Channels

The parallel degraded compound multi-receiver wiretap channel, where each user’s and each eavesdropper’s channel consists of $L$ independent sub-channels, i.e.,

$$Y_j^1 = (Y_{j1}^1, \ldots, Y_{jL}^1), \quad j = 1, \ldots, K_1$$
$$Y_k^2 = (Y_{k1}^2, \ldots, Y_{kL}^2), \quad k = 1, \ldots, K_2$$
$$Z_t = (Z_{t1}, \ldots, Z_{tL}), \quad t = 1, \ldots, K_Z$$
has the following overall transition probability
\[
p(y_1^1, \ldots, y_{K_1}^1, y_1^2, \ldots, y_{K_2}^2, z_1, \ldots, z_{K_z} | x) = \prod_{\ell=1}^L p(y_{1\ell}^1, \ldots, y_{K_1\ell}^1, y_{1\ell}^2, \ldots, y_{K_2\ell}^2, z_{1\ell}, \ldots, z_{K_z\ell} | x_{\ell})
\]
(7)

where \(X_\ell, \ell = 1, \ldots, L\), is the \(\ell\)th sub-channel’s input. We define the degradedness of the parallel compound multi-receiver wiretap channel in a similar fashion. In particular, we call a parallel compound multi-receiver wiretap channel degraded, if there exist two sequences of random variables
\[
Y^* = (Y_{1}^*, \ldots, Y_{L}^*) \\
Z^* = (Z_{1}^*, \ldots, Z_{L}^*)
\]
(8)
(9)
which satisfy Markov chains
\[
X_\ell \rightarrow Y_{1\ell}^1 \rightarrow Y^*_{\ell} \rightarrow Y_{2\ell}^2 \rightarrow Z^*_{\ell} \rightarrow Z_{t\ell}, \quad \forall(j, k, t, \ell)
\]
(10)

2.2 Gaussian Parallel Degraded Compound Multi-receiver Wiretap Channels

The Gaussian parallel compound multi-receiver wiretap channel is defined by
\[
Y_j^1 = X + N_j^1, \quad j = 1, \ldots, K_1 \\
Y_k^2 = X + N_k^2, \quad k = 1, \ldots, K_2 \\
Z_t = X + N_t^Z, \quad t = 1, \ldots, K_z
\]
(11)
(12)
(13)

where all column vectors \(\{Y_j^1\}_{j=1}^{K_1}, \{Y_k^2\}_{k=1}^{K_2}, \{Z_t\}_{t=1}^{K_z}, X, \{N_j^1\}_{j=1}^{K_1}, \{N_k^2\}_{k=1}^{K_2}, \{N_t^Z\}_{t=1}^{K_z}\) are of dimensions \(L \times 1\). \(\{N_j^1\}_{j=1}^{K_1}, \{N_k^2\}_{k=1}^{K_2}, \{N_t^Z\}_{t=1}^{K_z}\) are Gaussian random vectors with diagonal covariance matrices \(\{A_{j1}\}_{j=1}^{K_1}, \{A_{k2}\}_{k=1}^{K_2}, \{A_{tZ}\}_{t=1}^{K_z}\), respectively. The channel input \(X\) is subject to a trace constraint as
\[
E [X^\top X] = \text{tr} (E [XX^\top]) \leq P
\]
(14)

In this paper, we will be interested in Gaussian parallel degraded compound multi-receiver wiretap channels which means that the covariance matrices satisfy the following order
\[
A_{j1} \preceq A_{k2} \preceq A_{tZ}, \quad \forall(j, k, t)
\]
(15)
Since noise covariance matrices are diagonal, the order in (15) implies
\[ \Lambda_{1,j,\ell \ell} \leq \Lambda_{2,k,\ell \ell} \leq \Lambda_{Z,t,\ell \ell}, \quad \forall (j, k, t, \ell) \]
(16)
where \( \Lambda_{1,j,\ell \ell}, \Lambda_{2,k,\ell \ell}, \Lambda_{Z,t,\ell \ell} \) denote the \( \ell \)th diagonal element of \( \Lambda_{1,j}, \Lambda_{2,k}, \Lambda_{Z,t} \), respectively.

The diagonality of noise covariance matrices also ensures the existence of diagonal matrices \( \Lambda_{Y}^{*} \) and \( \Lambda_{Z}^{*} \) such that
\[ \Lambda_{1,j} \preceq \Lambda_{Y}^{*} \preceq \Lambda_{2,k} \preceq \Lambda_{Z}^{*} \preceq \Lambda_{t}^{Z}, \quad \forall (k, j, t) \]
(17)
For example, we can select \( \Lambda_{Y}^{*} \) as \( \Lambda_{Y}^{* \ell \ell} = \max_{j=1,...,K_1} \Lambda_{1,j,\ell \ell} \) which already satisfies (17) because of \( \max_{j=1,...,K_1} \Lambda_{1,j,\ell \ell} \leq \min_{k=1,...,K_2} \Lambda_{2,k,\ell \ell} \) which is due to (16). Similarly, we can select \( \Lambda_{Z}^{*} \). Thus, for Gaussian parallel compound multi-receiver channels, the two possible ways of defining degradedness, i.e., (2) and (3), are equivalent due to the equivalence of (15) and (17).

2.3 Gaussian MIMO Degraded Compound Multi-receiver Wiretap Channels

The Gaussian MIMO degraded compound multi-receiver wiretap channel is defined by
\[ Y_{1,j} = X + N_{1,j}, \quad j = 1, \ldots, K_1 \]
(18)
\[ Y_{2,k} = X + N_{2,k}, \quad k = 1, \ldots, K_2 \]
(19)
\[ Z_{t} = X + N_{Z,t}, \quad t = 1, \ldots, K_Z \]
(20)
where all column vectors \( \{Y_{1,j}\}_{j=1}^{K_1}, \{Y_{2,k}\}_{k=1}^{K_2}, \{Z_{t}\}_{t=1}^{K_Z}, X, \{N_{1,j}\}_{j=1}^{K_1}, \{N_{2,k}\}_{k=1}^{K_2}, \{N_{Z,t}\}_{t=1}^{K_Z} \) are of dimensions \( M \times 1 \). \( \{N_{1,j}\}_{j=1}^{K_1}, \{N_{2,k}\}_{k=1}^{K_2}, \{N_{Z,t}\}_{t=1}^{K_Z} \) are Gaussian random vectors with covariance matrices \( \{\Sigma_{1,j}\}_{j=1}^{K_1}, \{\Sigma_{2,k}\}_{k=1}^{K_2}, \{\Sigma_{Z,t}\}_{t=1}^{K_Z} \), respectively. Unlike in the case of Gaussian parallel channels, these covariance matrices are not necessarily diagonal. The channel input \( X \) is subject to a covariance constraint
\[ E [XX^\top] \preceq S \]
(21)
where \( S \succ 0 \).

In this paper, we study Gaussian MIMO degraded compound multi-receiver wiretap channels for which there exist covariance matrices \( \Sigma_{Y}^{*} \) and \( \Sigma_{Z}^{*} \) such that
\[ \Sigma_{1,j} \preceq \Sigma_{Y}^{*} \preceq \Sigma_{2,k} \preceq \Sigma_{Z}^{*} \preceq \Sigma_{t}^{Z}, \quad \forall (j, k, t) \]
(22)
We note that the order in (22), by which we define the degradedness, is more restrictive than
the other possible order that can be used to define the degradedness, i.e.,

\[
\Sigma^j \preceq \Sigma^k \preceq \Sigma^z, \quad \forall (j, k, t)
\] (23)

In [14], a specific numerical example is provided to show that the order in (23) strictly subsumes the one in (22).

### 2.4 Comments on Gaussian MIMO Degraded Compound Multi-receiver Wiretap Channels

We provide some comments about the way we define the Gaussian MIMO degraded compound multi-receiver wiretap channel. The first one is about the covariance constraint in (21). Though it is more common to define capacity regions under a total power constraint, i.e., \( \text{tr} \left( E \left[ XX^\top \right] \right) \leq P \), the covariance constraint in (21) is more general and it subsumes the total power constraint as a special case [17]. In particular, if we denote the secrecy capacity region under the constraint in (21) by \( C(S) \), then the secrecy capacity region under the trace constraint, \( \text{tr} \left( E \left[ XX^\top \right] \right) \leq P \), can be written as [17]

\[
C^{\text{trace}}(P) = \bigcup_{S: \text{tr}(S) \leq P} C(S)
\] (24)

The second comment is about our assumption that \( S \) is strictly positive definite. This assumption does not lead to any loss of generality because for any Gaussian MIMO compound multi-receiver wiretap channel with a positive semi-definite covariance constraint, i.e., \( S \succeq 0 \) and \( |S| = 0 \), we can always construct an equivalent channel with the constraint \( E \left[ XX^\top \right] \preceq S' \) where \( S' \succ 0 \) (see Lemma 2 of [17]), which has the same secrecy capacity region.

The last comment is about the assumption that the transmitter and all receivers have the same number of antennas. This assumption is implicit in the channel definition, see (18)-(20), and also in the definition of degradedness, see (22). However, we can extend the definition of the Gaussian MIMO degraded compound multi-receiver wiretap channel to include the cases where the number of transmit antennas and the number of receive antennas at each receiver are not necessarily the same. To this end, we first introduce the following channel model

\[
Y^1_j = H^1_j X + N^1_j, \quad j = 1, \ldots, K_1
\] (25)

\[
Y^2_k = H^2_k X + N^2_k, \quad k = 1, \ldots, K_2
\] (26)

\[
Z_t = H^z_t X + N^z_t, \quad t = 1, \ldots, K_Z
\] (27)

where \( H^1_j, H^2_k, H^z_t \) are the channel matrices of sizes \( r^1_j \times t, r^2_k \times t, r^z_t \times t \), respectively, and \( X \) is of size \( t \times 1 \). The channel outputs \( Y^1_j, Y^2_k, Z_t \) are of sizes \( r^1_j \times 1, r^2_k \times 1, r^z_t \times 1 \), respectively. The Gaussian noise vectors \( N^1_j, N^2_k, N^z_t \) are assumed to have identity covariance matrices.
To define degradedness for the channel model given in (25)-(27), we need the following definition from [14]: A receive vector \( Y_a = H_a X + N_a \) of size \( r_a \times 1 \) is said to be degraded with respect to \( Y_b = H_b X + N_b \) of size \( r_b \times 1 \), if there exists a matrix \( D \) of size \( r_a \times r_b \) such that \( DH_b = H_a \) and \( DD^T \preceq I \). Using this equivalent definition of degradedness, we now give the equivalent definition of degradedness for the channel model in (25)-(27). To this end, we first introduce two fictitious users with observations \( Y^* \) and \( Z^* \), which are given by

\[
Y^* = H^*_Y X + N^*_Y \tag{28}
\]

\[
Z^* = H^*_Z X + N^*_Z \tag{29}
\]

The Gaussian MIMO compound multi-receiver wiretap channel in (25)-(27) is said to be degraded if the following two conditions hold: i) \( Y^* \) is degraded with respect to any user from the first group, and any user from the second group is degraded with respect to \( Y^* \), and ii) \( Z^* \) is degraded with respect to any user from the second group, and any eavesdropper is degraded with respect to \( Z^* \), where degradedness here is with respect to the definition given above.

In the rest of the paper, we consider the channel model given in (18)-(20) instead of the channel model given in (25)-(27), which is more general. However, if we establish the secrecy capacity region for the Gaussian MIMO degraded compound multi-receiver wiretap channel defined by (18)-(20), we can also obtain the secrecy capacity region for the Gaussian MIMO degraded compound multi-receiver wiretap channel defined by (25)-(27) using the analysis carried out in Section V of [14] and Section 7.1 of [3]. Thus, focusing on the channel model in (18)-(20) does not result in any loss of generality.

### 3 Problem Statement and Main Results

In this paper, we consider two different communication scenarios for the degraded compound multi-receiver wiretap channel.

#### 3.1 The First Scenario: External Eavesdroppers

In the first scenario, the transmitter wants to send a confidential message to users in the first group and a different confidential message to users in the second group, where both messages need to be kept confidential from the eavesdroppers. In this case, we assume that there is only one eavesdropper, i.e., \( K_Z = 1 \). The graphical illustration of the first scenario is given in Figure 2.

An \((n, 2^{nR_1}, 2^{nR_2})\) code for the first scenario consists of two message sets \( \mathcal{W}_1 = \{1, \ldots, 2^{nR_1}\}, \mathcal{W}_2 = \{1, \ldots, 2^{nR_2}\} \), an encoder \( f : \mathcal{W}_1 \times \mathcal{W}_2 \rightarrow X^n \), one decoder for each legitimate user in the first group \( g^{1}_{j} : \mathcal{Y}_{j}^{1,n} \rightarrow \mathcal{W}_1, j = 1, \ldots, K_1 \), and one decoder for each legitimate user in the second group \( g^{2}_{k} : \mathcal{Y}_{k}^{2,n} \rightarrow \mathcal{W}_2, k = 1, \ldots, K_2 \). The probability of error is defined
\[ P_n^e = \max \{ P_{1,n}^e, P_{2,n}^e \} \] (30)

where \( P_{1,n}^e \) and \( P_{2,n}^e \) are given by

\[ P_{1,n}^e = \max_{j \in \{1, \ldots, K_1\}} \Pr \left[ g_j^1(Y_{1,j}^{1,n}) \neq W_1 \right] \] (31)

\[ P_{2,n}^e = \max_{k \in \{1, \ldots, K_2\}} \Pr \left[ g_k^2(Y_{2,k}^{2,n}) \neq W_2 \right] \] (32)

A secrecy rate pair \((R_1, R_2)\) is said to be achievable if there exists an \((n, 2^{nR_1}, 2^{nR_2})\) code which has \( \lim_{n \to \infty} P_n^e = 0 \) and

\[ \lim_{n \to \infty} \frac{1}{n} I(W_1, W_2; Z^n) = 0 \] (33)

where we dropped the subscript of \( Z_t \) since \( K_Z = 1 \). We note that (33) implies

\[ \lim_{n \to \infty} \frac{1}{n} I(W_1; Z^n) = 0 \quad \text{and} \quad \lim_{n \to \infty} \frac{1}{n} I(W_2; Z^n) = 0 \] (34)

From these definitions, it is clear that we are only interested in perfect secrecy rates of the channel. The secrecy capacity region is defined as the closure of all achievable secrecy rate pairs. A single-letter characterization of the secrecy capacity region is given as follows.

**Theorem 1** The secrecy capacity region of the degraded compound multi-receiver wiretap channel is given by the union of rate pairs \((R_1, R_2)\) satisfying

\[ R_1 \leq \min_{j=1, \ldots, K_1} I(X; Y_j^1|U, Z) \] (35)

\[ R_2 \leq \min_{k=1, \ldots, K_2} I(U; Y_k^2|Z) \] (36)

where the union is over all \((U, X)\) such that

\[ U \to X \to Y_j^1 \to Y^* \to Y_k^2 \to Z \] (37)

for any \((j, k)\) pair.

Showing the achievability of this region is rather standard, thus is omitted here. We provide the converse proof in Appendix A. The presence of the fictitious user with observation \( Y^* \) proves to be crucial in the converse proof. Essentially, it brings a conditional independence structure to the channel, which enables us to define the auxiliary random variable \( U \), which, in turn, provides the converse proof.

As a side note, if we disable the eavesdropper by setting \( Z = \phi \), the region in Theorem 1 reduces to the capacity region of the underlying degraded compound broadcast channel which
was established in [14].

### 3.1.1 Parallel Degraded Compound Multi-Receiver Wiretap Channels

In the upcoming section, we will consider the Gaussian parallel degraded compound multi-receiver wiretap channel. For that purpose, here, we provide the secrecy capacity region of the parallel degraded compound multi-receiver wiretap channel in a single-letter form.

**Theorem 2** The secrecy capacity region of the parallel degraded compound multi-receiver wiretap channel is given by the union of rate pairs \((R_1, R_2)\) satisfying

\[
R_1 \leq \min_{j=1,\ldots,K_1} \sum_{\ell=1}^{L} I(X_\ell; Y_{j\ell}^1|U_\ell, Z_\ell) \quad (38)
\]

\[
R_2 \leq \min_{k=1,\ldots,K_2} \sum_{\ell=1}^{L} I(U_\ell; Y_{k\ell}^2|Z_\ell) \quad (39)
\]

where the union is over all distributions of the form \(\prod_{\ell=1}^{L} p(u_\ell, x_\ell)\) such that

\[
U_\ell \rightarrow X_\ell \rightarrow Y_{j\ell}^1 \rightarrow Y_{j\ell}^* \rightarrow Y_{k\ell}^2 \rightarrow Z_\ell \quad (40)
\]

for any \((j, k, \ell)\) triple.

