Dinuclear manganese alkoxide complexes as catalysts for C–N bond cleavage of simple tertiary N,N-dialkylamides to give esters
Dinuclear manganese alkoxide complexes as catalysts for C–N bond cleavage of simple tertiary N,N-dialkylamides to give esters†

Haruki Nagae, Takahiro Hirai, Daiki Kato, Shusei Soma, Shin-ya Akebi and Kazushi Mashima

Amide bonds are stable due to the resonance between the nitrogen lone pair and the carbonyl moiety, and therefore the chemical transformation of amides, especially tertiary amides, involving C–N bond fission is considered one of the most difficult organic reactions, unavoidably requiring harsh reaction conditions and strong acids or bases. We report the catalytic C–N bond cleavage of simple tertiary N,N-dialkylamides to give corresponding esters using a catalyst system (2 mol% based on Mn atoms) of a tetranuclear manganese alkoxide, [Mn(acac)(OEt)(EtOH)]4 (1c), combined with four equivalents of 4,7-bis(dimethylamino)-1,10-phenanthroline (L1: Me2N-Phen). Regarding the reaction mechanism, we isolated a dinuclear manganese complex, [Mn(acac)(OEt)(Phen)]2 (6c), which was revealed as the catalytically active species for the esterification of tertiary amides.

Introduction

Amides are ubiquitous and abundant in a huge number of natural and synthetic organic compounds, such as proteins, poly(amides), and pharmaceuticals, due to the extraordinarily stable nature of the amide bond. The stability of the amide bond is attributed to the resonance between the nitrogen lone pair and the carbonyl moiety, and many researchers have attempted to diminish the resonance structure of the C–N bond by introducing the coordination of transition metals to the nitrogen atom, as exemplified by the complexation of N,N-(2-pyridyl)methylamides with Cu(a) sources,5,6 and constructing a twisted structure around the nitrogen atom,7 whose amide bonds were readily cleaved under mild conditions. Nonetheless, cleavage of the amide bond requires harsh reaction conditions such as using stoichiometric amounts of strong acids or bases at a high temperature. TiCl4- and FeCl3-catalyzed alcoholysis of inactivated primary amides was independently reported by Fisher et al. and Sun et al. but more than one equivalent of aqueous HCl was necessary.8 Shimizu et al. reported catalytic esterification of primary amides without using any additives by utilizing CeO2 as a heterogeneous catalyst under a high reaction temperature.9 Thus, catalytic transformation of amides to the corresponding esters or acids in an atom- and step-economical manner is in high demand. Recently, we reported a catalytic C–N bond cleavage of primary and secondary amides using a catalyst mixture of Sc[OTf]3 and boronic esters,10 and Atkinson et al. also reported Sc[OTf]3-catalyzed esterification of secondary amides.11 In addition, catalytic esterification of 8-aminooquinoline amides was achieved with Ni(tmdh)2 (TMHD = 2,2,6,6-tetramethyl-3,3-heptanediolate) in methanol.12

In contrast, the catalytic transformation of tertiary amides remains a challenging task, and only a few catalyst systems developed to date are able to break the stable C–N bond of tertiary amides. Recently, Garg and Houk reported that nickel(0) complexes served as catalysts to activate the C–N bond of tertiary amides bearing functional groups such as Ph or Boc via oxidative addition as a key step to afford the corresponding esters [Fig. 1A],13-15 and Danoun and Gosmini reported that low-valent cobalt species supported by 2,2′-bipyridine using metallic manganese as a reductant catalytically activated the C–N bond of activated amides bearing a Boc group to give the corresponding esters [Fig. 1B],16 though the oxidative addition of the C–N bond of activated amides bearing functional groups such as Ph, Boc, and Ts on the nitrogen atom into low-valent transition metals was reported to be involved in several catalytic reactions.17,19-20

