ROOT SYSTEMS IN NUMBER FIELDS

VLADIMIR L. POPOV\textsuperscript{1,2} AND YURI G. ZARHIN\textsuperscript{3}

Abstract. We classify the types of root systems $R$ in the rings of integers of number fields $K$ such that the Weyl group $W(R)$ lies in the group $\mathcal{L}(K)$ generated by $\text{Aut}(K)$ and multiplications by the elements of $K^\times$. We also classify the Weyl groups of root systems of rank $n$ which are isomorphic to a subgroup of $\mathcal{L}(K)$ for a number field $K$ of degree $n$ over $\mathbb{Q}$.

1. Introduction

In what follows, we call the type of a (not necessarily reduced) root system the type of its Dynkin diagram.

Let $L$ be a free Abelian group of a finite rank $n > 0$. We shall consider it as a lattice of full rank in the $n$-dimensional linear space $V := L \otimes \mathbb{Q}$ over $\mathbb{Q}$. Since every root is a integer linear combination of simple roots, for every type $R$ of the root systems of rank $n$, there is a subset $R$ in $L$ of rank $n$, which is a root system of type $R$. However, if the pair $(V, L)$ is endowed with an additional structure, then the Weyl group $W(R)$ of such a realization may be inconsistent with this structure. Say, if the space $V$ is endowed with a scalar product, then it may happen that the group $W(R)$ does not preserve it (for instance, if $n = 2$ and $e_1, e_2$ is an orthonormal basis in $L$, then $\{ \pm e_1, \pm e_2, \pm (e_1 + e_2) \}$ is the root system of type $A_2$ in $V$, whose Weyl group does not consist of orthogonal transformations). Therefore, it is of interest only finding such realizations, the Weyl group of which is consistent with some additional structures on the pair $(V, L)$.

A natural source of pairs $(V, L)$ is algebraic number theory, in which they arise in the form $(K, \mathcal{O}_K)$, where $K$ is a number field, and $\mathcal{O}_K$ is its

ring of integers. In this case, three subgroups are naturally distinguished in the group $GL_Q(K)$ of nondegenerate linear transformations of the linear space $K$ over $\mathbb{Q}$. The first one is the automorphism group $\text{Aut}(K)$ of the field $K$. The second is the image of the group monomorphism

$$\text{mult}: K^* \hookrightarrow GL_Q(K),$$

where $\text{mult}(a)$ is the operator of multiplication by $a \in K^*$:

$$\text{mult}(a): K \to K, \ x \mapsto ax.$$  \hspace{1cm} (2)

The third one is the subgroup $\mathcal{L}(K)$ in $GL_Q(K)$ generated by $\text{Aut}(K)$ and $\text{mult}(K^*)$.

**Definition 1.** We say that the type $R$ of (not necessarily reduced) root systems admits a realization in the number field $K$ if

(a) $[K: \mathbb{Q}] = \text{rk}(R)$;
(b) there is a subset $R$ of rank $\text{rk}(R)$ in $O_K$, which is a root system of type $R$;
(c) $W(R)$ is a subgroup of the group $\mathcal{L}(K)$.

In this case, the set $R$ is called a realization of the type $R$ in the field $K$.

It is worth noting that if we replace $O_K$ by $K$ in (b), we do not obtain a broader concept. Indeed, if $R$ is a subset of rank $\text{rk}(R)$ in $K$, which is a root system of type $R$ such that (a) and (c) hold, then there is a positive integer $m$ such that $m \cdot R := \{m\alpha \mid \alpha \in R\} \subset O_K$. Clearly the set $m \cdot R$ has rank $\text{rk}(R)$, it is a root system of type $R$, and $W(m \cdot R) = W(R)$.

In view of Definition 1 if a type $R$ of root systems admits a realization in a number field $K$, then the group $\mathcal{L}(K)$ contains a subgroup isomorphic to the Weyl group of a root system of type $R$. Our first main result is the classification of all the cases when the latter property holds:

**Theorem 1.** The following properties of the Weyl group $W(R)$ of a reduced root system $R$ of type $R$ and rank $n$ are equivalent:

(i) $W(R)$ is isomorphic to a subgroup $G$ of the group $\mathcal{L}(K)$, where $K$ is a number field of degree $n$ over $\mathbb{Q}$;
(ii) $R$ is contained in the following list:

$$A_1, \ A_2, \ B_2, \ G_2, \ 2A_1, \ 2A_1 + A_2, \ A_2 + B_2.$$  \hspace{1cm} (3)

The fact that a subgroup $G$ of the group $\mathcal{L}(K)$ is isomorphic to the Weyl group of a root system of rank $n = [K: \mathbb{Q}]$ and of type $R$ is not equivalent to the fact that $G = W(R)$, where $R$ is a root system of type $R$ in $O_K$. This is seen from comparing Theorem 1 with our second main result. The latter answers the question of which of the types of root systems in list (3) are realized in number fields:
Theorem 2. For every type \( R \) of root systems, the following properties are equivalent:

(i) there is a number field, in which \( R \) admits a realization;
(ii) \( \text{rk}(R) = 1 \) or \( 2 \).

For \( \text{rk}(R) = 1 \) or \( 2 \), the specific realizations of \( R \) in number fields see in Section 2.

