CLASSIFICATION OF QUADRUPLE
GALOIS CANONICAL COVERS I

FRANCISCO JAVIER GALLEGO AND BANGERE P. PURNAPRAJNA

Abstract. In this article we classify quadruple Galois canonical covers of
smooth surfaces of minimal degree. The classification shows that they are
either non-simple cyclic covers or bi-double covers. If they are bi-double, then
they are all fiber products of double covers. We construct examples to show
that all the possibilities in the classification do exist. There are implications
of this classification that include the existence of families with unbounded
geometric genus, in sharp contrast with triple canonical covers, and families
with unbounded irregularity, in sharp contrast with canonical covers of all other
degrees. Together with the earlier known results on double and triple covers,
a pattern emerges that motivates some general questions on the existence of
higher degree canonical covers, some of which are answered in this article.

Introduction

Classification problems are of central importance in algebraic geometry. In the
realm of algebraic surfaces, the geography of surfaces of general type, by far the
largest class of surfaces, is much less charted and understood. An important sub-
class of surfaces of general type are those whose canonical map is a cover of a
simpler surface, most notably, a surface of minimal degree. In the seventies and
eighties Horikawa and Konno ([Ho], [Ko]) classified these covers when the degree
of the cover is 2 and 3. In this article and in its sequel [GP4] we classify surfaces
of general type whose canonical map is a quadruple Galois cover of a surface of
minimal degree.

Covers of varieties of minimal degree have a ubiquitous presence in various con-
texts. They appear in the classification of surfaces of general type \( X \) with small \( c_2 \)
and play an important role in mapping the geography of surfaces of general type.
They are also the chief source in constructing new examples of surfaces of general
type, as the work of various geometers illustrates. These covers occur as well in the
study of linear series on important threefolds such as Calabi-Yau threefolds, as the
work in [BS], [GP1] and [OP] shows. They also become relevant in the study of

the canonical ring of a variety of general type, as can be seen in results from [GP2] and [Gr].

Compared to the canonical morphism of a curve, the canonical morphism of a surface is much more subtle and allows a much wider range of possibilities due to the existence of higher degree covers. The degree of the canonical morphism of a curve is bounded by 2. In contrast, results of Beauville show that the degree of the canonical morphism from a surface of general type $X$ onto a surface of minimal degree, or more generally, onto a surface with geometric genus $p_g = 0$, is bounded by 9 if $\chi(X) \geq 31$ (see [Ed]).

Surfaces of minimal degree are classically known to be linear $\mathbb{P}^2$, the Veronese surface in $\mathbb{P}^5$ and rational normal scrolls, which can be smooth (these include the smooth quadric hypersurface in $\mathbb{P}^3$) or singular (these are cones over a rational normal curve). As pointed out before, the classification of the canonical covers of these surfaces is only complete when the degree of the cover is 2 and 3. Horikawa also studied quadruple covers of linear $\mathbb{P}^2$. The next step in this classification is the study of quadruple covers of an arbitrary surface of minimal degree.

In this work we classify all quadruple Galois canonical covers of smooth surfaces of minimal degree $W$. In [GP4] we classify quadruple Galois covers of $W$ when $W$ is singular. There are many interesting consequences of the classification done here and in [GP4]. Our classification yields, among other things, some striking contrasts with double and triple covers. Before we look at them we state the main result of this article:

**Theorem 0.1.** Let $X$ be a canonical surface and let $W$ be a smooth surface of minimal degree. If the canonical bundle of $X$ is base-point-free and $X \longrightarrow W$ is a quadruple Galois canonical cover, then $W$ is either linear $\mathbb{P}^2$ or a smooth Hirzebruch surface $F_e$, with $0 \leq e \leq 2$, embedded by $|C_0 + mf|$ ($m \geq e + 1$). Let $G$ be the Galois group of $\varphi$.

A) If $G = \mathbb{Z}_4$, then $\varphi$ is the composition of two double covers $X_1 \overset{p_1}{\longrightarrow} W$ branched along a divisor $D_2$ and $X \overset{p_2}{\longrightarrow} X_1$, branched along the ramification of $p_1$ and $p_1^*D_1$, where $D_1$ is a divisor on $W$ and with trace zero module $p_1^*\mathcal{O}_W(-\frac{1}{4}D_1 - \frac{1}{4}D_2)$.

B) If $G = \mathbb{Z}_2^{\oplus 2}$, then $X$ is the fiber product over $W$ of two double covers of $W$ branched along divisors $D_1$ and $D_2$, and $\varphi$ is the natural morphism from the fiber product to $W$.

More precisely, $\varphi$ has one of the sets of invariants shown in the following table. Conversely, if $X \overset{\varphi}{\longrightarrow} W$ is either

I) the composition of two double covers $X_1 \overset{p_1}{\longrightarrow} W$, branched along a divisor $D_2$, and $X \overset{p_2}{\longrightarrow} X_1$, branched along the ramification of $p_1$ and $p_1^*D_1$, and with trace zero module $p_1^*\mathcal{O}_W(-\frac{1}{4}D_1 - \frac{1}{4}D_2)$, with $D_1$ and $D_2$ as described in rows 1, 3 and 5 of the table below; or

II) the fiber product over $W$ of two double covers $X_1 \overset{p_1}{\longrightarrow} W$ and $X_2 \overset{p_2}{\longrightarrow} W$, branched respectively along divisors $D_2$ and $D_1$, as described in rows 2, 4, 6, 7 and 8 of the table below,

then $X \overset{\varphi}{\longrightarrow} W$ is a Galois canonical cover whose Galois group is $\mathbb{Z}_4$ in case I and $\mathbb{Z}_2^{\oplus 2}$ in case II.
### Classification of Quadruple Galois Canonical Covers

| $W$ | $p_g(X)$ | $G$ | $D_1 \sim$ | $D_2 \sim$ | $q(X)$ | $c_1^2/c_2$ |
|-----|--------|-----|------------|------------|-------|-------------|
| $\mathbb{P}^2$ | 3 | $\mathbb{Z}_4$ | conic | quartic | 0 | $\frac{1}{11}$ |
| $\mathbb{P}^2$ | 3 | $\mathbb{Z}_2^{\oplus 2}$ | quartic | quartic | 0 | $\frac{1}{7}$ |
| $F_e$ | $2m - e + 2$ | $\mathbb{Z}_4$ | $(2m - e + 1)f$ | $4C_0 + (2e + 2)f$ | 0 | $\frac{2m - e}{4m - 2e + 9}$ |
| $F_e$ | $2m - e + 2$ | $\mathbb{Z}_2^{\oplus 2}$ | $2C_0 + (2m + 2)f$ | $4C_0 + (2e + 2)f$ | 0 | $\frac{2m - e}{4m - 2e + 9}$ |
| $F_0$ | $2m + 2$ | $\mathbb{Z}_4$ | $(2m + 4)f$ | $4C_0$ | 1 | $\frac{m}{2m + 3}$ |
| $F_0$ | $2m + 2$ | $\mathbb{Z}_2^{\oplus 2}$ | $2C_0 + (2m + 4)f$ | $4C_0$ | 1 | $\frac{m}{2m + 3}$ |
| $F_0$ | $2m + 2$ | $\mathbb{Z}_2^{\oplus 2}$ | $(2m + 2)f$ | $6C_0 + 2f$ | $m$ | $\frac{2m}{m + 9}$ |
| $F_0$ | $2m + 2$ | $\mathbb{Z}_2^{\oplus 2}$ | $(2m + 4)f$ | $6C_0$ | $m + 3$ | $2$ |

**Remark 0.2.** Note that, whereas $W$ is always simply connected, the intermediate cover $X_1$ in A) and I) of Theorem 0.1 is sometimes simply connected and sometimes not. An example of the former is the case in row 1 of the above table, provided $D_2$ is smooth, and the case in row 3, when $e = 0, 1$, provided again that $D_2$ is smooth (see [Mg]). An example of the latter is the case in row 5; in this case $\pi_1(X_1) = \mathbb{Z} \times \mathbb{Z}$, as $X_1$ is the product of a smooth elliptic curve and $\mathbb{P}^1$. That is why in order to determine $p_2$, in general, we need to specify not only the branch divisor but also the trace zero module of the cover.

Theorem 0.1 is split inside the paper into Corollary 2.5 and Theorems 4.1, 5.1, 5.2, 6.1 and 6.2. We also construct families of examples to show the existence of all the cases that appear in the classification. A notable fact that is not mentioned in the statement of the theorem is that there exist families of smooth surfaces of general type $X$ for every case described in rows 2, 4, 6, 7 and 8 of the above table (that is, all cases where $G = \mathbb{Z}_2^{\oplus 2}$). In comparison, we show that the quadruple cyclic canonical covers of smooth surfaces of minimal degree are always singular. We also show that quadruple cyclic canonical covers are non-simple cyclic.

One of the interesting implications of the main result of this article is the existence of families of quadruple canonical covers with unbounded geometric genus and the existence of families with unbounded irregularity. The unboundedness of the geometric genus is in sharp contrast with the situation of triple covers, and the unboundedness of the irregularity is in sharp contrast with the canonical covers of all other degrees. The geometric genus of canonical double covers is unbounded, but they are all regular, and even simply connected surfaces. The classification of triple covers by Konno shows that the geometric genus of canonical triple covers is bounded by 5 and that they are all regular. For quadruple Galois covers we show the existence of families of surfaces $X$ for each possible value of $p_g(X)$ (see rows 3 to 8 of the above table). We also show that there exist unbounded families of surfaces $X$ for each possible value of $q(X)$ (see rows 7 and 8 of the table).