On the other hand, we reported a catalytic C–N bond cleavage of N-alkyl-N-β-hydroxyethylamides via N,0-acyl rearrangement by manganese complexes supported by an N,N′,N′′,N′′-bidentate ligand21 and zinc complexes [Fig. 1C],22 though these catalysts required substrates with functional groups, such as a β-hydroxyethyl group on the nitrogen atom. Very recently, Shimizu and Siddiki reported the first example of the esterification of N,N-dialkylamides using CeO2 as a reusable heterogeneous catalyst, though the catalyst system requires a high reaction temperature and large amount of catalyst. In this
reaction, Lewis acid and base sites of the CeO₂ surface cooperatively activate the carbonyl moiety and alcohol (Fig. 1D). To achieve the esterification of simple N,N-dialkyl tertiary amides under milder reaction conditions, we focused our attention on cooperative activation of multinuclear complexes whose multi-metallic structure is often found in metalloenzymes. Herein, we report a new and efficient catalyst system of [Mn(acac)(OEt)(EtOH)]₄ (1c), as Mn(u) precursors to evaluate the general tendency that metal-alkoxide species accelerate the nucleophilic attack of the alkoxide group on the carbonyl group (2 mol% based on Mn atom), and 4,7-bis(dimethylamino)-1,10-phenanthroline (L₁: Mn₂N-Phen) (2 mol%) for the esterification of simple tertiary N,N-dialkylamides to give the corresponding esters with broad substrate scopes including halogenated amides (Fig. 1E). Furthermore, we determined a reaction mechanism by isolating an alkoxide-bridged manganese dinuclear complex [Mn(acac)(OEt)(Phen)]₂ (6e) as the key catalyst, and measuring kinetic studies in n-butanol which showed first-order rate dependence on the concentrations of N,N-dimethyl-2-naphthamide (2a) and 6e, indicating that the dinuclear alkoxide complex acted as a catalytically active species.

**Results and discussion**

We began by searching for the suitable catalyst among the reported alkoxy-bridged tetranuclear complexes, [M(tmhd)(OMe)(MeOH)]₄ (1a; M = Mn,30 Fe,31 Co,31 and Cu;32 1.0 mol%; x = 1 or 0; TMHD = 2,2,6,6-tetramethyl-3,5-

heptanedionate), as catalyst precursors with 4,7-bis(dimethylamino)-1,10-phenanthroline (L₁: Mn₂N-Phen, 1 mol%) for the catalytic esterification of N,N-dimethyl-2-naphthamide (2a) under the conditions of using n-butanol (0.25 mL) at reflux temperature for 18 h, and the results are shown in Table 1. The use of the manganese tetranuclear complex, [Mn(tmhd)(OMe)(MeOH)]₄ (1a), afforded 3a in 80% yield (entry 1). Iron and cobalt tetranuclear complexes exhibited lower catalytic activities (16% and 42% yields, respectively, entries 2 and 3) than the manganese complex. The copper tetranuclear complex, [Cu(tmhd)(OMe)]₄, which does not have methanol as a ligand, also showed low catalytic activity (49% yield, entry 4). Accordingly, we selected the manganese complex as the best catalyst precursor among the tetranuclear complexes, [M(tmhd)(OMe)(MeOH)]₄, we tested.

Next, we searched for the best manganese precursor for the catalytic esterification of 2a with n-butanol under the conditions of Mn precursors (1 mol% based on Mn atoms) and L₁ (1 mol%) at reflux temperature for 18 h, and the results are shown in Table 2. The manganese tetranuclear alkoxide complex [Mn(dbm)(OMe)(MeOH)]₄ (1b; DBM = dibenzoylmethanate) exhibited almost the same catalytic activity as 1a to give the corresponding ester 3a in 79% yield (entry 1), and a newly synthesized manganese complex, [Mn(acac)(OEt)(EtOH)]₄ (1c), showed the highest catalytic activity among the alkoy-bridged tetranuclear complexes to yield 3a in 90% yield (entry 2). We also surveyed other simple Mn precursors such as Mn(acac)₃, Mn(tmhd), Mn(hfac)₃ (HfAC = hexafluoroacetylacetone), and Mn(OAc)₂, but these catalyst precursors showed moderate activity to afford 3a in 85%, 57%, 52%, and 57% yields, respectively (entries 3–6). In the absence of the L₁ ligand, 1c

![Fig. 1 Catalytic esterification via the C–N bond cleavage of tertiary amides.](Image 14x290 to 26x354)