Terminology and notation
If \( R \) is the type of a root system, then the type of the direct sum of \( m \) copies of \( R \) is denoted by \( mR \). We say that \( R \) is irreducible if \( R \) is.
All root systems of type \( R \) have the same rank denoted by \( \text{rk}(R) \).
\( A_1' \) is the unique type of nonreduced root systems of rank 1.
By a number field \( K \) we mean an extension of a finite degree of the field \( \mathbb{Q} \).
\( \mu_K \) is the multiplicative group of all roots of unity in \( K \); it is a finite cyclic group.
\( \mathcal{O}_K \) is the ring of all integers in \( K \).
\( \mathcal{O}_K(d) \) is the set of all elements of \( \mathcal{O}_K \), whose norm is \( d \).
\text{ord}(g) \) is the order of an element \( g \) of a group
\( \langle g \rangle \) is a cyclic group with the generating element \( g \).
\( [G, G] \) is the commutator subgroup of a group \( G \).
For a prime number \( p \) and a non-zero integer \( n \), the \( p \)-adic valuation of \( n \) is denoted by \( \nu_p(n) \) (i.e., \( \nu_p(n) \) is the highest exponent \( e \) such that \( p^e \) divides \( n \)).
\( \varphi \) is Euler’s totient function, i.e., for every integer \( d > 0 \), the value \( \varphi(d) \) is the number of positive integers \( \leq d \) that are relatively prime to \( d \).

2. Ranks 1 and 2

The following examples show that every type \( R \) of root systems of rank 1 or 2 admits a realization in an number field \( K \).

Root systems of types \( A_1 \) and \( A_1' \)
In this case, \( K = \mathbb{Q} \), \( \mathcal{O}_K = \mathbb{Z} \) and \( \mathcal{L}(K) = \text{mult}(\mathbb{Q}^*) \). If \( \alpha \in \mathbb{Z}, \alpha \neq 0 \), then \( R := \{ \pm \alpha \} \) (respectively, \( R := \{ \pm \alpha, \pm 2\alpha \} \)) is a realization of type \( A_1 \) (respectively, \( A_1' \)) in the field \( K \), because \( W(R) = \langle \text{mult}(-1) \rangle \subset \mathcal{L}(K) \).

Root systems of types \( A_2 \) and \( G_2 \)
Let \( K \) be the third cyclotomic field: \( K = \mathbb{Q}(\sqrt{-3}) \). Then \( \mathcal{O}_K = \mathbb{Z} + \mathbb{Z} \omega \), where \( \omega = (1 + i\sqrt{3})/2 \), and \( \text{Aut}(K) = \langle c \rangle \), where \( c \) is the
complex conjugation $a \mapsto \overline{a}$. The bilinear form
\[ K \times K \to \mathbb{Q}, \quad (a, b) \mapsto \text{trace}_{K/\mathbb{Q}}(ab) = 2\text{Re}(ab), \]
defines on $K$ a structure of Euclidean space over $\mathbb{Q}$. Any element of $\mathcal{L}(K)$, whose order is finite (in particular, any reflection), is an orthogonal (with respect to this structure) transformation.

Since $r_1 := \text{mult}(-1)c \in \mathcal{L}(K)$ is a reflection with respect to 1, the transformation $\rho_1 \rho^{-1}$ for every $\rho \in \text{GL}_Q(K)$ is a reflection with respect to $\rho(1)$. For $\rho = \text{mult}(a)$, where $a \in K^*$, this yields the element
\[ r_a := \text{mult}(-a^{-1})c \]
of $\mathcal{L}(K)$, which is a reflection with respect to $a$.

The multiplicative group $\{\pm 1, \pm \omega, \pm \omega^2\}$ of all 6th roots of 1 coincides with $\mathcal{O}_K(1)$. Hence
\[ \mathcal{O}_K(1) = \{\pm \alpha_1, \pm \alpha_2, \pm (\alpha_1 + \alpha_2)\}, \]
where $\alpha_1 = 1$, $\alpha_2 = \omega^2$.

Therefore, $\mathcal{O}_K(1)$ is the root system of type $A_2$ with the base $\alpha_1, \alpha_2$. If $a \in \mathcal{O}_K(1)$, then $r_a(\mathcal{O}_K(1)) = \mathcal{O}_K(1)$.

So, $W(\mathcal{O}_K(1)) \subset \mathcal{L}(K)$. This means that $\mathcal{O}_K(1)$ is the realization of type $A_2$ in the field $K$.

Since we have
\[ \mathcal{O}_K(3) = (1 + \omega)\mathcal{O}_K(1), \]
the set $\mathcal{O}_K(3)$ is the root system of type $A_2$ with the base
\[ \beta_1 = (1 + \omega)\alpha_1, \beta_2 = (1 + \omega)\alpha_2. \]

If $a \in \mathcal{O}_K(3)$, then $r_a(\mathcal{O}_K(3)) = \mathcal{O}_K(3)$. Therefore, $W(\mathcal{O}_K(3)) \subset \mathcal{L}(K)$. Hence $\mathcal{O}_K(3)$ is yet another realization of type $A_2$ in the field $K$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1.png}
\caption{Elements of $\mathcal{O}_K$, $\mathcal{O}_K(1)$, and $\mathcal{O}_K(3)$ are depicted respectively by $\bullet$, $\circ$, and $\square$.}
\end{figure}
Since we have
\[ \mathcal{O}_K(1) \cup \mathcal{O}_K(3) \]
\[ = \{ \pm \alpha_1, \pm \beta_2, \pm (\alpha_1 + \beta_2), \pm (2\alpha_1 + \beta_2), \pm (3\alpha_1 + \beta_2), \pm (3\alpha_1 + 2\beta_2) \}, \]
the set \( \mathcal{O}_K(1) \cup \mathcal{O}_K(3) \) is the root system of type \( G_2 \) with the base \( \alpha_1, \beta_2 \)
(this is noted in [3, V, 16]). If \( a \in \mathcal{O}_K(3) \), \( b \in \mathcal{O}_K(1) \), then \( r_a(\mathcal{O}_K(1)) = \mathcal{O}_K(1) \), \( r_b(\mathcal{O}_K(3)) = \mathcal{O}_K(3) \). Therefore, \( \mathcal{W}(\mathcal{O}_K(1) \cup \mathcal{O}_K(3)) \subset \mathcal{L}(K) \).
Hence \( \mathcal{O}_K(1) \cup \mathcal{O}_K(3) \) is the realization of type \( G_2 \) in the field \( K \).

