Abstract. We study the spectrum of the Helmholtz equation in a two-dimensional infinite waveguide, containing a weak heterogeneity localized at an internal point, and obeying Dirichlet boundary conditions at its border. We use the variational theorem to derive the condition for which the lowest eigenvalue of the spectrum falls below the continuum threshold and a bound state appears, localized at the heterogeneity. We devise a rigorous perturbation scheme and derive the exact expression for the energy to third order in the heterogeneity.

1 Introduction

The existence of “trapped modes” in open geometries was first proved by Ursell\cite{1,2} studying beach waves in semi-infinite canals. Much later, Schult and collaborators\cite{3}, showed that the ground state of an electron constrained to move in an infinite symmetric cross, but otherwise free, is localized in the central region of the cross and its energy falls below the continuum threshold (recently Amore et al.\cite{4} have also studied the more general case of asymmetric crosses and asymmetric T- and L-shaped waveguides). Since reference\cite{3}, a large class of open geometries and of physical problems have been studied, observing the emergence of one or more localized modes. In particular, Exner and Seba\cite{5} have proved the existence of a bound state for an electron confined to a planar waveguide, with curvature decaying at infinity and obeying Dirichlet boundary conditions at the border; Goldstone and Jaffe\cite{6} have proved that an electron confined to an infinite tube of constant cross section, in two or more dimensions, has always a bound state, when the tube is not perfectly straight. The effect of bound states in infinite non-straight waveguides has been studied in\cite{7–12}. It is worth mentioning a recent pedagogical article by Londergan and Murdock\cite{13}, that illustrates different numerical methods for the solutions of confined systems, in particular two-dimensional waveguides.

Bulla et al.\cite{14} have obtained the expression for the fundamental energy of an infinite two-dimensional waveguide, where the upper border is slightly deformed, to second order in the parameter controlling the deformation. Their result proves that a bound state is always present, whenever the deformation corresponds to a local enlargement of the waveguide. Exner and Vugalter\cite{15} have then considered the interesting question of what happens when the leading expression of Bulla et al. vanishes, and whether a bound state can still exist. This situation corresponds to the case where the local deformation of the waveguide contains both a local enlargement and a local shrinking of the waveguide, which preserve the total area. They showed that the problem presents a critical behavior, related to the size of the deformation, where the bound state can be lost below a critical size.

A different but related problem, concerns the existence of bound states in open geometries, that are not necessarily deformed, but contain local heterogeneities. For the solvable case of an infinite, straight, two-dimensional waveguide, containing a segment of different density, Wang\cite{16} has proved the existence of bound states. Moreover, at least in two dimensions, the problem of studying the spectrum of a deformed waveguide can be reduced to the problem of studying the spectrum of a heterogeneous straight waveguide, by using a suitable conformal map which transforms one domain into the other. In a similar way one could study the spectrum of a waveguide both deformed and heterogeneous.

The purpose of the present work is to establish rigorously the conditions for the existence of bound states on general planar weakly deformed and heterogeneous waveguides, applying a perturbation method and calculating the exact general expression for the energy of the fundamental mode to third order in the parameter controlling the perturbation. When our formula is applied to the study of homogeneous and weakly deformed waveguides the “density” appearing in our expression is directly related to the conformal map used to transform the deformed waveguide into a straight one (for an example of use of conformal maps to the infinite waveguide...
see [12,17]). In this case our second order formula should be equivalent to the formula of [14] for a specific class of maps. Our results can also be used in more than two dimensions, to describe straight heterogenous waveguides (conformal maps are limited to two dimensions). Finally, we stress that the perturbation scheme used in the present paper, could be applied to include higher order perturbative contributions in a systematic way.

The paper is organized as follows: in Section 2 we describe the perturbation method used in the calculation and derive the exact expressions for the energy of the ground state up to third order in the perturbative parameter; in Section 3 we reproduce the second order expression for the energy of the ground state using the variational method; in Section 4 we discuss a simple solvable example for the energy of the ground state using the variational method; in Section 5 we present our conclusions.