![Table 1 Screening of alkxy-bridged tetranuclear complexes](Image 49x439 to 286x729)

| Entry | cat. | Yield [%]³ |
|-------|------|------------|
| 1     | [Mn(tmhd)(OMe)(MeOH)]₄ (1a) | 80         |
| 2     | [Fe(tmhd)(OMe)(MeOH)]₄      | 16         |
| 3     | [Co(tmhd)(OMe)(MeOH)]₄      | 42         |
| 4     | [Cu(tmhd)(OMe)]₄            | 49         |

³ Determined by GC analysis with dodecane as an internal standard.
exhibited low catalytic activity (entry 7, 22% yield). The yield of 3a was increased to >99% when increasing the catalyst loading of 1c to 2 mol% (entry 8). The use of 1 mol% of strong bases, such as KOMe and NaOMe, did not result in catalytic activity (entries 9 and 10). Thus, we selected catalyst 1c as the best precursor, and optimized the conditions using 2 mol% of 1c and L1 in n-butanol at reflux temperature for 18 h. Under the optimized reaction conditions, we detected signals of cationic manganese dinuclear complexes, [Mn(acac)(O\textsubscript{n}Bu)(Me\textsubscript{2}N-Phen)]\textsuperscript{2+} (m/z = 986.4) and [Mn(acac)(O\textsubscript{n}Bu)(Me\textsubscript{2}N-Phen)]\textsuperscript{2+} + H\textsuperscript{+} (m/z = 987.4), by ESI-MS spectroscopy. In addition, we isolated a dinuclear complex, [Mn(acac)(OEt)(Phen)]\textsuperscript{2}, and characterized it by single crystal X-ray analysis (vide infra).

We then searched for a suitable chelating nitrogen ligand for the catalytic esterification of \textsubscript{N,N}-dimethyl-2-naphthamide (2a) under the conditions of using [Mn(acac)(OEt)(EtOH)]\textsubscript{4}, \textsuperscript{1c} (1 mol% on Mn) and a nitrogen ligand (1.0 mol%) in refluxing n-butanol (5.5 equiv.) for 18 h, and the results are shown in Table 3. We first used 1,10-phenanthroline derivatives L2–L7. Electron-donating groups at 4,7-positions on 1,10-phenanthroline exhibited remarkable substituent effects for increasing catalytic activities: L2 with methoxy groups, L3 with methyl groups, and L5 with phenyl groups produced 3a in moderate yields (67%, 54%, and 68%, respectively; entries 1, 2, and 4). In contrast, 1,10-phenanthroline (L4) and L6 with electron-withdrawing chloro groups exhibited decreased catalytic activity, affording 36% and 27% yields of 3a, respectively (entries 3 and 5). The sterically congested chelating nitrogen ligand 2,9-dimethyl-1,10-phenanthroline (L7) gave 3a in 49% yield (entry 6). 4,4'-Substituted 2,2'-bipyridine derivatives, such as L8 with methoxy groups, L9 with tert-butyl groups, L10 with methyl groups, 2,2'-bipyridine (L11), and L12 with methyl ester groups, exhibited low catalytic activities (entries 7–11). In addition, 5,5'-dimethyl-2,2'-bipyridine (L13), 5,5'-bis(trifluoromethyl)-2,2'-bipyridine (L14), and 6,6'-dimethyl-2,2'-bipyridine (L15) produced 3a in low yields (28%, 19%, and 14%, respectively, entries 12–14). Monodentate pyridine derivatives L16–L20 afforded 3a in 16%, 18%, 19%, 29%, and 20% yields, respectively (entries 15–19), which was almost the same as the catalytic activity of 1c without any ligand (Table 2, entry 7).

### Table 2 Screening of manganese precursors

| Entry | [Mn] (X mol% on Mn) | 3a: Yield [%] |
|-------|---------------------|---------------|
| 1     | 1b                  | 79            |
| 2     | 1c                  | 90            |

\textsuperscript{a} Determined by GC analysis with dodecane as an internal standard.  
\textsuperscript{b} Without L1.  
\textsuperscript{c} 1 mol% of KOMe was used as the catalyst instead of 1c.  
\textsuperscript{d} 1 mol% of NaOMe was used as the catalyst instead of 1c.  
\textsuperscript{e} n.r. = No reaction.

