Abstract

The Inverse Amplitude Method is a powerful unitarization technique to enlarge the energy applicability region of Effective Lagrangians. It has been widely used to describe resonances from Chiral Perturbation Theory as well as for the Strongly Interacting Symmetry Breaking Sector. In this work we show how it can be slightly modified to account also for the sub-threshold region, incorporating correctly the Adler zeros required by chiral symmetry and eliminating spurious poles. These improvements produce negligible effects on the physical region.

1 Introduction

Effective Field Theories provide a systematic and model independent approach to systems whose symmetries and low energy degrees of freedom are known but whose description in terms of an underlying fundamental Quantum Field Theory is out of reach. The two cases of interest for this work are, on the one hand, Chiral Perturbation Theory (ChPT) [1] that describes effectively the low energy dynamics of hadrons, unaccessible to perturbative QCD calculations in terms of quarks and gluons and, on the other hand, the effective description of the Strongly Interacting Electroweak Symmetry Breaking Sector (SISBS) [2], whose underlying fundamental theory remains unknown.

Both cases have in common the existence of an spontaneous symmetry breaking of a global chiral $SU(N)_L \times SU(N)_R$ group down to an $SU(2L+R)$ group. The Goldstone Theorem implies the presence of $N^2 - 1$ massless Goldstone Bosons (GB) in the particle spectrum. These GB thus become the relevant degrees of freedom of the system below a chiral scale $\Lambda_{\chi}$, where an Effective Chiral Lagrangian can be built in terms of just those GB as the most general derivative expansion consistent with the known symmetries. Note that there is a well defined power counting so that divergences generated in loop diagrams that use vertices up to a given order can be renormalized into the coefficients of higher order terms. In this sense these Effective Theories are renormalizable order by order.

In addition, in both examples, there are small explicit symmetry breaking terms. For QCD the relatively small masses of the lightest three quarks provide a mass $M \ll \Lambda_{\chi}$ to the GB, identified with the pions, kaons and etas, so that the effective approach becomes in practice a derivative and mass expansion. For the SISBS, there is a local $SU(2)_L \times U(1)$ symmetry whose gauge bosons couple to the "would-be GB" that, in a unitary gauge, disappear from the spectrum, giving rise to gauge boson longitudinal components that thus acquire a mass $M_V$. In this way the $SU(2)_L \times U(1)$ gauge symmetry is spontaneously, but not explicitly, broken to the electromagnetic group $U(1)_{EM}$. In this case, in addition to the derivative expansion, one expands also in terms of electroweak coupling constants $g$ and $g'$. The so-called Equivalence Theorem (ET) [3] states that at high energies (in $R_5$ gauges, and to leading order in momenta over $M_V$ and $g$ and $g'$) amplitudes involving longitudinal gauge bosons can be calculated as if they were GB, which, being pseudoscalars, are much easier to handle. Although this is a high energy limit, there is a generalization to the Effective Lagrangian formalism [4], that, for practical purposes, allows us to identify, up to the difference in scales, the formalisms of $SU(2)$ ChPT and the SISBS and therefore, from now on we will be referring to ChPT, but keeping in mind that our results have a straightforward translation to the SISBS.
Both cases above are examples of strongly interacting systems whose most salient feature is the saturation
of unitarity and the associated resonant states, which lie beyond the reach of perturbative energy expansions.
Thus, it may seem that the use of effective Lagrangians is limited to energies below those resonances, whose
effects are encoded in the values of higher order effective coupling constants. However, since unitarity fixes
the imaginary part of inverse partial waves in the elastic region, the effective Lagrangian approach is also
useful in the resonant region, for instance, used inside a dispersion relation, in order to obtain the rest of
the amplitude. These techniques are known as unitarization methods, and reproduce simultaneously the low
energy expansion and the lightest resonances without including them explicitly in the Lagrangian. The great
advantage is that such resonances and their properties are generated without prejudices about their nature
or their existence. Also, since the Lagrangian symmetries and some features of the effective constants can
be directly related to the underlying theory, like QCD, one can study the properties of these states based
on more fundamental grounds. One of the most extensively used unitarization techniques is the Inverse
Amplitude Method (IAM) \cite{5, 6, 7, 8}, that uses the fully renormalized effective chiral expansion, without
any further approximation and without introducing any other spurious parameter, but just the effective
constants up to a given order. Within hadronic physics, it generates the well known vector resonances and
the more controversial scalars using parameters consistent with one loop ChPT, allowing to establish their
different nature in terms of their dependence on the number of colors. It has also been possible to extend it
up to two loops \cite{7, 9}, the finite temperature formalism \cite{10, 11} and to the pion-nucleon sector \cite{12}. Within
the SISBS \cite{13}, it provides the prediction of the general resonance spectrum and how well it could be detected
at LHC.

However, it is known \cite{7, 14} that the IAM fails to reproduce correctly the Adler zeros that appear in
the subthreshold region of some partial waves as a consequence of chiral symmetry \cite{15}. Furthermore, it
generates spurious poles, or “ghosts”, thus questioning its reliability in that region, and also casting some
doubts about the robustness of the results in the physical region if such structures were properly accounted
for.

The aim of this paper is to show that a very simple modification of the IAM can take into account correctly
those zeros and ghosts. This modification corresponds to terms that had been neglected in the original
dispersive derivation of the IAM since they contribute to higher orders in the chiral expansion. Actually, we
will check explicitly that such procedure is justified in the physical region, where these modifications yield
negligible contributions, thus showing the robustness of the standard IAM. However, apart from improving
the IAM consistency, these terms are essential in the sub-threshold region which is relevant to study the
effect of chiral symmetry restoration on resonances \cite{11}, or their dependence on quark masses \cite{16}.

In the next section we will thus revisit the standard IAM derivation from dispersive theory, where Adler
zeros are neglected, paying special attention to the role of those zeros in the subthreshold region. In section
3 we will present a naive way of extending the IAM amplitude, without using dispersion relations, that solves
the caveats in that region. Section 4 will show a dispersive derivation of a more general modified amplitude,
for the case of equal masses (e.g. \(\pi\pi\) scattering). The case of unequal masses, like in \(\pi K\) scattering, deserves
a separate discussion, for the reasons explained in section 5. Finally, in section 6 we will present some
numerical results for the modified amplitudes.