2 Perturbation theory

Following [18,19] we consider the Helmholtz equation for an inhomogeneous medium,

\[-\nabla^2 \Phi_n(x) = E_n \Sigma(x) \Phi_n(x),\]

where \(x \in \Omega_d, \) and \(\Omega_d\) is a region of \(\mathbb{R}^d.\) This region may either be finite or infinite, and the spectrum of the eigenvalues \(E_n\) can either be discrete, continuum or both. In particular, several aspects of the behavior of the spectrum of equation (1), in one or more dimensions, have been studied by one of the present authors. The aspects studied earlier include the description of non-perturbative methods for the calculation of the lowest part of the spectrum [18,20,21], of a perturbation method for the calculation of the eigenvalues of two-dimensional domains obtained from a small deformation of a reference (solvable) domain [22], the derivation of spectral zeta functions associated to heterogeneous systems in one and two dimensions [23] and the sum rules of heterogeneous domains in one or more dimensions, for different boundary conditions [19,24,25]. Observe that the density of the medium is a positive definite function, \(\Sigma(x) > 0\) for \(x \in \Omega_d.\)

For a straight and homogeneous waveguide the spectrum of the Helmholtz equation is continuous and thus one cannot use the operator corresponding to the homogeneous strip as the unperturbed operator, because of the infrared divergences which appear due to the contribution of the states of very soft momentum, just above the fundamental mode. To avoid the emergence of such divergences, in the different context of quantum mechanics and quantum field theory, Gat and Rosenstein [26] have devised a perturbation scheme which uses a regularized free theory and obtained explicit results for the bound state of weak short range potentials (thus reproducing a result first obtained by Simon [27]) and for the mass of the bound state meson in the Thirring model.

In the present case, the approach of Gat and Rosenstein requires the introduction of the operator

\[H = -\nabla^2 - 2\beta \delta(x),\]

where \(\beta > 0.\) The problem becomes

\[H \psi_0 = E_0 (1 + \lambda \sigma) \psi_0,\]

where \(\lambda\) is a dummy perturbation parameter and \(\sigma\) is a density perturbation (we assume that \(\sigma(x,y)\) corresponds to a localized inhomogeneity, i.e., \(\lim_{|x| \to \infty} \sigma(x,y) = 0).\) Note that \(\sigma(x,y) > 0\) corresponds to a locally denser medium.

We assume that

\[H |n⟩ = \epsilon_n |n⟩ , \quad \epsilon_0 < \epsilon_1 \leq \epsilon_2 \leq \ldots,\]

and that the lowest eigenvalue \(\epsilon_0\) is non-degenerate. In this case the label \(n\) denotes a collection of quantum numbers that describe all the degrees of motion of the problem. Then we have

\[(H - \epsilon_0) \psi_0 = \Delta E \psi_0 + \lambda E_0 \sigma \psi_0, \quad \Delta E = E_0 - \epsilon_0.\]

If we apply (0) from the left and resort to the intermediate normalization

\[\langle 0 | \psi_0 \rangle = 1, \quad \langle 0 | 0 \rangle = 1,\]

then equation (5) reduces to

\[\Delta E = -\lambda E_0 \langle 0 | \sigma | \psi_0 \rangle.\]

We define the projection operator

\[P = 1 - |0⟩⟨0|,\]

that satisfies \([H, P] = 0, \) \(P^2 = P\) and \(P |0⟩ = 0.\) It is also useful to define the operator

\[G = P (H - \epsilon_0)^{-1} P,\]

that enables us to rewrite equation (5) as

\[P \psi_0 = \Delta E G \psi_0 + \lambda E_0 G \sigma \psi_0.\]

Note that

\[(H - \epsilon_0) G^k = G^{k-1}, \quad k > 1,\]

\[(H - \epsilon_0) G = P.\]