### Table 3 Screening of ligands

| Entry | Ligand | Y Yield [%]\textsuperscript{a} |
|-------|--------|-------------------------------|
| 1     | L2     | 67                            |
| 2     | L3     | 54                            |
| 3     | L4     | 36                            |
| 4     | L5     | 68                            |
| 5     | L6     | 27                            |
| 6     | L7     | 49                            |
| 7     | L8     | 23                            |
| 8     | L9     | 20                            |
| 9     | L10    | 31                            |
| 10    | L11    | 33                            |

\textsuperscript{a} Determined by GC analysis with dodecane as an internal standard.
Consequently, we selected L1 as the best ligand for [Mn(acac)(OEt)(EtOH)], (1e) with 2 mol% catalyst loading.

We next evaluated the substrate scope for the esterification of N,N-dimethylamides (Table 4). N,N-dimethylbenzamide (2b) afforded n-butyl benzoate (3b) in a good yield (78%, entry 1). The electronic effects of the para-position on N,N-dimethylbenzamide were examined: 2e having a methoxy group slightly decreased the yield to 65% (entry 2), while substrates 2d and 2e with a trifluoromethyl group at the para- and meta-positions afforded 3d and 3e in the same high yield as 3b (3d: 84%, 3e: 77% yields, entries 3 and 4). Benzamides 2f-h having chloro, bromo, and iodo atoms at the para-position gave the corresponding products 3f-h in high yield without any loss of the C-X bond (entries 5-7). Notably, in the case of methyl substituted compounds, the steric congestion around the carbonyl moiety of the amides was crucial: 4-methyl- and 3-methyl derivatives 2i and 2j produced 3i in 77% yield and 3j in 27% yield, while N,N-dimethyl-2-methylbenzamide (2k) led to a trace amount of 3k (entries 8-10). 4-Cyano-N,N-dimethylbenzamide (2l) gave 3l in 86% yield (entry 11). On the other hand, the use of an aliphatic substituted amide, N,N-dimethyl-3-phenylpropanamide, afforded 12% of the corresponding ester 3m (entry 12). N,N-Dimethylisonicotinamide (2n) and N,N-dimethyl-2-furamide (2o) were converted to the corresponding esters 3n and 3o in 98% and 88% yields, respectively (entries 13 and 14).

We varied the alcohols used for the esterification of 2a (Table 5). We used alcohols with a low boiling point and sterically bulky secondary alcohols, and modified the reaction conditions by increasing the loading of 1e to 4 mol% based on Mn metal with L1 (4 mol%) and using a longer reaction time depending on the alcohols we assessed. The reaction with n-propanol at reflux temperature (120 °C) for 45 h gave n-propyl benzoate (4a) in 93% yield, although the reaction of n-propanol with 2 mol% of 1e and L1 for 45 h afforded 4a in lower yields (78%) (entries 1 and 2). Secondary alcohols such as 2-pentanol and 3-pentanol, respectively, afforded 4b and 4c in 69% and 43% yields at reflux temperature (140 °C and 135 °C, respectively) for 72 h (entries 3 and 4), while 4-heptanol produced the corresponding ester 4d in 78% yield at reflux temperature (170 °C) for 72 h (entry 5). Solid alcohols such as 2,2-dimethylpropanol, (4-methylphenyl)methanol, and piperonyl alcohol could be used for the esterification of 2a in toluene at 135 °C, giving the corresponding esters 4e (51% yield for 18 h reaction time), 4f (92% yield), and 4g (61% yield) (entries 6-8). When 3-methyl-1,3-butanediol was used for the esterification, 3-hydroxy-3-methylbutyl-2-naphthoate (4h) was selectively obtained in a moderate yield (53% yield, entry 8).

In contrast to the catalytic esterification of N,N-dimethylamides, in which volatile dimethylamine was readily removed, the addition of 1 equiv. of diethyl carbonate was required to trap liberated amines to accomplish smooth esterification of various substituents on the nitrogen atom of benzamide under conditions of using 1e (5 mol% based on Mn atom) with L1