2 The Inverse Amplitude Method

2.1 Dispersive derivation

The one-channel Inverse Amplitude Method (IAM) \cite{5, 6, 7, 8} can be obtained by using ChPT up to a given
order inside a dispersion relation. To simplify the discussion, let us first consider pion-pion scattering partial
wave amplitudes of definite isospin \(I\) and angular momentum \(J\), although for brevity we will simply call
them \(t\), whose analytic structure in the \(s\)-plane is shown in Fig. 1. The physical right hand cut comes from
unitarity and starts at threshold \(s_{th}\), while the left hand cut comes from the \(t,u\) channels.

The inverse of \(t(s)\) has the same analytic structure, except for the possible presence of poles corresponding
to zeros of \(t(s)\). In particular, chiral symmetry requires the existence of the so-called Adler zeros below
threshold in scalar partial waves \[^{[11]}^{[15]}\] , the case of interest in this work, which we denote by \(s_A\). Hence it is then possible to write the following dispersion relation for the inverse amplitude:

\[
\frac{1}{t(s)} = \frac{1}{t(z_0)} + \frac{s - z_0}{\pi} \int_{s_{th}}^{\infty} dz \frac{\text{Im} \ 1/t(z)}{(z - s)(z - z_0)} + \text{LC}(1/t) + \text{PC}(1/t). \tag{1}
\]

here and in the following, we will simply write \(z\) instead of \(z + i\epsilon\) with \(\epsilon > 0\) for the imaginary parts inside the cut integrals. Note that we have explicitly written the integral over the right hand cut (or physical cut, extending from threshold, \(s_{th}\) to infinity) but we have shortened by \(\text{LC}\) the equivalent expression for the left cut (from \(-\infty\) to \(0\)) and the pole contribution. We could do similarly with other cuts, if present, as in the \(\pi K\) case. In addition we have made one subtraction to ensure convergence, at a point \(z_0 \neq s_A, s_2\).

We now recall that unitarity, for physical values of \(s\) in the elastic region implies:

\[
\text{Im} t(s) = \sigma|t(s)|^2 \quad \Rightarrow \quad \text{Im} \frac{1}{t(s)} = -\sigma(s), \tag{2}
\]

where \(\sigma(s) = 2p_{CM}/\sqrt{s}\). Let us remark that since \(\text{Im} 1/t = -\sigma\) we know exactly the integrand over the elastic cut.

In contrast, ChPT amplitudes are obtained as a series expansion \(t(s) = t_2(s) + t_4(s) + \ldots\) where \(t_2(s) = O(p^2), t_4(s) = O(p^4)\) and \(p\) stands for the pion mass or momentum. Therefore elastic unitarity is not satisfied exactly, but only order by order as follows:

\[
\text{Im} t_2(s) = 0, \quad \text{Im} t_4(s) = \sigma(s)|t_2(s)|^2, \quad \ldots \tag{3}
\]

Let us also note that \(t_2(s)\) is a pure polynomial and has no cuts, and we can thus write a trivial dispersion relation for \(1/t_2(s)\) that reads

\[
\frac{1}{t_2(s)} = \frac{1}{t_2(z_0)} + PC(1/t_2), \tag{4}
\]

where now the pole contribution is due to \(s_2\), the Adler zero of \(t_2\). In addition, except for the poles, the function \(t_4(s)/t_2^2(s)\) has the same analytic cut structure of \(1/t\) and, using Eqs.\(^{(2)}\) and \(^{(3)}\), over the physical cut we find

\[
\text{Im} \frac{t_4(s)}{t_2^2(s)} = \sigma(s) = -\text{Im} \frac{1}{t(s)}. \tag{5}
\]

We can therefore write another dispersion relation similar to that of \(1/t(s)\), but for \(t_4(s)/t_2^2(s)\),

\[
\frac{t_4(s)}{t_2(s)^2} = \frac{t_4(z_0)}{t_2(z_0)^2} + \frac{s - z_0}{\pi} \int_{s_{th}}^{\infty} dz \frac{\text{Im} t_4(z)/t_2(z)}{(z - s)(z - z_0)} + \text{LC}(t_4/t_2^2) + \text{PC}(t_4/t_2^2), \tag{6}
\]

Figure 1: Pion-pion scattering partial waves analytic structure and integration contour.
where the pole contribution, once again, is due to the Adler zero of \( t_2 \).

We are now going to relate the dispersion relation for \( 1/t(s) \) with that for \( t_4(s)/t_2^2(s) \). As we already commented \( \text{Im} 1/t(s) = -\text{Im} t_4/t_2^2(s) \) on the right cut, and therefore the integrals over the physical cuts for \( 1/t(s) \) and \( t_4/t_2^2(s) \) are exactly opposite to each other. In addition, using ChPT we find that \( LC(1/t) \approx -LC(t_4/t_2^2) \), which is a well justified approximation, since, due to the subtraction, the integrand of \( LC \) is weighted at low energies, precisely where ChPT applies. Finally, we have to evaluate the subtraction constant in Eq. (1), and this can only be done as long as \( z_0 \) is in the low energy region, where it is perfectly justified to use ChPT to find \( 1/t(z_0) \approx 1/t_2(z_0) - t_4(z_0)/t_2(z_0)^2 \). However, note that this expansion is a very bad approximation for \( z_0 \) near \( s_2 \) or \( s_A \), where \( t_2 \) and \( t \) vanish. Therefore, we only know how to relate those dispersion relations for subtraction points \( z_0 \) in the low energy region, but sufficiently far from the Adler zeros. In section 6 we will check that the results have very little sensitivity to the choice of \( z_0 \) as long as it lies in this region. When this is the case, using Eqs. (1), (4) and (6) we can write \( 1/t(s) \) as

\[
\frac{1}{t(s)} \simeq \frac{1}{t_2(s)} - \frac{t_4(s)}{t_2(s)^2} - PC(1/t_2) + PC(t_4/t_2^2) + PC(1/t)
\]  

(7)

The standard dispersive derivation of the IAM \([6, 7]\) simply neglected the sum of pole contributions to arrive at

\[
t^{IAM}(s) \simeq \frac{t_2^2(s)}{t_2(s) - t_4(s)},
\]  

(8)

thus providing an elastic amplitude that satisfies unitarity and has the correct low energy expansion of ChPT up to the order we have used. When such amplitude is chirally expanded to \( O(p^4) \), this implies \([7]\) that the total pole contribution to \( t(s) \), even without its explicit calculation, has to be \( O(p^6) \). In sections 8, 11, 5 we will calculate it explicitly to arrive to the modified IAM.