Though Theorem 1 provides the secrecy capacity region for a rather general channel model including the parallel degraded compound multi-receiver channel as a special case, we still need a converse proof to show that the region in Theorem 1 reduces to the region in Theorem 2 for parallel channels. In other words, we still need to show the optimality of independent signalling on each sub-channel. This proof is provided in Appendix B.

### 3.1.2 Gaussian Parallel Degraded Compound Multi-Receiver Wiretap Channels

We now obtain the secrecy capacity region of the parallel Gaussian degraded compound multi-receiver wiretap channel. To that end, we need to evaluate the region given in Theorem 2 i.e., we need to find the optimal joint distribution \(\prod_{\ell=1}^{L} p(u_\ell, x_\ell)\). We first introduce the following theorem which will be instrumental in evaluating the region in Theorem 2 for Gaussian parallel channels.

**Theorem 3** Let \(N_1, N^*, N_2, N_Z\) be zero-mean Gaussian random variables with variances \(\sigma_1^2, \sigma_*^2, \sigma_2^2, \sigma_Z^2\), respectively, where

\[
\sigma_1^2 \leq \sigma_*^2 \leq \sigma_2^2 \leq \sigma_Z^2 \quad (41)
\]

Let \((U, X)\) be an arbitrarily dependent random variable pair, which is independent of \((N_1, N^*, N_2, N_Z)\), and the second-moment of \(X\) be constrained as \(E[X^2] \leq P\). Then, for
any feasible \((U, X)\), we can find a \(P^* \leq P\) such that
\[
h(X + N_Z|U) - h(X + N^*|U) = \frac{1}{2} \log \frac{P^* + \sigma^2_Z}{P^* + \sigma_2^*}
\] (42)

and
\[
h(X + N_Z|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{P^* + \sigma^2_Z}{P^* + \sigma_1^*} \] (43)
\[
h(X + N_Z|U) - h(X + N_2|U) \leq \frac{1}{2} \log \frac{P^* + \sigma^2_Z}{P^* + \sigma_2^*} \] (44)

for any \((\sigma_1^2, \sigma_2^2)\) satisfying the order in (41).

Costa’s entropy power inequality [15] plays a key role in the proof of this theorem. The proof of this theorem is provided in Appendix C.

We are now ready to establish the secrecy capacity region of the Gaussian parallel degraded compound multi-receiver wiretap channel.

**Theorem 4** The secrecy capacity region of the Gaussian parallel degraded compound multi-receiver wiretap channel is given by the union of rate pairs \((R_1, R_2)\) satisfying
\[
R_1 \leq \min_{j=1,\ldots,K_1} \sum_{\ell=1}^L \frac{1}{2} \log \left( 1 + \frac{\beta_\ell P_\ell}{\Lambda_{j,\ell}} \right) - \frac{1}{2} \log \left( 1 + \frac{\beta_\ell P_\ell}{\Lambda_{Z,\ell}} \right)
\] (45)
\[
R_2 \leq \min_{k=1,\ldots,K_2} \sum_{\ell=1}^L \frac{1}{2} \log \left( 1 + \frac{\bar{\beta}_\ell P_\ell}{\beta_\ell P_\ell + \Lambda_{k,\ell}} \right) - \frac{1}{2} \log \left( 1 + \frac{\bar{\beta}_\ell P_\ell}{\bar{\beta}_\ell P_\ell + \Lambda_{Z,\ell}} \right)
\] (46)

where the union is over all \(\{P_\ell\}_{\ell=1}^L\) such that \(\sum_{\ell=1}^L P_\ell = P\) and \(\bar{\beta}_\ell = 1 - \beta_\ell \in [0, 1], \ell = 1, \ldots, L\).

The proof of this theorem is provided in Appendix D. Here, \(P_\ell\) denotes the part of the total available power \(P\) which is devoted to the transmission in the \(\ell\)th sub-channel. Furthermore, \(\beta_\ell\) denotes the fraction of the power \(P_\ell\) of the \(\ell\)th sub-channel spent for the transmission to users in the first group.

### 3.1.3 Gaussian MIMO Degraded Compound Multi-receiver Wiretap Channels

In this section, we first obtain the secrecy capacity region of the Gaussian MIMO degraded compound multi-receiver wiretap channel when \(K_2 = 1\), and then partially characterize the secrecy capacity region for the case \(K_2 > 1\). To that end, we need to evaluate the region given in Theorem 4. In other words, we need to find the optimal random variable pair \((U, X)\).

We are able to do this for the entire capacity region when there is only one user in the second group, i.e., \(K_2 = 1\). For this, we need the following theorem.
Theorem 5 Let \((N_1, N^*, N_Z)\) be zero-mean Gaussian random vectors with covariance matrices \(\Sigma_1, \Sigma^*, \Sigma_Z\), respectively, where

\[\Sigma_1 \preceq \Sigma^* \preceq \Sigma_Z\] (47)

Let \((U, X)\) be arbitrarily dependent random vector, which is independent of \((N_1, N^*, N_Z)\), and let the second moment of \(X\) be constrained as \(E[XX^\top] \preceq S\). Then, for any feasible \((U, X)\), we can find a positive semi-definite matrix \(K^*\) such that 

\[h(X + N_Z|U) - h(X + N^*|U) = \frac{1}{2} \log \frac{|K^* + \Sigma_Z|}{|K^* + \Sigma^*|} \] (48)

and

\[h(X + N_Z|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{|K^* + \Sigma_Z|}{|K^* + \Sigma_1|} \] (49)

for any \(\Sigma_1\) satisfying the order in (47).

The proof of this theorem can be found in [3]. Using this theorem, we can establish the secrecy capacity region of the Gaussian MIMO degraded compound multi-receiver wiretap channel when \(K_2 = 1\) as follows.

Theorem 6 The secrecy capacity region of the Gaussian MIMO degraded compound channel when \(K_2 = 1\) is given by the union of rate pairs \((R_1, R_2)\) satisfying

\[R_1 \leq \min_{j=1,...,K_1} \frac{1}{2} \log \frac{|K + \Sigma^j_j|}{|\Sigma^j_j|} - \frac{1}{2} \log \frac{|K + \Sigma_Z|}{|\Sigma_Z|} \] (50)

\[R_2 \leq \frac{1}{2} \log \frac{|S + \Sigma^2_k|}{|K + \Sigma^2_k|} - \frac{1}{2} \log \frac{|S + \Sigma_Z|}{|K + \Sigma_Z|} \] (51)

where we dropped the subscript of \(\Sigma^2_k\) since \(K_2 = 1\), and the union is over all positive semi-definite matrices \(K\) such that \(K \preceq S\).

The proof of this theorem is given in Appendix E.

We now consider the case \(K_2 > 1\). We first note that since the secrecy capacity region given in Theorem 6 is convex, the boundary of this region can be written as the solution of the following optimization problem

\[
\max_{(U,X)} \min_{j=1,...,K_1} R_{1j} + \mu \min_{k=1,...,K_2} R_{2k}
\] (52)
where $R_{1j}$ and $R_{2k}$ are given by

$$R_{1j} = I(X; Y_j^1 | U, Z) = I(X; Y_j^1 | U) - I(X; Z | U)$$  \hspace{1cm} (53)

$$R_{2k} = I(U; Y_k^2 | Z) = I(U; Y_k^2) - I(U; Z)$$  \hspace{1cm} (54)

respectively, and the maximization is over all $(U, X)$ such that $E [XX^T] \preceq S$. In the sequel, we show that jointly Gaussian $(U, X)$ is the maximizer for (52) when $\mu \leq 1$. To this end, we need to consider the optimal Gaussian solution for (52), i.e., the solution of (52) when $(U, X)$ is restricted to be Gaussian. The corresponding optimization problem is

$$\max_{0 \preceq K \preceq S} \min_{j=1,...,K_1} R_{1j}^G(K) + \mu \min_{k=1,...,K_2} R_{2k}^G(K)$$  \hspace{1cm} (55)

where $R_{1j}^G(K)$ and $R_{2k}^G(K)$ are given by

$$R_{1j}^G(K) = \frac{1}{2} \log \frac{|K + \Sigma_j^1|}{|\Sigma_j^1|} - \frac{1}{2} \log \frac{|K + \Sigma|}{|\Sigma|}$$  \hspace{1cm} (56)

$$R_{2k}^G(K) = \frac{1}{2} \log \frac{|S + \Sigma_k^2|}{|K + \Sigma_k^2|} - \frac{1}{2} \log \frac{|S + \Sigma|}{|K + \Sigma|}$$  \hspace{1cm} (57)

We assume that the maximum for (55) occurs at $K = K^*$, and the corresponding rate pair is $(R_1^*, R_2^*)$, i.e.,

$$R_1^* = \min_{j=1,...,K_1} R_{1j}^G(K^*)$$  \hspace{1cm} (58)

$$R_2^* = \min_{k=1,...,K_2} R_{2k}^G(K^*)$$  \hspace{1cm} (59)

The KKT conditions that this optimal covariance matrix $K^*$ needs to satisfy are given in the following lemma.

**Lemma 1** The optimal covariance matrix for (55), $K^*$, needs to satisfy

$$\sum_{j=1}^{K_1} \lambda_{1j}(K^* + \Sigma_j^1)^{-1} - (K^* + \Sigma_Z)^{-1} + M = \mu \sum_{k=1}^{K_2} \lambda_{2k}(K^* + \Sigma_k^2)^{-1} - \mu(K^* + \Sigma_Z)^{-1} + M_S$$  \hspace{1cm} (60)

where $\sum_{j=1}^{K_1} \lambda_{1j} = 1$, and $\lambda_{1j} \geq 0$ with equality if $R_{1j}^G(K^*) > R_1^*$; $\sum_{k=1}^{K_2} \lambda_{2k} = 1$, and $\lambda_{2k} \geq 0$ with equality if $R_{2k}^G(K^*) > R_2^*$; and $M$ and $M_S$ are positive semi-definite matrices which satisfy $K^*M = MK^* = 0$ and $(S - K^*)M_S = M_S(S - K^*) = 0$, respectively.

\footnote{With this assumption, we implicitly assume that the maximum in (55) occurs at a single rate pair $(R_1^*, R_2^*)$. In fact, there might be more than one rate pair where the maximum occurs. Even if this is the case, we can simply consider only one of them, since our ultimate goal is to show that the maximum in (52) is equal to the maximum in (55).}
The proof of this lemma is given in Appendix F.

To show that both (52) and (55) have the same value when \( \mu \leq 1 \), we use the following optimization result due to [14].

Lemma 2 ([14], Lemma 2) Let \( U, X, \{N^1_j\}_{j=1}^{K_1}, \{N^2_k\}_{k=1}^{K_2}, N_Z \) be as defined before. The following expression

\[
\sum_{j=1}^{K_1} \lambda_{ij} h(X + N^1_j|U) - \mu \sum_{k=1}^{K_2} \lambda_{2k} h(X + N^2_k|U) - (1 - \mu) h(X + N_Z|U)
\]

(61)

is maximized by jointly Gaussian \((U, X)\) when \( \mu \leq 1 \). Furthermore, the optimal covariance matrix needs to satisfy (60), where \( M \) and \( M_S \) are as they are defined in Lemma 1.

In [14], a weaker version of this lemma is proved. This weaker version requires the existence of a covariance matrix \( K^* \) for which the Lagrange multiplier \( M \) in (60) is zero. However, using the channel enhancement technique [17], this requirement can be removed. Using Lemma 2 in conjunction with Lemma 1, we are able to characterize the secrecy capacity region partially for the case \( K_2 > 1 \).

Theorem 7 The boundary of the secrecy capacity region of the degraded Gaussian MIMO compound multi-receiver wiretap channel is given by the solution of the following optimization problem

\[
\max_{0 \preceq K \preceq S} \min_{j=1,\ldots,K_1} R^G_{1j}(K) + \mu \min_{k=1,\ldots,K_2} R^G_{2k}(K)
\]

(62)

for \( \mu \leq 1 \). That is, for this part of the secrecy rate region, jointly Gaussian auxiliary random variables and channel inputs are optimal.

The proof of this theorem is given in Appendix F.

3.2 The Second Scenario: Layered Confidential Messages

In the second scenario, the transmitter wants to send a confidential message to users in the first group which needs to be kept confidential from the second group of users and eavesdroppers. The transmitter also wants to send a different confidential message to users in the second group, which needs to be kept confidential from the eavesdroppers. As opposed to the first scenario, in this case, we do not put any restriction on the number of eavesdroppers. The graphical illustration of the second scenario is given in Figure 3. The situation where there is only one user in each group and one eavesdropper was investigated in [16]. Hence, this second scenario can be seen as a generalization of the model in [16] to a compound channel setting. Following the terminology of [16], we call this channel model the degraded compound multi-receiver wiretap channel with layered messages.
An \((n, 2^{nR_1}, 2^{nR_2})\) code for the degraded compound multi-receiver wiretap channel with\(^*\)layered messages consists of two message sets \(\mathcal{W}_1 = \{1, \ldots, 2^{nR_1}\}, \mathcal{W}_2 = \{1, \ldots, 2^{nR_2}\}\) and an encoder \(f : \mathcal{W}_1 \times \mathcal{W}_2 \rightarrow \mathcal{X}^n\), one decoder for each legitimate user in the first group \(g^1_j : \mathcal{Y}_j^{1,n} \rightarrow \mathcal{W}_1, \ j = 1, \ldots, K_1\), and one decoder for each legitimate user in the second group \(g^2_k : \mathcal{Y}_k^{2,n} \rightarrow \mathcal{W}_2, \ k = 1, \ldots, K_2\). The probability of error is defined as

\[P^n_e = \max\{P^{1,n}_e, P^{2,n}_e\}\] (63)

where \(P^{1,n}_e\) and \(P^{2,n}_e\) are given by

\[P^{1,n}_e = \max_{j \in \{1, \ldots, K_1\}} \Pr [g^1_j(Y_j^{1,n}) \neq W_1]\] (64)

\[P^{2,n}_e = \max_{k \in \{1, \ldots, K_2\}} \Pr [g^2_k(Y_k^{2,n}) \neq W_2]\] (65)

A secrecy rate pair is said to be achievable if there exists an \((n, 2^{nR_1}, 2^{nR_2})\) code which has

\[\lim_{n \rightarrow \infty} P^n_e = 0,\]

\[\lim_{n \rightarrow \infty} \frac{1}{n} I(W_2; Z^n_t) = 0, \quad t = 1, \ldots, K_Z\] (66)

and

\[\lim_{n \rightarrow \infty} \frac{1}{n} I(W_1; Y_k^{2,n}|W_2) = 0, \quad k = 1, \ldots, K_2\] (67)

We note that these two secrecy conditions imply

\[\lim_{n \rightarrow \infty} \frac{1}{n} I(W_1, W_2; Z^n_t) = 0, \quad t = 1, \ldots, K_Z\] (68)

Furthermore, it is clear that we are only interested in perfect secrecy rates of the channel. The secrecy capacity region is defined as the closure of all achievable secrecy rate pairs. A single-letter characterization of the secrecy capacity region is given as follows.

**Theorem 8** The secrecy capacity region of the degraded compound multi-receiver wiretap channel with layered messages is given by the union of rate pairs \((R_1, R_2)\) satisfying

\[R_1 \leq \min_{j=1, \ldots, K_1} I(X; Y_j^1|U, Y_k^2)\] (69)

\[R_2 \leq \min_{k=1, \ldots, K_2} I(U; Y_k^2|Z_t)\] (70)

where the union is over all random variable pairs \((U, X)\) such that

\[U \rightarrow X \rightarrow Y_j^1 \rightarrow Y^* \rightarrow Y_k^2 \rightarrow Z^* \rightarrow Z_t\] (71)
for any triple \((j, k, t)\).