We obviously have

\[G^k = P (H_0 - \epsilon_0)^k P = \sum_{n \neq 0} |n⟩⟨n|/(\epsilon_n - \epsilon_0)^k.\]

In order to solve equations (7) and (10) we apply perturbation theory and expand

\[\psi_0 = |0⟩ + \sum_{j=1}^{\infty} \psi_0^{(j)} \lambda^j,\]

\[E_0 = \epsilon_0 + \sum_{j=1}^{\infty} E_0^{(j)} \lambda^j,\]
so that
\[ \langle 0 | \psi_0^{(k)} \rangle = 0, \quad k > 0. \] (14)

Now equations (7) and (10) become
\[ E_0^{(k)} = -\sum_{j=0}^{k-1} E_j^{(j)}(0) \sigma |\psi_0^{k-j-1}\rangle, \quad k > 0, \] (15)
and
\[ \psi_0^{(k)} = \sum_{j=1}^{k} E_0^{(j)} G |\psi_0^{(k-j)}\rangle + \sum_{j=0}^{k-1} E_0^{(j)} G \sigma |\psi_0^{(k-j-1)}\rangle. \] (16)

For the first three orders we have:
\[ -k = 1 \]
\[ E_0^{(1)} = -\epsilon_0 |0\rangle \sigma |0\rangle, \]
\[ \psi_0^{(1)} = E_0^{(1)} G |0\rangle + \epsilon_0 G \sigma |0\rangle = \epsilon_0 G \sigma |0\rangle, \] (17)
\[ -k = 2 \]
\[ E_0^{(2)} = -\epsilon_0^2 |0\rangle \sigma G \sigma |0\rangle + \epsilon_0 |0\rangle \sigma |0\rangle^2, \]
\[ \psi_0^{(2)} = \epsilon_0 E_0^{(1)} G^2 |0\rangle + \epsilon_0^2 G \sigma G \sigma |0\rangle + E_0^{(1)} G \sigma |0\rangle, \] (18)
\[ -k = 3 \]
\[ E_0^{(3)} = \epsilon_0^3 |0\rangle \sigma^2 G \sigma |0\rangle |0\rangle \sigma |0\rangle - \epsilon_0^3 |0\rangle \sigma G \sigma G \sigma |0\rangle + 3\epsilon_0^2 |0\rangle \sigma G \sigma |0\rangle |0\rangle \sigma |0\rangle - \epsilon_0^3 |0\rangle \sigma |0\rangle^3. \] (19)

In order to apply the general formulas above to a concrete case, we consider the infinite strip defined by \((x, y) \in (0, b/2) \times (0, b/2)\) and assume Dirichlet boundary conditions at \(x = \pm b/2\).

The basis set of eigenfunctions of \(H\) is given by:
\[ \Psi_{p,n}(x, y) = \psi_n(y) \otimes \begin{cases} \phi_p(x), & \text{ground state,} \\ \phi_p^{(e)}(x), & \text{even,} \\ \phi_p^{(o)}(x), & \text{odd}, \end{cases} \]
where the longitudinal wave functions are
\[ \phi_0(x) = \sqrt{b} e^{-|x|}, \]
\[ \phi_p^{(e)}(x) = \frac{\sqrt{2}}{\sqrt{p^2 + \beta^2}} [p \cos(px) - \beta \sin(px)], \]
\[ \phi_p^{(o)}(x) = \sqrt{2} \sin(px), \] (20)
and the transverse wave functions are
\[ \psi_n(y) = \sqrt{\frac{2}{b}} \sin \left[ \frac{n \pi}{b} (y + b/2) \right]. \] (21)

The corresponding eigenvalues are
\[ \epsilon_{0,n} = -\beta^2 + \frac{n^2 \pi^2}{b^2}, \]
\[ \epsilon_p^{(e)} = \epsilon_p^{(o)} = p^2 + \frac{n^2 \pi^2}{b^2}. \] (22)