### 2.2 IAM properties and its naive derivation

Incidentally, we can recast Eq. (2) as:

\[
t(s) = \frac{1}{\text{Re} t^{-1}(s) - i \sigma(s)},
\]  

(9)

and thus it seems that the IAM can also be derived in a much simpler way by replacing \( \text{Re} t^{-1} \) by its \( O(p^4) \) ChPT expansion \( \text{Re} t^{-1} = (t_2 - \text{Re} t_4)/t_2^2 \). This is the way unitarization methods are usually presented, although it makes no use of the strong analytic constraints of amplitudes, which are indeed absent in Eq. (9). Furthermore, immediately the criticism is raised that the ChPT expansion cannot be used at high energies.

However, note that the dispersive one-channel IAM derivation in the previous section imposes analyticity in the form of two dispersive integrals and makes use of the ChPT expansion (up to one-loop in this case) for the subtraction constants and the left cut. The use of ChPT for the subtraction constants is well justified, since it is used at \( s = z_0 \) in the low-energy region. Since the integral extends to infinity, ChPT may seem a worse approximation for the left cut or possible inelastic cuts, however, the subtraction suppresses the high energy region that contributes little, as explained above. Furthermore, when the IAM is used for physical values of \( s \) above the physical threshold, the left cut is damped by an additional \( 1/(z - s) \) factor, and not only the high energy part, but its whole contribution is rather small. There are no model dependent assumptions, but just approximations to a given order, and therefore the approach provides an elastic amplitude that satisfies unitarity and has the correct ChPT expansion up to that given order. It also is straightforward to extend it to higher orders \([7, 9]\).

Moreover, Eq. (2) is only valid on the physical cut, whereas the dispersive derivation allows us to consider the amplitude in the complex plane, and, in particular, look for poles of the associated resonances. Actually, already ten years ago \([7]\) the poles for the \( \rho(770), K^*(892) \) and most interestingly, the controversial \( \sigma \) (also called \( f_0(600) \)), where generated without any model dependent assumptions.

Obviously, and contrary to a wide belief, the IAM contains a left cut and respects crossing symmetry up to, of course, the order in the ChPT expansion that has been used. The confusion may come from the fact
that the IAM has also been applied in a coupled channel formalism, for which there is still no dispersive derivation and has been frequently used by approximating further the amplitudes neglecting tadpole and left cut terms [17]. But, strictly speaking that would not be the full IAM, which definitely has a left cut.

2.3 IAM caveats: Adler zeros and ghosts

To end this section, we recall that in the dispersive derivation the sum of pole terms (PC) in Eq. (4) is neglected, since it yields a higher order contribution [7]. However, this leads to a couple of problems related to the presence of the Adler zeros below threshold in the scalar waves. Let us first note that despite we have used in the IAM the ChPT expansion up to next to leading order (NLO), due to the $t_2(s)^2$ factor in the numerator, it vanishes at $s_2$, which is only the leading order (LO) chiral approximation to the exact Adler zero $s_A$. In addition it is a double zero instead of a single zero. This, as we will see, leads to the appearance of a spurious pole on the real axis close to the Adler zero. As a consequence, the predictions of the standard IAM below threshold and in particular, around the Adler zero position, are not reliable.

In fact, note that since the interval $s \in (0, s_{th})$ lies within the convergence region of the chiral expansion and $t_2$ changes sign at $s = s_2$, $t_2 - t_4$ turns out to be, for the cases of interest here, a continuous, monotonically increasing (or decreasing) function in $(0, s_{th})$ that changes sign from $s = 0$ to $s = s_{th}$. Therefore, there is one single point $\tilde{s}$ where the denominator of $\mathcal{S}$ vanishes, which, as long as $t_4(s_2) \neq 0$, produces the spurious pole below threshold discussed above, i.e., a not-observed $\pi\pi$ bound state.

For instance, let us consider $I = J = 0 \pi\pi$ scattering (for the values of the low-energy constants quoted in section [6]). This is an attractive channel, so that $t_2 - t_4$ is positive at threshold. Since that function is negative at $s = 0$ and at $s = s_2$, $\tilde{s} > s_2$ in that case, as showed in the upper right panel of Fig. 2, we find $\tilde{s} \simeq (110 \text{ MeV})^2$ and $s_2 \simeq (99 \text{ MeV})^2$. In the $I = 2, J = 0$ channel, which is repulsive, $t_2 - t_4$ is positive at $s = 0$ and negative at $s = s_2$ ($t_4(s_2) > 0$) so that $\tilde{s} < s_2$. In that channel, $\tilde{s} \simeq (196 \text{ MeV})^2$ and $s_2 \simeq (198 \text{ MeV})^2$ as seen also in Fig. 2.

Let us also point out that, together with the first Riemann sheet spurious pole just discussed, the IAM has a companion pole in the second Riemann sheet below threshold. For instance, the second-sheet IAM for $\pi\pi$ scattering reads:

$$t(s)^{\text{IAM,II sheet}} = \frac{t_2(s)^2}{t_2(s) - t_4(s) - 2\tilde{\sigma}(s)t_2^2(s)} \quad (10)$$

where $\tilde{\sigma}(s) = i\sigma(s - i0^+) = \sqrt{4m_2^2/s - 1}$ for $0 < s < 4m_2^2$. Thus, if we are dealing with an attractive channel, like the 00 one, the denominator of (10) is positive near threshold (dominated by $t_2 > 0$) and diverges to minus infinity as $s \to 0^+$, so that it must have at least one zero, which again generates a pole if $t_4(s_2) \neq 0$. Since $-\tilde{\sigma}t_2^2$ in Eq. (10) is also an increasing function, there will be only one such pole.