The proof of this theorem is given in Appendix \(G\). Similar to the converse proof of Theorem 1, the presence of the fictitious users \(Y^*\) and \(Z^*\) plays an important role here as well. In particular, these two random variables introduce a conditional independence structure to the channel which enables us to define the auxiliary random variable \(U\) that yields a tight outer bound. Despite this similarity in the role of fictitious users in converse proofs, there is a significant difference between Theorems 1 and \(G\); in particular, it does not seem to be possible to extend Theorem 1 to an arbitrary number of eavesdroppers, while Theorem \(G\) holds for any number of eavesdroppers. This is due to the difference of two communication scenarios. In the second scenario, since we assume that users in the second group as well as the eavesdroppers wiretap users in the first group, we are able to provide a converse proof for the general situation of arbitrary number of eavesdroppers.

As an aside, if we set \(K_1 = K_2 = K_Z = 1\), then as the degraded compound multi-receiver wiretap channel with layered messages reduces to the degraded multi-receiver wiretap channel with layered messages of [16], the secrecy capacity region in Theorem \(G\) reduces to the secrecy capacity region of the channel model in [16].

### 3.2.1 Parallel Degraded Compound Multi-receiver Wiretap Channels with Layered Messages

In the next section, we investigate the Gaussian parallel degraded compound multi-receiver wiretap channel with layered messages. To that end, here we obtain the secrecy capacity region of the parallel degraded compound multi-receiver wiretap channel with layered messages in a single-letter form as follows.

**Theorem 9** The secrecy capacity region of the parallel degraded compound multi-receiver wiretap channel with layered messages is given by the union of rate pairs \((R_1, R_2)\) satisfying

\[
R_1 \leq \min_{j=1,...,K_1} \sum_{\ell=1}^{L} I(X_\ell; Y_{j\ell}^1 | U_\ell, Y_{k\ell}^2) \tag{72}
\]

\[
R_2 \leq \min_{k=1,...,K_2} \sum_{t=1}^{L} I(U_\ell; Y_{k\ell}^2 | Z_t) \tag{73}
\]

where the union is over all \(\prod_{\ell=1}^{L} p(u_\ell, x_\ell)\) such that

\[
U_\ell \rightarrow X_\ell \rightarrow Y_{j\ell}^1 \rightarrow Y_\ell^* \rightarrow Y_{k\ell}^2 \rightarrow Z_t^* \rightarrow Z_t \tag{74}
\]

for any \((\ell, j, k, t)\).

Since parallel degraded compound multi-receiver wiretap channels with layered messages is a special case of the degraded compound multi-receiver wiretap channel, Theorem \(G\) implic-
itly gives the secrecy capacity region of parallel degraded compound multi-receiver wiretap channels with layered messages. However, we still need to show that the region in Theorem 8 is equivalent to the region in Theorem 9. That is, we need to prove the optimality of independent signalling in each sub-channel. The proof of Theorem 9 is provided in Appendix H.

3.2.2 Gaussian Parallel Degraded Compound Multi-receiver Wiretap Channels with Layered Messages

We now obtain the secrecy capacity region of Gaussian parallel degraded compound multi-receiver wiretap channels with layered messages. To that end, we need to evaluate the region given in Theorem 9, i.e., we need to find the optimal distribution \( \prod_{\ell=1}^{L} p(u_{\ell}, x_{\ell}) \). We first introduce the following theorem, which is an extension of Theorem 3.

**Theorem 10** Let \( N_1, N^*, N_2, \bar{N}, N_Z \) be zero-mean Gaussian random variables with variances \( \sigma_1^2, \sigma^*_2, \sigma^2_2, \sigma^2_Z \), respectively, where

\[
\sigma_1^2 \leq \sigma^*_2 \leq \sigma^2_2 \leq \sigma^2_Z
\]  

(75)

Let \((U, X)\) be an arbitrarily dependent random variable pair, which is independent of \((N_1, N^*, N_2, \bar{N}, N_Z)\), and the second moment of \(X\) be constrained as \(E[X^2] \leq P\). Then, for any feasible \((U, X)\), we can find a \(P^* \leq P\) such that

\[
h(X + \bar{N}|U) - h(X + N^*|U) = \frac{1}{2} \log \frac{P^* + \sigma^2}{P^* + \sigma^*_2}
\]  

(76)

and

\[
h(X + N_Z|U) - h(X + N_2|U) \leq \frac{1}{2} \log \frac{P^* + \sigma^2_Z}{P^* + \sigma^2_2}
\]  

(77)

\[
h(X + N_2|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{P^* + \sigma^2_2}{P^* + \sigma^2_1}
\]  

(78)

for any \((\sigma_1^2, \sigma^2_2, \sigma^2_Z)\) satisfying the order in (75).

The proof of this theorem is given in Appendix H. The proof of this theorem basically relies on Theorem 3 and Costa’s entropy power inequality [15].

Using this theorem, we can establish the secrecy capacity region of the Gaussian parallel degraded compound multi-receiver wiretap channel with layered messages as follows.

**Theorem 11** The secrecy capacity region of the Gaussian parallel degraded compound multi-receiver wiretap channel with layered messages is given by the union of rate pairs \((R_1, R_2)\)
satisfying

\[ R_1 \leq \min_{k=1, \ldots, K_1} \sum_{\ell=1}^{L} \frac{1}{2} \log \left( 1 + \frac{\beta_\ell P_\ell}{A_{j,\ell}} \right) - \frac{1}{2} \log \left( 1 + \frac{\beta_\ell P_\ell}{A_{k,\ell}} \right) \] (79)

\[ R_2 \leq \min_{t=1, \ldots, K_2} \sum_{\ell=1}^{L} \frac{1}{2} \log \left( 1 + \frac{\beta_\ell P_\ell}{\beta_\ell P_\ell + A_{t,\ell}} \right) - \frac{1}{2} \log \left( 1 + \frac{\beta_\ell P_\ell}{\beta_\ell P_\ell + A_{Z,\ell}} \right) \] (80)

where \( \beta_\ell = 1 - \beta_\ell \in [0, 1], \ell = 1, \ldots, L, \) and the union is over all \( \{P_\ell\}_{\ell=1}^{L} \) such that \( \sum_{\ell=1}^{L} P_\ell = P \).

The proof of this theorem is given in Appendix J. Similar to Theorem 4, here also, \( P_\ell \) denotes the amount of power \( P \) devoted to the transmission in the \( \ell \)th sub-channel. Similarly, \( \beta_\ell \) is the fraction of the power \( P_\ell \) of the \( \ell \)th sub-channel spent for the transmission to users in the first group.

### 3.2.3 Gaussian MIMO Degraded Compound Multi-receiver Wiretap Channels with Layered Messages

We now obtain the secrecy capacity region of the Gaussian MIMO degraded compound multi-receiver wiretap channel with layered messages. To that end, we need to evaluate the region given in Theorem 8, i.e., find the optimal random vector pair \((U, X)\). We are able to find the optimal random vector pair \((U, X)\) when there is only one user in the second group, i.e., \( K_2 = 1 \). To obtain that result, we first need the following generalization of Theorem 5.

**Theorem 12** Let \((N_1, N_2, N^*, N_Z)\) be Gaussian random vectors with covariance matrices \( \Sigma_1, \Sigma_2, \Sigma^*, \Sigma_Z \), respectively, where

\[ \Sigma_1 \preceq \Sigma_2 \preceq \Sigma^* \preceq \Sigma_Z \] (81)

Let \((U, X)\) be an arbitrarily dependent random vector pair, which is independent of \((N_1, N_2, N^*, N_Z)\), and the second moment of \( X \) be constrained as \( E[XX^\top] \preceq S \). Then, for any feasible \((U, X)\), there exists a positive semi-definite matrix \( K^* \) such that \( K^* \preceq S \), and it satisfies

\[ h(X + N^*|U) - h(X + N_2|U) = \frac{1}{2} \log \frac{|K^* + \Sigma^*|}{|K^* + \Sigma_2|} \] (82)

and

\[ h(X + N_Z|U) - h(X + N_2|U) \leq \frac{1}{2} \log \frac{|K^* + \Sigma_Z|}{|K^* + \Sigma_2|} \] (83)

\[ h(X + N_2|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{|K^* + \Sigma_2|}{|K^* + \Sigma_1|} \] (84)
for any $(\Sigma_1, \Sigma_Z)$ satisfying the order in (81).

The proof of this theorem is given in Appendix L. Using this theorem, we can find the secrecy capacity region of the Gaussian MIMO degraded compound multi-receiver wiretap channel with layered messages when $K_2 = 1$ as follows.

**Theorem 13** The secrecy capacity region of the Gaussian MIMO degraded compound multi-receiver wiretap channel with layered messages when $K_2 = 1$ is given by the union of rate pairs $(R_1, R_2)$ satisfying

\[
R_1 \leq \min_{j=1, \ldots, K_1} \frac{1}{2} \log \frac{|K + \Sigma^j_1|}{|\Sigma_j^1|} - \frac{1}{2} \log \frac{|K + \Sigma_j^2|}{|\Sigma^2|} \tag{85}
\]

\[
R_2 \leq \min_{t=1, \ldots, K_Z} \frac{1}{2} \log \frac{|S + \Sigma^2_t|}{|K + \Sigma^2|} - \frac{1}{2} \log \frac{|S + \Sigma^2_t|}{|K + \Sigma^2|} \tag{86}
\]

where the union is over all positive semi-definite matrices $K$ such that $K \preceq S$.

The proof of this theorem is given in Appendix M. As an aside, if we set $K_1 = K_Z = 1$ in this theorem, we can recover the secrecy capacity region of the degraded multi-receiver wiretap channel with layered messages that was established in [16].

4 Conclusions

In this paper, we studied two different communication scenarios for the degraded compound multi-receiver wiretap channel. In the first scenario, the transmitter wants to send a confidential message to users in the first group, and a different confidential message to users in the second group, where both messages are to be kept confidential from an eavesdropper. We establish the secrecy capacity region of the general discrete memoryless channel model, the parallel channel model, and the Gaussian parallel channel model. For the Gaussian MIMO channel model, we obtain the secrecy capacity region when there is only one user in the second group. We also provide a partial characterization of the secrecy capacity region when there are an arbitrary number of users in the second group.

In the second scenario we study, the transmitter sends a confidential message to users in the first group which is wiretapped by both users in the second group and eavesdroppers. In addition to this message sent to the first group of users, the transmitter sends a different message to users in the second group which needs to be kept confidential only from the eavesdroppers. In this case, we do not put any restriction on the number of eavesdroppers. As in the first scenario, we establish the secrecy capacity region for the general discrete memoryless channel model, the parallel channel model, and the Gaussian parallel channel model. For the Gaussian MIMO channel model, we obtain the secrecy capacity region when there is only one user in the second group.
Appendices

A Proof of Theorem 1

Achievability is clear. We provide the converse proof. For an arbitrary code achieving the secrecy rates \((R_1, R_2)\), there exist \((\epsilon_{1,n}, \epsilon_{2,n})\) and \(\gamma_n\) which vanish as \(n \to \infty\) such that

\[
H(W_1|Y_j^1, j = 1, \ldots, K_1) \leq n\epsilon_{1,n}
\]

\[
H(W_2|Y_k^2, k = 1, \ldots, K_2) \leq n\epsilon_{2,n}
\]

\[
I(W_1, W_2; Z^n) \leq n\gamma_n
\]

where (87) and (88) are due to Fano’s lemma, and (89) is due to the perfect secrecy requirement stated in (33).

We define the following auxiliary random variables

\[
U_i = W_2Y^i-1 Z_i+1, \quad i = 1, \ldots, n
\]

which satisfy the following Markov chain

\[
U_i \rightarrow X_i \rightarrow Y_{j,i}^1 \rightarrow Y_i^* \rightarrow Y_{k,i}^2 \rightarrow Z_i, \quad i = 1, \ldots, n
\]

for any \((j, k)\) pair. The Markov chain in (91) is a consequence of the fact that the channel is memoryless and degraded.
We first bound the rate of the second message:

\begin{align*}
  nR_2 &= H(W_2) \\  &\leq I(W_2; Y_k^{2,n}) + n\epsilon_{2,n} \\  &\leq I(W_2; Y_k^{2,n}) - I(W_2; Z^n) + n(\epsilon_{2,n} + \gamma_n) \\  &= I(W_2; Y_k^{2,n}|Z^n) + n(\epsilon_{2,n} + \gamma_n) \\  &= \sum_{i=1}^{n} I(W_2; Y_k^{2,i-1}|Y_k^{2,i-1}, Z^n) + n(\epsilon_{2,n} + \gamma_n) \\  &= \sum_{i=1}^{n} I(W_2; Y_k^{2,i-1}|Y_k^{2,i-1}, Z_i, Z_{i+1}) + n(\epsilon_{2,n} + \gamma_n) \\  &\leq \sum_{i=1}^{n} I(Y_k^{2,i-1}, Z_i, Z_{i+1}, W_2; Y_k^{2,i-1}, Z_i) + n(\epsilon_{2,n} + \gamma_n) \\  &\leq \sum_{i=1}^{n} I(Y_k^{2,i-1}, Z_i, Z_{i+1}, W_2; Y_k^{2,i-1}, Z_i) + n(\epsilon_{2,n} + \gamma_n) \\  &= \sum_{i=1}^{n} I(U_i; Y_k^{2,i-1}, Z_i) + n(\epsilon_{2,n} + \gamma_n)
\end{align*}

where (93) is due to (88), (94) is a consequence of (89), (95) comes from the Markov chain

\[ W_2 \rightarrow Y_k^{2,n} \rightarrow Z^n, \quad k = 1, \ldots, K_2 \]

which is a consequence of the fact that the channel is degraded, (97) comes from the Markov chain

\[ Z_i^{i-1} \rightarrow Y_k^{2,i-1} \rightarrow (Y_k^{2,i-1}, Z_i^{n}, W_2), \quad k = 1, \ldots, K_2 \]

which is due to the fact that the channel is degraded and memoryless, and (100) is a consequence of the Markov chain

\[ Y_k^{2,i-1} \rightarrow Y^{*,i-1} \rightarrow (W_2, Z_i^{n}, Y_k^{2,i}), \quad k = 1, \ldots, K_2 \]

which is due to the Markov chain in (2) and the fact that the channel is memoryless.
Next we bound the rate of the first message:

\[
R_1 = H(W_1) = H(W_1 | W_2) 
\leq I(W_1; Y_j^{1,n} | W_2) + n\epsilon_1, n
\]

\[
\leq I(W_1; Y_j^{1,n} | W_2) - I(W_1; Z^n | W_2) + n(\epsilon_1, n + \gamma_n)
\]

\[
= I(W_1; Y_j^{1,n} | W_2, Z^n) + n(\epsilon_1, n + \gamma_n)
\]

\[
= \sum_{i=1}^{n} I(W_1; Y_{j,i}^{1,n} | W_2, Z^n, Y_j^{1,i-1}) + n(\epsilon_1, n + \gamma_n)
\]

\[
= \sum_{i=1}^{n} I(W_1; Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y_j^{1,i-1}, Z_i) + n(\epsilon_1, n + \gamma_n)
\]

\[
\leq \sum_{i=1}^{n} I(X_i, W_1; Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y_j^{1,i-1}, Y^{*,i-1}, Z_i) + n(\epsilon_1, n + \gamma_n)
\]

\[
= \sum_{i=1}^{n} I(X_i; Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y_j^{1,i-1}, Y^{*,i-1}, Z_i) + n(\epsilon_1, n + \gamma_n)
\]

\[
\leq \sum_{i=1}^{n} H(Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Z_i) - H(Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y_j^{1,i-1}, Y^{*,i-1}, Z_i, X_i)
\]

\[
+ n(\epsilon_1, n + \gamma_n)
\]

\[
\leq \sum_{i=1}^{n} H(Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y^{*,i-1}, Z_i) - H(Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y_j^{1,i-1}, Y^{*,i-1}, Z_i, X_i)
\]

\[
+ n(\epsilon_1, n + \gamma_n)
\]

\[
\leq \sum_{i=1}^{n} H(Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y^{*,i-1}, Z_i) - H(Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y^{*,i-1}, Z_i, X_i)
\]

\[
+ n(\epsilon_1, n + \gamma_n)
\]

\[
= \sum_{i=1}^{n} I(X_i; Y_{j,i}^{1,n} | W_2, Z_{i+1}^n, Y^{*,i-1}, Z_i) + n(\epsilon_1, n + \gamma_n)
\]

\[
= \sum_{i=1}^{n} I(X_i; Y_{j,i}^{1,n} | U_i, Z_i) + n(\epsilon_1, n + \gamma_n)
\]

where (107) is due to (87), (108) is a consequence of (89), (109) comes from the Markov chain

\[
(W_2, W_1) \rightarrow Y_j^{1,n} \rightarrow Z^n, \quad j = 1, \ldots, K_1
\]
which is due to the fact that the channel is degraded, (111) comes from the Markov chain

\[ Z_{i-1} \rightarrow Y_{j,i} \rightarrow (W_1, W_2, Y_{j,i}^1, Z_{i}^n), \quad j = 1, \ldots, K_1 \]  

(121)

which is a consequence of the fact that the channel is degraded and memoryless, (112) follows from the Markov chain

\[ Y_{j,i}^{*,i-1} \rightarrow Y_{j,i}^{1,i-1} \rightarrow (W_1, W_2, Y_{j,i}^1, Z_{i}^n), \quad j = 1, \ldots, K_1 \]

(122)

which results from the Markov chain in (2) and the fact that the channel is memoryless, (113) is a consequence of the Markov chain

\[(Y_{j,i}, Z_i) \rightarrow X_i \rightarrow (Y_{j,i}^{*,i-1}, Y_{j,i}^{1,i-1}, Z_{i+1}^n, W_1, W_2), \quad j = 1, \ldots, K_1\]  

(123)

which is due to the fact that the channel is memoryless, (116) comes from the fact that conditioning cannot increase entropy, and (117) is again due to the Markov chain in (123).