**Root systems \( B_2, 2A_1, BC_2, 2A', \) and \( A + A' \)**

Let \( K \) be the fourth cyclotomic field: \( K = \mathbb{Q}(\sqrt{-1}) \). Then \( \mathcal{O}_K = \mathbb{Z} + \mathbb{Z} i \) and \( \text{Aut}(K) = \langle c \rangle \), where \( c \) is the complex conjugation \( a \mapsto \overline{a} \).

As above, \( \mathcal{O}_K \) defines on \( K \) a structure of Euclidean space over \( \mathbb{Q} \), and any element of \( \mathcal{L}(K) \) of finite order (in particular, any reflection) is an orthogonal (with respect to this structure) transformation.

As above, for every \( a \in K^* \), the element \( r_a \in \mathcal{L}(K) \), given by formula (5), is a reflection with respect to \( a \).

The multiplicative group \( \{ \pm 1, \pm i \} \) of all 4th roots of 1 coincides with \( \mathcal{O}_K(1) \). Therefore,
\[ \mathcal{O}_K(1) = \{ \pm \alpha_1, \pm \alpha_2 \} \]
is the root system of type \( 2A_1 \) with the base \( \alpha_1 = 1, \alpha_2 = i \). If \( a \in \mathcal{O}_K(1) \), then \( r_a(\mathcal{O}_K(1)) = \mathcal{O}_K(1) \). Hence \( r_a \in \mathcal{W}(\mathcal{O}_K(1)) \); therefore, \( \mathcal{W}(\mathcal{O}_K(1)) \subset \mathcal{L}(K) \). So, \( \mathcal{O}_K(1) \) is the realization of type \( 2A_1 \) in \( K \).

Since we have
\[ \mathcal{O}_K(2) = (1 + i)\mathcal{O}_K(1), \]
the set \( \mathcal{O}_K(2) \) is the root system of type \( 2A_1 \) with the base
\[ \beta_1 = (1 + i)\alpha_1, \beta_2 = (1 + i)\alpha_2. \]
If \( a \in \mathcal{O}_K(2) \), then \( r_a(\mathcal{O}_K(2)) = \mathcal{O}_K(2) \). Therefore, \( \mathcal{W}(\mathcal{O}_K(2)) \subset \mathcal{L}(K) \).
Hence \( \mathcal{O}_K(2) \) is yet another realization of type \( 2A_1 \) in \( K \).

Since we have
\[ \mathcal{O}_K(1) \cup \mathcal{O}_K(2) = \{ \pm \alpha_1, \pm \beta_2, \pm (\alpha_1 + \beta_2), \pm (2\alpha_1 + \beta_2) \}, \]
the set \( \mathcal{O}_K(1) \cup \mathcal{O}_K(2) \) is the root system of type \( B_2 \) with the base \( \alpha_1, \beta_2 \). If \( a \in \mathcal{O}_K(2), b \in \mathcal{O}_K(1) \), then \( r_a(\mathcal{O}_K(1)) = \mathcal{O}_K(1), r_b(\mathcal{O}_K(2)) = \mathcal{O}_K(2) \). Therefore, \( \mathcal{W}(\mathcal{O}_K(1) \cup \mathcal{O}_K(2)) \subset \mathcal{L}(K) \), hence \( \mathcal{O}_K(1) \cup \mathcal{O}_K(2) \) is the realization of type \( B_2 \) in the field \( K \).

Since we have
\[ \mathcal{O}_K(4) = 2\mathcal{O}_K(1), \]
the group $W(\mathcal{O}_K(4))$ coincides with the group $W(\mathcal{O}_K(1))$. Therefore, $\mathcal{O}_K(4)$ is yet another realization of type $2A_1$ in $K$. Since
\[
\mathcal{O}_K(1) \cup \mathcal{O}_K(2) \cup \mathcal{O}_K(4) = \{ \pm \alpha_1, \pm 2\alpha_1, \pm \beta_2, \pm (\alpha_1 + \beta_2), \pm 2(\alpha_1 + \beta_2), \pm (2\alpha_1 + \beta_2) \},
\]
the set $\mathcal{O}_K(1) \cup \mathcal{O}_K(2) \cup \mathcal{O}_K(4)$ is the root system of type $BC_2$ with the base $\alpha_1, \beta_2$. In view of $W(\mathcal{O}_K(1) \cup \mathcal{O}_K(2) \cup \mathcal{O}_K(4)) \subset \mathcal{L}(K)$, it is the realization of type $BC_2$ in $K$.