### Table 4: Scope and limitation of amides 2

| Entry | R1 | 3: Yield% | Entry | R1 | 3: Yield% |
|-------|----|----------|-------|----|----------|

| 8d    |   | 135        | 4g: 61    |
| 9d,e  |   | 135        | 4h: 53    |

*a Isolated yield. b 2 mol% of 1e (based on Mn) and L1 were used. c Reaction time was 72 h. d 1.2 equiv. of alcohol was used in toluene solution. e Reaction time was 18 h.
Cyclic derivatives of benzamide with piperidine 5a, morpholine 5b, and pyrrolidine 5c were converted into n-butyl benzoate 3b in 81%, 88%, and 76% yields, respectively (entries 1–3), though acyclic N,N-diethylbenzamide (5d) significantly decreased the yield of 3b, 25% (entry 4), probably due to the steric hindrance around the carbonyl group of 5d. Esterification of N-methyl-N-phenylbenzamide (5e) and 1-benzoyl pyrrole (5f) gave 3b in 93% and 92% yields, respectively (entries 5 and 6). Moreover, the manganese catalyst system effectively mediated the esterification of secondary and primary amides, such as N-methylbenzamide (5g: 60% yield), N-(quinolin-8-yl) benzamide (5h: 83% yield), and benzamide (5i: 82% yield) (entries 7–9).

When we conducted a large scale reaction by using 0.996 g of 2a under the conditions of using 1c (2.0 mol%) and L1 (2.0 mol%) in refluxing n-butanol (2.5 mL, 5.5 equiv.) for 72 h, we obtained 1.07 g of corresponding 3a in 94% yield (eqn (1)).

Regarding the reaction mechanism, we isolated an alkoxide-bridged Mn(II) dinuclear complex, [Mn(acac)(OEt)(Phen)]2 (6c: 47% yield), by treating complex 1c with 1,10-phenanthroline (L4) (eqn (3)), as the corresponding manganese complex containing Me2N-Phen (L1) provided no single crystals suitable for X-ray analysis. Complex 6c was characterized by elemental analysis and X-ray analysis due to its paramagnetic nature. In the solid state, complex 6c has a dimeric structure, in which two manganese centers are doubly bridged by two μ-ethoxy groups and each manganese atom adopts a distorted octahedral structure (Fig. 2).

We determined a power value on the concentration of substrate 2a using time normalization analysis.44 A mixture of 2a (0.600, 0.800, and 1.00 M) and [Mn(acac)(OEt)(Phen)]2 (6c, 60.7 mg, 80 μmol, 40 mM) in n-butanol (2.0 mL) with dodecane as an internal standard was refluxed at 145 °C and the time course of the yield of 3a was determined by GC analysis. As shown in Fig. 3, the concentration of 3a was plotted against a normalized time scale, \( \sum [2a]^a dt \), and we adjusted the power value, a, until all the corrected conversion curves overlay. As a result, we determined that the value of a was 1 (Fig. 3c). We
also determined a power value on the concentration of the catalyst \([\text{Mn(acac)(OEt)(Phen)}]_2\) (6c) by using a normalized time scale analysis.34 A mixture of 2a (398.5 mg, 2.00 mmol, 2.00 M) and 6c (30 mM, 50 mM, and 70 mM) in n-butanol (1.00 mL) with dodecane as an internal standard was refluxed at 145°C. As shown in Fig. 4, the concentration of 3a was plotted against a normalized time scale, \(t[6c]\), and we determined that the value of \(n\) was 1 (Fig. 4c). The first-order rate dependency of 6c suggested that the dinuclear manganese complex 6c acted as a catalytically active species, whose dinuclear function was comparable to that found for an alkoxide-bridged cobalt dinuclear complex active for catalytic transesterification.35

On the basis of these results, we propose a reaction mechanism of the catalytic esterification of simple tertiary \(N,N\)-dialkylamides described in Scheme 1. The first step is the coordination of amide 2 onto a manganese atom of complex 6c, affording dinuclear complex A. The alkoxo group bound to the manganese center in A attacks the carbonyl group of the amide moiety to cleave a C–N bond via intermediate B, in which an \(N^\#N\)-bidentate ligand with electron-donating groups at the para-positions accelerated the nucleophilic attack. According to the kinetics, the nucleophilic attack of the alkoxide on the carbonyl group is the rate-determining step. The intermediate B is transformed to C, forming a manganese complex D, where the resulting ester coordinates to the manganese atom bearing a dimethylamido moiety. Finally, protonolysis of the manganese-amido moiety using alcohol produces dimethylamine and the dinuclear Mn(II)-alkoxide complex together with the release of ester 3.