Next, we define a uniformly distributed random variable \( Q \in \{1, \ldots, n\} \), and \( U = (Q, U_Q), X = X_Q, Y_j = Y_{j,Q}, Y_k = Y_{k,Q}, \) and \( Z = Z_Q \). Using these definitions in (101) and (119), we obtain the single-letter expressions in Theorem 1.

\[ \text{B Proof of Theorem 2} \]

The achievability of this region follows from Theorem 1 by selecting \((U, X) = (U_1, X_1, \ldots, U_L, X_L)\) with a joint distribution of the product form \( p(u, x) = \prod_{\ell=1}^{L} p(u_\ell, x_\ell) \). We next provide the converse proof. To that end, we define the following auxiliary random variables

\[ U_{\ell,i} = W_2 Y_{j,i}^{*,i-1} Z_{i+1}^n Y_{[1:\ell-1],i}^* Z_{[\ell+1:L],i}, \quad i = 1, \ldots, n, \quad \ell = 1, \ldots, L \]

(124)

which satisfy the Markov chain

\[ U_{\ell,i} \rightarrow X_{\ell,i} \rightarrow (Y_{j,\ell,i}^1, Y_{k,\ell,i}^2, Z_{\ell,i}) \]

(125)

for any \((j, k, \ell)\) triple because of the facts that the channel is memoryless and sub-channels are independent.

We bound the rate of the second message. Following the same steps as in the converse
proof of Theorem \[ \text{[1]} \] we get to (97). Then,

\[ nR_2 \leq \sum_{i=1}^{n} \left( I(W_2; Y_{k,i}^2 | Y_{k,i-1}^2, Z_{n+1}^i, Z_i) + n(\epsilon_{2,n} + \gamma_n) \right) \]  

(126)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_2; Y_{k,\ell,i}^2 | Y_{k,i}^2, Z_{n+1}^i, Z_i, Y_{k[1:\ell-1],i}^2) + n(\epsilon_{2,n} + \gamma_n) \]  

(127)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_2; Y_{k,\ell,i}^2 | Y_{k,i}^2, Z_{n+1}^i, Z_{[\ell+1:L],i}, Y_{k[1:\ell-1],i}, Z_{\ell,i}) + n(\epsilon_{2,n} + \gamma_n) \]  

(128)

\[ \leq \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(Y_{k,i}^{2,i-1}, Z_{n+1}^i, Z_{[\ell+1:L],i}, Y_{k[1:\ell-1],i}, Y_{[1:\ell-1],i}, W_2; Y_{k,\ell,i}^2 | Z_{\ell,i}) + n(\epsilon_{2,n} + \gamma_n) \]  

(129)

\[ \leq \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(Y_{k,i}^{2,i-1}, Y_{[1:\ell-1],i}, Z_{n+1}^i, Z_{[\ell+1:L],i}, Y_{k[1:\ell-1],i}, Y_{[1:\ell-1],i}, W_2; Y_{k,\ell,i}^2 | Z_{\ell,i}) + n(\epsilon_{2,n} + \gamma_n) \]  

(130)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(Y_{k,i}^{2,i-1}, Y_{[1:\ell-1],i}, Z_{n+1}^i, Z_{[\ell+1:L],i}, W_2; Y_{k,\ell,i}^2 | Z_{\ell,i}) + n(\epsilon_{2,n} + \gamma_n) \]  

(131)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(U_{\ell,i}; Y_{k,\ell,i}^2 | Z_{\ell,i}) + n(\epsilon_{2,n} + \gamma_n) \]  

(132)

where (128) follows from the Markov chain

\[ Z_{[1:\ell-1],i} \rightarrow Y_{k[1:\ell-1],i}^2 \rightarrow (W_2, Y_{k,i}^{2,i-1}, Z_{n+1}^i, Z_{[\ell:L],i}, Y_{k[1:\ell-1],i}) \]  

(133)

which is a consequence of the facts that the channel is degraded and memoryless, and sub-channels are independent, and (131) is due to the Markov chain

\[ (Y_{k,i}^{2,i-1}, Y_{k[1:\ell-1],i}) \rightarrow (Y_{[1:\ell-1],i}, Y_{[1:\ell-1],i}) \rightarrow (W_2, Z_{n+1}^i, Z_{[\ell:L],i}, Y_{k[1:\ell-1],i}) \]  

(134)

which is a consequence of the Markov chain in (10) and the facts that the channel is memoryless and sub-channels are independent.

We next bound the rate of the first message. Again, following the same steps as in the
converse proof of Theorem 1, we get to (111). Then,

\[ nR_1 \leq \sum_{i=1}^{n} I(W_1; Y_{j,i}^{1} | W_2, Y_{j}^{1,i-1}, Z_{i+1}^{n}, Z_{i}) + n(\epsilon_{1,n} + \gamma_{n}) \]

(135)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_1; Y_{j,i}^{1} | W_2, Y_{j}^{1,i-1}, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{i}) + n(\epsilon_{1,n} + \gamma_{n}) \]

(136)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_1; Y_{j,i}^{1} | W_2, Y_{j}^{1,i-1}, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i) + n(\epsilon_{1,n} + \gamma_{n}) \]

(137)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_1; Y_{j,i}^{1} | W_2, Y_{j}^{1,i-1}, Y_{1+i,1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i) + n(\epsilon_{1,n} + \gamma_{n}) \]

(138)

\[ \leq \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(X_{\ell}, i; W_1; Y_{j,i}^{1} | W_2, Y_{j}^{1,i-1}, Y_{i}^{*}, i-1, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i) \]

+ n(\epsilon_{1,n} + \gamma_{n})

(139)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(X_{\ell}, i; Y_{j,i}^{1} | W_2, Y_{j}^{1,i-1}, Y_{i}^{*}, i-1, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i) \]

+ n(\epsilon_{1,n} + \gamma_{n})

(140)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} H(Y_{j,i}^{1} | W_2, Y_{j}^{1,i-1}, Y_{i}^{*}, i-1, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i) \]

\[ - H(Y_{j,i}^{1} | W_2, Y_{j}^{1,i-1}, Y_{i}^{*}, i-1, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i, X_{\ell}, i) \]

+ n(\epsilon_{1,n} + \gamma_{n})

(141)

\[ \leq \sum_{i=1}^{n} \sum_{\ell=1}^{L} H(Y_{j,i}^{1} | W_2, Y_{i}^{*}, i-1, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i) \]

\[ - H(Y_{j,i}^{1} | W_2, Y_{i}^{*}, i-1, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i, X_{\ell}, i) \]

+ n(\epsilon_{1,n} + \gamma_{n})

(142)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} H(Y_{j,i}^{1} | W_2, Y_{i}^{*}, i-1, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i) \]

\[ - H(Y_{j,i}^{1} | W_2, Y_{i}^{*}, i-1, Z_{i+1}^{n}, Y_{j}^{1,[\ell-1],i}; Z_{\ell}, i, X_{\ell}, i) + n(\epsilon_{1,n} + \gamma_{n}) \]

(143)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(X_{\ell}, i; Y_{j,i}^{1} | U_{\ell}, i, Z_{\ell}, i) + n(\epsilon_{1,n} + \gamma_{n}) \]

(144)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(X_{\ell}, i; Y_{j,i}^{1} | U_{\ell}, i, Z_{\ell}, i) + n(\epsilon_{1,n} + \gamma_{n}) \]

(145)
where (137) follows from the Markov chain
\[ Z_{[1:L-1],i} \rightarrow Y_{j[1:L-1],i} \rightarrow (W_1, W_2, Y_{1,i}^{1:i-1}, Z_{i+1}^n, Y_{j_L,i}^1, Z_{[L:L],i}) \] (146)

which is due to the facts that the channel is degraded and memoryless, and sub-channels are independent, (138) comes from the Markov chain
\[ (Y^{*i-1}, Y_{[1:L-1],i}^*) \rightarrow (Y_{j[1:L-1],i}^{1:i-1}, Y_{j[1:L-1],i}^1) \rightarrow (W_1, W_2, Z_{i+1}^n, Z_{[L:L],i}, Y_{j_L,i}^1) \] (147)

which results from the Markov chain in (10) and the facts that the channel is memoryless, and sub-channels are independent, (140) comes from the Markov chain
\[ (Y_{j_L,i}^1, Z_{[L:L],i}) \rightarrow X_{\ell,i} \rightarrow (W_1, W_2, Y_{1,i}^{1:i-1}, Y^{*i-1}, Z_{i+1}^n, Y_{j[1:L-1],i}^1, Y_{j[1:L-1],i}^*, Z_{[L:L],i}) \] (148)

which is a consequence of the facts that the channel is memoryless, and sub-channels are independent, (142) results from the fact that conditioning cannot increase entropy, and (143) is due to the Markov chain in (148).

Next, we define a uniformly distributed random variable \( Q \in \{1, \ldots, n\} \), and \( U_\ell = (Q, U_{\ell,Q}), X = X_{\ell,Q}, Y_{j_L}^1 = Y_{j_L,Q}^1, Y_{k_L}^2 = Y_{k_L,Q}^2, \) and \( Z_L = Z_{\ell,Q} \). Using these definitions in (132) and (145), we obtain the single-letter expressions in Theorem 2. Finally, we note that although auxiliary random variables \( \{U_\ell\}_{\ell=1}^L \) are dependent, their joint distribution does not affect the bounds in Theorem 2. Thus, without loss of generality, we can select them to be independent.

C Proof of Theorem 3

We first note that
\[ \frac{1}{2} \log \frac{\sigma_Z^2}{\sigma_Z^2} \leq h(X + N^*|U) - h(X + N_Z|U) \leq \frac{1}{2} \log \frac{P + \sigma_Z^2}{P + \sigma_Z^2} \] (149)

where the right-hand side can be shown via the entropy power inequality [18, 19]. To show the left-hand side, let us define a Gaussian random variable \( \tilde{N} \) with variance \( \sigma_Z^2 - \sigma_N^2 \), and independent of \((U, X, N^*)\). Thus, we can write down the difference of differential entropy
terms in (149) as

\[
h(X + N^*|U) - h(X + N_Z|U) = h(X + N^*|U) - h(X + N^* + \tilde{N}|U) = -I(\tilde{N}; X + N^* + \tilde{N}|U) \tag{150}
\]

\[
= -h(\tilde{N}|U) + h(\tilde{N}|U, X + N^* + \tilde{N}) \geq -h(\tilde{N}|U) + h(\tilde{N}|U, X + N^* + \tilde{N}, X) \tag{153}
\]

\[
= -h(\tilde{N}) + h(\tilde{N}|N^* + \tilde{N}) \tag{154}
\]

\[
= \frac{1}{2} \log \frac{\sigma^2}{\sigma^2_Z} \tag{155}
\]

where (153) is due to the fact that conditioning cannot increase entropy and (154) is a consequence of the fact that \((U, X)\) and \((N^*, \tilde{N})\) are independent.

Equation (149) implies that there exists \(P^*\) such that \(P^* \leq P\) and

\[
h(X + N^*|U) - h(X + N_Z|U) = \frac{1}{2} \log \frac{P^* + \sigma^2}{P^* + \sigma^2_Z} \tag{156}
\]

which will be used frequently hereafter.

We now state Costa’s entropy power inequality [15] which will be used in the upcoming proof:

**Lemma 3 ([15], Theorem 1)** Let \((U, X)\) be an arbitrarily dependent random variable pair, which is independent of \(N\), where \(N\) is a Gaussian random variable. Then, we have

\[
e^{2h(X + \sqrt{tN}|U)} \geq (1 - t)e^{2h(X|U)} + te^{2h(X + N|U)}, \quad 0 \leq t \leq 1 \tag{157}
\]

We now consider (13). We first note that we can write \(N^*\) as

\[
N^* = N_1 + \sqrt{t_1}\tilde{N}_1 \tag{158}
\]

where \(\tilde{N}_1\) is a Gaussian random variable with variance \(\sigma^2_Z - \sigma^2\), which is independent of \((U, X, N_1)\). \(t_1\) in (158) is given by

\[
t_1 = \frac{\sigma^2 - \sigma^2_1}{\sigma^2_Z - \sigma^2_1} \tag{159}
\]

where it is clear that \(t_1 \in [0, 1]\). Using (158) and Costa’s entropy power inequality [15], we

---

\[2\]Although, Theorem 1 of [15] states the inequality for a constant \(U\), using Jensen’s inequality, the current form of the inequality for an arbitrary \(U\) can be shown.
get
\[ e^{2h(X+N^*|U)} = e^{2h(X+N_1+\sqrt{t_1}\tilde{N}_1|U)} \]
\[ \geq (1 - t_1)e^{2h(X+N_1|U)} + t_1e^{2h(X+N_Z|U)} \]

which is equivalent to
\[ (1 - t_1)e^{2[h(X+N_1|U) - h(X+N_Z|U)]} + t_1 \leq e^{2[h(X+N^*|U) - h(X+N_Z|U)]} \]
\[ = \frac{P^* + \sigma^2}{P^* + \sigma^2_Z} \]

where (163) is obtained by using (156). Equation (163) is equivalent to
\[ h(X + N_1|U) - h(X + N_Z|U) \leq \frac{1}{2} \log \left( \frac{P^* + \sigma^2}{P^* + \sigma^2_Z} \right) \]
\[ = \frac{1}{2} \log \left( \frac{P^*}{P^* + \sigma^2_Z} + \frac{1}{1 - t_1} \frac{\sigma^2 - t_1\sigma^2_Z}{P^* + \sigma^2_Z} \right) \]
\[ = \frac{1}{2} \log \frac{P^* + \sigma^2}{P^* + \sigma^2_Z} \]

where we used the definition of \( t_1 \) given in (159) to obtain (166). Equation (166) proves (43).

We now consider (44). First, we note that we can write \( N_2 \)
\[ N_2 = N^* + \sqrt{t_2}\tilde{N}_Z \]

where \( \tilde{N}_Z \) is a Gaussian random variable with variance \( \sigma^2_Z - \sigma^2 \), which is independent of \( (U, X, N^*) \). \( t_2 \) in (167) is given by
\[ t_2 = \frac{\sigma^2 - \sigma^2_Z}{\sigma^2_Z - \sigma^2} \]

where it is clear that \( t_2 \in [0, 1] \). Using (167) and Costa’s entropy power inequality [15], we get
\[ e^{2h(X+N_2|U)} = e^{2h(X+N^*+\sqrt{t_2}\tilde{N}_Z|U)} \]
\[ \geq (1 - t_2)e^{2h(X+N^*|U)} + t_2e^{2h(X+N_Z|U)} \]
which is equivalent to
\[ e^{2[h(X+N_Z|U) - h(X+N_2|U)]} \geq (1 - t_2) e^{2[h(X+N^*|U) - h(X+N_2|U)]} + t_2 \]  
\[ = (1 - t_2) \frac{P^* + \sigma^2_Z}{P^* + \sigma^2_Z} + t_2 \]  
\[ = \frac{P^* + \sigma^2_Z}{P^* + \sigma^2_Z} \]  
\[ \text{(173)} \]

where (173) is obtained by using the definition of \( t_2 \) given in (168). Equation (173) is equivalent to
\[ h(X + N_2|U) - h(X + N_Z|U) \leq \frac{1}{2} \log \frac{P^* + \sigma^2_Z}{P^* + \sigma^2_Z} \]  
\[ \text{(174)} \]

which is (44). This completes the proof of Theorem 3.