The classification of quadruple covers provides other significant contrast with double and triple covers and clearly brings out the marked difference between even and odd degree covers. The only smooth targets of quadruple Galois canonical covers that occur are linear $\mathbb{P}^2$ and rational normal scrolls which correspond to only...
three Hirzebruch surfaces, namely $F_0$, $F_1$ and $F_2$. In the case of canonical double covers, linear $P^2$ and smooth rational scrolls corresponding to every Hirzebruch surface appear as an image of the canonical morphism. In the case of canonical triple covers, the list is reduced drastically and the only possible smooth target is linear $P^2$.

The geography of Chern numbers of quadruple Galois canonical covers is markedly different from that of double and triple canonical covers. For double covers the ratio $c_1^2/c_2$ approaches $1/5$ as $p_g$ approaches $\infty$, $c_1^2/c_2$ always being less than $1/5$. In the case of triple covers, $c_1^2/c_2$ only takes three values, the largest of them being $1/7$. For both double and triple covers, $(c_1^2, c_2)$ lies well below the line $c_1^2 = 2c_2$. By contrast, quadruple Galois covers have a much richer geography and traverse a larger region, as can be seen from the previous table. In particular, Chern pairs $(c_1^2, c_2)$ from different families approach two different lines, namely, $c_1^2 = \frac{1}{2}c_2$ and $c_1^2 = 2c_2$. The latter line is actually attained.

The classification of quadruple covers of singular targets in [GP4] together with earlier results on double and triple covers exhibit a striking pattern. Indeed, we show that quadruple covers of singular targets form a bounded family with respect to both the geometric genus and irregularity as in the case of double and triples covers of singular targets. The results in this article and in [GP4] predict a precise numerology, regarding $p_g$ and $q$, that might hold for higher degree covers. The following facts make it clear what we mean: there do not exist canonical covers of odd degree of smooth scrolls (see [GP2] Proposition 3.3) and there do not exist Galois canonical covers $X \rightarrow W$ of prime degree $p > 3$ of surfaces $W$ of minimal degree if $X$ is regular or if $W$ is smooth (see Theorem 7.2, Corollary 7.3 and [GP2, Corollary 3.2]). This motivates us to pose a general question (see Question 7.4) on the non-existence of higher, prime degree Galois canonical covers of surfaces of minimal degree.

The classification obtained in this article and in [GP4] has further applications. In a forthcoming paper we determine the ring generators of the quadruple covers classified here and in [GP4]. These results show that quadruple Galois covers serve as examples and counterexamples to some questions on graded rings and normal generation of linear systems on an algebraic surface.

1. Notation and conventions

Convention. We work over an algebraically closed field of characteristic 0.

Notation 1.1. We will follow these conventions:

(1) Throughout this article, unless otherwise stated, $W$ will be an embedded smooth projective algebraic surface of minimal degree, i.e., whose degree is equal to its codimension in projective space plus 1.

(2) Throughout this article, unless otherwise stated, $X$ will be a projective algebraic normal surface with at worst canonical singularities (that is, rational double points). We will denote by $\omega_X$ the canonical bundle of $X$.

We recall the following standard notation:

(3) By $F_e$ we denote the Hirzebruch surface whose minimal section has self-intersection $-e$. If $e > 0$ let $C_0$ denote the minimal section of $F_e$ and let $f$ be one of the fibers of $F_e$. If $e = 0$, $C_0$ will be a fiber of one of the families of lines and $f$ will be a fiber of the other family of lines.
If $a, b$ are integers such that $0 < a \leq b$, consider two disjoint linear subspaces $P^a$ and $P^b$ of $P^{a+b+1}$. We denote by $S(a, b)$ the smooth rational normal scroll obtained by joining corresponding points of a rational normal curve in $P^a$ and a rational normal curve of $P^b$. Recall that $S(a, b)$ is the image of $F_e$ by the embedding induced by the complete linear series $|C_0 + mf|$, with $a = m - e$, $b = m$, and $m \geq e + 1$.

If $a = b$, the linear series $|mC_0 + f|$ also gives a minimal degree embedding of $F_0$, equivalent to the previous one by the automorphism of $P_1 \times P_1 = F_0$ swapping the factors. In this case our convention will always be to choose $C_0$ and $f$ so that, when $W$ is a smooth rational normal scroll, $W$ is embedded by $|C_0 + mf|$.

If in addition $m = 1$, $C_0$ and $f$ are indistinguishable in both $F_0$ and $S(1, 1)$, so, in such a case, for us $C_0$ will denote the fiber of any of the families of lines of $F_0$ and $f$ will denote the fiber of the other family.

For details about rational ruled surfaces and rational singularities we refer the reader to ([Ba]).

**Definition 1.2.** Let $X$ and $W$ be as in the previous notation.

a) We will say that a surjective morphism $X \xrightarrow{\varphi} W$ is a canonical cover of $W$ if $X$ is a surface of general type whose canonical bundle $\omega_X$ is ample and base-point-free and $\varphi$ is the canonical morphism of $X$.

b) If $G$ is a finite group acting on $X$ so that $X/G = W$ and $X \xrightarrow{\varphi} W$ is the projection from $X$ to $X/G$, then we will say that $X \xrightarrow{\varphi} W$ is a Galois cover with group $G$.

**Remark 1.3.** If $X \xrightarrow{\varphi} W$ is a Galois cover, $\varphi$ is flat since $W$ is smooth.

**Remark 1.4.** Although we have assumed $X$ to have canonical singularities, some results hold in greater generality. Precisely, if for the purpose of this remark we ignore notation 2) above and $X$ is assumed to be a normal, locally Gorenstein surface instead, then Definition 1.2 still makes sense and Theorems 4.1, 5.1, 5.2, 6.1 and 6.2 hold. We can further relax the hypotheses on $X$ in the converse parts of Theorems 4.1, 5.1, 5.2, 6.1 and 6.2, and they hold if $X$ is just assumed to be smooth in codimension 1, since in that case these covers are Gorenstein.

2. **Some general results on quadruple canonical covers**

The fact that a cover $X \xrightarrow{\varphi} W$ is induced by the canonical morphism imposes certain constraints on $\varphi^*O_X$. In this section we exploit this to obtain some useful information on the vector bundle structure of $\varphi^*O_X$. We get more information if $\varphi^*O_X$ splits as a direct sum of line bundles. This is the case for Galois covers, so we will use the results of this section when we study Galois covers in the subsequent sections.

**Proposition 2.1.** Let $X \xrightarrow{\varphi} W$ be a quadruple canonical cover of $W$. Let $H = O_w(1)$.

1. Then $\varphi_*O_X$ is a vector bundle on $W$ and

$$\varphi_*O_X = O_w \oplus E \oplus (\omega_w \otimes H^*)$$

with $E$ a vector bundle over $W$ of rank 2.
(2) If in addition \( \varphi_*\mathcal{O}_X \) splits as a sum of line bundles, then
\[
\varphi_*\mathcal{O}_X = \mathcal{O}_W \oplus L_1^* \oplus L_2^* \oplus (\omega_w \otimes H^*)
\]
with \( L_1^* \otimes L_2^* = \omega_w \otimes H^* \).

Proof. Recall that, by Definition 1.2, \( \varphi \) is finite, \( W \) is smooth and \( X \) is locally Cohen-Macaulay. Then \( \varphi \) is flat and hence \( \varphi_*\mathcal{O}_X \) is a vector bundle over \( \mathcal{O}_W \) of rank 4. Moreover, \( \varphi_*\mathcal{O}_X = \mathcal{O}_W \oplus E' \), where \( E' \) is the trace zero module of \( \varphi \). From relative duality we have
\[
\varphi_*\omega_X = (\varphi_*\mathcal{O}_X)^* \otimes \omega_w.
\]

On the other hand, by hypothesis, \( \omega_X = \varphi^*H \), hence, by projection formula,
\[
\varphi_*\omega_X = \varphi_*\mathcal{O}_X \otimes H.
\]

Then
\[
\omega_w \oplus (\omega_w \otimes (E')^*) = H \oplus (E' \otimes H).
\]

Since \( \omega_w = H \) is not possible, for \( W \) a rational surface, \( E' = E \oplus (\omega_w \otimes H^*) \), with \( E \) a vector bundle of rank 2. If \( \varphi_*\mathcal{O}_X \) splits, let \( E = L_1^* \oplus L_2^* \). Then
\[
\omega_w \oplus (\omega_w \otimes L_1^*) \oplus (\omega_w \otimes L_2^*) \oplus H = H \oplus (H \otimes L_1^*) \oplus (H \otimes L_2^*) \oplus \omega_w.
\]

Then taking the determinant of both sides of the equality gives \( (L_1^* \otimes L_2^*)\otimes^2 = (\omega_w \otimes H^*)\otimes^2 \). Since \( W \) is either \( \mathbb{P}^2 \) or a Hirzebruch surface, then \( L_1^* \otimes L_2^* = \omega_w \otimes H^* \). \( \square \)

Now we study in more detail the possible splittings of \( \varphi_*\mathcal{O}_X \) depending on what surface \( W \) is. We start with this observation about linear \( \mathbb{P}^2 \):

**Proposition 2.2.** Let \( X \xrightarrow{\varphi} W \) be a canonical cover. If \( W \) is linear \( \mathbb{P}^2 \), then \( X \) is regular if and only if \( \varphi_*\mathcal{O}_W \) splits as a direct sum of line bundles.