Finally, the realizations of types $2A'_1$ and $A_1 + A'_1$ in $K$ are respectively
\[
\mathcal{O}_K(1) \cup \mathcal{O}_K(4) \quad \text{and} \quad \mathcal{O}_K(1) \cup \{ \pm 2 \}.
\]

Summing up, we have the following

**Proposition 1.** Every type of root systems of rank $\leq 2$ admits a realization in a number field.

3. **Group $\mathcal{L}(K)$ and its finite subgroups**

Below $K$ is a number field of degree $n$ over $\mathbb{Q}$.

**Theorem 3.** The group $\mathcal{L}(K)$ is a semidirect product of its normal subgroup $\text{mult}(K^*)$ and the subgroup $\text{Aut}(K)$. Therewith,
\[
g \cdot \text{mult}(a) \cdot g^{-1} = \text{mult}(g(a)) \quad \text{for any} \ a \in K^*, \ g \in \text{Aut}(K). \quad (6)
\]
Proof. First, check that the set of all products mult(α)g, where α ∈ K*, g ∈ Aut(K), is a subgroup of GL_Q(K). Let a_1, a_2 ∈ K* and g_1, g_2 ∈ Aut(K). Then, for each v ∈ K,

\[ \text{mult}(a_1)g_1\text{mult}(a_2)g_2(v) = a_1(g_1(a_2g_2(v))) = a_1(g_1(a_2))(g_1(g_2(v))). \]

This yields

\[ \text{mult}(a_1)g_1\text{mult}(a_2)g_2 = \text{mult}(a_1(g_1(a_2)))g_1g_2. \] (7)

From (7) we infer that the inverse of mult(α)g is mult(g^{-1}(a^{-1})g^{-1}). Thus the set of all products mult(α)g is a subgroup of GL_Q(K).

On the other hand,

\[ \text{mult}(a)g(1) = a(g(1)) = a1 = a, \]

hence the linear operator mult(α)g uniquely determines α, and therefore, g as well. This implies that the map

\[ \psi : L(K) \rightarrow \text{Aut}(K), \quad \text{mult}(α)g \mapsto g, \]

is well defined. By (7), the map (8) is a group epimorphism and \( \ker(\psi) = \text{mult}(K^*) \).

Finally, (6) straightforwardly follows from (7). \( \square \)

**Lemma 1.** For any finite subgroup G of L(K), there is a (cyclic) subgroup H of μ_K such that mult(H) ⊆ G and

1. the sequence 1 → H → G → ψ(G) → 1 is exact;
2. |G| = |H| · |ψ(G)|;
3. |H| divides |μ_K|;
4. φ(|H|) divides n;
5. |ψ(G)| divides |Aut(K)|, which divides n;
6. if \( p \geq 2 \) is a prime integer, then \( ν_p(|G|) \leq 2ν_p(n) + 1 \).

Proof. Since μ_K is the set of all elements of finite order in K*, and (1) is a group monomorphism, the existence of H and (i) follow from (9). Since μ_K is cyclic, H is cyclic as well.

Statements (ii), (iii), (v) are clear.

Let θ be a generator of the cyclic group H. Then \([Q(θ) : Q] = φ(\text{ord}(θ)) = φ(|H|)\). Whence (iv), because Q(θ) is a subfield of K.

Let \( ν_p(|μ_K|) = d \) and let ζ ∈ μ_K be a primitive \( p^d \)-th root of unity. From Q(ζ) ⊆ K and \([Q(ζ) : Q] = φ(p^d) = p^d-1(p-1)\) we infer that \( p^d-1(p-1) \) divides n. Hence \( ν_p(n) \geq d-1 = ν_p(|μ_K|) - 1 \). This and (ii), (iii), (v) then imply \( ν_p(|G|) ≤ ν_p(|μ_K|) + ν_p(n) ≤ 2ν_p(n) + 1 \), which proves (vi). \( \square \)
Lemma 2. Let $W(R)$ be the Weyl group of a root system $R$. Then
\[ \nu_2(|W(R)|) \geq \left\lfloor \frac{\text{rk}(R) + 1}{2} \right\rfloor. \] (10)

Proof. First, note that, given an integer $m > 0$, then
\[ \nu_2(m!) \geq \left\lfloor \frac{m + 1}{2} \right\rfloor \text{ if } m \neq 1, 3. \] (11)
Indeed, let $s = \left\lfloor \frac{m}{2} \right\rfloor$. Then the product of all even integers between 1 and $m$ is $2s \cdot s!$, hence $\nu_2(m!) \geq s$. Therefore, (11) holds for $m$ even, because then $\left\lfloor \frac{m + 1}{2} \right\rfloor = s$. If $m$ is odd, then we have $\left\lfloor \frac{m + 1}{2} \right\rfloor = s + 1$. If, moreover, $m \geq 5$, then $s!$ is even, hence $2s \cdot s!$ is divisible by $2s + 1$. Therefore, (11) holds in this case as well.

Next, suppose that $R$ is irreducible of type $R$. By (1) we have

\begin{align*}
\text{Table 1} \\
|W(R)| & \quad A_\ell, \ell \geq 1 & \quad (\ell + 1)! \\
|W(R)| & \quad B_\ell, \ell \geq 2 & \quad 2^\ell \cdot \ell! \\
|W(R)| & \quad C_\ell, \ell \geq 2 & \quad 2^\ell \cdot \ell! \\
|W(R)| & \quad D_\ell, \ell \geq 4 & \quad 2^{\ell-1} \cdot \ell!
\end{align*}

| $R$ | $E_6$ | $E_7$ | $E_8$ | $F_4$ | $G_2$ |
|-----|-----|-----|-----|-----|-----|
| $|W(R)|$ | $2^{7} \cdot 3^{4} \cdot 5$ | $2^{10} \cdot 3^{4} \cdot 5 \cdot 7$ | $2^{14} \cdot 3^{5} \cdot 5^2 \cdot 7$ | $2^{7} \cdot 3^{2}$ | $2^{4} \cdot 3$ |

Then (10) directly follows from Tables 1 and (11).