D Proof of Theorem 4

Achievability is clear. We provide the converse proof. To this end, let us fix the distribution \( \prod_{\ell=1}^L p(u_\ell, x_\ell) \) such that
\[ E \left[ X^2_\ell \right] = P_\ell, \quad \ell = 1, \ldots, L \]  
\[ \text{(175)} \]
and \( \sum_{\ell=1}^L P_\ell \leq P \). We first establish the bound on \( R_2 \) given in (46). To this end, we start with (39). Using the Markov chain \( U_\ell \rightarrow Y_{k\ell}^2 \rightarrow Z_\ell \), we have
\[ R_2 \leq \min_{k=1,\ldots,K_2} \sum_{\ell=1}^L I(U_\ell; Y_{k\ell}^2) - I(U_\ell; Z_\ell) \]  
\[ = \min_{k=1,\ldots,K_2} \sum_{\ell=1}^L \left[ h(Y_{k\ell}^2) - h(Z_\ell) \right] + \left[ h(Z_\ell|U) - h(Y_{k\ell}^2|U) \right] \]  
\[ \leq \min_{k=1,\ldots,K_2} \sum_{\ell=1}^L \frac{1}{2} \log \frac{P_k + \Lambda_{k,\ell}}{P_k + \Lambda_{Z,\ell}} + \left[ h(Z_\ell|U) - h(Y_{k\ell}^2|U) \right] \]  
\[ \text{(178)} \]

where (178) comes from the fact that Gaussian \( X_\ell \) maximizes
\[ h(Y_{k\ell}^2) - h(Z_\ell) \]  
\[ \text{(179)} \]
which can be shown via the entropy power inequality [18, 19]. We now use Theorem 3. For that purpose, we introduce the diagonal covariance matrix \( \Lambda^* \) which satisfies
\[ \Lambda^1_j \preceq \Lambda^* \preceq \Lambda^2_k \]  
\[ \text{(180)} \]
for any \((j, k)\) pair, and in particular, for the diagonal elements of these matrices, we have

\[
\Lambda_{j,j} \leq \Lambda_{k,k} \leq \Lambda_{2,k}
\]

for any triple \((j, k, \ell)\). Thus, due to Theorem 3, for any selection of \(\{(U_\ell, X_\ell)\}_{\ell=1}^L\), there exists a \(P_\ell^*\) such that

\[
P_\ell^* \leq P_\ell
\]

\[
h(Z_\ell|U_\ell) - h(Y_{j\ell}|U_\ell) \geq \frac{1}{2} \log \frac{P_\ell^* + \Lambda_{Z,\ell\ell}}{P_\ell^* + \Lambda_{j,\ell\ell}}
\]

\[
h(Z_\ell|U_\ell) - h(Y_{k\ell}|U_\ell) \leq \frac{1}{2} \log \frac{P_\ell^* + \Lambda_{Z,\ell\ell}}{P_\ell^* + \Lambda_{k,\ell\ell}}
\]

for any triple \((j, k, \ell)\). Using (184) in (178), we get

\[
R_2 \leq \min_{k=1, \ldots, K_1} \frac{1}{L} \sum_{\ell=1}^L I(X_\ell; Y_{j\ell}|U_\ell) - I(X_\ell; Z_\ell|U_\ell)
\]

\[
\leq \min_{j=1, \ldots, K_1} \frac{1}{2} \sum_{\ell=1}^L \log \frac{P_\ell^* + \Lambda_{j,\ell\ell}}{P_\ell^* + \Lambda_{Z,\ell\ell}} - \frac{1}{2} \log \frac{P_\ell^* + \Lambda_{2,k,\ell\ell}}{P_\ell^* + \Lambda_{Z,\ell\ell}}
\]

\[
= \min_{j=1, \ldots, K_1} \frac{1}{2} \sum_{\ell=1}^L \log \frac{P_\ell^* + \Lambda_{j,\ell\ell}}{P_\ell^* + \Lambda_{Z,\ell\ell}} - \frac{1}{2} \log \frac{P_\ell^* + \Lambda_{j,\ell\ell}}{P_\ell^* + \Lambda_{Z,\ell\ell}}
\]

where (188) comes from (183). Since we defined \(P_\ell^* = \beta_\ell P_\ell\), (188) is the desired bound on \(R_1\) given in (45), completing the proof.

### E Proof of Theorem 6

The main tools for the proof of Theorem 6 are Theorem 5, and the following so-called worst additive noise lemma [20, 21].

**Lemma 4** Let \(N\) be a Gaussian random vector with covariance matrix \(\Sigma\), and \(K_X\) be a
positive semi-definite matrix. Consider the following optimization problem,

$$\min_{p(x)} \ I(N; N + X) \quad \text{s.t.} \quad \text{Cov}(X) = K_X$$ \hspace{1cm} (189)$$

where $X$ and $N$ are independent. A Gaussian $X$ is the minimizer of this optimization problem.

We first bound $R_2$. Assume we fixed the distribution of $(U, X)$ such that $\text{Cov}(X) = K_X$. Then, we have

$$R_2 \leq I(U; Y^2) - I(U; Z)$$  \hspace{1cm} (190)
$$= h(Y^2) - h(Z) + [h(Z|U) - h(Y^2|U)]$$  \hspace{1cm} (191)
$$\leq \frac{1}{2} \log \frac{|S + \Sigma^2|}{|S + \Sigma_Z|} + [h(Z|U) - h(Y^2|U)]$$  \hspace{1cm} (192)

To show (192), consider $\tilde{N}$ which is a Gaussian random vector with covariance matrix $\Sigma_Z - \Sigma^2$, and is independent of $(U, X, N^2)$. Thus, we can write

$$h(Y^2) - h(Z) = h(Z|\tilde{N}) - h(Z)$$  \hspace{1cm} (193)
$$= -I(\tilde{N}; X + N^2 + \tilde{N})$$  \hspace{1cm} (194)
$$\leq \frac{1}{2} \log \frac{|K_X + \Sigma^2|}{|K_X + \Sigma_Z|}$$  \hspace{1cm} (195)
$$\leq \frac{1}{2} \log \frac{|S + \Sigma^2|}{|S + \Sigma_Z|}$$  \hspace{1cm} (196)

where (195) is due to Lemma 4, and (196) follows from the fact that

$$\frac{|A|}{|A + B|} \leq \frac{|A + \Delta|}{|A + B + \Delta|}$$  \hspace{1cm} (197)

for $A \succeq 0, B \succ 0, \Delta \succeq 0$ [3, 17].

For the rest of the proof, we need Theorem 5. According to Theorem 5, for any $(U, X)$, there exists a $0 \preceq K \preceq \text{Cov}(X|U)$ such that

$$h(Z|U) - h(Y^2|U) = \frac{1}{2} \log \frac{|K + \Sigma_Z|}{|K + \Sigma^2|}$$  \hspace{1cm} (198)
$$h(Z|U) - h(Y^j|U) \geq \frac{1}{2} \log \frac{|K + \Sigma_Z|}{|K + \Sigma^j|}, \quad j = 1, \ldots, K_1$$  \hspace{1cm} (199)

because $\Sigma^j \preceq \Sigma^2$, $j = 1, \ldots, K_1$. Using (198) in (192) yields

$$R_2 \leq \frac{1}{2} \log \frac{|S + \Sigma^2|}{|K + \Sigma^2|} - \frac{|S + \Sigma_Z|}{|K + \Sigma_Z|}$$  \hspace{1cm} (200)

33
which is the desired bound on $R_2$.

The desired bound on $R_1$ can be obtained as follows

$$R_1 \leq \min_{j=1,\ldots,K_1} I(X; Y_j^1 | U) - I(X; Z | U)$$

(201)

$$= \min_{j=1,\ldots,K_1} h(Y_j^1 | U) - h(Z | U) - \frac{1}{2} \log \frac{|\Sigma_j^1|}{|\Sigma_Z|}$$

(202)

$$\leq \min_{j=1,\ldots,K_1} \frac{1}{2} \log \frac{|K + \Sigma_j^1|}{|K + \Sigma_Z|} - \frac{1}{2} \log \frac{|\Sigma_j^1|}{|\Sigma_Z|}$$

(203)

$$= \min_{j=1,\ldots,K_1} \frac{1}{2} \log \frac{|K + \Sigma_j^1|}{|\Sigma_j^1|} - \frac{1}{2} \log \frac{|K + \Sigma_Z|}{|\Sigma_Z|}$$

(204)

where (203) is due to (199). This completes the proof of Theorem 6.

F Proofs of Lemma 1 and Theorem 7

F.1 Proof of Lemma 1

The optimization problem in (55) can be put into the following alternative form

$$\max_{0 \preceq K \preceq S} a + \mu b$$

(205)

s.t. $R^G_{1j}(K) \geq a, \quad j = 1, \ldots, K_1$

(206)

$R^G_{2k}(K) \geq b, \quad k = 1, \ldots, K_2$

(207)

which has the Lagrangian

$$\mathcal{L}(K) = a + \mu b + \sum_{j=1}^{K_1} \lambda_{1j} \left( R^G_{1j}(K) - a \right) + \mu \sum_{k=1}^{K_2} \lambda_{2k} \left( R^G_{2k}(K) - b \right) + \text{tr}(KM)$$

$$+ \text{tr}((S - K)M_S)$$

(208)
where $\mathbf{M}$ and $\mathbf{M}_S$ are positive semi-definite matrices, and $\{\lambda_{1j}\}_{j=1}^{K_1}$ and $\{\lambda_{2k}\}_{k=1}^{K_2}$ are non-negative. The KKT conditions are given by

$$
\frac{\partial \mathcal{L}(\mathbf{K})}{\partial a} \bigg|_{a=R_i^*} = 0
$$
(209)

$$
\frac{\partial \mathcal{L}(\mathbf{K})}{\partial b} \bigg|_{b=R_2^*} = 0
$$
(210)

$$
\nabla_{\mathbf{K}} \mathcal{L}(\mathbf{K}) \bigg|_{\mathbf{K}=\mathbf{K}^*} = 0
$$
(211)

$$
\lambda_{1j}(R_{1j}^G(\mathbf{K}^*) - R_{1j}^* ) = 0, \quad j = 1, \ldots, K_1
$$
(212)

$$
\lambda_{2k}(R_{2k}^G(\mathbf{K}^*) - R_{2k}^* ) = 0, \quad k = 1, \ldots, K_2
$$
(213)

$$
\text{tr} (\mathbf{K}^* \mathbf{M}) = 0
$$
(214)

$$
\text{tr} ((\mathbf{S} - \mathbf{K}^*) \mathbf{M}_S) = 0
$$
(215)

The KKT conditions in (209) and (210) yield $\sum_{j=1}^{K_1} \lambda_{1j} = 1$ and $\sum_{k=1}^{K_2} \lambda_{2k} = 1$, respectively. Furthermore, the KKT conditions in (212) and (213) imply $\lambda_{1j} = 0$ when $R_{1j}^G(\mathbf{K}^*) > R_{1j}^*$ and $\lambda_{2k} = 0$ when $R_{2k}^G(\mathbf{K}^*) > R_{2k}^*$, respectively. The KKT condition in (211) results in (60). Finally, since $\text{tr}(\mathbf{AB}) = \text{tr}(\mathbf{BA}) \geq 0$ when $\mathbf{A} \succeq \mathbf{0}$ and $\mathbf{B} \succeq \mathbf{0}$, we need to have $\mathbf{K}^* \mathbf{M} = \mathbf{M} \mathbf{K}^* = \mathbf{0}$ and $(\mathbf{S} - \mathbf{K}^*) \mathbf{M}_S = \mathbf{M}_S (\mathbf{S} - \mathbf{K}^*) = \mathbf{0}$.
F.2 Proof of Theorem

Let us fix \( \{\lambda_{ij}\}_{j=1}^{K_1} \) and \( \{\lambda_{2k}\}_{k=1}^{K_2} \) as they are defined in Lemma 1. We have

\[
\begin{align*}
\max_{0 \preceq K \preceq S} \min_{j=1,\ldots,K_1} R_{1j}^G(K) + \mu \min_{k=1,\ldots,K_2} R_{2k}^G(K) \\
&\leq \max_{(U;X)} \min_{j=1,\ldots,K_1} R_{1j} + \mu \min_{k=1,\ldots,K_2} R_{2k} \\
&\leq \max_{(U;X)} \sum_{j=1}^{K_1} \lambda_{1j} \left[ I(X;Y_j^1|U) - I(X;Z|U) \right] + \mu \sum_{k=1}^{K_2} \lambda_{2k} \left[ I(U;Y_k^2) - I(U;Z) \right] \\
&= \max_{(U;X)} \sum_{j=1}^{K_1} \lambda_{1j} \left[ h(Y_j^1|U) - h(Z|U) - \frac{1}{2} \log \frac{\Sigma_j^1}{\Sigma Z} \right] + \mu \sum_{k=1}^{K_2} \lambda_{2k} \left( h(Y_k^2) - h(Z) \right) \\
&= \max_{0 \preceq K \preceq S} \sum_{j=1}^{K_1} \lambda_{1j} \left[ \frac{1}{2} \log \frac{|K + \Sigma_j^1|}{|\Sigma_j^1|} - \frac{1}{2} \log \frac{|K + \Sigma Z|}{|\Sigma Z|} \right] \\
&\quad + \mu \sum_{k=1}^{K_2} \lambda_{2k} \left[ \frac{1}{2} \log \frac{|S + \Sigma_k^2|}{|K + \Sigma_k^2|} - \frac{1}{2} \log \frac{|S + \Sigma Z|}{|K + \Sigma Z|} \right] \\
&= \max_{0 \preceq K \preceq S} \min_{j=1,\ldots,K_1} R_{1j}^G(K) + \mu \min_{k=1,\ldots,K_2} R_{2k}^G(K)
\end{align*}
\]

(216)

(217)

(218)

(219)

(220)

(221)

(222)

where (219) comes from the fact that

\[
\begin{align*}
\lambda_{2k} \left( h(Y_k^2) - h(Z) \right) 
\end{align*}
\]

which is a consequence of the worst additive lemma in Lemma 1, (220) results from Lemma 2, (221) is due to Lemmas 1 and 2. Thus, we have shown that

\[
\max_{0 \preceq K \preceq S} \min_{j=1,\ldots,K_1} R_{1j}^G(K) + \mu \min_{k=1,\ldots,K_2} R_{2k}^G(K) = \max_{(U;X)} \min_{j=1,\ldots,K_1} R_{1j} + \mu \min_{k=1,\ldots,K_2} R_{2k}
\]

(223)

for \( \mu \leq 1 \), which completes the proof of the theorem.
Proof of Theorem 8

We first show the achievability of the region given in Theorem 8, then provide the converse proof.

G.1 Achievability

We fix the distribution $p(u, x)$.