Proof. By Proposition 2.1 we know that
\[
\varphi_*\mathcal{O}_X = \mathcal{O}_W \oplus E \oplus \omega_w (-1).
\]

Since \( W = \mathbb{P}^2 \), the intermediate cohomology of line bundles on \( W \) vanishes, so by projection formula \( H^1(\varphi^*\mathcal{O}_W(k)) = H^1(E(k)) \). By Kodaira vanishing and duality \( H^1(\varphi^*\mathcal{O}_W(k)) = 0 \) except maybe if \( k = 0,1 \). Then \( X \) is regular if and only if \( H^1(E(k)) = 0 \) for all \( k \), and by Horrocks’ Splitting Criterion, this is equivalent to the splitting of \( E \). Thus \( X \) is regular if and only if \( \varphi_*\mathcal{O}_X \) splits as a direct sum of line bundles. \( \square \)

The following proposition tells how the restriction of \( \varphi_*\mathcal{O}_X \) to a smooth curve in \(|\omega_X| \) splits:

**Proposition 2.3.** Let \( W \) be a surface of minimal degree \( r \), not necessarily smooth, let \( X \xrightarrow{\varphi} W \) be a canonical cover of degree 4 and let \( C \) be a general smooth irreducible curve in \( |\omega_w (1)| \). If \( X \) is regular, then
\[
(\varphi_*\mathcal{O}_X)|_C = \mathcal{O}_{\mathbb{P}^1} \oplus \mathcal{O}_{\mathbb{P}^1}(-r-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-r-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-2r-2).
\]

Proof. See [GP2] Lemma 2.3 for details. \( \square \)
Finally we describe more accurately the splitting of $\varphi_*O_X$ in the case where $X$ is regular:

**Proposition 2.4.** Let $X \to W$ be a quadruple canonical cover. If $\varphi_*O_X$ splits as a direct sum of line bundles, then:

1. If $W$ is linear $\mathbb{P}^2$, then
   \[ \varphi_*O_X = O_{\mathbb{P}^2} \oplus O_{\mathbb{P}^2}(-2) \oplus O_{\mathbb{P}^2}(-2) \oplus O_{\mathbb{P}^2}(-4) ; \]

2. If $W$ is not the Veronese surface; and
3. If $W$ is a rational normal scroll and $X$ is regular, then
   \[ \varphi_*O_X = O_w \oplus O_w(-C_0 - (m + 1)f) \]
   \[ \oplus O_w(-2C_0 - (e + 1)f) \oplus O_w(-3C_0 - (m + e + 2)f), \]
   where $2m - e$ is the degree of $W$.

**Proof.** To prove (1) recall that, by Proposition 2.2, $X$ is regular. Then by Proposition 2.3 the restriction of $\varphi_*O_X$ to a line of $W$ is
\[ O_{\mathbb{P}^1} \oplus O_{\mathbb{P}^1}(-2) \oplus O_{\mathbb{P}^1}(-2) \oplus O_{\mathbb{P}^1}(-4), \]
so (1) is clear.

For (2) $W$ is isomorphic to $\mathbb{P}^2$ and $O_w(1) = O_{\mathbb{P}^2}(2)$. Then, by Proposition 2.1 $\varphi_*O_X = O_{\mathbb{P}^2} \oplus E \oplus O_{\mathbb{P}^2}(-5)$. Let $C$ be a smooth conic in $W$. If $X$ is irregular, then by Proposition 2.4 $\varphi_*O_X$ cannot split completely. If $X$ is regular, then according to Proposition 2.3
\[ \left( \varphi_*O_X \right)_C = O_{\mathbb{P}^1} \oplus O_{\mathbb{P}^1}(-5) \oplus O_{\mathbb{P}^1}(-5) \oplus O_{\mathbb{P}^1}(-10). \]
Then if $E = L_1^* \oplus L_2^*$ with $L_1$ and $L_2$ line bundles, $L_1^*|C = L_2^*|C = O_{\mathbb{P}^1}(-5)$, but since $C$ is a conic the degrees of $L_1|C$ and $L_2|C$ are even integers, so we get a contradiction.

For (3) recall that $\omega_w = O_w(-2C_0 - (e + 2)f)$ and that $O_w(1) = O_w(C_0 + mf)$. Then it follows by assumption and Proposition 2.1 that
\[ \varphi_*O_X = O_w \oplus L_1^* \oplus L_2^* \oplus O_w(-3C_0 - (m + e + 2)f), \]
and $L_1 \otimes L_2 = O_w(3C_0 + (m + e + 2)f)$. Then, if we set $L_1 = O_w(a_1C_0 + b_1f)$ and $L_2 = O_w(a_2C_0 + b_2f)$, it follows that
\[ a_1 + a_2 = 3, \]
\[ b_1 + b_2 = m + e + 2. \]
We now show that $a_i \geq 1$ for $i = 1, 2$. Since $\varphi$ is induced by the complete linear series of $\varphi^*O_w(C_0 + mf)$, then $(1 - a_i)C_0 + (m - b_i)f$ is non-effective. Then, if $a_i \leq 0$, $b_i \geq m + 1$. On the other hand, since $X$ is regular and $H^1(L_1^*) \subset H^1(\varphi_*O_X) = 0$, it follows that $H^1(O_w(-a_iC_0 - b_i f)) = 0$. Then, if $a_i \leq 0$, $b_i \leq 1$, then $m \leq 0$, which is impossible, because $m \geq e + 1 \geq 1$. Then, since $a_1 + a_2 = 3$, $a_i$ is either 1 or 2. Let us set $a_1 = 1$. Then, since $(1 - a_1)C_0 + (m - b_1)f$ cannot be effective, $b_1 \geq m + 1$. On the other hand, $a_2 = 2$, and since $0 = h^1(L_2^*) = h^1(O_w(-2C_0 - b_2 f)) = h^1(O_w(b_2 - e - 2f)) = h^1(O_{\mathbb{P}^1}(b_2 - e - 2))$, then $b_2 \geq e + 1$. Since $b_1 + b_2 = m + e + 2$, then $b_1 = m + 1$ and $b_2 = e + 1$.

The purpose of this paper is to study canonical quadruple Galois covers, and we will focus on them in the next sections. Meanwhile, Proposition 2.4 already yields a fact regarding these covers which is worth remarking. Note that a canonical Galois
cover of the Veronese surface is flat, because the Veronese surface is smooth. Then, 
being \( \varphi \) flat and Galois, \( \varphi_*O_X \) splits completely, so we have this

**Corollary 2.5.** There are no quadruple Galois canonical covers of the Veronese surface.

### 3. General description of quadruple Galois canonical covers

If \( X \overset{\varphi}{\longrightarrow} W \) is a Galois cover, it is well known that the action on \( X \) of the Galois group decomposes \( \varphi_*O_X \) as a direct sum of eigensheaves. On the other hand \( \varphi_*O_X \) is a sheaf of \( O_W \)-algebras, whose multiplicative structure can be described explicitly and is well known (see for instance [HM] or [Ca]). In the case of Galois canonical covers of surfaces, Proposition 2.1 (2) gives us some extra information, and the multiplicative structure becomes simpler to state. This is done in Remark 3.1 below; in Corollary 3.2 we translate this data into a geometric description.

**Remark 3.1.** Let \( X \overset{\varphi}{\longrightarrow} W \) be a quadruple Galois canonical cover with Galois group \( G \) and let

\[
\varphi_*O_X = O_W \oplus L_1^* \oplus L_2^* \oplus L_3^*
\]

be the splitting of \( \varphi_*O_X \) as a sum of line bundles induced by the action of \( G \), for which \( L_1 \otimes L_2 = L_3 \) (this is possible by Proposition 2.1 (2)). Then

1. If \( G = \mathbb{Z}_2 \times \mathbb{Z}_2 \), there exist effective Cartier divisors \( D_1, D_2 \) and \( D_3 \) so that the multiplicative structure of \( \varphi_*O_X \) works as follows:

\[
L_1^* \otimes L_1^* \xrightarrow{-D_3+D_2} O_W, \\
L_2^* \otimes L_2^* \xrightarrow{-D_1} O_W, \\
L_2^* \otimes L_3^* \xrightarrow{-D_1} O_W, \\
L_3^* \otimes L_3^* \xrightarrow{-D_1+D_2} O_W.
\]

2. If \( G = \mathbb{Z}_4 \), there exist effective Cartier divisors \( D_1 \) and \( D_2 \) on \( W \) so that the multiplicative structure of \( \varphi_*O_X \) works as follows:

\[
L_1^* \otimes L_1^* \xrightarrow{-D_1} L_2^*, \\
L_1^* \otimes L_2^* \xrightarrow{-D_1} L_3^*, \\
L_1^* \otimes L_3^* \xrightarrow{-D_1+D_2} O_W, \\
L_2^* \otimes L_2^* \xrightarrow{-D_2} O_W, \\
L_2^* \otimes L_3^* \xrightarrow{-D_2} O_W, \\
L_3^* \otimes L_3^* \xrightarrow{-D_1+D_2} O_W.
\]

**Corollary 3.2.** Let \( X \overset{\varphi}{\longrightarrow} W \) be a canonical Galois cover of a smooth surface of minimal degree with Galois group \( G \) and keep the notation in Remark 3.1. Then,