It is convenient to use Dirac notation
\[ \psi_n(y) \to |n\rangle \; ; \; \phi_0(x) \to |0\rangle \]
\[ \phi_p^{(e)}(x) \to |p^{(e)}\rangle \; ; \; \phi_p^{(o)}(x) \to |p^{(o)}\rangle \]
and
\[ \Psi_{p,n}(x, y) \to \left\{ \begin{array}{c} |0, n\rangle, \\ |p^{(e)}, n\rangle, \\ |p^{(o)}, n\rangle. \end{array} \right. \] (23)

The completeness of the longitudinal basis reads
\[ |0\rangle \langle 0| + \int_0^\infty dp \frac{dp}{2\pi} [p^{(e)} \langle p^{(e)}| + |p^{(o)}\rangle \langle p^{(o)}|] = 1, \] (24)
while the completeness of the transverse basis is
\[ \sum_{n=1}^\infty |n\rangle \langle n| = \mathbb{I}. \] (25)

The correct physics is recovered after taking the limit \(\beta \to 0\), for which one has
\[ \lim_{\beta \to 0} E_0^{(1)} = 0. \] (27)

### 2.1 First order

To first order we have
\[ E_0^{(1)} = \langle 0, 1| V^{(1)} |0, 1 \rangle \]
\[ = \frac{\beta}{2} \int_{-\infty}^{\infty} dx \int_{-b/2}^{b/2} dy \; e^{-\beta |x|} \psi_1(y) \left[ \hat{H}_0 \sigma + \sigma \hat{H}_0 \right] \times e^{-\beta |x|} \psi_1(y) \]
\[ = -\beta \epsilon_{0,1} \int_{-\infty}^{\infty} dx \int_{-b/2}^{b/2} dy \; e^{-\beta |x|} \psi_1(y) \sigma(x, y) \times e^{-\beta |x|} \psi_1(y). \] (26)

The correct physics is recovered after taking the limit \(\beta \to 0\), for which one has
\[ \lim_{\beta \to 0} E_0^{(1)} = 0. \] (27)

### 2.2 Second order

Using the explicit expressions for \(G(x, x') = \langle x| \hat{\Omega} |x'\rangle\) given in Appendix, we write the second contribution
\[ \lim_{\beta \to 0^+} E_0^{(2)} = - \lim_{\beta \to 0^+} \epsilon_{0,1}^2 \langle 0, 1 | \sigma \hat{\Omega} \sigma |0, 1 \rangle \]
\[ = - \lim_{\beta \to 0^+} \epsilon_{0,1}^2 \int_{-\infty}^{\infty} dx \int_{-b/2}^{b/2} dy \int_{-\infty}^{\infty} dx' \times \int_{-b/2}^{b/2} dy' \sigma(x, y) \sigma(x', y') \times G(x, x') \phi_0(x) \phi_0(x') \psi_1(y) \psi_1(y') \]
\[ = -\frac{\pi^4}{b^6} \int_{-\infty}^{\infty} dx \int_{-b/2}^{b/2} dy \; \sigma(x, y) \cos^2 \left( \frac{\pi y}{b} \right)^2. \] (28)
2.3 Third order

Using the expressions for $G$ and $F$ in Appendix we can obtain the explicit form of the third order correction
\[
\lim_{\beta \to 0^+} E_0^{(3)} = \frac{2\pi^6}{b^3} \left( \int_{-\infty}^{\infty} dx_1 \int_{-b/2}^{b/2} dy_1 \cos^2 \left( \frac{\pi y_1}{b} \right) \sigma(x_1) \right) \times \int_{-\infty}^{\infty} dx_2 \int_{-b/2}^{b/2} dy_2 \times \left[ \left| x_1 - x_2 \right| \sigma(x_1) \sigma(x_2) \right] G_2^{(0)}(x_1, y_1, x_2, y_2).
\]

Notice that $G_2^{(0)}(x_1, y_1, x_2, y_2)$ involves transversal modes and it correlates the perturbations of the density in a region centered at the origin of size $dx \ll b$. This behavior is somehow complementary to that of the first term which is less sensitive to this region, due to the factor $\left| x_1 - x_2 \right|$ appearing in the integral.