**Codebook generation:**

- Generate $2^{n(R_2 + \tilde{R}_2)}$ length-$n$ $u$ sequences through $p(u) = \prod_{i=1}^{n} p(u_i)$. Consider the permutation $\pi_U$ on $\{1, \ldots, K_Z\}$ such that

$$I(U; Z_{\pi_U(1)}) \leq \ldots \leq I(U; Z_{\pi_U(K_Z)})$$  

We set $\tilde{R}_2$ as

$$\tilde{R}_2 = \max_{t=1, \ldots, K_Z} I(U; Z_t) = I(U; Z_{\pi_U(K_Z)})$$

We index $u$ sequences as $u(w_2, \tilde{w}_{21}, \ldots, \tilde{w}_{2K_Z})$ where $w_2 \in \{1, \ldots, 2^{nR_2}\}$, and $\tilde{w}_{2t} \in \{1, \ldots, 2^{n\tilde{R}_2}\}$, $t = 1, \ldots, K_Z$. $\tilde{R}_{2t}$ is given by

$$\tilde{R}_{2t} = I(U; Z_{\pi_U(t)}) - I(U; Z_{\pi_U(t-1)}), \quad t = 1, \ldots, K_Z$$

where we set $I(U; Z_{\pi_U(0)}) = 0$. We note that

$$\sum_{t=1}^{m} \tilde{R}_{2t} = I(U; Z_{\pi_U(m)})$$

and in particular, for $m = K_Z$,

$$\sum_{t=1}^{K_Z} \tilde{R}_{2t} = I(U; Z_{\pi_U(K_Z)}) = \max_{t=1, \ldots, K_Z} I(U; Z_t) = \tilde{R}_2$$

- For each $u$, generate $2^{n(R_1 + \tilde{R}_1)}$ length-$n$ $x$ sequences through $p(x|u) = \prod_{i=1}^{n} p(x_i|u_i)$. Consider the permutation $\pi_X$ on $\{1, \ldots, K_2\}$ such that

$$I(X; Y^2_{\pi_X(1)}|U) \leq \ldots \leq I(X; Y^2_{\pi_X(K_2)}|U)$$
We set \( \tilde{R}_1 \) as
\[
\tilde{R}_1 = I(X; Y^2_{\pi X(K_2)}|U) = \max_{k=1,\ldots,K_2} I(X; Y^2_k|U) \tag{230}
\]
We index \( x \) sequences as \( x(w_1, \tilde{w}_{11}, \ldots, \tilde{w}_{1K_2}|w_2) \) where \( w_2 = (w_2, \tilde{w}_{21}, \ldots, \tilde{w}_{2K_2}) \), \( w_1 \in \{1, \ldots, 2^{nR_1}\} \), and \( \tilde{w}_{1k} \in \{1, \ldots, 2^{nR_1k}\} \), \( k = 1, \ldots, K_2 \). \( \tilde{R}_{1k} \) is given by
\[
\tilde{R}_{1k} = I(X; Y^2_{\pi X(k)}|U) - I(X; Y^2_{\pi X(k-1)}|U), \quad k = 1, \ldots, K_2 \tag{231}
\]
where we set \( I(X; Y^2_{\pi X(0)}|U) = 0 \). We note that
\[
\sum_{k=1}^m \tilde{R}_{1k} = I(X; Y^2_{\pi X(m)}|U) \tag{232}
\]
and in particular, for \( m = K_2 \), we have
\[
\sum_{k=1}^{K_2} \tilde{R}_{1k} = I(X; Y^2_{\pi X(K_2)}|U) = \max_{k=1,\ldots,K_2} I(X; Y^2_k|U) = \tilde{R}_1 \tag{233}
\]

**Encoding:**
If \((w_1, w_2)\) is the message to be transmitted, we pick \( \{\tilde{w}_{1k}\}_{k=1}^{K_2} \) and \( \{\tilde{w}_{2t}\}_{t=1}^{K_Z} \) independently and uniformly, and send the corresponding \( x \).

**Decoding:**
The legitimate users can decode the messages with vanishingly small probability of error, if the rates satisfy
\[
R_1 + \tilde{R}_1 \leq \min_{j=1,\ldots,K_1} I(X; Y^1_j|U) \tag{234}
\]
\[
R_2 + \tilde{R}_2 \leq \min_{k=1,\ldots,K_2} I(U; Y^2_k) \tag{235}
\]
where we used the degradedness of the channel. Plugging the expressions for \( \tilde{R}_1 \) and \( \tilde{R}_2 \) given in (225) and (230), we can get
\[
R_1 \leq \min_{j=1,\ldots,K_1} \left( I(X; Y^1_j|U) - I(X; Y^2_j|U) \right) \tag{236}
\]
\[
R_2 \leq \min_{k=1,\ldots,K_2} \left( I(U; Y^2_k) - I(U; Z_t) \right) \tag{237}
\]
which is the same as the region given in Theorem 8 because of the degradedness of the
Equivocation computation:

We now show that this coding scheme satisfies the secrecy requirements given in (66) and (67). We start with (66)

\[ H(W_2 | Z_{πU(t)}^n) = H(W_2, Z_{πU(t)}^n) - H(Z_{πU(t)}^n) \]  
\[ = H(W_2, Z_{πU(t)}^n, U^n) - H(U^n | W_2, Z_{πU(t)}^n) - H(Z_{πU(t)}^n) \]  
\[ = H(U^n) + H(W_2, Z_{πU(t)}^n | U^n) - H(U^n | W_2, Z_{πU(t)}^n) - H(Z_{πU(t)}^n) \]  
\[ ≥ H(U^n) - I(U^n; Z_{πU(t)}^n) - H(U^n | W_2, Z_{πU(t)}^n) \]  
\[ (238) \]
\[ (239) \]
\[ (240) \]
\[ (241) \]

where we treat each term separately. Since \( U^n \) can take \( 2^{n(R_2 + \tilde{R}_2)} \) values uniformly, for the first term, we have

\[ H(U^n) = n(R_2 + \tilde{R}_2) \]  
\[ (242) \]

Following Lemma 8 of [1], the second term in (241) can be bounded as

\[ I(U^n; Z_{πU(t)}^n) ≤ nI(U; Z_{πU(t)}) + n\epsilon_{2,n} \]  
\[ (243) \]

where \( \epsilon_{2,n} → \infty \) as \( n → \infty \). We now consider the third term of (241)

\[ H(U^n | W_2, Z_{πU(t)}^n) \leq H(U^n, \tilde{W}_{2(t+1)}, \ldots, \tilde{W}_{2KZ} | W_2, Z_{πU(t)}^n) \]  
\[ ≤ H(\tilde{W}_{2(t+1)}, \ldots, \tilde{W}_{2KZ}) + H(U^n | W_2, \tilde{W}_{2(t+1)}, \ldots, \tilde{W}_{2KZ}, Z_{πU(t)}^n) \]  
\[ (244) \]
\[ (245) \]

The first term in (245) is

\[ H(\tilde{W}_{2(t+1)}, \ldots, \tilde{W}_{2KZ}) = \sum_{l=t+1}^{K_Z} H(\tilde{W}_l) \]  
\[ (246) \]
\[ = \sum_{l=t+1}^{K_Z} n\tilde{R}_l \]  
\[ (247) \]
\[ = nI(U; Z_{πU(t)}) - nI(U; Z_{πU(t)}) \]  
\[ (248) \]

where (246) is due to the independence of \( \{\tilde{W}_{2l}\}_{l=1}^{K_Z} \), (247) is due to the fact that \( \tilde{W}_{2l} \) can take \( 2^{n\tilde{R}_l} \) values uniformly and independently for \( t = 1, \ldots, K_Z \), and in (248), we used the definitions of \( \{\tilde{R}_{2l}\}_{l=1}^{K_Z} \) given in (226). We next consider the second term in (245). For that purpose, we note that given

\[ \left( W_2 = w_2, \tilde{W}_{2(t+1)} = \tilde{w}_{2(t+1)}, \ldots, \tilde{W}_{2KZ} = \tilde{w}_{2KZ} \right) \]  
\[ (249) \]
$U^n$ can take $2^{nI(U;Z_{\pi_U(t)})}$ values. Thus, given the side information in (249), the $\pi_U(t)$th eavesdropper can decode $U^n$ with vanishingly small probability of error, which implies that

$$H(U^n|W_2, \hat{W}_{2(t+1)}, \ldots, \hat{W}_{2K_2}, Z_{\pi_U(t)}^n) \leq n\gamma_{2,n}$$

due to Fano’s lemma where $\gamma_{2,n} \to 0$ as $n \to \infty$. Hence, plugging (248) and (250) in (251) yields

$$H(U^n|W_2, Z_{\pi_U(t)}^n) \leq nI(U;Z_{\pi_U(K_2)}) - nI(U;Z_{\pi_U(t)}) + n\gamma_{2,n}$$

Finally, using (242), (243) and (251) in (241) yields

$$H(W_2|Z_{\pi_U(t)}^n) \geq n(R_2 + \tilde{R}_2) - n\epsilon_{2,n} - nI(U;Z_{\pi_U(K_2)}) - n\gamma_{2,n}$$

$$= nR_2 - n(\epsilon_{2,n} + \gamma_{2,n})$$

where we used (225). Since (253) implies (66), the proposed coding scheme ensures perfect secrecy for the second group of users.

We now consider the second secrecy requirement given in (67).

$$H(W_1|W_2, Y_{\pi_X(k)}^{2,n}) \geq H(W_1|W_2, Y_{\pi_X(k)}^{2,n}, U^n)$$

$$= H(W_1|Y_{\pi_X(k)}^{2,n}, U^n)$$

$$= H(W_1, Y_{\pi_X(k)}^{2,n}|U^n) - H(Y_{\pi_X(k)}^{2,n}|U^n)$$

$$= H(X^n, W_1, Y_{\pi_X(k)}^{2,n}|U^n) - H(X^n|W_1, Y_{\pi_X(k)}^{2,n}, U^n) - H(Y_{\pi_X(k)}^{2,n}|U^n)$$

$$= H(X^n|U^n) + H(W_1, Y_{\pi_X(k)}^{2,n}|U^n, X^n) - H(X^n|W_1, Y_{\pi_X(k)}^{2,n}, U^n)$$

$$- H(Y_{\pi_X(k)}^{2,n}|U^n)$$

$$\geq H(X^n|U^n) - I(X^n; Y_{\pi_X(k)}^{2,n}|U^n) - H(X^n|W_1, Y_{\pi_X(k)}^{2,n}, U^n)$$

where (255) is due to the Markov chain $W_2 \to U^n \to (W_1, Y_{\pi_X(k)}^{2,n})$ which originates from the coding scheme we proposed. Since given $U^n = u^n$, $X^n$ can take $2^{n(R_1 + \tilde{R}_1)}$ values uniformly and independently, the first term in (259) is

$$H(X^n|U^n) = n(R_1 + \tilde{R}_1)$$

Following Lemma 8 of [1], the second term in (259) can be bounded as

$$I(X^n; Y_{\pi_X(k)}^{2,n}|U^n) \leq nI(X; Y_{\pi_X(k)}^2|U) + n\epsilon_{1,n}$$

(261)
where $\epsilon_{1,n} \to 0$ as $n \to \infty$. We now consider the third term in (259)

$$
H(X^n|W_1, U^n, Y^{2,n}_{\pi_X(k)}) \leq H(X^n, \tilde{W}_{1(k+1)}, \ldots, \tilde{W}_{1K_2}|W_1, U^n, Y^{2,n}_{\pi_X(k)}) \\
\leq H(\tilde{W}_{1(k+1)}, \ldots, \tilde{W}_{1K_2}) + H(X^n|W_1, U^n, Y^{2,n}_{\pi_X(k)}, \tilde{W}_{1(k+1)}, \ldots, \tilde{W}_{1K_2})
$$

(263)

where the first term is given by

$$
H(\tilde{W}_{1(k+1)}, \ldots, \tilde{W}_{1K_2}) = \sum_{l=k+1}^{K_2} H(\tilde{W}_{1l})
$$

(264)

$$
= \sum_{l=k+1}^{K_2} n\tilde{R}_{1l}
$$

(265)

$$
= nI(X; Y^{2}_{\pi_X(K_2)}|U) - nI(X; Y^{2}_{\pi_X(k)}|U)
$$

(266)

where (264) is due to the independence of $\{\tilde{W}_{1k}\}_{k=1}^{K_2}$, (265) comes from the fact that $\tilde{W}_{1k}$ can take $2^{n\tilde{R}_{1k}}$ values uniformly and independently, and in (266), we used (231). We now bound the second term of (263). For that purpose, we first note that given

$$
\left( U^n = u^n, \ W_1 = w_1, \ \tilde{W}_{1(k+1)} = \tilde{w}_{1(k+1)}, \ldots, \ \tilde{W}_{1K_2} = \tilde{w}_{1K_2} \right)
$$

(267)

$X^n$ can take $2^{nI(X; Y^{2}_{\pi_X(k)}|U)}$ values. Thus, given the side information in (267), the $\pi_X(k)$th user in the second group can decode $X^n$ with vanishingly small probability of error leading to

$$
H(X^n|W_1, U^n, Y^{2,n}_{\pi_X(k)}, \tilde{W}_{1(k+1)}, \ldots, \tilde{W}_{1K_2}) \leq n\gamma_{1,n}
$$

(268)

due to Fano’s lemma where $\gamma_{1,n} \to 0$ as $n \to \infty$. Plugging (266) and (268) into (263) yields

$$
H(X^n|W_1, U^n, Y^{2,n}_{\pi_X(k)}) \leq nI(X; Y^{2}_{\pi_X(K_2)}|U) - nI(X; Y^{2}_{\pi_X(k)}|U) + n\gamma_{1,n}
$$

(269)

Finally, using (260), (261) and (269) in (259) results in

$$
H(W_1|W_2, Y^{2,n}_{\pi_X(k)}) \geq nR_1 + n\tilde{R}_1 - nI(X; Y^{2}_{\pi_X(K_2)}|U) - n(\epsilon_{1,n} + \gamma_{1,n})
$$

(270)

$$
= nR_1 - n(\epsilon_{1,n} + \gamma_{1,n})
$$

(271)

where we used (230). Since this implies (67), the proposed coding scheme ensures perfect secrecy for the first group of users, completing the proof.
G.2 Converse

First, we note that for an arbitrary code achieving the secrecy rate pairs \((R_1, R_2)\), there exist \((\epsilon_1, \epsilon_2)\) and \((\gamma_1, \gamma_2)\) which vanish as \(n \to \infty\) such that

\[
H(W_1|Y_{j,n}^{1,n}) \leq n\epsilon_1, \quad j = 1, \ldots, K_1
\]  
(272)

\[
H(W_2|Y_{k,n}^{2,n}) \leq n\epsilon_2, \quad k = 1, \ldots, K_2
\]  
(273)

\[
I(W_2; Z_{t,n}^{n}) \leq n\gamma_2, \quad t = 1, \ldots, K_Z
\]  
(274)

\[
I(W_1; Y_{k,n}^{2,n}|W_2) \leq n\gamma_1, \quad k = 1, \ldots, K_2
\]  
(275)

where (272) and (273) are due to Fano’s lemma, and (274) and (275) come from perfect secrecy requirements in (66) and (67).