1. If \( G = \mathbb{Z}_2 \times \mathbb{Z}_2 \), \( X \) is the fiber product over \( W \) of two double covers, \( X_1 \overset{p_1}{\longrightarrow} W \) and \( X_2 \overset{p_2}{\longrightarrow} W \), branched along \( D_2 \) and \( D_1 \), respectively, and \( \varphi \) is the natural map from the fiber product to \( W \);

2. If \( G = \mathbb{Z}_4 \), the cover \( X \overset{\varphi}{\longrightarrow} W \) is obtained as a composition of two double covers, \( X \overset{p_2}{\longrightarrow} X' \) and \( X' \overset{p_1}{\longrightarrow} W \), as follows:
   a) \( p_1 \) is branched along \( D_2 \);
   b) \( p_2 \) is branched along the ramification of \( p_1 \) and along \( p^{-1}D_1 \), and its trace zero module is \( p_1^*(L_1^*) \).
Proof: If \( G = \mathbb{Z}_2 \times \mathbb{Z}_2 \), then the \( O_W \)-algebra \( p_* O_X \) has three subalgebras \( O_{w_i} \oplus L_i^* \) corresponding to three double covers \( X_i \xrightarrow{p_i} W \) for \( i = 1, 2, 3 \) which are branched along \( D_j + D_k \) where \( i \neq j, j \neq k, k \neq i \). Recall (see Remark 3.1) that \( L_1 \oplus L_2 = L_3 \) and therefore \( D_3 = 0 \), hence \( X_1 \xrightarrow{p_1} W \) is branched along \( D_2 \) and \( X_2 \xrightarrow{p_2} W \) is branched along \( D_1 \). Then a local argument shows that the algebra structure of \( p_* O_X \) described in Remark 3.1 (1) is in fact the tensor product over \( O_w \) of the algebras \( O_{w_i} \oplus L_i^* \) and \( O_w \oplus L_2^* \).

If \( G = \mathbb{Z}_4 \), then the \( O_w \)-algebra \( p_* O_X \) has one proper subalgebra, namely \( O_w \oplus L_2^* \). This induces an intermediate cover \( X' \xrightarrow{p_1} W \), branched along \( D_2 \). Looking locally at the multiplicative structure described in Remark 3.1 (2) yields the rest of the geometric description of \( p_2 \).

\[ \square \]

4. Galois Covers of \( \mathbb{P}^2 \)

In this section we deal with the easier case of canonical covers of the projective plane. A priori one could distinguish two cases: either \( W \) is linear \( \mathbb{P}^2 \) or \( W \) is the Veronese surface. However, as pointed out in Corollary 2.3 there are no canonical quadruple Galois covers of the Veronese surface, so we will only have to study the case of \( W \) being linear \( \mathbb{P}^2 \).

\textbf{Theorem 4.1.} Let \( W \) be linear \( \mathbb{P}^2 \) and let \( X \twoheadrightarrow W \) be a quadruple Galois canonical cover.

(1) If the Galois group of \( \varphi \) is \( \mathbb{Z}_4 \), then \( \varphi \) is the composition of two flat double covers \( X_1 \xrightarrow{p_1} W \) and \( X \xrightarrow{p_2} X_1 \); the cover \( p_1 \) is branched along a quartic and the cover \( p_2 \) is branched along the ramification of \( p_1 \) and the pullback by \( p_1 \) of a conic, and its trace zero module is \( p_1^* O_{\mathbb{P}^2}/(2) \).

(2) If the Galois group of \( \varphi \) is \( \mathbb{Z}_2 \times \mathbb{Z}_2 \), then \( X \) is the fiber product over \( W \) of two double covers of linear \( \mathbb{P}^2 \), each of them branched along a quartic, and \( \varphi \) is the natural map from the fiber product to \( W \).

Conversely, let \( X \twoheadrightarrow W \) be a cover of linear \( \mathbb{P}^2 \).

(1') If \( \varphi \) is the composition of two flat double covers \( X_1 \xrightarrow{p_1} W \) and \( X \xrightarrow{p_2} X_1 \) as described in 1) above, then \( \varphi \) is a Galois canonical cover with group \( \mathbb{Z}_4 \).

(2') If \( \varphi \) is the natural map to \( W \) from the fiber product over \( W \) of two double covers as described in 2) above, then \( \varphi \) is a Galois canonical cover with group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \).

\textbf{Proof.} Corollary 3.2 tells the general structure of \( \varphi \), so, to prove (1) and (2) we only need to find out the degrees of the branch divisors. This follows from Proposition 2.3. Now we prove the converse. Clearly, a cover \( \varphi \) as in (1') is Galois with group \( \mathbb{Z}_4 \). Likewise, a cover \( \varphi \) as in (2') is Galois with group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \). On the other hand, it easily follows from the ramification formula that the canonical of \( X \) is \( \varphi^* O_{\mathbb{P}^2}(1) \), so in particular \( X \) is a surface of general type and \( \omega_X \) is base-point-free. Finally to prove that \( \varphi \) is indeed the morphism induced by \( H^0(\omega_X) \) we see that \( H^0(\varphi^* O_{\mathbb{P}^2}(1)) = H^0(O_{\mathbb{P}^2}(1)) \). Indeed, a morphism as in 1') or 2') satisfies

\[ \varphi_* O_X = O_{\mathbb{P}^2} \oplus O_{\mathbb{P}^2}(-2) \oplus O_{\mathbb{P}^2}(-2) \oplus O_{\mathbb{P}^2}(-4), \]

hence the equality follows from pushing down \( \varphi^* O_{\mathbb{P}^2}(1) \) to \( W \) and computing global sections there. \[ \square \]
We further describe the Galois covers appearing in Theorem 4.1.

**Corollary 4.2.** Let \( W \) be linear \( \mathbb{P}^2 \) and let \( X \xrightarrow{\varphi} W \) be a Galois canonical cover of degree 4. If the Galois group of \( \varphi \) is \( \mathbb{Z}_4 \), then \( X \) is singular and the mildest possible set of singularities on \( X \) consists of 8 points of type \( A_1 \).

**Proof.** Just observe that \( X_1 \xrightarrow{p_1} W \) is branched along a quartic \( D_2 \) of \( \mathbb{P}^2 \) and \( X \xrightarrow{p_2} X_1 \) is branched along the ramification of \( p_1 \) and \( p_1^* D_1 \), where \( D_1 \) is a conic of \( \mathbb{P}^2 \). If \( D_1 \) and \( D_2 \) are both smooth and meet transversally, then \( X_1 \) is smooth and the branch locus of \( p_2 \) has 8 singular points of type \( A_1 \), so \( X \) is smooth except at 8 points, which are singularities of type \( A_1 \). \( \square \)

We end the section by remarking the existence of examples of covers like those appearing in Theorem 4.1.

**Proposition 4.3.** Let \( W \) be linear \( \mathbb{P}^2 \).

1. There exist canonical covers \( X \xrightarrow{\varphi} W \) with Galois group \( \mathbb{Z}_4 \) (that is, covers as in Theorem 4.1 (1)) with 8 singularities of type \( A_1 \) as only singularities.
2. There exist canonical covers \( X \xrightarrow{\varphi} W \) with Galois group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \) (that is, covers as in Theorem 4.1 (2)) with \( X \) smooth.

**Proof.** We first deal with (1). By the converse part in Theorem 4.1 and following the notation and arguments of the proof of Corollary 4.2 it suffices to choose a smooth quartic as \( D_1 \) and a smooth conic as \( D_2 \), meeting transversally. This is possible by Bertini. Analogously, for (2) it suffices to pick two smooth quartics, meeting transversally, as branch divisors. Note that, in both cases, one can construct examples of \( X \) with worse singularities by allowing \( D_1 + D_2 \) to have worse singularities. \( \square \)

## 5. Bidouble covers of rational normal scrolls

In the next two sections we proceed to classify quadruple Galois canonical covers of smooth rational normal scrolls. We start by those with Galois group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \).

Having in account Corollary 3.2, we already know that they are the fiber product of two double covers. Thus to complete their description we will find out what are the branch loci of the double covers. We start with the case where \( X \) is regular.

**Theorem 5.1.** Let \( W = S(m-e, m) \) be a smooth rational normal scroll. If \( X \) is regular and \( X \xrightarrow{\varphi} W \) is a Galois canonical cover with Galois group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \), then \( X \) is the fiber product over \( W \) of two double covers of \( X_1 \xrightarrow{p_1} W \) and \( X_2 \xrightarrow{p_2} W \) and \( \varphi \) is the natural map from the fiber product to \( W \). Let the branch divisors \( D_2 \), \( D_1 \) of \( p_1, p_2 \) be linearly equivalent to \( 2a_2 C_0 + 2b_2 f \) and \( 2a_1 C_0 + 2b_1 f \), respectively. Then \( 0 \leq e \leq 2, m \geq e + 1, a_1 = 1, a_2 = 2, b_1 = m + 1 \) and \( b_2 = e + 1 \).

Conversely, let \( W = S(m, m-e) \) be such that \( 0 \leq e \leq 2 \) and \( m \geq e + 1 \) and let \( X \xrightarrow{\varphi} W \) be the natural map to \( W \) from the fiber product over \( W \) of two flat double covers \( p_1 \) and \( p_2 \) with branch divisors as described above. Then \( X \) is regular and \( X \xrightarrow{\varphi} W \) is a Galois canonical cover with Galois group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \).