**Conclusions**

In summary, we provide the first example of catalytic esterification of simple tertiary \(N,N\)-dialkylamides under neutral conditions using the catalyst system \([\text{Mn(acac)(OEt)(EtOH)}]\)_2 (1c, 2 mol% based on Mn metal) and 4,7-bis(dimethylamino)-1,10-phenanthroline (L1: Me₂N-Phen, 2 mol%). Regarding the reaction mechanism, we isolated the alkoxide-bridged manganese dinuclear complex \([\text{Mn(acac)(OEt)(Phen)}]_2\) (6c) as the key catalyst, and conducted kinetic studies in which the velocity obeys \(k_{\text{obs}}[2a][6c]\). It is notable that such a catalytic performance of the dinuclear manganese complex 6c is related to the mechanism of metalloenzymes that regulate the transformation of carboxylic derivatives. Further mechanistic studies and catalytic application of a Mn-based catalyst system are ongoing in our laboratory.

**Experimental section**

All manipulations involving air- and moisture-sensitive organometallic compounds were carried out under argon using the
standard Schlenk technique or an argon-filled glovebox. n-Propanol, 2-propanol, n-butanol, 2-pentanol, 3-pentanol, 4-heptanol, and diethyl carbonate were distilled under an argon atmosphere from CaH₂. 3-Methyl-1,3-butadiene was distilled under an argon atmosphere by using Kugelrohr. 2,4-Pentadiene was distilled under an argon atmosphere from P₂O₅. THF, diethyl ether, hexane, and toluene were dried and deoxygenated using a Grubbs column (Glass Contour Solvent Dispensing System, Nikko Hansen & Co., Ltd.). Ethanol and methanol were distilled under an argon atmosphere from the corresponding magnesium alkoxide. DMSO-d₆ was dried over MS₄A in a J-Young Schlenk under an argon atmosphere. Wako super dehydrated DMF was degassed and kept in a J-Young Schlenk under an argon atmosphere. Lithium ethoxide was prepared by treating metal lithium with ethanol in hexane suspension. All other reagents were purchased from commercial resources and used without further purification. NMR spectra were recorded on a Bruker AV 400M spectrometer operating at 400 MHz (¹H NMR), at 100 MHz (¹³C{¹H} NMR) and at 376 MHz (¹⁹F{¹H} NMR) in 5 mm NMR tubes. All ¹H NMR chemical shifts were reported in ppm relative to the TMS at 0.00 ppm or residual solvent protons in DMSO-d₆ using a Grubbs column (Glass Contour Solvent Dispensing System, Nikko Hansen & Co., Ltd.). ¹³C{¹H} NMR chemical shifts were reported in ppm relative to carbon resonance in chloroform-d₆ at δ 77.16 and DMSO-d₆ at δ 39.52. All ¹⁹F{¹H} NMR chemical shifts were reported in ppm relative to the external reference a,a,a-trifluorotoluene at δ ~63.9. Melting points were recorded using a BUCHI Melting Point M-565 and YANACO MP-J3. IR spectra were recorded on a JASCO FT/IR 4000 spectrometer. Mass spectra (MS) and high resolution mass spectra (HRMS) were recorded using a JEOL JMS-700. ESI-mass spectrometric data were obtained using a BRUKER microTOF-II spectrometer. GC analyses were recorded on a Shimadzu GC-2014 gas chromatograph with J&W Scientific DB-5 and Shimadzu SH-Rtx-50 columns. Flash column chromatography was performed using silica gel 60 (0.040–0.063 mm, 230–400 mesh ASTM).

General procedure for catalytic esterification of N,N-dimethyl-2-naphthaldehyde (1 mol%)

The mixture of catalyst precursor (5.0 μmol based on Mn atoms), ligand (5.0 μmol), and N,N-dimethyl-2-naphthaldehyde (99.6 mg, 5.0 × 10⁻² mol) in n-butanol (2.50 × 10⁻¹ mL) was refluxed at 135 °C for 18 hours under an argon atmosphere in a slin Schlenk (φ 10 mm). After cooling to room temperature, yields were determined using the following procedures.

1) GC yield: metal salts were removed by filtration through silica gel with ethyl acetate. The yield was determined by GC analysis with dodecane as an internal standard.