We now define the following auxiliary random variables

\[
U_i = W_2 Y_{s, i}^{s, i-1} Z_{i+1}^{s, n}, \quad i = 1, \ldots, n
\]  
(276)

which satisfy the Markov chains

\[
U_i \to X_i \to Y_{j,i}^{1} \to Y_{i}^{s} \to Y_{k,i}^{2} \to Z_{t,i}^{s} \to Z_{t,i}, \quad i = 1, \ldots, n
\]  
(277)

for any \((j, k, t)\) triple. The Markov chain in (277) is a consequence of the fact that the channel is memoryless and degraded.
We first establish the desired bound on $R_2$ as follows

\begin{align*}
nR_2 &= H(W_2) \\ &\leq I(W_2; Y_k^{2,n}) + n\epsilon_{2,n} \\ &\leq I(W_2; Y_k^{2,n}) - I(W_2; Z^n_t) + n(\epsilon_{2,n} + \gamma_{2,n}) \\ &= I(W_2; Y_k^{2,n} | Z^n_t) + n(\epsilon_{2,n} + \gamma_{2,n}) \\ &= \sum_{i=1}^{n} I(W_2; Y_k^{2,i} | Z^n_t, Y_k^{2,i-1}) + n(\epsilon_{2,n} + \gamma_{2,n}) \\ &= \sum_{i=1}^{n} I(W_2; Y_k^{2,i} | Z^n_{t,i+1}, Y_k^{2,i-1}, Z_{t,i}) + n(\epsilon_{2,n} + \gamma_{2,n}) \\ &\leq \sum_{i=1}^{n} I(Z^n_{t,i+1}, Y_k^{2,i-1}, Z^n_{t,i+1}, Y_k^{2,i-1}, W_2; Y_k^{2,i} | Z_{t,i}) + n(\epsilon_{2,n} + \gamma_{2,n}) \\ &\leq \sum_{i=1}^{n} I(U_i; Y_k^{2,i} | Z_{t,i}) + n(\epsilon_{2,n} + \gamma_{2,n}) 
\end{align*}

where (281) is due to the Markov chain \[ W_2 \to Y_k^{2,n} \to Z^n_t \] which comes from the fact that the channel is degraded, (283) results from the Markov chain \[ Z^n_t \to Y_k^{2,i-1} \to (W_2, Y_k^{2,i}, Z^n_{t,i}) \] which is a consequence of the fact that the channel is memoryless and degraded, and (286) is due to the Markov chain \[ (Z^n_{t,i+1}, Y_k^{2,i}) \to (Z^n_{t,i+1}, Y^{*,i-1}) \to (W_2, Y_k^{2,i}, Z_{t,i}) \] which is a consequence of the Markov chain in (2).
We now establish the bound on $R_1$ as follows

$$nR_1 = H(W_1)$$

$$= H(W_1 | W_2)$$

$$\leq I(W_1; Y_j^{1,n} | W_2) + n\epsilon_{1,n}$$

$$\leq I(W_1; Y_j^{1,n} | W_2) - I(W_1; Y_k^{2,n} | W_2) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$= I(W_1; Y_j^{1,n} | W_2, Y_k^{2,n}) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$= \sum_{i=1}^{n} I(W_1; Y_j^{1,i} | W_2, Y_k^{2,n}, Y_j^{1,i-1}) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$= \sum_{i=1}^{n} I(W_1; Y_j^{1,i} | W_2, Y_k^{2,n}, Y_j^{1,i-1}, Y_j^{2,n}) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$= \sum_{i=1}^{n} I(W_1; Y_j^{1,i} | W_2, Y_k^{2,n}, Y_j^{1,i-1}, Y_k^{2,n}, Z_{i+1}, Y_{s,i-1}, Y_{k,i}) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$= \sum_{i=1}^{n} I(X_i; W_1, Y_j^{1,i} | U_i, Y_k^{2,n}, Y_j^{1,i-1}, Y_k^{2,n}) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$\leq \sum_{i=1}^{n} I(X_i; W_1, Y_j^{1,i} | U_i, Y_k^{2,n}, Y_j^{1,i-1}, Y_k^{2,n}) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$= \sum_{i=1}^{n} H(Y_j^{1,i} | U_i, Y_k^{2,n}, Y_j^{1,i-1}, Y_k^{2,n}) - H(Y_j^{1,i} | U_i, Y_k^{2,n}, Y_j^{1,i-1}, Y_k^{2,n}, X_i)$$

$$+ n(\epsilon_{1,n} + \gamma_{1,n})$$

$$= \sum_{i=1}^{n} H(Y_j^{1,i} | U_i, Y_k^{2,n}, Y_j^{1,i-1}, Y_k^{2,n}) - H(Y_j^{1,i} | U_i, Y_k^{2,n}, X_i) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$\leq \sum_{i=1}^{n} H(Y_j^{1,i} | U_i, Y_k^{2,n}) - H(Y_j^{1,i} | U_i, Y_k^{2,n}, X_i) + n(\epsilon_{1,n} + \gamma_{1,n})$$

$$= \sum_{i=1}^{n} I(X_i; Y_j^{1,i} | U_i, Y_k^{2,n}) + n(\epsilon_{1,n} + \gamma_{1,n})$$

where (295) is due to the Markov chain

$$(W_1, W_2) \rightarrow Y_j^{1,n} \rightarrow Y_k^{2,n}$$

which comes from the degradedness of the channel, (297) results from the Markov chain

$$Y_k^{2,i-1} \rightarrow Y_j^{1,i-1} \rightarrow (W_1, W_2, Y_j^{1,i}, Y_k^{2,n})$$
which is again due to the degradedness of the channel, (298) is a consequence of the Markov chain

\[(Z^{*,n}_{i+1}, Y^{*,i-1}_{i+1}) \rightarrow (Y^{2,n}_{k,i+1}, Y^{1,i-1}_{j,i}) \rightarrow (W_2, W_1, Y^1_{j,i}, Y^2_{k,i}) \tag{308}\]

which results from the Markov chain in (2), (301) comes from the Markov chain

\[(Y^2_{k,i}, Y^1_{j,i}) \rightarrow X_i \rightarrow (W_1, W_2, U_i, Y^2_{k,i+1}, Y^1_{j,i}) \tag{309}\]

which is due to the fact that the channel is memoryless, (303) is also due to the Markov chain in (309), and (304) comes from the fact that conditioning cannot increase entropy.

Single-letterization can be accomplished as outlined in the proofs of Theorems 1 and 2, completing the converse proof.

H Proof of Theorem 9

The achievability of the region given in Theorem 9 can be shown by selecting \((U, X) = (U_1, X_1, \ldots, U_L, X_L)\) with a joint distribution of the form \(p(u, x) = \prod_{\ell=1}^L p(u_\ell, x_\ell)\). We next provide the converse proof. To that end, we define the following auxiliary random variables

\[U_{\ell,i} = W_2 Y^{*,i-1}_{i+1} Z^{*,n}_{i+1,i} Y^{*,i}_{i+1,i} Z^{*,t}_{i+1,i}, \quad i = 1, \ldots, n, \quad \ell = 1, \ldots, L \tag{310}\]

which satisfy the Markov chains

\[U_{\ell,i} \rightarrow X_{\ell,i} \rightarrow Y^1_{j\ell,i} \rightarrow Y^2_{k\ell,i} \rightarrow Z^*_{\ell,i} \rightarrow Z^{*,t}_{\ell,i}, \quad i = 1, \ldots, n, \quad \ell = 1, \ldots, L \tag{311}\]

for any \((j, k, t)\) triple. These Markov chains are a consequence of the facts that the channel is memoryless and degraded, and sub-channels are independent.

We first establish the desired bound on \(R_2\). For that purpose, following the proof of
Theorem 8, we get

\[ nR_2 \leq \sum_{i=1}^{n} I(W_2; Y_{k,i}^2 | Y_{k,i}^{2,i-1}, Z_{t,i+1}, Z_{t,i}) + n(\epsilon_{2,n} + \gamma_{2,n}) \]  

(312)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_2; Y_{k,\ell,i}^2 | Y_{k,i}^{1,i-1}, Z_{t,i+1}, Z_{t,\ell,i}, Y_{k,[\ell-1],i}) + n(\epsilon_{2,n} + \gamma_{2,n}) \]  

(313)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_2; Y_{k,i}^2 | Y_{k,i}^{2,i-1}, Z_{t,i+1}, Z_{t,[\ell-1]:L,i}, Y_{k,[\ell-1]:L,i}, Z_{t,i}) + n(\epsilon_{2,n} + \gamma_{2,n}) \]  

(314)

\[ \leq \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(Y_{*,i-1}; Z_{i+1}, Y_{*,[\ell+1]:L,i}, Y_{*,[1:\ell-1],i}, Y_{k,i}^{2,i-1}, Z_{t,i+1}, Z_{t,[\ell+1]:L,i}, Y_{k,[\ell-1]:L,i}, W_2; Y_{k,\ell,i}^2 | Z_{t,i}) \] 

\[ + n(\epsilon_{2,n} + \gamma_{2,n}) \]  

(315)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(Y_{*,i-1}; Z_{i+1}, Y_{*,[\ell+1]:L,i}, Y_{*,[1:\ell-1],i}, W_2; Y_{k,\ell,i}^2 | Z_{t,i}) + n(\epsilon_{2,n} + \gamma_{2,n}) \]  

(316)

\[ = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(U_{t,i}; Y_{k,\ell,i}^2 | Z_{t,i}) + n(\epsilon_{2,n} + \gamma_{2,n}) \]  

(317)

where (314) comes from the Markov chain

\[ Z_{t,[\ell-1],i} \rightarrow Y_{k,[\ell-1],i} \rightarrow (W_2, Y_{k,\ell,i}^2, Y_{k,i}^{2,i-1}, Z_{t,i+1}, Z_{t,[\ell,L],i}) \]  

(318)

which is a consequence of the facts that the channel is memoryless and sub-channels are independent, (316) results from the Markov chain

\[ (Y_{k,i}^{2,i-1}, Z_{t,i+1}, Z_{t,[\ell+1]:L,i}, Y_{k,[\ell-1],i}) \rightarrow (Y_{*,i-1}, Z_{i+1}, Y_{*,[\ell+1]:L,i}, Y_{*,[1:\ell-1],i}) \rightarrow (W_2, Y_{k,\ell,i}^2, Z_{t,i}) \]  

(319)

which is a consequence of the Markov chain in (10).
We now bound $R_1$. Following the proof of Theorem 8, we get

\begin{align*}
nR_1 & \leq \sum_{i=1}^{n} I(W_1; Y_{j,i}^1|W_2, Y_{j,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}) + n(\epsilon_{1,n} + \gamma_{1,n}) \\
& = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_1; Y_{j,\ell,i}^1|W_2, Y_{j,\ell,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}, Y_{j,\ell-1,i}^1) + n(\epsilon_{1,n} + \gamma_{1,n}) \\
& = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_1; Y_{j,\ell,i}^1|W_2, Y_{j,\ell,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}, Y_{j,\ell-1,i}^1, Y_{k,\ell,i}^1) + n(\epsilon_{1,n} + \gamma_{1,n}) \\
& = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(W_1; Y_{j,\ell,i}^1|U_{\ell,i}, Y_{j,\ell,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}, Y_{j,\ell-1,i}^1, Y_{k,\ell,i}^2) + n(\epsilon_{1,n} + \gamma_{1,n}) \\
& \leq \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(X_{\ell,i}, W_1; Y_{j,\ell,i}^1|U_{\ell,i}, Y_{j,\ell,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}, Y_{j,\ell-1,i}^1, Y_{k,\ell,i}^2) + n(\epsilon_{1,n} + \gamma_{1,n}) \\
& = \sum_{i=1}^{n} \sum_{\ell=1}^{L} H(Y_{j,\ell,i}^1|U_{\ell,i}, Y_{j,\ell,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}, Y_{j,\ell-1,i}^1, Y_{k,\ell,i}^2) + n(\epsilon_{1,n} + \gamma_{1,n}) \\
& = \sum_{i=1}^{n} \sum_{\ell=1}^{L} H(Y_{j,\ell,i}^1|U_{\ell,i}, Y_{j,\ell,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}, Y_{j,\ell-1,i}^1, Y_{k,\ell,i}^2) - H(Y_{j,\ell,i}^1|U_{\ell,i}, Y_{k,\ell,i}^2, X_{\ell,i}) + n(\epsilon_{1,n} + \gamma_{1,n}) \\
& \leq \sum_{i=1}^{n} \sum_{\ell=1}^{L} H(Y_{j,\ell,i}^1|U_{\ell,i}, Y_{k,\ell,i}^2) - H(Y_{j,\ell,i}^1|U_{\ell,i}, Y_{k,\ell,i}^2, X_{\ell,i}) + n(\epsilon_{1,n} + \gamma_{1,n}) \\
& = \sum_{i=1}^{n} \sum_{\ell=1}^{L} I(X_{\ell,i}, Y_{j,\ell,i}^1|U_{\ell,i}, Y_{k,\ell,i}^2) + n(\epsilon_{1,n} + \gamma_{1,n})
\end{align*}

where (322) is due to the Markov chain

\[ Y_{k,[1:\ell-1],i}^2 \rightarrow Y_{j,[1:\ell-1],i}^1 \rightarrow (W_1, W_2, Y_{j,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}, Y_{j,\ell,i}) \]

which is a consequence of the degradedness of the channel, and the fact that sub-channels are independent and memoryless, (323) results from the Markov chain

\[ (Y_{s,i}^{1,i-1}, Z_{s,i+1}^{s,n}, Z_{[1:\ell-1],i}^{s}, Y_{s}^{*}) \rightarrow (Y_{j,i}^{1,i-1}, Y_{k,i+1}^{2}, Y_{k,i}^{2}, Y_{j,\ell,i}) \rightarrow (W_1, W_2, Y_{j,\ell,i}^1, Y_{k,\ell,i}^2) \]

which is a consequence of the Markov chain in (10), (325) and (327) come from the Markov
chain
\[(W_1, U_{\ell,i}, Y_{j}^{1,i-1}, Y_{k,i+1}^{2,n}, Y_{k[i+1;\ell],i}^{2}, Y_{j[i;\ell-1],i}^{1}) \to X_{\ell,i} \to (Y_{k,i}^{2}, Y_{j,i}^{1}) \] (332)

which is a consequence of the fact that sub-channels are independent and memoryless.

We can obtain the desired single-letter expressions as it is done in the proof of Theorem 2, completing the proof.

I Proof of Theorem 10

According to Theorem 3, there exists a \( P^* \leq P \) such that
\[ h(X + \tilde{N}|U) - h(X + N^*|U) = \frac{1}{2} \log \frac{P^* + \tilde{\sigma}^2}{P^* + \sigma^2_*} \] (333)
\[ h(X + \tilde{N}|U) - h(X + N_2|U) \leq \frac{1}{2} \log \frac{P^* + \tilde{\sigma}^2}{P^* + \sigma^2_2} \] (334)
\[ h(X + \tilde{N}|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{P^* + \tilde{\sigma}^2}{P^* + \sigma^2_1} \] (335)

for any \((\sigma^2_1, \sigma^2_2)\) as long as they satisfy
\[ \sigma^2_1 \leq \sigma^2_* \leq \sigma^2_2 \leq \tilde{\sigma}^2 \] (336)

We first show (78). To this end, we note that (333) and (334) imply
\[ h(X + N_2|U) - h(X + N^*|U) \geq \frac{1}{2} \log \frac{P^* + \sigma^2_*}{P^* + \sigma^2_2} \] (337)

Furthermore, (333) and (335) imply
\[ h(X + N^*|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{P^* + \sigma^2_*}{P^* + \sigma^2_1} \] (338)

Combining (337) and (338) yields
\[ h(X + N_2|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{P^* + \sigma^2_*}{P^* + \sigma^2_1} \] (339)

which is the desired result in (78).

We now show (77). We first note that we can write \( \tilde{N} \) as
\[ \tilde{N} = N_2 + \sqrt{t}\tilde{N}_Z \] (340)

where \( \tilde{N}_Z \) is a zero-mean Gaussian random variable with variance \( \sigma^2_Z - \sigma^2_2 \), and independent
of \((U, X, N_2)\). \(t\) in (340) is given by

\[
t = \frac{\tilde{\sigma}^2 - \sigma^2}{\sigma_Z^2 - \sigma^2}
\]  

(341)

where it is clear that \(t \in [0, 1]\). We now use Costa’s entropy power inequality [15] to arrive

\[
e^{2h(X + \tilde{N}|U)} = e^{2h(X + N_2 + \sqrt{t} \tilde{N}_Z|U)}
\]

\[
\geq (1 - t)e^{2h(X + N_2|U)} + te^{2h(X + N_2|U)}
\]

(342)

which is equivalent to

\[
e^{2[h(X + \tilde{N}|U) - h(X + N_2|U)]} \geq (1 - t) + te^{2[h(X + N_2|U) - h(X + N_2|U)]}
\]

(343)

which can be written as

\[
h(X + N_Z|U) - h(X + N_2|U) \leq \frac{1}{2} \log \left( \frac{1}{t} e^{2[h(X + \tilde{N}|U) - h(X + N_2|U)]} - \frac{1 - t}{t} \right)
\]

(344)

(345)

\[
\leq \frac{1}{2} \log \left( \frac{1}{t} \frac{P^* + \tilde{\sigma}^2}{P^* + \sigma_Z^2} - \frac{1 - t}{t} \right)
\]

(346)

\[
= \frac{1}{2} \log \left[ \frac{P^*}{P^* + \sigma_2^2} - \frac{1 - t}{t} \frac{\tilde{\sigma}^2}{P^* + \sigma_2^2} \right]
\]

(347)

\[
= \frac{1}{2} \log \frac{P^* + \sigma_Z^2}{P^* + \sigma_2^2}
\]

(348)

where (346) is due to (334) and (348) comes from (341). Since (348) is the desired result in

(34)

this completes the proof.