**Proof.** Since \( X \) is regular, Proposition 2.3 (3) yields

\[
\varphi_* \mathcal{O}_X = \mathcal{O}_W \oplus \mathcal{O}_W(-C_0 - (m+1)f) \oplus \mathcal{O}_W(-2C_0 - (e+1)f) \oplus \mathcal{O}_W(-3C_0 - (m + e + 2)f).
\]
Then Remark 3.1 and Corollary 3.2 tell us that $X$ is the fiber product over $W$ of two double covers of $X_1 \xrightarrow{p_1} W$ and $X_2 \xrightarrow{p_2} W$ with trace zero modules $L_1^* = \mathcal{O}_W(-2C_0 - (e+1)f)$ and $L_2^* = \mathcal{O}_W(-C_0 - (m+1)f)$, respectively, or equivalently, branched along divisors $D_2 \sim 4C_0 + 2(e+1)f$ and $D_1 \sim 2C_0 + 2(m+1)f$, respectively. Thus $a_1 = 1, a_2 = 2, b_1 = m+1$ and $b_2 = e+1$. Recall that $W$ is isomorphic to the Hirzebruch surface $F_e$. Since $W$ is smooth, $m \geq e+1$, hence the only thing left to prove is $e \leq 2$. The covers $p_1$ and $p_2$ fit in the commutative diagram

$$
\begin{array}{c}
X \\ \downarrow p_1' \\
X_1
\end{array}
\begin{array}{c}
\rightarrow \\
\downarrow p_1
\end{array}
\begin{array}{c}
X_2 \xrightarrow{p_1} W \\
\downarrow p_2
\end{array}
\begin{array}{c}
\rightarrow \\
\downarrow p_2 \\
W
\end{array}
$$

where $p_1'$ and $p_2'$ are also double covers. Moreover the branch divisor of $p_1'$ is $p_2^*D_2$. Suppose that $e \geq 3$. Then, since $D_2$ is linearly equivalent to $4C_0 + (2e+2)f$, $D_2$ has $2C_0$ as a fixed component. Then the branch divisor of $p_1'$ is non-reduced, so $X$ is non-normal and we get a contradiction. Therefore $e = 0, 1$ or 2.

To prove the converse assume now that $X \xrightarrow{\varphi} W$ is the natural map from the fiber product over a smooth scroll $W = S(m, m-e)$ of two double covers $p_1$ and $p_2$ of $W$, branched, respectively, along divisors $D_2$ linearly equivalent to $2a_2C_0 + 2b_2f$ and $D_1$ linearly equivalent to $2a_1C_0 + 2b_1f$. Assume in addition that $0 \leq e \leq 2$, $a_1 = 1, a_2 = 2, b_1 = m+1$ and $b_2 = e+1$. Then it is clear that $\varphi$ is a Galois cover with Galois group $\mathbb{Z}_2 \times \mathbb{Z}_2$ and

$$
\varphi_* \mathcal{O}_X = \mathcal{O}_W \oplus \mathcal{O}_W(-a_1C_0 - b_1f) \\
\oplus \mathcal{O}_W(-a_2C_0 - b_2f) \oplus \mathcal{O}_W(-(a_1 + a_2)C_0 - (b_1 + b_2)f).
$$

A standard computation shows that none of the four direct summands of $p_*\mathcal{O}_X$ have intermediate cohomology, hence $H^1(\mathcal{O}_X) = 0$. On the other hand if $L_2 = \mathcal{O}_W(a_1C_0 + b_1f)$ and $L_1 = \mathcal{O}_W(a_2C_0 + b_2f)$, then $L_1 \oplus L_2 = \mathcal{O}_W(3C_0 + (m+e+2)f) = \omega^*_W(1)$. Then, by the ramification formula $\omega_X = \varphi^*\omega_W(1)$ so $X$ is a surface of general type whose canonical bundle is base-point-free. The only thing left to be shown is that $X \xrightarrow{\varphi} W$ is the canonical morphism of $X$. For that it is enough to see that $H^0(\mathcal{O}_W(1)) = H^0(\omega_X)$. But

$$
H^0(\omega_X) = H^0(\varphi^*\mathcal{O}_W(C_0 + mf)) \\
= H^0(\mathcal{O}_W(C_0 + mf)) \oplus H^0(\mathcal{O}_W((1-a_1)C_0 + (m-b_1)f)) \\
\oplus H^0(\mathcal{O}_W((1-a_2)C_0 + (m-b_2)f)) \\
\oplus H^0(\mathcal{O}_W(1-a_1-a_2)C_0 + (m-b_1-b_2)f).
$$

Now, because of the restrictions on $a_1, a_2, b_1$ and $b_2$, $H^0(\mathcal{O}_W((1-a_1)C_0 + (m-b_1)f))$, $H^0(\mathcal{O}_W((1-a_2)C_0 + (m-b_2)f))$ and $H^0(\mathcal{O}_W(1-a_1-a_2)C_0 + (m-b_1-b_2)f)$ vanish.

Now we go on to classify Galois quadrupe covers with group $\mathbb{Z}_2 \times \mathbb{Z}_2$ when $X$ is irregular:

**Theorem 5.2.** Let $W$ be a smooth rational normal scroll $S(m, m-e)$. If $X$ is irregular and $X \xrightarrow{\varphi} W$ is a Galois canonical cover with Galois group $\mathbb{Z}_2 \times \mathbb{Z}_2$, then $X$ is the fiber product over $W$ of two double covers of $X_1 \xrightarrow{p_1} W$ and $X_2 \xrightarrow{p_2} W$. 

and \( \varphi \) is the natural map from the fiber product to \( W \). Let the branch divisors \( D_2, D_1 \) of \( p_1, p_2 \) be linearly equivalent to \( 2a_2C_0 + 2b_2f \) and \( 2a_1C_0 + 2b_1f \), respectively. Then \( e = 0, m \geq 1 \) and one of the following happens:

1. \( a_1 = 0, a_2 = 3, b_1 = m + 1, b_2 = 1. \)
2. \( a_1 = 0, a_2 = 3, b_1 = m + 2, b_2 = 0. \)
3. \( a_1 = 1, a_2 = 2, b_1 = m + 2, b_2 = 0. \)

In addition, in case (1), \( q(X) = m; \) in case (2), \( q(X) = m + 3; \) and in case (3), \( q(X) = 1. \)

Conversely, let \( X \xrightarrow{\varphi} W \) be the natural map to \( W = S(m, m) \) from the fiber product over \( W \) of two flat double covers \( p_1 \) and \( p_2 \) with branch divisors satisfying (1), (2), or (3) above. Then \( X \) is irregular and \( X \xrightarrow{\varphi} W \) is a Galois cover with Galois group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \).

Proof. From Proposition 2.1 and Corollary 3.2 it follows that \( X \) is the fiber product of two double covers branched along divisors

\[
D_2 \sim 2(a_2C_0 + b_2f) \quad \text{and} \quad D_1 \sim 2(a_1C_0 + b_1f),
\]

respectively, that

\[
\varphi^*\mathcal{O}_X = \mathcal{O}_W \oplus \mathcal{O}_W (-a_1C_0 - b_1f)
\]

\[
\oplus \mathcal{O}_W (-a_2C_0 - b_2f) \oplus \mathcal{O}_W ((-a_1 + a_2)C_0 - (b_1 + b_2)f)
\]

and \( \omega_w(-1) = \mathcal{O}_W (-a_1 + a_2)C_0 - (b_1 + b_2)f \). Since \( \omega_w = \mathcal{O}_W (-2C_0 - (e + 2)f) \), we obtain

\[
a_1 + a_2 = 3, \quad b_1 + b_2 = m + e + 2.
\]

On the other hand since \( D_1 \) is effective and linearly equivalent to \( 2(a_1C_0 + b_1f) \), then \( a_1, b_1 \geq 0 \). We set \( a_1 = 0, 1 \) (in which case, \( a_2 = 3, 2 \). Since \( \varphi \) is induced by the complete linear series of \( \varphi^*\mathcal{O}_w(C_0 + m) \), then \( H^0(\mathcal{O}_w(1-a_1)C_0 + (m-b_1)f) = 0 \), hence \( b_1 \geq m+1 \), and from \( 5.2.1 \), \( b_2 \leq e+1 \). Since both \( b_1 \) and \( b_2 \) are non-negative, \( m + 1 \leq b_1 \leq m + e + 2 \) and \( 0 \leq b_2 \leq e + 1 \).

Now assume \( a_1 = 0 \). Then \( D_2 \) is linearly equivalent to \( 6C_0 + 2b_2f \). Assume also that \( e \geq 1 \). Then \( 2C_0 \) is a fixed component of \( D_2 \), therefore by the argument made in the proof of Theorem 5.1 \( X \) would be non-normal, hence, if \( a_1 = 0 \), then \( e = 0 \). Then, we have two possibilities: first, \( b_1 = m + 1 \) and \( b_2 = 1 \), and second, \( b_1 = m + 2 \) and \( b_2 = 0 \). In the first case, \( q(X) = m \). In the second case, \( q(X) = m + 3 \).