In conclusion, the existence of the perturbative Adler zeros and the fact that the IAM amplitude does not reproduce them well leads to the presence of spurious poles. Similar conclusion had been noticed in [18]. In the next sections, we present, first, a very simple construction of a modified IAM, along the lines of the previously discussed naïve derivation of the standard IAM obtained without using dispersion relations, that solves these problems and next we show two dispersive derivations of the modified IAM. One of them is subtracted at arbitrary $z_0$ (within the range of validity of our approximations) and the other one at the Adler zero. We will show how the modified IAM obtained naïvely corresponds to a particular limit of the first dispersive approach and comes out directly in the second. Finally, we will also show that the differences between the modified IAM formulae are negligible numerically, and that, while fixing the above mentioned problems, the modified IAM does not yield any significant modification over the standard IAM in the physical region and to the resonance poles. Therefore, the results obtained so far in the literature with the IAM remain valid.
3 Modified IAM: Naive derivation

First of all we will set some notation: as before, we denote by $s_A$ the Adler zero of the “complete” partial wave, namely $t(s_A) = 0$. In addition, we will also use the approximations to the Adler zero at LO, $s_2$, and NLO, $s_2 + s_4$. Thus, $t_2(s_2) = 0$ and $t_2(s_2 + s_4) + t_4(s_2 + s_4) = 0$.

In this section we present a naive, and intuitive, derivation leading to a partial wave definition which does not have the Adler zero related problems discussed above. The derivation follows closely [11], where this problem was addressed in the context of real pion scattering poles arising by medium effects such as temperature and density. In that paper, there was not a formal proof based on dispersion relations, as the one we will present here later, and it was limited to pion-pion scattering.

From the discussion in the previous sections, it is clear that if we modify the inverse amplitude as

$$1/tIAM(s) \rightarrow 1/tIAM(s) + A(s)/t_2^2$$

with $A(s)$ an analytic function at least off the real axis, real for real $s$, the unitarity and analytic properties of the amplitude remain unaltered. The modified IAM, (from now on called mIAM), reads then:

$$t^{mIAM}(s) = \frac{t_2^2(s)}{t_2(s) - t_4(s) + A^{mIAM}(s)}.$$  \hspace{1cm} (11)

Consider now the case of $\pi\pi$ scattering, where we have simply $t_2(s) = t_2'(s_2)(s - s_2)$ with $t_2'(s_2)$ constant. Then the Laurent expansion around $s = s_2$ of the standard IAM reads:

$$\frac{1}{tIAM(s)} = -\frac{t_4(s_2)}{t'_2(s_2)(s - s_2)^2} + \frac{t_2'(s_2) - t_4'(s_2)}{t'_2(s_2)^2(s - s_2)} + O(s - s_2)^0.$$  \hspace{1cm} (12)

The idea is that if we want the amplitude to have only an Adler zero of order one at $s = s_A$, we must subtract from $1/tIAM$ the above double and single pole contributions at $s = s_2$ and add a single pole at $s_A$, i.e,

$$\frac{1}{t^{mIAM}(s)} = \frac{1}{tIAM(s)} + \frac{t_4(s_2)}{t'_2(s_2)(s - s_2)^2} - \frac{t_2'(s_2) - t_4'(s_2)}{t'_2(s_2)^2(s - s_2)} + \frac{c}{s - s_A},$$  \hspace{1cm} (13)

where $c$ is a so far undetermined constant that, as we will show now, can be fixed by demanding that the mIAM formula matches the perturbative ChPT series to fourth order, namely $A = O(p^6)$.

In practice, it is simpler to keep track of the different chiral powers by counting the powers of $f^{-2}$, where $f$ is the pion decay constant. Thus, since $t_2'(s_2) = O(f^{-2})$, $t_4 = O(f^{-4})$, and $s_4 = O(f^{-2})$, expanding the expression $t_2(s_2 + s_4) + t_4(s_2 + s_4) = 0$ around $s_2$ we find:

$$s_4 = -t_4(s_2)/t'_2(s_2) + O(f^{-4}).$$  \hspace{1cm} (14)

Using this in Eq. (13) with $s_A = s_2 + s_4 + O(f^{-4})$, and requiring that Eq. (11) matches the chiral expansion at low energies, we find the first two orders of the chiral expansion for $c$:

$$c = \frac{1}{t'_2(s_2)} - \frac{t_4'(s_2)}{t'_2(s_2)^2} + O(f^{-2}),$$  \hspace{1cm} (15)

which leads to

$$A^{mIAM}(s) = t_4(s_2) - \frac{(s_2 - s_A)(s - s_2)}{s - s_A} [t'_2(s_2) - t'_4(s_2)].$$  \hspace{1cm} (16)

Therefore, the mIAM in Eq. (11) with $A^{mIAM}(s)$ in Eq. (16) and $s_A$ approximated by its chiral expansion given above, matches the chiral expansion of the amplitude up to fourth order and has the Adler zero at the same position and with the same order as the perturbative amplitude. Furthermore, we have solved in turn the spurious pole problem. In fact, since $A^{mIAM}(s_2) = t_4(s_2)$, the denominator of Eq. (11) vanishes at $s = s_2$. But, for $s \neq s_2$ we have shown that $A^{mIAM}(s) = O(f^{-6})$ and therefore our previous argument about the monotonous behavior of the denominator still holds, so that the denominator vanishes only at $s = s_2$, where there is no pole contribution. The same holds for the spurious second-sheet poles. In Fig. 2 we show
the mIAM amplitude in the $I = J = 0$ channel, which we observe that is not singular below threshold and remains close to the standard IAM result away from the Adler zero region. The same situation takes place in the $I = 2, J = 0$ channel. Finally, we have checked that, as expected from our previous arguments, the $f_0(600)$ or $\sigma$ pole remains at the same place either using the second Riemann sheet extensions of the mIAM or the IAM (see Table I).

In the next sections, we will check how a modified IAM can also be obtained by considering explicitly the pole contributions in the dispersive derivation, thus ensuring the correct analytic properties of the amplitude. We will also show that the modified formula obtained with the naive derivation in this section can also be obtained as a particular case.