J Proof of Theorem 11

Achievability is clear. We provide the converse proof. We fix the distribution \(\prod_{\ell=1}^{L} p(u_\ell, x_\ell)\) such that

\[
E \left[ X_{\ell}^2 \right] = P_\ell, \quad \ell = 1, \ldots, L
\]

(349)
and $\sum_{\ell=1}^{L} P_{\ell} = P$. We first establish the bound on $R_2$ given in (80). To this end, we start with (73). Using the Markov chain $U_\ell \rightarrow Y_{k\ell}^2 \rightarrow Z_{t\ell}$, we have

$$R_2 \leq \min_{k=1, \ldots, K_2} \sum_{t=1}^{K_Z} I(U_\ell; Y_{k\ell}^2) - I(U_\ell; Z_{t\ell})$$

(350)

$$= \min_{k=1, \ldots, K_2} \sum_{t=1}^{K_Z} h(Y_{k\ell}^2) - h(Z_{t\ell}) + \left[ h(Z_{t\ell}|U_\ell) - h(Y_{k\ell}^2|U_\ell) \right]$$

(351)

$$\leq \min_{k=1, \ldots, K_2} \sum_{t=1}^{K_Z} \frac{1}{2} \log \frac{P_{\ell} + \Lambda_{k,\ell}^Z}{P_{\ell} + \Lambda_{k,\ell}^Z} + \left[ h(Z_{t\ell}|U_\ell) - h(Y_{k\ell}^2|U_\ell) \right]$$

(352)

where (352) comes from the fact that

$$h(Y_{k\ell}^2) - h(Z_{t\ell})$$

(353)

is maximized by Gaussian distribution which can be shown by using the entropy power inequality [18, 19]. We now use Theorem 10. For that purpose, we introduce $\Lambda^*_Y$ and $\Lambda^*_Z$ which satisfy

$$\Lambda^*_j \leq \Lambda^*_Y \leq \Lambda^*_k \leq \Lambda^*_Z \leq \Lambda^*_t$$

(354)

for any $(j, k, t)$ triple, and in particular, for the diagonal, elements of these matrices, we have

$$\Lambda^*_j,\ell \leq \Lambda^*_Y,\ell \leq \Lambda^*_k,\ell \leq \Lambda^*_Z,\ell \leq \Lambda^*_t,\ell$$

(355)

for any $(j, k, t, \ell)$. Thus, due to Theorem 10 for any selection of $\{(U_\ell, X_\ell)\}_{\ell=1}^{L}$, we have

$$P^*_\ell \leq P_\ell$$

(356)

$$h(Z_{t\ell}|U_\ell) - h(Y_{k\ell}^2|U_\ell) \leq \frac{1}{2} \log \frac{P^*_\ell + \Lambda^*_Z,\ell}{P^*_\ell + \Lambda^*_k,\ell}$$

(357)

$$h(Y_{k\ell}^2|U_\ell) - h(Y_{j\ell}^1|U_\ell) \geq \frac{1}{2} \log \frac{P^*_\ell + \Lambda^*_k,\ell}{P^*_\ell + \Lambda^*_j,\ell}$$

(358)

for any $(k, j, t, \ell)$. Using (357) in (352) yields

$$R_2 \leq \min_{k=1, \ldots, K_2} \sum_{t=1}^{K_Z} \frac{1}{2} \log \frac{P_\ell + \Lambda^*_k,\ell}{P_\ell + \Lambda^*_k,\ell} = \frac{1}{2} \log \frac{P^*_\ell + \Lambda^*_Z,\ell}{P^*_\ell + \Lambda^*_Z,\ell}$$

(359)

By defining $P^*_\ell = \beta_\ell P_\ell$ and $\tilde{\beta}_\ell = 1 - \beta_\ell$, $\ell = 1, \ldots, L$, where $\beta_\ell \in [0, 1]$ due to (356), we get the desired bound on $R_2$ given in (80).

We now bound $R_1$. We start with (72). Using the Markov chain $U_\ell \rightarrow X_\ell \rightarrow Y_{j\ell}^1 \rightarrow Y_{k\ell}^2$, we have

$$R_1 \leq \min_{j=1, \ldots, J} \sum_{\ell=1}^{L} I(X_\ell; Y_{j\ell}^1) - I(X_\ell; Y_{k\ell}^2)$$

(360)

$$= \min_{j=1, \ldots, J} \sum_{\ell=1}^{L} h(Y_{j\ell}^1) - h(Y_{k\ell}^2) + \left[ h(Y_{k\ell}^2|X_\ell) - h(Y_{j\ell}^1|X_\ell) \right]$$

(361)

$$\leq \min_{j=1, \ldots, J} \sum_{\ell=1}^{L} \frac{1}{2} \log \frac{P_{\ell} + \Lambda_{j,\ell}^Z}{P_{\ell} + \Lambda_{j,\ell}^Z} + \left[ h(Y_{k\ell}^2|X_\ell) - h(Y_{j\ell}^1|X_\ell) \right]$$

(362)

where (362) comes from the fact that

$$h(Y_{j\ell}^1) - h(Y_{k\ell}^2)$$

(363)

is maximized by Gaussian distribution which can be shown by using the entropy power inequality [18, 19]. We now use Theorem 10. For that purpose, we introduce $\Lambda^*_Y$ and $\Lambda^*_Z$ which satisfy

$$\Lambda^*_j \leq \Lambda^*_Y \leq \Lambda^*_k \leq \Lambda^*_Z \leq \Lambda^*_t$$

(364)

for any $(j, k, t)$ triple, and in particular, for the diagonal, elements of these matrices, we have

$$\Lambda^*_j,\ell \leq \Lambda^*_Y,\ell \leq \Lambda^*_k,\ell \leq \Lambda^*_Z,\ell \leq \Lambda^*_t,\ell$$

(365)

for any $(j, k, t, \ell)$. Thus, due to Theorem 10 for any selection of $\{(X_\ell, Y_\ell)\}_{\ell=1}^{L}$, we have

$$P^*_\ell \leq P_\ell$$

(366)

$$h(Y_{k\ell}^2|X_\ell) - h(Y_{j\ell}^1|X_\ell) \leq \frac{1}{2} \log \frac{P^*_\ell + \Lambda^*_Z,\ell}{P^*_\ell + \Lambda^*_k,\ell}$$

(367)

$$h(Y_{j\ell}^1|X_\ell) - h(Y_{k\ell}^2|X_\ell) \geq \frac{1}{2} \log \frac{P^*_\ell + \Lambda^*_k,\ell}{P^*_\ell + \Lambda^*_j,\ell}$$

(368)

for any $(k, j, t, \ell)$. Using (367) in (362) yields

$$R_1 \leq \min_{j=1, \ldots, J} \sum_{\ell=1}^{L} \frac{1}{2} \log \frac{P_{\ell} + \Lambda^*_k,\ell}{P_{\ell} + \Lambda^*_k,\ell} = \frac{1}{2} \log \frac{P^*_\ell + \Lambda^*_Z,\ell}{P^*_\ell + \Lambda^*_Z,\ell}$$

(369)

By defining $P^*_\ell = \beta_\ell P_{\ell}$ and $\tilde{\beta}_\ell = 1 - \beta_\ell$, $\ell = 1, \ldots, L$, where $\beta_\ell \in [0, 1]$ due to (366), we get the desired bound on $R_1$ given in (80).
we have

\[ R_1 \leq \min_{j=1,\ldots,K_1} \sum_{\ell=1}^L \left[ I(X_{\ell j}; Y_{1j\ell}\mid U_{\ell}) - I(X_{\ell j}; Y_{2k\ell}\mid U_{\ell}) \right] \tag{360} \]

\[ = \min_{j=1,\ldots,K_1} \sum_{\ell=1}^L h(Y_{1j\ell}\mid U_{\ell}) - h(Y_{2k\ell}\mid U_{\ell}) - \frac{1}{2} \log \frac{\Lambda^1_{j,\ell \ell}}{\Lambda^2_{k,\ell \ell}} \tag{361} \]

\[ \leq \min_{j=1,\ldots,K_1} \sum_{\ell=1}^L \frac{1}{2} \log \left( 1 + \frac{\beta P_{\ell} \Lambda^1_{j,\ell \ell}}{\Lambda^2_{k,\ell \ell}} \right) - \frac{1}{2} \log \left( 1 + \frac{\beta P_{\ell} \Lambda^1_{j,\ell \ell}}{\Lambda^2_{k,\ell \ell}} \right) \tag{362} \]

where (362) is due to (358). Since (363) is the desired bound on \( R_1 \) given in (79), this completes the proof.

### K Background Information for Appendix L

In Appendix L, we need some properties of the Fisher information and the differential entropy, which are provided here.

**Definition 1 ([3], Definition 3)** Let \((U, X)\) be an arbitrarily correlated length-\(n\) random vector pair with well-defined densities. The conditional Fisher information matrix of \(X\) given \(U\) is defined as

\[ J(X\mid U) = E \left[ \rho(X\mid U) \rho(X\mid U)^\top \right] \tag{364} \]

where the expectation is over the joint density \(f(u, x)\), and the conditional score function \(\rho(x\mid u)\) is

\[ \rho(x\mid u) = \nabla \log f(x\mid u) = \left[ \frac{\partial \log f(x\mid u)}{\partial x_1} \ldots \frac{\partial \log f(x\mid u)}{\partial x_n} \right]^\top \tag{365} \]

The following lemma will be used in the upcoming proof. In fact, an unconditional version of this lemma is proved in Lemma 6 of [3].

**Lemma 5** Let \(T, U, V_1, V_2\) be random vectors such that \((T, U)\) and \((V_1, V_2)\) are independent. Moreover, let \(V_1, V_2\) be Gaussian random vectors with covariance matrices \(\Sigma_1, \Sigma_2\) such that \(0 \prec \Sigma_1 \preceq \Sigma_2\). Then, we have

\[ J^{-1}(U + V_2\mid T) - \Sigma_2 \succeq J^{-1}(U + V_1\mid T) - \Sigma_1 \tag{366} \]
The following lemma is also instrumental for the upcoming proof whose proof can be found in [3].

**Lemma 6 ([3], Lemma 8)** Let $K_1, K_2$ be positive semi-definite matrices satisfying $0 \preceq K_1 \preceq K_2$, and $f(K)$ be a matrix-valued function such that $f(K) \succeq 0$ for $K_1 \preceq K \preceq K_2$. Then, we have

$$\int_{K_1}^{K_2} f(K) dK \preceq 0 \quad (367)$$

The following generalization of the de Bruin identity [18, 19] is due to [22]. In [22], the unconditional form of this identity, i.e., the case where $U = \phi$, is proved. However, its generalization to this conditional form for an arbitrary $U$ is rather straightforward, and given in Lemma 16 of [3].

**Lemma 7 ([3], Lemma 16)** Let $(U, X)$ be an arbitrarily correlated random vector pair with finite second order moments, and be independent of the random vector $N$ which is zero-mean Gaussian with covariance matrix $\Sigma_N \succ 0$. Then, we have

$$\nabla_{\Sigma_N} h(X + N|U) = \frac{1}{2} J(X + N|U) \quad (368)$$

### Proof of Theorem 12

According to Theorem 5, for any selection of $(U, X)$, there exists a $K^* \succeq S$ such that

$$h(X + N^*|U) - h(X + N_2|U) = \frac{1}{2} \log \frac{|K^* + \Sigma^*|}{|K^* + \Sigma_2|} \quad (369)$$

$$h(X + N^*|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{|K^* + \Sigma^*|}{|K^* + \Sigma_1|} \quad (370)$$

for any $\Sigma_1$ such that $\Sigma_1 \preceq \Sigma_2$. Furthermore, $K^*$ satisfies [3]

$$K^* \preceq J^{-1}(X + N^*|U) - \Sigma^* \quad (371)$$

Equations (369) and (370) already imply

$$h(X + N_2|U) - h(X + N_1|U) \geq \frac{1}{2} \log \frac{|K^* + \Sigma_2|}{|K^* + \Sigma_1|} \quad (372)$$

for any $\Sigma_1$ such that $\Sigma_1 \preceq \Sigma_2$, which is the desired inequality in (84).

We now prove (83). For that purpose, we note that (371) implies

$$K^* \preceq J^{-1}(X + N|U) - \Sigma_N \quad (373)$$
for any Gaussian random vector $\mathbf{N}$, independent of $(U, X)$, with covariance matrix $\Sigma_N$ such that $\Sigma_N \succeq \Sigma^*$ because of Lemma 5. The order in (373) is equivalent to

$$J(X + N|U) \leq (K^* + \Sigma_N)^{-1}, \quad \Sigma^* \succeq \Sigma_N$$

(374)

Now, we can obtain (83) as follows

$$h(X + N|Z|U) - h(X + N_2|U) = h(X + N|Z|U) - h(X + N^*|U) + h(X + N|U) - h(X + N_2|U)$$

(375)

$$= h(X + N|Z|U) - h(X + N|U) + \frac{1}{2} \log \frac{|K^* + \Sigma^*|}{|K^* + \Sigma_2|}$$

(376)

$$\leq \frac{1}{2} \int_{\Sigma^*} J(X + N|U) \, d\Sigma_N + \frac{1}{2} \log \frac{|K^* + \Sigma^*|}{|K^* + \Sigma_2|}$$

(377)

$$\leq \frac{1}{2} \int_{\Sigma^*} (K^* + \Sigma_N)^{-1} \, d\Sigma_N + \frac{1}{2} \log \frac{|K^* + \Sigma^*|}{|K^* + \Sigma_2|}$$

(378)

$$\leq \frac{1}{2} \log \frac{|K^* + \Sigma_Z|}{|K^* + \Sigma_2|}$$

(379)

where (376) is due to (369), (377) is obtained by using Lemma 7 and (378) comes from Lemma 6 by noting (374). Since (379) is the desired inequality in (83), this completes the proof.

**M Proof of Theorem 13**

We first establish the desired bound on $R_2$ given in (86) as follows

$$R_2 \leq \min_{t=1, \ldots, K_z} I(U; Y^2) - I(U; Z_t)$$

(380)

$$= \min_{t=1, \ldots, K_z} h(Y^2) - h(Z_t) + \left[ h(Z_t|U) - h(Y^2|U) \right]$$

(381)

$$\leq \min_{t=1, \ldots, K_z} \frac{1}{2} \log \frac{|S + \Sigma^2|}{|S + \Sigma^2|} + \left[ h(Z_t|U) - h(Y^2|U) \right]$$

(382)

where (380) comes from Theorem 8 by noting the Markov chain $U \rightarrow Y^2 \rightarrow Z_t$, and (382) can be obtained by using the worst additive noise lemma, i.e., Lemma 4 as it is done in the proof of Theorem 6. We now use Theorem 12. According to Theorem 12, for any selection of $(U, X)$, there exists a positive semi-definite matrix $K$ such that $K \preceq S$ and

$$h(Z_t|U) - h(Y^2|U) \leq \frac{1}{2} \log \frac{|K + \Sigma^2|}{|K + \Sigma^2|}$$

(383)

$$h(Y^2|U) - h(Y^j|U) \geq \frac{1}{2} \log \frac{|K + \Sigma^2_j|}{|K + \Sigma^2_j|}$$

(384)
for any \((j, t)\) pair. Using (383) in (382) yields

\[ R_2 \leq \min_{t=1, \ldots, K_2} \frac{1}{2} \log \frac{|S + \Sigma^2|}{|K + \Sigma^2|} - \frac{1}{2} \log \frac{|S + \Sigma^2_t|}{|K + \Sigma^2_t|} \quad (385) \]

which is the desired bound on \(R_2\) given in (80).

We now obtain the desired bound on \(R_1\) given in (85) as follows

\[ R_1 \leq \min_{j=1, \ldots, K_1} I(X; Y^1_j|U) - I(X; Y^2|U) \quad (386) \]

\[ = \min_{j=1, \ldots, K_1} h(Y^1_j|U) - h(Y^2|U) - \frac{1}{2} \log \left| \frac{\Sigma^1_j}{\Sigma^2} \right| \quad (387) \]

\[ \leq \min_{j=1, \ldots, K_1} \frac{1}{2} \log \left| \frac{K + \Sigma^1_j}{\Sigma^1_j} \right| - \frac{1}{2} \log \left| \frac{K + \Sigma^2}{\Sigma^2} \right| \quad (388) \]

where (386) comes from Theorem 8 by noting the Markov chain \(U \rightarrow X \rightarrow Y^1_j \rightarrow Y^2\) and (388) is obtained by using (384). Since (388) is the desired bound on \(R_1\) given in (85), this completes the proof.