Now assume \( a_1 = 1 \). Then \( D_2 \) is linearly equivalent to \( 4C_0 + 2b_2f \), and as we argued in the proof of Theorem 5.1 if \( e \geq 3 \), \( X \) would be non-normal, hence \( 0 \leq e \leq 2 \). Moreover, if \( b_2 < \frac{4e}{7} \), \( D_2 \) would have \( 2C_0 \) as a fixed component and \( X \) would be non-normal, hence \( b_2 \geq \frac{4e}{7} \). Recall also that \( b_2 \leq e + 1 \). Let us now assume that \( b_2 = e + 1 \). Then \( b_1 = m + 1 \) and in that case

\[
\varphi^*\mathcal{O}_X = \mathcal{O}_W \oplus \mathcal{O}_W (-C_0 + (m + 1)f)
\]

\[
\oplus \mathcal{O}_W (-2C_0 - (e + 1)f) \oplus \mathcal{O}_W (-3C_0 - (m + e + 2)f).
\]

But then \( H^1(\mathcal{O}_w), H^1(\mathcal{O}_w(-C_0 - (m + 1)f)), H^1(\mathcal{O}_w(-2C_0 - (e + 1)f)) \) and \( H^1(\mathcal{O}_w(-3C_0 - (m + e + 2)f)) \) all vanish, hence \( X \) would be regular. Therefore \( \frac{4e}{7} \leq b_2 \leq e \). This implies that \( e = 0 \) and \( b_2 = 0 \), in which case \( b_1 = m + 2 \). Then \( q(X) = 1 \). With this we prove that \( W = S(m, m) \) and that the only possibilities for the \( a_i \)s, \( b_i \)s are (1), (2) and (3).
To prove the converse, assume now that $X \xrightarrow{\varphi} W$ is the fiber product over $W$ of two double covers $p_1$ and $p_2$ of $W$, branched, respectively, along divisors $D_2$ linearly equivalent to $2a_2C_0 + 2b_2f$ and $D_1$ linearly equivalent to $2a_1C_0 + 2b_1f$ satisfying one of the cases (1), (2) or (3). Then it is clear that $\varphi$ is a Galois cover with Galois group $\mathbb{Z}_2 \times \mathbb{Z}_2$, and

$$\varphi_*\mathcal{O}_X = \mathcal{O}_W \oplus \mathcal{O}_W (-a_1C_0 - b_1f)$$

$$\oplus \mathcal{O}_W (-a_2C_0 - b_2f) \oplus \mathcal{O}_W (- (a_1 + a_2)C_0 - (b_1 + b_2)f)$$

with $a_1, a_2, b_1, b_2$ satisfying (1), (2) or (3). Computing the cohomology of the four direct summands of $\varphi_*\mathcal{O}_X$ in each case shows that $X$ is always irregular. On the other hand, $\omega_X = \varphi^*\mathcal{O}_W(1)$ by the ramification formula and, in particular, $\omega_X$ is base-point-free and $X$ is a surface of general type. Finally one easily sees that $X \xrightarrow{\varphi} W$ is the canonical morphism of $X$ by showing that $H^0(\mathcal{O}_W (1)) = H^0(\omega_X)$ as in the proof of Theorem 5.1.

□

Remark 5.3. The description of $D_1$ and $D_2$ yields that, in case (2) of Theorem 5.2, $X$ is actually the product of a curve of genus $m + 1$ and a curve of genus 3. This type of surface appears in the examples constructed by Beauville in $[Be]$. In the cases described in Theorem 5.2 (1), Theorem 5.2 (3) and Theorem 5.2 there is also a simpler description for $X$: it can be seen as a double cover, branched along a suitable divisor, of the product of $C \times \mathbb{P}^1$, where $C$ is a curve of genus $m$ or 1, respectively.

We end the section showing the existence of canonical covers such as the ones classified in Theorems 5.1 and 5.2.

Proposition 5.4. There exist families of canonical Galois quadruple covers $X \xrightarrow{\varphi} W$ as in Theorem 5.1 and Theorem 5.2 (1), (2) and (3) with $X$ smooth.

Proof. Families satisfying Theorem 5.1 for $W$ isomorphic to $F_0$ and $F_1$ have been constructed in $[GP2]$ Examples 3.4 and 3.5 (see also $[Pe]$ for an example of a bidual cover of $\mathbb{P}^1 \times \mathbb{P}^1$). To construct the remaining examples we argue as in Proposition 4.3. By the converse part of Theorems 5.1 and 5.2 we only need to construct the fiber product of two double covers $X_1 \xrightarrow{p_1} W$ and $X_2 \xrightarrow{p_2} W$ branched along suitable divisors $D_2$ and $D_1$ satisfying the conditions in the statement of Theorems 5.1 and 5.2. Precisely if we choose $D_1$ and $D_2$ smooth and meeting transversally, $X$ will be smooth. This can be achieved using Bertini once we study how the divisors $D_1$ and $D_2$ are in each case. Indeed, if we are in the situation of Theorem 5.1 when $W$ is isomorphic to $F_2$, then $D_1 \sim 2C_0 + (m + 1)f$ is very ample and $D_2$, since it is linearly equivalent to $4C_0 + 6f$, is of the form $C_0 + D'_2$, with $D'_2 \cdot C_0 = 0$ and $D'_2$ base-point-free.

In the cases of Theorem 5.2 (1), (2) and (3) recall that $W$ is isomorphic to $F_0$. In the case of Theorem 5.2 (1) $D_1 \sim 2(m + 1)f$, hence it can be chosen as the union of $2(m + 1)$ distinct lines in one of the two fibrations of $F_0$, and $D_2$ is linearly equivalent to $6C_0 + 2f$, which is very ample.

In the case of Theorem 5.2 (3), $D_1 \sim 2C_0 + (m + 2)f$ is very ample and $D_2 \sim 4C_0$ can be chosen as the union of 4 distinct lines of one of the fibrations of $F_0$. Finally, in the case of Theorem 5.2 (2), $D_1$ and $D_2$ can both be taken as the union of distinct lines. Note that one can construct $X$ having singularities if $D_1 + D_2$ is allowed to have worse singularities. □
6. Cyclic covers of rational normal scrolls

In this section we study canonical Galois covers, with group \( \mathbb{Z}_4 \), of rational normal scrolls. We again split the cases \( X \) regular and \( X \) irregular. One of the facts we prove is that these covers are never simple cyclic, as in the case of \( \mathbb{P}^2 \). As we will see in Section 7, there are deeper reasons for this. Another interesting fact we see is that these covers are always singular, having at best singularities of type \( A_1 \).

**Theorem 6.1.** Let \( X \xrightarrow{\varphi} W \) be a Galois canonical cover of degree 4 and Galois group \( \mathbb{Z}_4 \) with \( X \) regular and let \( W = S(m - e, m) \) be a smooth rational normal scroll. Then \( \varphi \) is the composition of two flat double covers \( X_1 \xrightarrow{p_1} W \) and \( X \xrightarrow{p_2} X_1 \) which are as follows:

1. The cover \( p_1 \) is branched along a divisor \( D_2 \) on \( W \).
2. The cover \( p_2 \) is branched along the ramification of \( p_1 \) and \( p_1^*D_1 \) and has trace zero module \( p_1^*O_Y\left(-\frac{1}{2}D_1 - \frac{1}{2}D_2\right) \), where \( D_1 \) is a divisor on \( W \).
3. The scroll \( W = 5(m - e, m) \), with \( 0 \leq e \leq 2 \) and \( m \geq e + 1 \), and the divisors \( D_1 \sim (2m - e + 1)f, D_2 \sim 4C_0 + (2e + 2)f \).

Conversely, let \( X \xrightarrow{\varphi} W \) be the composition of two flat double covers \( X_1 \xrightarrow{p_1} W \) and \( X \xrightarrow{p_2} X_1 \) as described above; then \( \varphi \) is a Galois canonical cover of \( W \) with Galois group \( \mathbb{Z}_4 \) and \( X \) is regular.

**Proof.** Corollary 3.2 says that \( \varphi \) is the composition of two double covers \( X_1 \xrightarrow{p_1} W \), branched along a divisor \( D_2 \), and \( X \xrightarrow{p_2} X_1 \), branched along the ramification of \( p_1 \) and \( p_1^*D_1 \), and, according to Remark 3.1,

\[ \varphi_*O_X = O_w \oplus L_1^* \oplus L_2^* \oplus L_3^* , \]

where \( L_1 \otimes L_2 = L_3 \). Moreover,

\[ L_3 = \omega_w^*(1), L_1^\otimes = L_2 \otimes O_w(D_1), L_2^\otimes = O_w(D_2), \]

\( p_1^*L_1^* \) is the trace zero module of \( p_2 \) and \( L_2^* \) is the trace zero module of \( p_1 \). From this we obtain that the trace zero module of \( p_2 \) is \( p_1^*L_1^* = p_1^*O_Y\left(-\frac{1}{2}D_1 - \frac{1}{2}D_2\right) \).

Now we show that \( W, D_1 \) and \( D_2 \) satisfy (3). Recall that \( W \) is isomorphic to \( \mathbb{F}_4 \).

Since \( X \) is regular we can apply Proposition 2.4 (3). Then, since \( L_3 = \omega_w^*(1) \) we have either

\[ L_1^* = O_w(-C_0 - (m + 1)f), L_2^* = O_w(-2C_0 - (e + 1)f) \]

and \( L_3^* = O_w(-3C_0 - (m + e + 2)f) \) or

\[ L_2^* = O_w(-C_0 - (m + 1)f), L_1^* = O_w(-2C_0 - (e + 1)f) \]

and \( L_3^* = O_w(-3C_0 - (m + e + 2)f) \).