After inspecting equation (29) we discover that, whenever the second order contribution vanishes, the third order contribution vanishes as well. To assess the presence of a bound state in this case, one should therefore calculate the further perturbative orders for the energy and check the sign of the first non-vanishing term.

3 Variational method

In this section we want to derive the second order correction obtained using perturbation theory, in a much simpler way, using the variational theorem. In this case we use the formulation of the problem corresponding to equation (1):
\[
-\nabla^2 \psi(x, y) = E \Sigma(x, y) \psi(x, y),
\]
where the solution obeys Dirichlet boundary conditions at the border
\[
\psi(x, \pm b/2) = 0,
\]
and decays at infinity
\[
\lim_{|x| \to \infty} \psi(x, y) = 0.
\]

The variational theorem provides an upper bound for the lowest eigenvalue
\[
W = -\frac{\langle \phi | \nabla^2 | \phi \rangle}{\langle \phi | \Sigma | \phi \rangle} \geq E_0.
\]

We calculate $W$ using the trial function
\[
\varphi = \sqrt{a e^{-\alpha|x|} \frac{\sqrt{\pi}}{b} \sin \left( \frac{n \pi |y + b/2|}{b} \right)},
\]
where $a$ is a variational parameter. Working in the limit of weak inhomogeneities, $\Sigma(x, y) = 1 + \sigma(x, y)$, with $\sigma(x, y) \ll 1$, one obtains the approximate value
\[
a \approx \frac{\pi^2}{b^3} \left( \int_{-\infty}^{\infty} \int_{-b/2}^{b/2} \sigma(x, y) \cos \left( \frac{\pi y}{b} \right)^2 dy dx \right),
\]
and the approximate energy
\[
W \approx \frac{\pi^2}{b^3} - \frac{\pi^4}{b^5} \left( \int_{-\infty}^{\infty} \int_{-b/2}^{b/2} \sigma(x, y) \left( \cos \left( \frac{\pi y}{b} \right)^2 dy dx \right)^2,
\]
which coincides with the second order result obtained in the previous section.

Notice that a bound state is present only if $a > 0$, implying the condition
\[
\int_{-\infty}^{\infty} \int_{-b/2}^{b/2} \sigma(x, y) \cos \left( \frac{\pi y}{b} \right)^2 dy dx > 0.
\]

4 A solvable example

Consider an infinite heterogeneous waveguide of width $b$, parallel to the $x$ axis, and obeying Dirichlet boundary conditions on $x = \pm b/2$. Let the density be
\[
\Sigma(x, y) = \begin{cases} 1 + \sigma, & |x| < \delta/2, \\ 1, & |x| \geq \delta/2. \end{cases}
\]

The Helmholtz equation in this case is
\[
-\nabla^2 \psi(x, y) = E \psi(x, y)
\]
for $|x| > \delta/2$, and
\[
-\nabla^2 \psi(x, y) = E(1 + \sigma) \psi(x, y)
\]
for $|x| < \delta/2$. We look for a localized solution
\[
\psi(x, y) = \sqrt{\frac{2}{b}} \sin \left( \frac{\pi n_y (b/4 + y)}{b} \right)
\]
and impose the continuity of the solution and of its derivative at $x = \pm \delta/2$:
\[
a_1 = a_2 = a_3 = a_4 \cos \left( \frac{dp_2}{2} \right) e^{\pm dp_2 \tan \left( \frac{dp_2}{2} \right)},
\]
where
\[
p_1 = p_2 \tan \left( \frac{dp_2}{2} \right).
\]
Matching the solutions at the boundaries between the regions one obtains

\[ \frac{\pi^2}{b^2} - p_2^2 \tan^2 \left( \frac{dp_2}{2} \right) = \frac{\pi^2 + p_2^2}{1 + \sigma}, \] (44)

which provides a transcendental equation for \( p_2 \).