4 Modified IAM: dispersive derivation for equal masses.

4.1 Pole Contribution to the standard derivation

The derivation of the modified IAM from dispersion theory follows that in section 2 up to Eq.(7), but keeping the pole contributions, which, by evaluating the corresponding residues, read:

\[
PC(1/t_2) = \frac{1}{t_2'(s_2)} \left( \frac{1}{s-s_2} - \frac{1}{z_0-s_2} \right) \tag{17}
\]

\[
PC(t_4/t_2^2) = \frac{1}{t_2'(s_2)} \left( \frac{1}{(s-s_2)^2} - \frac{1}{(z_0-s_2)^2} \right) + \frac{t_4'(s_2)}{t_2'(s_2)^2} \left( \frac{1}{s-s_2} - \frac{1}{z_0-s_2} \right) \tag{18}
\]

\[
PC(1/t) = \frac{1}{t'(s_A)} \left( \frac{1}{s-s_A} - \frac{1}{z_0-s_A} \right) \tag{19}
\]

where we have assumed a single zero in $t(s_A)$, as the presence of the $1/(s-s_A)$ factor in $PC(1/t)$ shows. As we have discussed above, and as it is detailed in the Appendix, by expanding chirally $-PC(1/t_2) + PC(t_4/t_2^2) + PC(1/t)$, the poles contribute to $t(s)$ at higher order, and that is why they were customarily neglected. However, these pole contributions contain the terms needed to have the Adler zero in the correct position. In addition, by taking the limit $s \to s_2$, $(-PC(1/t_2) + PC(t_4/t_2^2))$ tends to the term needed to cancel the double zero of the IAM in $s_2$, see Eq.(12), and the spurious pole will also disappear.

In summary, the modified IAM obtained from dispersive relations subtracted at $z_0$, that we will denote by $z_0IAM$, can be written again as:

\[
t^{z_0IAM}(s) \simeq \frac{t_2^z(s)}{t_2(s) - t_4(s) + A^{z_0IAM}(s)}, \tag{20}
\]

where now

\[
A^{z_0IAM}(s) = A^{mIAM}(s) - \frac{t_2(s)^2}{t_2(z_0)^2} A^{mIAM}(z_0) \tag{21}
\]

Of course, the position of the Adler zero for the total amplitude is not known, but since we have been working with ChPT to one loop, we can impose the Adler zero to be located in its one-loop position, namely, in the above formulae, we have to replace $s_A \to s_2+s_4$ which is obtained from the equation $t_2(s_2+s_4)+t_4(s_2+s_4) = 0$ as explained in Section 3. Thus, to obtain (21) we have made use of $t_2(s) = t_2'(s_2)(s-s_2)$ and chirally expanded $1/t'(s_A) \simeq 1/t_2'(s_2) - t_4'(s_2)/t_2'(s_2)^2$, which is perfectly justified near $s_A$. Note that we can use the chiral expansions around $s_A$ and $s_2$ because we no longer expand the inverse of the amplitudes but that of their derivatives, as they appear in the residues of the pole contributions.

Note that, once again, the factor $A^{mIAM}(s)$ that appeared in the previous section is present, but now there is an additional and very similar piece that carries a $z_0$ dependence, which occurs due to our truncation of the ChPT series when approximating the subtraction constants and pole contributions. This additional term in $A^{z_0IAM}$ is also $O(f^{-6})$ but, as we will see below, as long as $z_0$ lies within the range where our approximations remain valid, it is numerically small not only in the physical region but also below threshold.
Therefore, this term can be dropped without spoiling the right chiral behavior of the amplitude in the subthreshold region, obtaining again the mIAM in section 3 which, for the moment, we have justified only numerically.

Furthermore, it is tempting to take the $z_0 \to \infty$ limit in Eq. (21) and recover the mIAM of the previous section by noting that the second term in Eq. (21) vanishes in that limit. However, this is just a formal justification of our naive derivation since, actually, we required for the subtraction point $z_0$ to remain in the low energy applicability region of ChPT. Nevertheless, we will see in the next section that there is an alternative dispersive derivation of the mIAM, which is somewhat different from the standard dispersive derivation since it requires subtractions at the Adler zero of each function.

4.2 Subtraction at the Adler zeros

The way to derive Eq. (16) from dispersive theory is to make the subtractions at the place where we already have a pole. Note, however, that $1/t$ has its pole in the Adler zero at $s_A$ whereas $t_4/t_2^2$ has its pole at $s_2$, so that we have to write

$$\frac{1}{t(s)} = \frac{s - s_A}{\pi} \int_{RC} dz \frac{\sigma(z)}{(z - s_A)(z - s)} + LC(1/t) + PC(1/t),$$

(22)

$$\frac{t_4(s)}{t_2^2(s)^2} = \frac{s - s_2}{\pi} \int_{RC} dz \frac{\sigma(z)}{(z - s_2)(z - s)} + LC(t_4/t_2^2) + PC(t_4/t_2^2),$$

(23)

where, for brevity, we have already used the elastic unitarity condition Eq. (5). As usual, we will approximate $LC(1/t) \simeq -LC(t_4/t_2^2)$, since that is the result of the chiral expansion at low energies where the integral is weighted. In the above relations, the pole contributions $PC(1/t)$ and $PC(t_4/t_2^2)$ come now from a double and triple pole respectively, and read

$$PC(1/t) = \frac{1}{t'(s_A)(s - s_A)} - \frac{t''(s_A)}{2t'(s_A)^2},$$

(24)

$$PC(t_4/t_2^2) = \frac{t_4(s_2)}{t_2^2(s_2)^2(s - s_2)^2} + \frac{t'_4(s_2)}{t_2^2(s_2)^2(s - s_2)} + \frac{t''_4(s_2)}{2t_2^2(s_2)^2}.$$  

(25)

In addition, it is important to remark that these pole contributions diverge either on $s_2$ or $s_A$, so that, for $s \simeq s_2$ or $s \simeq s_A$ they are, by far, the dominant contributions, since at the same time the right and left cut terms tend to zero, and therefore become negligible.