**Case 1:** \( L_1^* = O_w(-C_0 - (m + 1)f), L_2^* = O_w(-2C_0 - (e + 1)f) \). From the previous description, \( \varphi \) is the composition of \( X_1 \xrightarrow{p_1} W \), where \( p_1 \) is a double cover branched along a divisor \( D_2 \) linearly equivalent to \( 4C_0 + (2e + 2)f \), and \( X \xrightarrow{p_2} X_1 \), where \( p_2 \) is a double cover branched along the ramification of \( p_1 \) and \( p_1^*D_1 \), where \( D_1 \) is linearly equivalent to \( (2m - e + 1)f \). Recall that \( X \) is normal, hence the components of \( D_1 + D_2 \) have multiplicity 1 and in particular, the fixed part of \( |4C_0 + (2e + 2)f| \) contains \( C_0 \) with multiplicity at most 1. Thus \( e \leq 2 \).
Case 2: \( L_2^* = \mathcal{O}_w(-C_0 - (m + 1)f), L_1^* = \mathcal{O}_w(-2C_0 -(e + 1)f). \) Again from the description above, \( \varphi \) is the composition of \( X_1 \xrightarrow{p_1} W \), where \( p_1 \) is a double cover branched along a divisor \( D_2 \) linearly equivalent to \( 2C_0 + (2m + 2)f \), and \( X \xrightarrow{p_2} X_1 \), where \( p_2 \) is a double cover branched along the ramification of \( p_1 \) and \( p_1^* D_1 \), where \( D_1 \) is linearly equivalent to \( 3C_0 + (2e - m + 1)f \). Recall that \( X \) is normal, hence the components of \( D_1 + D_2 \) have multiplicity 1 and, in particular, the fixed part of \(|3C_0 + (2e - m + 1)f|\) contains \( C_0 \) with multiplicity at most 1. Thus \( m \leq 1 \), and in fact \( m = 1 \) and \( e = 0 \). So finally, \( W = F_0 \), \( D_1 \) is linearly equivalent to \( 3C_0 \) and \( D_2 \) is linearly equivalent to \( 2C_0 + 4f \). After interchanging \( C_0 \) and \( f \) we see that \( D_1 \) and \( D_2 \) satisfy (3) when we set \( e = 0 \) and \( m = 1 \).

Now we prove the converse. It is clear that the morphism \( \varphi \) is a Galois cover with group \( \mathbb{Z}_4 \). The ramification formula tells us that

\[
\omega_\chi = \varphi^*(\omega_w \otimes \mathcal{O}_w(3C_0 + (m + e + 2)f)) = \varphi^*(\mathcal{O}_w(1)),
\]

so \( X \) is a surface of general type with a base-point-free canonical bundle. It is also clear, in both (1) and (2), that

\[
\varphi_* \mathcal{O}_X = \mathcal{O}_w \oplus \mathcal{O}_w(-C_0 - (m + 1)f) \\
\oplus \mathcal{O}_w(-2C_0 - (e + 1)f) \oplus \mathcal{O}_w(-3C_0 -(m + e + 2)f).
\]

Then to see that \( \varphi \) is the canonical morphism of \( X \) we compare \( H^0(\omega_\chi) = H^0(\varphi^* \mathcal{O}_w(1)) \) and \( H^0(\mathcal{O}_w(1)) \). The group \( H^0(\varphi^* \mathcal{O}_w(1)) \) can be computed pushing \( \varphi^* \mathcal{O}_w(1) \) down to \( W \) and using (6.1.1), and one sees at once that \( H^0(\omega_\chi) = H^0(\mathcal{O}_w(1)) \). Finally we see that \( H^1(\mathcal{O}_\chi) = 0 \) also by pushing down to \( W \) and using (6.1.1). \( \square \)

**Theorem 6.2.** Let \( X \xrightarrow{\varphi} W \) be a canonical Galois cover of degree 4 and Galois group \( \mathbb{Z}_4 \) with \( X \) irregular and let \( W = S(m - e, m) \) be a smooth rational normal scroll. Then the irregularity of \( X \) is \( q(X) = 1 \) and \( W \) is isomorphic to \( F_0 \). Moreover, \( \varphi \) is the composition of two flat double covers \( X_1 \xrightarrow{p_1} W \) and \( X \xrightarrow{p_2} X_1 \) which are as follows:

1. The cover \( p_1 \) is branched along a divisor \( D_2 \) on \( W \).
2. The cover \( p_2 \) is branched along the ramification of \( p_1 \) and \( p_1^* D_1 \) and has trace zero module \( p_1^* \mathcal{O}_Y(-\frac{1}{2}D_1 - \frac{1}{4}D_2) \), where \( D_1 \) is a divisor on \( W \).
3. The scroll \( W = S(m, m) \), with \( m \geq 1 \), and the divisors \( D_1 \sim (2m + 4)f \) and \( D_2 \sim 4C_0 \).

Conversely, if \( X \xrightarrow{\varphi} W \) is the composition of two double covers \( X_1 \xrightarrow{p_1} W \) and \( X \xrightarrow{p_2} X_1 \) as described above, then \( \varphi \) is a canonical Galois cover of \( W \) with Galois group \( \mathbb{Z}_4 \) and \( X \) is irregular.

**Proof.** Using Remark 3.4 and Corollary 3.2 as in the proof of Theorem 5.1 we conclude that \( \varphi \) is the composition of two double covers. The first one is \( X_1 \xrightarrow{p_1} W \), is branched along a divisor \( D_2 \) and has trace zero module \( L_2^* \). The second cover is \( X \xrightarrow{p_2} X_1 \), is branched along the ramification of \( p_1 \) and \( p_1^* D_1 \) and has trace zero module \( p_1^* L_1 \). Then \( L_2^* \otimes L_1 = \mathcal{O}_w(D_1), L_2^* \otimes L_2 = \mathcal{O}_w(D_2) \) and moreover, \( L_1 \otimes L_2 = L_3 = \omega_w^*(1) \). Recall that \( W = F_e \) and let \( L_1 = \mathcal{O}_w(a_1 C_0 + b_1 f) \) and
$L_2 = \mathcal{O}_w(a_2 C_0 + b_2 f)$. Then we have

$$a_1 + a_2 = 3,$$

$$b_1 + b_2 = m + e + 2.$$

Since $L_1^{\otimes 2} \otimes L_2 = \mathcal{O}_w(D_1)$ and $L_2^{\otimes 2} = \mathcal{O}_w(D_2)$ are effective, then $a_2 \leq 2a_1$, $b_2 \leq 2b_1$ and $a_2, b_2 \geq 0$. Then $a_1, b_1 \geq 0$ also. Moreover, $a_1, b_1 \geq 1$, otherwise we will contradict $a_1 + a_2 = 3$ or $b_1 + b_2 = m + e + 2$. We see that $a_1$ cannot be 2. If $a_1 = 2$, then $D_1 \sim 3C_0 + (2b_1 - b_2)f$, $D_2 \sim 2C_0 + 2b_2f$, $L_1 = \mathcal{O}_w(2C_0 + b_1 f)$ and $L_2 = \mathcal{O}_w(C_0 + b_2 f)$. Since $X$ is irregular, and $H^1(\mathcal{O}_w) = H^1(L_2) = H^1(L_1^\otimes) = 0$, then $H^1(L_1) \neq 0$. This implies $b_1 \leq e$. Then $b_1 + b_2 = m + e + 2$ implies $b_2 \geq m + 2$.

On the other hand, since $X$ is normal, $C_0$ has at most multiplicity 1 in the fixed part of $[3C_0 + (2b_1 - b_2)f]$, and this implies $2b_1 - 2b_2 \geq 0$. Then we have $2e - (m + 2) - 2e \geq 0$, which is a contradiction. Then the only possibilities are $a_1 = 1$ or $a_1 = 3$.

**Case 1:** $a_1 = 1$. Then $a_2 = 2$ and $X$ irregular implies $b_2 \leq e$, since $L_2^\otimes$ has to be special. The fact that $X$ is normal implies $-3e + 2b_2 \geq 0$, since $D_2$ cannot have $2C_0$ as a fixed component. Then $b_2 = e = 0$, and, summarizing, $e = 0, a_1 = 1, a_2 = 2, b_1 = m + 2$, and $b_2 = 0$. This implies $D_1 \sim (2m + 4)f$ and $D_2 \sim 4C_0$.

**Case 2:** $a_1 = 3$. Then $D_1 \sim 6C_0 + (2b_1 - b_2)f$, and since $X$ is normal, $C_0$ has at most multiplicity 1 in the fixed part of $|D_1|$, hence $2b_1 - b_2 - 5e \geq 0$. Now since $H^0(\varphi^*\mathcal{O}_w(C_0 + mf)) = H^0(\mathcal{O}_w(C_0 + mf))$, we have that $b_2 > m$, hence $b_1 < e + 2$. Then we get $2e - 4 - m - 5e = -3e - m + 4 > 0$. But $m \geq e + 1$, so this gives $-4e + 3 > 0$, hence $e = 0$. In this case, $b_1 = 1$ and $m \geq 1$. Then $b_2 = m + 1 \geq 2$, and since $D_1$ is effective, $b_2 = 2$ and $m = 1$. Summarizing, $e = 0, m = 1, a_1 = 3, a_2 = 2, b_1 = 1$ and $b_2 = 2$. Then $D_1 \sim 6C_0$ and $D_2 \sim 4f$. After interchanging $C_0$ and $f$ we see that $D_1$ and $D_2$ satisfy (3) when we set $m = 1$.