We find

\[ p_2 = \sum_{n=0}^{\infty} c_n \sigma^n. \] (45)

We find

\[ p_2^2 = \frac{\pi^2 \sigma}{b^2} - \frac{\pi^4 \delta^2 \sigma^2}{4b^4} + \frac{\pi^4 \delta^2 \sigma^3}{12b^6} (\pi^2 \delta^2 - 3b^2) + \sigma^4 \left( \frac{150 \pi^6 b^2 \delta^4 - 23 \pi^8 \delta^6}{720b^6} \right)
+ \frac{\pi^6 \delta^4 \sigma^5}{5040b^{10}} (630b^4 - 686 \pi^2 b^2 \delta^2 + 67 \pi^4 \delta^4) + \ldots \]

and

\[ p_1 = \frac{\pi^2 \delta \sigma}{b^2} - \frac{\pi^4 \delta^3 \sigma^2}{12b^4} + \frac{\sigma^4 (\pi^6 \delta^5 - 5 \pi^4 b^2 \delta^3)}{406b^6}
+ \frac{\sigma^4 (210 \pi^6 b^2 \delta^5 - 23 \pi^8 \delta^7)}{2520b^8}
+ \frac{\pi^6 \delta^5 \sigma^5}{18144b^{10}} (1134b^4 - 882 \pi^3 b^2 \delta^2 + 67 \pi^4 \delta^4) + \ldots \]

The eigenvalue is

\[ E = \frac{\pi^2}{b^2} - \frac{\pi^4 \delta^2 \sigma^2}{4b^4} + \frac{\pi^6 \delta^4 \sigma^3}{12b^6} + \frac{\sigma^4 (90 \pi^6 b^2 \delta^4 - 23 \pi^8 \delta^6)}{720b^8}
+ \frac{\pi^8 \delta^6 \sigma^5 (67 \pi^2 \delta^2 - 525b^2)}{5040b^{10}} + \ldots \] (46)

When we apply to this model the explicit formula obtained with perturbation theory (to second and third orders) or with the variational theorem (to second order), we reproduce the coefficients of the formula above to the corresponding orders.

5 Conclusions

We have derived the exact expressions for the energy of the fundamental mode of an infinite heterogeneous waveguide, in two or more dimensions, to third order in the small parameter controlling the heterogeneity. For the two-dimensional case our results also apply to an infinite, heterogeneous and locally deformed waveguide. Our results show that, when the second order perturbative term does not vanish, a bound state is always present when the heterogeneity corresponds to a small region of higher density; in the case in which the second order perturbative term vanishes, the third order correction vanishes as well and it is not possible to determine whether a bound state exists.

While the problem of the emergence of trapped modes in weakly deformed waveguides has been studied earlier by several authors, to the best of our knowledge this is the first calculation for the case of a weakly heterogeneous (and possibly also deformed) waveguide. Moreover, even the case of weakly deformed homogeneous waveguide, the formulas derived in this paper do not coincide with the formulas derived in earlier works, since they are expressed in terms of a different parameter of expansion (the density perturbation, in our case). Finally, another important aspect of our method is the fact that the same formula can be applied to different geometries, using the appropriate conformal map to reduce the deformed waveguide to a straight strip, whereas the approaches in the literature have been limited to specific classes of homogeneous geometries (for example, the formula derived by Bulla et al. is specific to asymmetric waveguides, but cannot be applied to a broken strip; our formula can deal with both).