Outside that region, the other terms become relevant and the difference with our previous derivations is that now we also approximate the $1/t$ integral term over the right cut by using $(s - s_A)/(z - s_A) \simeq (s - s_2)/(z - s_2)$, which is its LO chiral expansion. This is a remarkably good approximation for the dispersion relation as long as $z$ is sufficiently far from $s_2$ and $s_A$, which is indeed the case right cut integral. Of course, the $1/t$ right cut term should vanish at $s_A$ and now it does not, but, as we have just commented, the pole contribution diverges precisely at $s_A$ and thus is largely dominant over the integral, which therefore can be completely neglected.

Once again, we simply add Eqs. (22) and (23) to obtain the mIAM equation:

$$\frac{1}{tmIAM(s)} = -\frac{t_4(s)}{t_2^2(s)^2} + \frac{t_4(s_2)}{t_2^2(s_2)^2(s - s_2)^2} + \frac{t'_4(s_2)}{t_2^2(s_2)^2(s - s_2)} + \frac{1}{t'(s_A)(s - s_A)},$$

(26)

where, in the pole contributions, we have used that

$$-\frac{t''(s_A)}{2t'(s_A)^2} + \frac{t''_4(s_2)}{2t_2^2(s_2)^2} = O(f^{-2}),$$

(27)

which, once again, can be safely neglected since it correspond to the chiral expansion at very low energies.
Finally, if we evaluate perturbatively

\[ \frac{1}{t'(s_A)} \simeq \frac{1}{t_2'(s_2)} - \frac{t_4'(s_2)}{t_2'(s_2)^2} + O(f^{-2}), \tag{28} \]

and add 0 to Eq. (26) written as \(1/t_2(s) - 1/(t_2'(s_2)(s - s_2))\), we obtain for \(t(s)\) Eq. (11) with \(A(s)\) given by Eq. (10), i.e., we recover our naive derivation of the modified IAM by subtracting at the Adler zeros.

Note however, that in contrast to the derivation where we used an arbitrary \(z_0\), now all subtractions have been performed in the very low energy region so that chiral expansions for pole terms are well justified within ChPT. The price to pay is that in the right cut integral terms we have approximated \(s_A\) by \(s_2\), which is irrelevant in the Adler zero region since the pole contributions dominate there, and a remarkably good approximation in the physical and resonance regions. Of course, we have still used exact elastic unitarity in the integrands over the physical cut, which ensures that the modified IAM satisfies exact elastic unitarity.

5 Modified IAM: unequal masses.

When dealing with unequal masses, as in the \(\pi K\) scattering case that we will use for reference, in addition to the left and right cuts, there is also a circular cut centered at \(s = 0\) with radius \(\sqrt{m_K^2 - m_s^2}\) that contributes to the dispersion relation. This circular cut lies in the low energy region within the applicability range of ChPT and thus, as we do with the left cut, we will approximate the inverse amplitude by its ChPT series to fourth order. Taking into account that \(t_2(s)\) has no cuts we will have \(CC(1/t) = -CC(t_4/t_2)\), where \(CC\) stands for the circular cut contribution. This is the same approximation used before for the left cut and therefore we obtain the same IAM dispersive derivation. Hence, there is still the same problem with Adler zeros and spurious poles.

The solution given in previous sections works similarly well for the \(I = 3/2\) and \(J = 0\) partial wave. However, for the \(I = 1/2, J = 0\) \(\pi K\) scattering channel complications arise due to the form of the LO partial wave \(t_2(s)\) which has two zeros instead of one.

\[ t_2(s) = \frac{5(s - s_{2+})(s - s_{2-})}{128 \pi f s}, \tag{29} \]

with \(s_{2\pm} = \frac{1}{2} \left( m_K^2 + m_s^2 \pm 2 \sqrt{4m_K^2 - 7m_K^2 m_s^2 + 4m_s^4} \right) \) whose values are \(s_{2+} = 0.24 \text{ GeV}^2\), and \(s_{2-} = -0.13 \text{ GeV}^2\). In particular, this means that, contrary to the previous cases \(t''(s_{2\pm}) \neq 0\), which complicates the derivation of a modified IAM. Nevertheless, once again we have found for this special case of the \(I = 1/2, J = 0\) channel, a naive and two dispersive derivations, that we detail next.

5.1 Naive derivation, \(I = 1/2, J = 0\) channel

Following section 3, we define \(1/t IAM = 1/t IAM + A IAM(s)/t_2^2(s)\) with \(A IAM(s)\) an analytic function at least off the real axis and real for real \(s\) to preserve the unitarity and analytic properties of the original amplitude. Next we expand \(1/t IAM\) in Laurent series around \(s = s_{2+}\), taking into account that now \(t_2''(s) \neq 0\), obtaining

\[ \frac{1}{t IAM(s)} = -\frac{t_4(s_2)}{t_2'(s_{2+})^2(s - s_{2+})^2} + \frac{t_2'(s_{2+}) - t_4'(s_{2+})}{t_2'(s_{2+})^2(s - s_{2+})} + \frac{t_4(s_{2+})t_2''(s_{2+})}{t_2'(s_{2+})^3(s - s_{2+})} + O(s - s_{2+})^0. \tag{30} \]

As in section 3 we subtract the pole at \(s_{2+}\) and add a pole at \(s_A\) to the inverse amplitude, and the constant in the \(s_A\) pole term is calculated perturbatively in order to match the chiral expansion at low energies. Note that, following our previous arguments, we do not need to subtract the \(s_{2-}\) pole, since \(\text{Im} t_4 \neq 0\) on the LC, so that no spurious pole will appear in that region. Proceeding then as in section 3 we get now:

\[ A IAM(s) = \frac{t_2(s_2)^2}{t_2'(s_{2+})^2} \left[ \frac{t_4(s_{2+})}{(s - s_{2+})^2} - \frac{(s_{2+} - s_A)}{(s - s_{2+})(s - s_A)} \left( \frac{t_2'(s_{2+}) - t_4'(s_{2+})}{t_2'(s_{2+})} + \frac{t_4(s_{2+})t_2''(s_{2+})}{t_2'(s_{2+})} \right) \right]. \tag{31} \]
Then, Eq. (11) with $A^{mIAM}(s)$ above unitarizes the $I = 1/2$, $J = 0$ channel and has an Adler zero of the correct chiral order and has no spurious pole. Let us remark that the above $A^{mIAM}(s)$ is a generalization also valid for the equal mass case, since it is reduced to the $A^{mIAM}(s)$ we already obtained in Eq. (16) when $t'^4_2(s_{2+}) = 0$.