In the case of an arbitrary root system
\[ R = R_1 + \cdots + R_d, \] (12)
where $R_i$ is an irreducible root system for every $i$, we have
\[ \text{rk}(R) = \text{rk}(R_1) + \cdots + \text{rk}(R_d) \] (13)
and $W(R)$ splits into the product
\[ W(R) = W(R_1) \times \cdots \times W(R_d) \] (14)
where $W(R_i)$ is the Weyl group of $R_i$. It follows from (14) that, for every prime integer $p \geq 2$,
\[ \nu_p(|W(R)|) = \sum_{i=1}^{d} \nu_p(|W(R_i)|). \] (15)

Given that for every $W(R_i)$ the desired inequality is proved, we then deduce from (15) that
\[ \nu_2(|W(R)|) \geq \sum_{i=1}^{d} \left\lfloor \frac{\text{rk}(R_i) + 1}{2} \right\rfloor. \] (16)

Now (10) follows from (16) because of the inequality
\[ \left\lfloor \frac{a+b+1}{2} \right\rfloor \leq \left\lfloor \frac{a+1}{2} \right\rfloor + \left\lfloor \frac{b+1}{2} \right\rfloor, \] (17)
which holds for all integers $a$ and $b$. To prove \((17)\), note that if we replace $a$ by $a + 2$ then the both sides of \((17)\) would increase by 1. So it suffices to verify the cases $a = 0$ and $a = 1$. If $a = 0$, then the first summand of the right-hand side of \((17)\) is zero and we get the equality.

If $a = 1$, then, for the left-hand side of \((17)\), we have

$$(1 + b + 1)/2 = 1 + b/2 \leq (1 + 1)/2 + [(b + 1)/2],$$

which proves \((17)\). □

Below some of the arguments are based on the information that readily follows from Tables 1. It is convenient to collect it in Tables 2, where we use the same notation as in Tables 1 and, for every prime integer $p \geq 2$, put $\nu_p(R) := \nu_p(|W(R)|)$.

**Tables 2**

| $\ell$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
|--------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|
| $\nu_2(R)$ | 1 | 1 | 3 | 3 | 4 | 4 | 7 | 7 | 8 | 8 | 10 | 10 | 11 | 11 | 15 | 15 |
| $\nu_3(R)$ | 0 | 1 | 1 | 1 | 2 | 2 | 2 | 4 | 4 | 4 | 5 | 5 | 6 | 6 | 6 | 6 |

| $\ell$ | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
|--------|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|
| $\nu_2(R)$ | 3 | 3 | 7 | 8 | 10 | 11 | 15 | 16 | 18 | 19 | 22 | 23 | 25 | 26 | 31 |
| $\nu_3(R)$ | 0 | 1 | 1 | 1 | 2 | 2 | 2 | 4 | 4 | 4 | 5 | 5 | 5 | 6 | 6 |

| $\ell$ | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
|--------|---|---|---|---|---|---|---|----|----|----|----|----|----|
| $\nu_2(R)$ | 6 | 7 | 9 | 10 | 14 | 15 | 17 | 18 | 21 | 22 | 24 | 25 | 30 |
| $\nu_3(R)$ | 1 | 1 | 2 | 2 | 4 | 4 | 4 | 5 | 5 | 5 | 6 | 6 |

| $R$ | $\nu_2(R)$ | $\nu_3(R)$ |
|------|-------------|-------------|
| $E_6$ | 7 | 4 |
| $E_7$ | 10 | 4 |
| $E_8$ | 14 | 5 |
| $F_4$ | 7 | 2 |
| $G_2$ | 4 | 1 |

Below, for every type $R$ of root systems, we put $\emptyset + R := R$.

**Proposition 2.** Let $R$ be a root system of type $R$.

(i) If $R = S_1 + S_2$, then

$$\nu_2(S_1) \leq \nu_2(R) - [(\text{rk}(S_2) + 1)/2].$$

In particular, if $R_i$ is the type of $R_i$ in \((12)\), then

$$\nu_2(R_i) \leq \nu_2(R) - [(n - \text{rk}(R_i) + 1)/2] < \nu_2(R).$$
Proposition 3. This follows from Lemma 2, (13), (15), and Tables 2.

Proof. A positive integer. If the group \(L_m\) to the Weyl group a root system of type \(m\), in particular, if \(m\) Abelian 2-group of order 2, we shall consider respectively the cases \(n\)

Proof. In view of (14) and Tables 1, the group \(L\) contains a subgroup \(G\) isomorphic to the Weyl group a root system of type \(m\), then \(2^{m-1}\) divides \(n\). In particular, if \(m = n\), then \(n = 1\) or 2.

Proof. In view of (14) and Tables 1, the group \(G\) is an elementary Abelian 2-group of order \(2^n\). From this, Lemma (i)(ii), and the cyclicity of \(H\), we infer that \(|H| = 1\) or 2, hence, respectively, \(|\psi(G)| = 2^n\) or \(2^{m-1}\). The claim then follows from Lemma (v). □

Proposition 4. Let \(K\) be a number field of degree \(n\) over \(\mathbb{Q}\) and let \(m\) be a positive integer. If the group \(\mathcal{L}(K)\) contains a subgroup \(G\) isomorphic to the Weyl group a root system of type \(m\), then \(2^{m-1}\) divides \(n\). In particular, if \(m = n\), then \(n = 1\) or 2.