2) NMR yield: metal complexes were removed by filtration through silica gel with CDCl₃ twice. The yield was determined by ¹H NMR analysis with phenanthrene as an internal standard.

General procedure for preparation of amides

Amides were synthesized by standard condensation reaction using the corresponding acyl chlorides and amines. Products were purified by silica gel flash column chromatography or distillation under reduced pressure using Kugelrohr, and characterized by ¹H NMR and ¹³C{¹H} NMR spectroscopies.

Preparation of ligands, substrate amides, and manganese complexes

Synthesis of 1-benzoyl pyrrole (5f). Equivalents of substrates were modified from the literature. Sodium hydride (60% oil dispersion, 599.8 mg, 15.0 mmol) was washed with 2 mL of dried and deoxygenated hexane three times under an argon atmosphere, and dried in vacuo. After refilling argon, dried and deoxygenated THF (20 mL) was added, and the suspension was cooled to 0 °C in an ice bath. Pyrrole (0.690 mL, 10.0 mmol) was slowly added to the reaction mixture and the mixture was stirred at 0 °C for 90 minutes. Then benzoyl chloride (1.70 mL, 15.0 mmol) was slowly added to the mixture at 0 °C. After warming to room temperature, the reaction mixture was stirred overnight. Then, the reaction mixture was quenched by water, and the water layer was extracted with 20 mL of EtOAc three times. The combined organic layer was washed with 1 M HCl aq. twice, sat. NaHCO₃ aq., and brine, and dried over Na₂SO₄. The crude products were obtained by removal of solvent in vacuo, and purified by flash column chromatography (silica gel, hexane : EtOAc = 20 : 1), and distillation using Kugelrohr (>0.05 mmHg, 125–135 °C) to give a colorless liquid (1.23 g, 7.18 mmol, 72% yield).

Synthesis of 4,7-bisdimethylamino-1,10-phenanthroline (Me₂N-Phen). A suspension of 4,7-dichloro-1,10-phenanthroline (1.48 g, 5.94 mmol) in DMF (50 mL) was refluxed for 30 h under an argon atmosphere. After cooling to room temperature, all volatiles were removed in vacuo. Then the residue was dissolved in 1 M NaOH aq. (50 mL) and THF (70 mL), and the solution was extracted with DCM (50 mL × 3). The combined organic layer was washed with 1 M NaOH aq. twice and brine, and dried over Na₂SO₄. Removal of volatiles in vacuo gave the crude product as a brown solid, and the product was purified by washing with EtOAc (3 mL × 3) to give a purple solid (741.1 mg, 2.78 mmol, 47% yield). ¹H NMR (400 MHz, DMSO-d₆, 30 °C) δ 8.74 (d, J = 5.0 Hz, 2H), 7.96 (s, 2H), 7.11 (d, J = 5.0 Hz, 2H), 3.01 (s, 12H); ¹³C{¹H} NMR (100 MHz, DMSO-d₆, 30 °C) δ 157.0, 149.4, 147.6, 121.4, 120.6, 109.6, 43.7.

Synthesis of [Mn(tmhd)(OMe)(MeOH)]₄ (1a). [Mn(tmhd)₄(O-Me)(MeOH)]₄ was prepared according to the literature. Mcl₂ (629 mg, 5.00 mmol) and 2,2,6,6-tetramethylheptane-dione (1.00 mL, 5.00 mmol, 1.0 equiv.) were dissolved in 10 mL of methanol. In another flask, KOH (701 mg, 10 mmol, 2.0 equiv.) was dissolved in methanol. The two solutions were slowly mixed to form a yellow precipitate. The supernatant was removed by using a cannula, and the residues were extracted with toluene, and layered with methanol to induce recrystallization to give 1a as a yellow solid in 82% yield (1.23 g, 1.02 mmol).

Synthesis of [M(n)(tmhd)(OMe)(MeOH)]₄ (M = Fe, Co, Cu³⁺). [M(n)(tmhd)(OMe)(MeOH)]₄ was prepared according to the literature. Mcl₂ and 2,2,6,6-tetramethylheptane-dione (1.0 equiv.) were dissolved in methanol. In another flask, KOH (2.0 equiv.) was dissolved in methanol. The two solutions were
slowly mixed to form a precipitate, immediately. The supernatant was removed by using a cannula, and the residues were extracted with toluene, and layered with methanol to induce recrystallization. M = Fe: deep red solid, 1.09 g, 0.900 mmol, 80% yield, M = Co: burgundy solid, 152 mg, 0.124 mmol, 64% yield, M = Cu: deep blue solid, 22.2 mg, 20.0 μmol, 11% yield.