Apart from this naive formal derivation we can follow a dispersive approach, detailed next, in which we make use of analyticity and the ChPT series is only used within its applicability region.

### 5.2 Dispersive derivation at $z_0$, $I = 1/2$, $J = 0$ channel

The derivation follows exactly that of section 2.1 but now, due to the additional zero, $s_{2-}$, of $t_2$, which lies on the negative axis, we cannot simply write, as usually done, $\int_{LC} \text{Disc} t_4/t^2_2 = 2i \int_{LC} \text{Im} t_4/t^2_2$, nor $\int_{LC} \text{Disc} 1/t_2 = 0$, where $\text{Disc} f = f(x + i\epsilon) - f(x - i\epsilon)$ with real $x$. This zero also modifies the form of the dispersion relation for $1/t_2$, that now reads

$$\frac{1}{t_2(s)} = \frac{1}{t_2(z_0)} + PC_+(1/t_2) + PC_-(1/t_2), \quad PC_{\pm}(1/t_2) = \frac{1}{t^2_2(s_{2\pm})} \left( \frac{1}{s - s_{2\pm}} - \frac{1}{z_0 - s_{2\pm}} \right) \tag{32}$$

Following the same steps as in section 2.1, we approximate $1/t$ on the left cut by its chiral expansion, but now taking into account that, as mentioned above, $\int_{LC} dz \text{Disc} (1/t_2(z)) \neq 0$, i.e.

$$\text{LC}(1/t) = \frac{s - z_0}{2\pi i} \int_{LC} \frac{\text{Disc} 1/t_2(z)}{(z - s)(z - z_0)} \approx \frac{s - z_0}{2\pi i} \int_{LC} \frac{\text{Disc} (1/t_2(z) - t_4(z)/t^2_2(z))}{(z - s)(z - z_0)} \tag{33}$$

where we now get $-\text{LC}(t_4/t^2_2)$ as before, and a new term coming from $1/t_2$,

$$\frac{s - z_0}{2\pi i} \int_{LC} \frac{\text{Disc} 1/t_2(z)}{(z - s)(z - z_0)} = \frac{s - z_0}{2\pi i} \int_{LC} \frac{(1/t_2(z + i\epsilon) - 1/t_2(z - i\epsilon))}{(z - s)(z - z_0)} \tag{34}$$

\begin{align*}
\int_{LC} \frac{(z - s_{2-})/t_2(z)}{(z - s)(z - z_0)} & = -(s - z_0) \int_{LC} \frac{\delta(z - s_{2-})}{(z - s)(z - z_0)} = \frac{1}{t^2_2(s_{2-})} \left( \frac{1}{s - s_{2-}} - \frac{1}{z_0 - s_{2-}} \right)
\end{align*}

which is equal to $PC_-(1/t_2)$, so they will cancel in the expression for $1/t$. Thus we again obtain Eq. (17), but now the explicit expression for $PC(t_4/t^2_2)$ at $s = s_{2+}$ is different from Eq. (18) because $t'^2_2(s) \neq 0$,

$$PC(t_4/t^2_2) = \frac{t_4(s_{2+})}{t'^2_2(s_{2+})} \left( \frac{1}{(s - s_{2+})^2} - \frac{1}{(z_0 - s_{2+})^2} \right) + \frac{t'_4(s_{2+})t'^2_2(s_{2+})}{t'^2_2(s_{2+})^2} \left( \frac{1}{s - s_{2+}} - \frac{1}{z_0 - s_{2+}} \right) \tag{35}$$

Finally, we get

$$t^{z0IAM}(s) = \frac{t^2_2(s)^2}{t^2_2(s) - t^4_4(s) + A^{z0IAM}(s)} \tag{36}$$

with

$$A^{z0IAM}(s) = t^2_2(s) \left( -PC_+(1/t_2) + PC(t_4/t^2_2) + PC(1/t) \right) \tag{37}$$

where, again, we evaluate $1/4'(s_A)$ in $PC(1/t)$ perturbatively, obtaining for $A(s)$

$$A^{zIAM}(s) = A^{mIAM}(s) - \frac{t^2_2(s)^2}{t_2(z_0)^2} A^{mIAM}(z_0) \tag{38}$$

Formally, this looks the same as Eq. (21) but now $A^{mIAM}(s)$ is of a more general form. Indeed, we obtain again $A^{mIAM}(s)$ plus a term depending on $z_0$, which is also $O(f^{-6})$. Nevertheless we will see that, as long as $z_0$ remains in the range of validity of the approximations, the latter is numerically small not only in the physical region but also in the subthreshold region, so that it can be neglected to obtain the naive simpler formula, thus justifying numerically the mIAM and the IAM.

However, a derivation of the mIAM that differs from the standard one since subtractions are made at the Adler zeros is also possible for the unequal mass case, and we detail it next.
5.3 Dispersive derivation subtracting at the Adler zeros, $I = 1/2$, $J = 0$ channel

The derivation follows closely that in section 4.2 but now we will have extra terms (not negligible in the chiral expansion) coming from $\text{Disc} \, 1/t_2$ in the left cut when $s_A$ is expanded around $s_2$. In addition, the expressions for the pole contributions are more complicated because $t'_2(s) \neq 0$.