Proof. First, in Step 1, we shall show that \(n \in \{1, 2, 4, 6, 8, 16\}\). Then, in Steps 2, 3, and 4, we shall consider respectively the cases \(n = 6, 8,\) and 16, and eliminate each of them.

Step 1

Lemma (vi) yields \(\nu_2(|G|) \leq 2\nu_2(n) + 1\). By Lemma 2 we have \(\nu_2(|G|) \geq [(n + 1)/2]\). Therefore,

\[
[(n + 1)/2] \leq 2\nu_2(n) + 1. \tag{20}
\]

Let \(n \geq 3\). Then \(2 \leq [(n + 1)/2]\). In view of (20), this implies that \(\nu_2(n) \geq 1\), i.e., \(n\) is even. Since \(n/2 \leq [(n + 1)/2]\), from (20) we infer

\[
2^{n/2} \leq 2^{[(n+1)/2]} \leq 2^{2\nu_2(n)+1} \leq 2n^2. \tag{21}
\]
In addition, if \( n \) is not a power of 2, then \( 2^{\nu_2(n)} \cdot 3 \leq n \), so (21) yields
\[
2^{n/2} \leq 2^{2\nu_2(n)+1} \leq 2(n/3)^2.
\] (22)

If in (22) we replace \( n \) by \( n+2 \) then the left-hand side will be multiplied by 2 while the right-hand side will be multiplied by \( (1+2/n)^2 < 2 \), because \( n > 4 \). Taking into account that (22) becomes equality if \( n = 6 \), we conclude that \( n = 6 \) if \( n \geq 3 \) is not a power of 2.

Now suppose that \( n = 2^s \), where \( s \geq 2 \). Then (20) yields
\[
2^s - 1 \leq 2^s + 1
\]
and therefore \( s = 2, 3 \) or 4, i.e., \( n = 4, 8 \) or 16 respectively.

Taking into account all \( n < 3 \), we conclude that \( n \in \{1, 2, 4, 6, 8, 16\} \).

In Steps 2, 3, and 4, we use the notation of (12), (14) introduced in the proof of Lemma 2. The type of \( R_i \) is denoted by \( R_i \).

**Step 2**

Arguing on the contrary, assume that \( n = 6 \). Since \( \nu_2(n) = 1 \), Lemma (vi) yields \( \nu_2(R) \leq 3 \). From Proposition (ii) we then infer that \( R = aA_1 + bA_2 \), where \( x = a, y = b \) is a solution of the system
\[
\begin{align*}
x + 2y &= 6, \\
x + y &\leq 3.
\end{align*}
\] (23)

It is easily seen that (23) has only one solution in non-negative integers, namely, \( x = 0, y = 3 \). Thus \( R = 3A_2 \). Hence, from Tables 1 and (14) we obtain
\[
|G| = 2^3 \cdot 3^3.
\] (24)

Lemma (v) implies that \( |\psi(G)| = 1, 2, 3 \) or 6. From Lemma (ii) and (24) we then infer that \( |H| \) is one of the integers \( 2^3 \cdot 3^3, 2^2 \cdot 3^3, 2^3 \cdot 3^2 \) or \( 2^2 \cdot 3^2 \). Hence, respectively, \( \varphi(|H|) = 2^3 \cdot 3^2, 2^2 \cdot 3^3, 2^3 \cdot 3^1 \) or \( 2^2 \cdot 3^1 \). Since neither of these integers divides 6, this contradicts Lemma (iv). So we proved that \( n \neq 6 \).

**Step 3**

Arguing on the contrary, assume that \( n = 8 \). We have \( \nu_2(n) = 3, \nu_3(n) = 0 \). Therefore, Lemma (vi) yields \( \nu_2(R) \leq 7 \) and \( \nu_3(R) \leq 1 \). From Proposition (iii) we then deduce that (18), (19) hold, where
\[
\begin{align*}
\text{rk}(X) + a + 2b &= 8, \\
\nu_2(X) + a + 3b &\leq 7.
\end{align*}
\] (25) (26)

In turn, (25), (26) yield: \( a + 3b \geq a + 2b \) \( \implies 8 - \text{rk}(X) \geq 8 - 5 = 3 \), hence \( \nu_2(X) \leq 7 - (a + 3b) \leq 7 - 3 = 4 \). This, (19), and Table 2 show that
\[
X \in \{A_2, A_3, A_4, B_3, C_3, G_2, \emptyset\}.
\] (27)
Next, from \((25)\), \((26)\) we obtain
\[ b \leq \text{rk}(X) - \nu_2(X) - 1. \]
Tables 2 imply that the right-hand side of the latter inequality is negative if
\[ X \in \{ A_3, B_3, C_3, G_2, \emptyset \}. \]
Since this is impossible, from \((27)\) we conclude that \( X = A_2 \) or \( A_4 \). In each of these cases, there is a unique pair \((a, b)\) of non-negative integers satisfying \((25), (26)\), namely, \((a, b) = (6, 0)\) for \( X = A_2 \), and \((a, b) = (4, 0)\) for \( X = A_4 \). So, \( R = 6A_1 + A_2 \) or \( 4A_1 + A_4 \).