We would like to stress that our method can only be applied to problems where the eigenvalues are analytical in the expansion parameter. For example, the original calculation of Gat and Rosenstein of the lowest eigenvalue of the Schrödinger operator \(-\frac{d^2}{dx^2} + V(x)\), with \(V(x)\) a finite potential well and \(\lambda \to 0\), could be possible because, in that case the eigenvalue is analytical in \(\lambda\); for the case of two dimensions, however Simon \[27\] has proved the non-analyticity of the lowest eigenvalue of \(-\Delta + \lambda V\), for \(\lambda \to 0\) and the method of Gat and Rosenstein cannot be applied. The case of infinite parallel plates in three dimensions, containing an heterogeneity at some internal region, is likely to display a non-analytical behavior and, in such case, could not be addressed with our method.

Appendix: Green’s function

We define the operator

\[ \hat{\cal O} \equiv \left[ \sum_{n=2}^{\infty} \frac{1}{\epsilon_{0,n} - \epsilon_{0,1}} |0, n \rangle \langle 0, n| + \sum_{n=1}^{\infty} \int_0^\infty \frac{dp}{2\pi} \frac{1}{\epsilon_{p,n} - \epsilon_{0,1}} |p, n \rangle \langle p, n| \right], \] (A.1)

which obeys the relation

\[ (\hat{\cal H}_0 - \epsilon_{0,1}) \hat{\cal O} = \left[ \sum_{n=2}^{\infty} |0, n \rangle \langle 0, n| + \sum_{n=1}^{\infty} \int_0^\infty \frac{dp}{2\pi} |p, n \rangle \langle p, n| \right] \]
\[ \equiv \hat{1} - |0, 1 \rangle \langle 0, 1|. \] (A.2)