**Synthesis of [Mn(dbm)(OMe)(MeOH)]₄ (1b).** MnCl₂ (629 mg, 5.00 mmol) and dibenzoylmethane (1.12 g, 5.00 mmol, 1.0 equiv.) were dissolved in 10 mL of methanol. In another flask, KOMe (10 mmol, 2.0 equiv.) was dissolved in methanol. The two solutions were slowly mixed, and yellow powder was immediately precipitated. The supernatant was removed by using a cannula, and the residues were extracted with toluene, and layered with methanol to induce recrystallization to give 1b as an orange solid (258 mg, 0189 mmol, 15% yield).

**Synthesis of [Mn(acac)(OEt)(EOH)]₄ (1c).** MnCl₂ (629 mg, 5.00 mmol) and acetylacetone (0.530 mL, 5.00 mmol, 1.0 equiv.) were dissolved in 10 mL of ethanol. In another flask, LiOEt (10 mmol, 2.0 equiv.) was dissolved in ethanol. The two solutions were slowly mixed, and yellow powder was immediately precipitated. The supernatant was removed by using a cannula, and the residues were extracted with toluene, and layered with ethanol to induce recrystallization to give 1c as a pale yellow solid (1.00 g, 1.02 mmol, 82% yield). m.p. 282–290 °C (dec.), anal. calcd for C₃₈H₄₀N₄O₆Mn₂: C, 60.16; H, 5.31; N, 7.39; found: C, 60.10; H, 0.0940 mmol, 47% yield). m.p. 230–234 °C (dec.), anal. calcd for C₃₆H₇₂O₁₆Mn₄: C, 44.09; H, 7.40; found: C, 43.96; H, 7.69.

**Synthesis of Mn(u) alkoxide-bridged binuclear complex 6c.** A solution of 1c (99.6 mg, 0.101 mmol) and 1,10-phenanthroline (73.2 mg, 0.406 mmol, 4.00 equiv.) in toluene (10 mL) was heated at 100 °C for 18 hours under an argon atmosphere. Then, the residues were extracted with toluene (20 mL) at 100 °C, and the solution was slowly cooled to −20 °C. The supernatant was removed by using a cannula, and the resulting solid was dried under reduced pressure to give a deep red solid (71.3 mg, 0.406 mmol, 4.00 equiv.).

**X-ray crystallographic analyses.** Crystals of 1c and 6c were handled similarly. The crystal was mounted on a CryoLoop (Hampton Research Corp.) with a layer of light mineral oil and placed in a nitrogen stream at 113(1) K. Measurements were made on a Rigaku XtaLAB P200 system with graphite-monochromated Mo-Kα (0.71075 Å) radiation. The structures of complexes 1c and 6c were solved using direct methods (SIR2025) in the CrystalClear program. The structures were refined on F² using the full-matrix least-squares method, using SHELXL-2013. H-atoms were included in the refinement on calculated positions riding on their carrier atoms. The function minimized was \( \sum[w(Fo^2 - Fc^2)^2] \) with \( P = (max(Fo^2) + 2Fo^2)/3 \) and \( \sigma^2(Fo^2) \) from counting statistics. The functions R1 and wR2 were \( \sum(|Fo| - |Fc|)/|Fo| \) and \( \sum(wFo^2 - Fc^2)^2/\sum(wFo^2) \), respectively. Crystal data and structure refinement parameters are listed in Table S1.† The ORTEP-3 program was used to draw the molecules.

33 N,N-Dimethylamide could not be used as a substrate in Ni(0) catalysed esterification (see ref. 15). In addition, the esterification of 2a by the catalyst system Mn(acac)₂ (10 mol%) with 2,2’-bipyridine (10 mol%), which is the same as our previous catalyst system (see ref. 27), in nBuOH at reflux temperature for 18 h afforded the corresponding ester 3a in 68% yield.