We now consider these possibilities.

Assume that \( R = 6A_1 + A_2 \). Then \( G \) contains a subgroup isomorphic to the Weyl group of a root system of type \( 6A_1 \). Hence \( 2^{6-1} \) divides \( n = 8 \) by Proposition 3. This contradiction proves that, in fact, \( R \neq 6A_1 + A_2 \).

Next, assume that \( R = 4A_1 + A_4 \). Then Tables 1 and \((14)\) yield
\[ |G| = 2^7 \cdot 3 \cdot 5. \]
Hence, if \(|\psi(G)| = 1, 2, 4, \) or \( 8 \), then, respectively, \(|H| = 2^7 \cdot 3 \cdot 5, 2^6 \cdot 3 \cdot 5, 2^6 \cdot 3 \cdot 5 \) or \( 2^4 \cdot 3 \cdot 5 \), and, accordingly, \( \varphi(|H|) = 2^9, 2^8, 2^7 \) or \( 2^6 \). Contrary to Lemma \((i)\) (whose notation we use) yields \( \nu_2(R) \leq 5, \nu_3(R) \leq 1 \). By Proposition \((ii)\) we then conclude that \((18), (19)\) hold, where
\[ \begin{align*}
\text{rk}(X) + a + 2b &= 16, \\
\nu_2(X) + a + 3b &\leq 9.
\end{align*} \]
But \((23)\) implies \( b \leq \text{rk}(X) - \nu_2(X) - 7 \), and, in view of \((19)\) and Tables 2, the right-hand side of this inequality is negative. This refutes our assumption and proves that \( n \neq 8 \).

**Step 4**

Arguing on the contrary, assume that \( n = 16 \). We have \( \nu_2(n) = 4, \nu_3(n) = 0 \). Therefore, Lemma \((vi)\) yields \( \nu_2(R) \leq 9, \nu_3(R) \leq 1 \). By Proposition \((ii)\) we then conclude that \((18), (19)\) hold, where
\[ \begin{align*}
\text{rk}(X) + a + 2b &= 16, \\
\nu_2(X) + a + 3b &\leq 9.
\end{align*} \]
But \((23)\) implies \( b \leq \text{rk}(X) - \nu_2(X) - 7 \), and, in view of \((19)\) and Tables 2, the right-hand side of this inequality is negative. This refutes our assumption and proves that \( n \neq 16 \). \(\square\)

4. PROOFS OF THEOREMS 1 AND 2

**Proof of Theorem 1**

(i)\(\Rightarrow\)(ii) Assume that (i) holds. In view of Proposition 4 we have to show that if \( n = 4 \), then \( R \) is either \( A_2 + B_2 \) or \( 2A_1 + A_2 \).

So, let \( n = 4 \). Then Lemma \((v)\) (whose notation we use) yields
\[ |\psi(G)| = 1, 2, \) or 4. \( (30)\)
Next, we have \( \nu_2(n) = 2, \nu_3(n) = 0 \). Therefore, Lemma \((vi)\) yields \( \nu_2(R) \leq 5, \nu_3(R) \leq 1 \). From Proposition \((ii)\) and Tables 2 we then deduce that
\[ R \in \{ A_1, A_1 + A_3, A_1 + B_3, A_1 + C_3, 2A_1 + A_2, 2A_1 + B_2, 4A_1, A_2 + B_2 \}. \]
Assume that \( R = A_4 \). Then from Tables 1 we obtain

\[ |G| = 2^3 \cdot 3 \cdot 5. \]  

(31)

From Lemma (ii) and (31) we infer that, respectively to (30), we have \( \varphi(|H|) = 2^5, 2^4, \) or \( 2^3 \). Contrary to Lemma (iv), neither of the latter integers divides 4. This contradiction shows that, in fact, \( R \neq A_4 \).

Assume that \( R = A_1 + B_3 \) or \( A_1 + C_3 \). Then Tables 1 and (14) yield

\[ |G| = 2^5 \cdot 3. \]  

(32)

From Lemma (ii) and (32) we infer that, respectively to (30), we have \( |H| = 2^5 \cdot 3, 2^4 \cdot 3, \) or \( 2^3 \cdot 3 \), and, accordingly, \( \varphi(|H|) = 2^4, 2^3, \) or \( 2^2 \). So, as above we conclude that, in fact, \( R \neq A_1 + B_3 \) or \( A_1 + C_3 \).

Assume that \( R = A_1 + A_3 \). Then Tables 1 and (14) yield

\[ |G| = 2^4 \cdot 3. \]  

(33)

Lemma (ii) and (33) imply that, respectively to (30), we have \( |H| = 2^4 \cdot 3, 2^3 \cdot 3, \) or \( 2^2 \cdot 3 \), and, accordingly, \( \varphi(|H|) = 2^3, 2^2, \) or \( 2^1 \). Since only the last integer divides 4, by Lemma (iv) we conclude that \( \psi(G) = 4 \).

The latter equality implies that the group \( \psi(G) \) is Abelian. From this and Lemma (i) we infer that \( [G, G] \varsubsetneq \ker(\psi) = H \). Since the group \( H \) is Abelian, we conclude that the group \( [G, G] \) is Abelian as well. But \( G \) is isomorphic to \( W(R) = W(R_1) \times W(R_2) \), where the types of \( R_1 \) and \( R_2 \) are respectively \( A_1 \) and \( A_3 \). Therefore, \( [G, G] \) contains a subgroup isomorphic to \( W(R_2), W(R_2) \). The latter is the alternating group on 4 letters, hence non-Abelian. This contradiction shows that, in fact, \( R \neq A_1 + A_3 \).