Equivalently,

\[ G(x, x') \equiv \langle x| \hat{\cal O} |x' \rangle \] (A.3)
obey the equation
\[
(H_0 - \epsilon_0,1)G(x,x') = \langle x|1|x'\rangle - \langle x(0,1)|0,1|x'\rangle
= \delta(x-x') - \psi_{01}(x)|\psi_{01}(x'). \tag{A.4}
\]
Clearly
\[
\lim_{\beta \to 0^+} (H_0 - \epsilon_{0,1})G(x,x') = \delta(x-x'). \tag{A.5}
\]
Let us now work on the explicit expression of \(G(x,x')\):
\[
G(x,x') = \sum_{n=2}^{\infty} \phi_0(x)\phi_0(x')\psi_n(y)\psi_n(y')
+ \sum_{n=1}^{\infty} \int_0^\infty \frac{dp}{2\pi} \phi_0(x)\phi_p(x')\psi_n(y)\psi_n(y')
+ \sum_{n=2}^{\infty} \int_0^\infty \frac{dp}{2\pi} \phi_0(x)\phi_p(x')\psi_n(y)\psi_n(y')
+ \sum_{n=2}^{\infty} \int_0^\infty \frac{dp}{2\pi} \phi_0(x)\phi_p(x')\psi_n(y)\psi_n(y')
\equiv G_0(x,x') + G_1(x,x') + G_2(x,x'). \tag{A.6}
\]
We observe that \(\lim_{\beta \to 0^+} G_0(x,x') = \infty\), and that
\[
G_0(x,x') = \frac{1}{\beta} G^{(-1)}_0(x,x') + G^{(0)}_0(x,x') + \beta G^{(1)}_0(x,x')
+ \ldots
\tag{A.7}
\]
\[
G_1(x,x') = \beta G^{(1)}_1(x,x') + \ldots
\tag{A.8}
\]
\[
G_2(x,x') = G^{(0)}_2(x,x') + \beta G^{(1)}_2(x,x') + \ldots
\tag{A.9}
\]
The explicit expressions are
\[
G_0(x,x') = \cos\left(\frac{\pi y_1}{b}\right)\cos\left(\frac{\pi y_2}{b}\right)
\times \left[ \frac{1}{2b\beta} - \frac{|x_1| + 2|x_1 - x_2| + |x_2|}{2b} + O(\beta) \right],
\tag{A.10}
\]
\[
G_1(x,x') = \frac{b\beta}{4\pi^2} \left( \cos\left(\frac{\pi (y_1 - y_2)}{b}\right) + \cos\left(\frac{\pi (y_1 + y_2)}{b}\right) \right)
+ 2i \left( \log\left( -e^{-\frac{\pi (y_1 - y_2)}{b}} \right) \sin\left(\frac{\pi (y_1 - y_2)}{b}\right) \right)
+ \log\left( -e^{-\frac{\pi (y_1 + y_2)}{b}} \sin\left(\frac{\pi (y_1 + y_2)}{b}\right) \right)
+ O(\beta^2),
\tag{A.11}
\]
\[
G_2(x,x') = \sum_{n=2}^{\infty} \frac{e^{\pm \pi n x/\beta}}{\pi \sqrt{n^2 - 1}} \sin\left(\frac{\pi n (b + 2y_1)}{2b}\right)
\times \sin\left(\frac{\pi n (b + 2y_2)}{2b}\right) + O(\beta).
\tag{A.12}
\]
Similarly we define
\[
F(x,x') \equiv \langle x|\hat{A}|x'\rangle
= \sum_{n=2}^{\infty} \frac{\phi_0(x)\phi_0(x')\psi_n(y)\psi_n(y')}{(\epsilon_0,1 - \epsilon_{n,0})^2}
+ \sum_{n=1}^{\infty} \int_0^\infty \frac{dp}{2\pi} \phi_0(x)\phi_p(x')\psi_n(y)\psi_n(y')
+ \sum_{n=2}^{\infty} \int_0^\infty \frac{dp}{2\pi} \phi_0(x)\phi_p(x')\psi_n(y)\psi_n(y')
+ \sum_{n=2}^{\infty} \int_0^\infty \frac{dp}{2\pi} \phi_0(x)\phi_p(x')\psi_n(y)\psi_n(y')
\equiv F_0(x,x') + F_1(x,x') + F_2(x,x'). \tag{A.13}
\]
For our present purposes it is sufficient to calculate \(F_0\):
\[
F_0(x,x') = \cos\left(\frac{\pi y_1}{b}\right)\cos\left(\frac{\pi y_2}{b}\right)
\left( \frac{1}{8\beta^3} - \frac{|x_1| + |x_2|}{8\beta^2} \right)
+ \frac{4|x_1| |x_2| + 16x_1x_2 - 6 \left( x_1^2 + x_2^2 \right)}{32b^3} + O(\beta^0),
\tag{A.14}
\]
We find it convenient to report some identities which are useful in the calculation of the third (and higher) orders,
\[
(H_0 - E_0^{(0)}) |0,1\rangle = 0,
\tag{A.15}
\]
\[
(H_0 - E_0^{(0)}) = \hat{\Omega} \left( H_0 - E_0^{(0)} \right) = \sum_{n=2}^{\infty} |0, n\rangle \langle 0, n| + \sum_{n=1}^{\infty} \int_0^\infty \frac{dp}{2\pi} |p, n\rangle \langle p, n| \equiv \hat{P},
\tag{A.16}
\]
where \(\hat{P}\) is a projection operator \(\hat{P}^2 = \hat{P}\) that can be used to express the completeness of the basis in the form
\[
\sum_{n=2}^{\infty} |0, 1\rangle \langle 0, 1| + \hat{P} = \hat{1}. \tag{A.17}
\]
In terms of this operator we also have
\[
\sigma \hat{P} \sigma = \sigma^2 - \sigma |0, 1\rangle \langle 0, 1|, \sigma\hat{P}\left( H_0 - E_0^{(0)} \right) = \sigma \left( H_0 - E_0^{(0)} \right).
\tag{A.18}
\]
Finally
\[
\left( H_0 - E_0^{(0)} \right) \hat{A} = \hat{\Omega}. \tag{A.20}
\]