Finally the irregularity of $X$ is $h^1(\mathcal{O}_x) = h^1(\varphi_*\mathcal{O}_x)$. We observe that the computation of $a_1, a_2, b_1$ and $b_2$ yields that $\varphi_*\mathcal{O}_x$ is

$$\mathcal{O}_w \oplus \mathcal{O}_w(-C_0 - (m + 2)f) \oplus \mathcal{O}_w(-2C_0) \oplus \mathcal{O}_w(-3C_0 - (m + 2)f)$$

or

$$(6.2.1) \quad \mathcal{O}_w \oplus \mathcal{O}_w(-3C_0 - f) \oplus \mathcal{O}_w(-2f) \oplus \mathcal{O}_w(-3C_0 - 3f)$$

so $h^1(\mathcal{O}_x) = h^1(\mathcal{O}_w(-2C_0))$ or $h^1(\mathcal{O}_x) = h^1(\mathcal{O}_w(-2f))$, and in both cases, are equal to 1.

We now prove the converse. It is clear that $\varphi$ is Galois with Galois group $\mathbb{Z}_4$. Now if $L_2^\otimes$ is the trace zero module of $p_1$ and $p_2L_1^\otimes$ is the trace zero module of $p_2$, then $L_1 \otimes L_2 = \mathcal{O}_w(\frac{1}{2}D_1 + \frac{1}{4}D_2)$. Then if $D_1$ and $D_2$ are as in (1) or (2), $L_1 \otimes L_2 = \omega_*^1(1)$. Then the ramification formula also implies that $\omega_X = \varphi^*\mathcal{O}_w(1)$, therefore $X$ is a surface of general type with a base-point-free canonical bundle. Finally it is also clear that $\varphi_*\mathcal{O}_x$ is as in $(6.2.1)$, so arguing as in the end of the proof of Theorem 6.1, we see that $\varphi$ is the canonical morphism and $X$ is irregular. 

**Corollary 6.3.** Let $W$ be a smooth rational scroll of degree $r$ and let $X \leftarrow W$ be a Galois canonical cover with Galois group $\mathbb{Z}_4$ (i.e., a cover like the ones classified in Theorems 6.1 and 6.2). Then $X$ is singular. Moreover,

1. if $X$ is regular, then the mildest possible set of singularities on $X$ consists of $4(r + 1)$ singular points of type $A_1$ and
2. if $X$ is irregular the singularities of $X$ are exactly $4(r + 4)$ points of type $A_1$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Proof. The proof is similar to the proof of Corollary 4.2. In this occasion, $D_1 \cdot D_2 = 4(r + 1)$ if $X$ is regular (see Theorem 6.1 (1) and (2)) and $D_1 \cdot D_2 = 4(r + 4)$ if $X$ is irregular (see Theorem 6.2 (1) and (2)). The surface $X$ has the mildest possible set of singularities if $X_1$ is smooth and the branch locus of $X \xrightarrow{p_2} X_1$ has the mildest possible set of singularities. This happens if $D_1$ and $D_2$ are smooth and meet transversally. In this case the branch locus of $p_2$ has only singularities of type $A_1$, and so does $X$. Now, if $X$ is irregular, Theorem 6.2 together with the fact that $X$ is normal implies that $D_1$ is a union of distinct lines of one of the fibrations of $\mathbb{P}^1 \times \mathbb{P}^1$ and $D_2$ is a union of distinct lines of the other fibration, so $D_1$ and $D_2$ are smooth and meet transversally in any case. \hfill $\Box$

Proposition 6.4. There exist families of quadruple Galois canonical covers as in Theorems 6.1 and 6.2 which have singularities as mild as possible (see Corollary 6.3).

Proof. According to the converse part in Theorems 6.1 and 6.2 we just have to construct a composition of double covers $X \xrightarrow{p_2} X_1$ and $X_1 \xrightarrow{p_1} W$ branched along suitable divisors. Let $D_1$ and $D_2$ be as in Theorems 6.1 and 6.2. Using the same arguments of Corollary 4.2 and Proposition 4.3, in order for $X$ to have singularities as mild as possible and, in any case, only $A_1$ singularities, it suffices to choose $D_1$ and $D_2$ smooth and meeting transversally. We see that such a choice is indeed possible. For a cover as in Theorem 6.1 (1), $D_1 \sim (2m - e + 1)f$ and $D_2 \sim 4C_0 + (2e + 2)f$. Then we choose $D_1$ as the union of $2m - e + 1$ different fibers. The divisor $4C_0 + (2e + 2)f$ is base-point-free if $e = 0, 1$ and if $e = 2$ is $(3C_0 + 6f) + C_0$, with $3C_0 + 6f$ base-point-free and $(3C_0 + 6f) \cdot C_0 = 0$. Thus by Bertini $D_1$ and $D_2$ can be chosen smooth and intersecting transversally. Finally, in Theorem 6.2, $D_1$ and $D_2$ are the union of distinct smooth lines belonging to the two fibrations of the ruled surface $F_0$. Note that, if $X$ is regular, one can construct $X$ with worse singularities allowing $D_1 + D_2$ to have worse singularities. \hfill $\Box$

7. NON-EXISTENCE OF SIMPLE CYCLIC COVERS

In Sections 4, 5 and 6, we have seen that quadruple cyclic canonical covers of smooth surfaces of minimal degree are never simple cyclic. This situation does not only hold for covers of degree 4, but is more general. For instance, if $X$ is regular and $W$ is a surface of minimal degree, whether smooth or singular, the authors proved in [GP2] the non-existence of simple cyclic canonical covers of degree larger than 3.

In the next theorem we prove the non-existence of simple cyclic canonical covers of degree larger than or equal to 3 when $X$ is an arbitrary surface of general type and $W$ is a smooth rational normal scroll.

Theorem 7.1. Let $W$ be a smooth rational normal scroll, and let $X \xrightarrow{\varphi} W$ be a canonical cover of degree $n$. If $X \xrightarrow{\varphi} W$ is a Galois cover and $n \geq 3$, then $\varphi$ is not simple cyclic.

Proof. Let us assume $\varphi$ is simple cyclic. Then

$$\varphi^*\mathcal{O}_X = \mathcal{O}_W \oplus L^{-1} \oplus \cdots \oplus L^{-n+1}.$$ 

Recall that $W$ is isomorphic to $F_\omega$. On the one hand

$$\omega_X = \varphi^*\mathcal{O}_W (1) = \varphi^*\mathcal{O}_W (C_0 + mf),$$
with $m \geq e + 1$. On the other hand,

$$\omega_X = \varphi^*(\omega_W \otimes L^{-n+1}) = \varphi^*(O_W (-2C_0 - (e + 2)f) \otimes L^{-n+1}).$$

Thus $\varphi^*L^{-n+1} = \varphi^*O_W (3C_0 + (m + e + 2)f)$, so that $L^{-n+1}$ and $O_W (3C_0 + (m + e + 2)f)$ are numerically equivalent in $W$. Since $W$ is a Hirzebruch surface, $L^{-n+1} = O_W (3C_0 + (m + e + 2)f)$, and $3$ and $m + e + 2$ are both multiple of $n - 1$. Since $n \geq 3$ by assumption, this makes $n = 4$. Then, Theorems 6.1 and 6.2 tell that $\varphi$ is not simple cyclic. This can also be seen directly as follows: since $\varphi$ is induced by the complete series of $O_W (C_0 + mf)$, then $O_W ((m - \frac{1}{2}(m + e + 2))f)$ should be non-effective; this together with $m \geq e + 1$ implies $e < 0$, a contradiction.

After Theorem 7.1 we now summarize the status of the existence of simple cyclic canonical covers in the following theorem. To see the scope of the result, we remark that Theorem 7.2 implies the non-existence of Galois canonical covers of prime degree $p$ of smooth scrolls, $\mathbb{P}^2$ or the Veronese surface, if $p \geq 5$. If in addition $X$ is regular, the next theorem assures that, if $p \geq 5$, then there are no Galois canonical covers of prime degree $p$ of any surface of minimal degree.

**Theorem 7.2.** Let $W$ be a surface of minimal degree, not necessarily smooth, and let $X \xrightarrow{\varphi} W$ be a Galois canonical cover. If $X$ is regular or $W$ is smooth, and if $\varphi$ is simple cyclic, then $\deg \varphi \leq 3$.

**Proof.** If $X$ is regular, the result follows from [GP2, Corollary 3.2]. So we will assume that $X$ is irregular and $W$ smooth. The surface $W$ cannot be isomorphic to $\mathbb{P}^2$, for if it were, since $\varphi$ is simple cyclic, $\varphi_*O_X$ would split completely, and so $X$ would be regular. Thus $W$ is a smooth rational normal scroll. Then we conclude that $\deg \varphi \leq 3$ by applying Theorem 7.1.

**Corollary 7.3.** Let $W$ be a surface of minimal degree, not necessarily smooth, and let $X \xrightarrow{\varphi} W$ be a Galois canonical cover. If $X$ is regular or $W$ is smooth and $\varphi$ is a Galois canonical cover of prime degree, then $\deg \varphi \leq 3$.

**Proof.** If $\deg \varphi = p$ is prime, then $G$ is cyclic of order $p$, and the stabilizer of any $x \in X$ is either $\{id\}$ or $G$, so $\varphi$ is simple cyclic.

These results hint towards a positive solution to the following very interesting question regarding Galois canonical covers of prime degree larger than 3:

**Question 7.4.** If $X \xrightarrow{\varphi} W$ is a Galois canonical cover of prime degree, is $\deg \varphi \leq 3$?