Assume that \( R = 2A_1 + B_2 \). Then \( W(R) = W(R_1) \times W(R_2) \times W(R_3) \), where \( R_1 \) and \( R_2 \) are of type \( A_1 \), and \( R_3 \) is of type \( B_2 \). Tables 1 yield \( |W(R_1)| = |W(R_2)| = 2, |W(R_3)| = 8 \). Since \( W(R_3) \) is non-Abelian, this implies that \( G \) does not contain an element of order \( \geq 8 \). On the other hand, as \( |G| = 2^5 \), Lemma (ii),(v) yields \( |H| \geq 2^5 / 2^2 = 8 \). As \( H \) is cyclic, this implies that \( G \) contains an element of order \( \geq 8 \). This contradiction means that, in fact, \( R \neq 2A_1 + B_2 \).

If \( R = 4A_1 \), then \( 2^{4-1} \) divides \( n = 4 \) by Proposition 3. This contradiction means that \( R \neq 4A_1 \).

The proof of (i)\( \Rightarrow \) (ii) is now completed.

(ii)\( \Rightarrow \) (i) If \( R \in \{ A_2, B_2, G_2, 2A_1 \} \), then (i) follows from Proposition 1 and Definition 1.

Consider the case \( R = A_2 + B_2 \).
Let $K$ be the biquadratic field $\mathbb{Q}(\sqrt{-3}, \sqrt{-1})$. Then

$$K = \mathbb{Q}(\sqrt{-3}) \otimes \mathbb{Q} \mathbb{Q}(\sqrt{-1}).$$

This equality determines the natural homomorphism

$$\mathcal{L}(\mathbb{Q}(\sqrt{-3})) \times \mathcal{L}(\mathbb{Q}(\sqrt{-1})) \to \mathcal{L}(K),$$

whose restriction to $\text{Aut}(\mathbb{Q}(\sqrt{-3})) \times \text{Aut}(\mathbb{Q}(\sqrt{-1}))$ is an isomorphism with $\text{Aut}(K)$ (see [2, Chap. VIII, §1, Thm. 5]). Homomorphism (34) is surjective and its kernel is $\{ (\text{mult}(a), \text{mult}(a^{-1})) | a \in \mathbb{Q}^* \}$.

Let $R_1$ and $R_2$ be respectively the realizations of type $A_2$ in $\mathbb{Q}(\sqrt{-3})$ and of type $B_2$ in $\mathbb{Q}(\sqrt{-1})$ constructed in the proof of Proposition 1. Since $-1 \notin W(R_1)$, the restriction of homomorphism (34) to the group $W(R_1) \times W(R_2)$ is an embedding. Therefore, its image is the subgroup of $\mathcal{L}(K)$ isomorphic to the Weyl group of a root system of type $A_2 + B_2$.

This proves that (i) holds if $R = A_2 + B_2$.

Now consider the case $R = A_2 + 2A_1$.

If $R_3$ is a subset of $R_2$, which is a realization of type $2A_1$ in $K$, then the restriction of homomorphism (34) to $W(R_1) \times W(R_3)$ is the subgroup of $\mathcal{L}(K)$ isomorphic to the Weyl group of a root system of type $A_2 + 2A_1$. Thus (i) holds if $R$ is of this type.

This completes the proof of (ii)$\Rightarrow$(i) and that of Theorem 1. □

**Proof of Theorem 2**. (i)$\Rightarrow$(ii) In view of Theorem 1 and Definition 1 we have to show that if $R = A_2 + B_2$ or $A_2 + 2A_1$, then $R$ admits no realizations in the number fields. Arguing on the contrary, assume that this is not the case, so $R$ admits a realization in a number field $K$.

The linear space $K$ over $\mathbb{Q}$ is then a direct sum of two 2-dimensional linear subspaces $L_1$ and $L_2$ such that

(a) $L_i$ is the linear span of $R_i := R \cap L_i$ over $\mathbb{Q}$ for every $i$;
(b) $R_1$ is a root system in $L_1$ of type $A_2$;
(c) $R_2$ is a root system in $L_2$ of type $B_2$ or $2A_1$;
(d) $R = R_1 \bigcup R_2$.

Let $\iota: \text{GL}_\mathbb{Q}(L_1) \times \text{GL}_\mathbb{Q}(L_2) \hookrightarrow \text{GL}_\mathbb{Q}(K)$ be the natural embedding. Then

$$W(R) = \iota(W(R_1)) \times \iota(W(R_2)).$$

In view of (b), the group $\iota(W(R_1))$ is isomorphic to the symmetric group on three letters, hence contains an element $z$ of order 3. By (35), the fixed points set $K^z$ of $z$ has the property

$L_2 \subseteq K^z$.

According to Theorem 3 there are uniquely defined elements $a \in K^*$ and $g \in \text{Aut}(K)$ such that $z = \text{mult}(a)g$. From (36) we infer that
ord(g) divides ord(z) = 3. Since ord(g) divides |Aut(K)|, which, in turn, divides dim_Q(K) = 4, we conclude that

\[ z = \text{mult}(a). \] (37)

As ord(z) \neq 1, we have a \neq 1. From this, (37), and (2) we infer that \( K^z = 0 \) contrary to (36). This completes the proof of (i) \( \Rightarrow \) (ii).

(ii) \( \Rightarrow \) (i) This follows from Proposition 1. □