We again expand the left cut to NLO:

$$
\text{LC}(1/t) \simeq \frac{s - s_{2+} - s_4}{2\pi i} \int_{\text{LC}} dz \frac{\text{Disc} \left(1/t_2(z) - t_4(z)/t_2(z)^2\right)}{(z - s)(z - s_{2+})} \left(1 + \frac{s_4}{z - s_{2+}}\right)
$$

$$
\simeq -LC(t_4/t_2^2) + \frac{s - s_{2+}}{t'(s_{2-})(s - s_{2-})(s - s_{2+})} - \frac{t'_2(s_{2+})t'_2(s_{2-})(s_{2+} - s_{2-})}{t'_2(s_{2+})},
$$

(39)

where we obtain $-LC(t_4/t_2^2)$ plus two extra terms. The pole contributions now read

$$
\text{PC}(1/t) = \frac{1}{t'(s_A)(s - s_A)} - \frac{t''(s_A)}{2t'(s_A)^2},
$$

(40)

$$
\text{PC}(t_4/t_2^2) = \frac{t_4(s_{2+})}{t'_2(s_{2+})^2(s - s_{2+})^2} + \frac{s - s_{2+}}{t'_2(s_{2+})^2 - t'_2(s_{2+})^3} \frac{1}{s - s_{2+}}
$$

$$
+ \frac{t'_2(s_{2+})}{2t'_2(s_{2+})^2} - \frac{t'_2(s_{2+})^3}{t'_2(s_{2+})^3} + \frac{3t_4(s_{2+})t'_2(s_{2+})^2}{4t'_2(s_{2+})^4} - \frac{t_2(s_{2+})}{3t'_2(s_{2+})^3},
$$

(41)

where all terms in $\text{PC}(1/t)$ will be evaluated perturbatively excepting $1/(s - s_A)$, that is the one that gives the needed pole at $s_A$ to the inverse amplitude. Then, adding the dispersion relations for $1/t$ and $t_4/t_2^2$, and using that

$$
\frac{1}{t_2(s)} = \frac{t'_2(s_{2+})(s - s_{2+})}{2t'_2(s_{2+})^2} + \frac{s - s_{2+}}{t'_2(s_{2-})(s - s_{2-})(s - s_{2+})} - \frac{t'_2(s_{2+})}{2t'_2(s_{2+})^2},
$$

(42)

we thus arrive to $A^{mIAM}$ in Eq. 31 plus $O(f^{-6})$ terms that can be safely neglected since they all correspond to the chiral expansion at very low energies.

6 Numerical Results: comparison between different approaches and $z_0$ sensitivity.

In this section we compare numerically the IAM with the modified methods we have derived. The precise values of the ChPT low energy constants are not relevant for what we want to show here. Just for illustration, we taken for SU(2) ChPT the typical values of $t'_1 = 0.82$, $t'_2 = 6.2$ from the second reference in [1], at a renormalization scale $\mu = 770$ MeV. The values $t'_1 = -3.7$, $t'_2 = 5.0$ have been obtained from an IAM fit to $\pi \pi$ scattering data. In particular, we have used the same data sets used in the IAM fits of the second reference in [3] but we have updated the controversial $f_0(600)$ channel by using the choice of data explained in [19] consistent with forward dispersion relations and Roy equations as shown in [20]. For $\pi K$ scattering we have chosen the central values of the SU(3) ChPT constants of the IAM I set in the last reference of [8].

We show in Fig. 2 several plots comparing the IAM and mIAM results for the modulus of different partial waves of $\pi \pi$ and $\pi K$ elastic scattering in the scalar channel. We see that both methods are indistinguishable in the physical region, shown in the left column, and only differ in the Adler zero region which is shown in detail in the right column. Note that the IAM has a spurious pole and a double zero in that region, whereas the mIAM does not have such pole and its zero is simple.

We have also calculated the $\sigma$ and $\kappa$ pole positions with the IAM and the mIAM, obtaining the same pole position within $\sim 1$ MeV, as shown in Table 1

In the derivation of the $z_0$ IAM, we have an arbitrary subtraction point $z_0 \neq s_2, s_A$, but we only know how to calculate the amplitude at $z_0$ if we can use the chiral expansion $1/t(z_0) \simeq 1/t_2(z_0) - t_4(z_0)/t_2(z_0)^2$, which is only valid if $z_0$ lies on the low energy region. Also, due to $t_2$ having a zero at $s_2$, the above expansion is a
Figure 2: Comparison between the IAM and the mIAM for different isospin $I$ partial waves of $\pi\pi$ and $\pi K$ in the scalar $J = 0$ channel. The left column covers the region from the left cut up to 1 GeV. The only significant differences between both methods occurs in the region around the Adler zeros of each partial wave, which is shown in detail in the right column.
| Method       | $\sigma$ pole       | $\kappa$ pole       |
|--------------|---------------------|---------------------|
| IAM          | 443.71 – $i$ 217.58 | 742.4 – $i$ 216.2   |
| mIAM         | 443.68 – $i$ 217.56 | 725.3 – $i$ 216.3   |
| $z_0$IAM, $z_0 = s_{th}$ | 443.82 – $i$ 216.99 | 727.7 – $i$ 210.0   |

Table 1: $\sigma$ and $\kappa$ pole positions calculated with the IAM, the mIAM and the $z_0$IAM with $z_0 = s_{th}$

very bad approximation if $z_0$ is near $s_2$. We can estimate how close $z_0$ could be from $s_A$ and $s_2$ by looking at the expansion

$$\frac{1}{t(z_0)} \approx \frac{1}{t_2(z_0)} - \frac{t_4(z_0)}{t_2(z_0)^2} \approx \frac{1}{t_2(z_0)} \left( 1 + \frac{s_4}{(z_0 - s_2)^2} + \cdots \right). \quad (43)$$

where we have only made explicit the $s_4/(z_0 - s_2)$ pole term. Hence, for our approximations to remain valid, we have to make sure that the ratio $s_4/(z_0 - s_2)$ is small enough. Thus, we show in Fig. 3 the contour plots in the energy and $z_0$ plane of the relative difference between the mIAM and the $z_0$IAM

$$\Delta = \frac{|t^mIAM(s) - t^{z_0IAM}(s)|}{\frac{1}{2}|t^mIAM(s) + t^{z_0IAM}(s)|}, \quad (44)$$

as a function of the energy and $z_0$. We show two contour lines corresponding to $\Delta = 10\%$ and $5\%$. We see that, as long as the choice of $z_0$ is sufficiently far from $s_A$ and $s_2$ (the white lines in the plots) the result of the $z_0$IAM differs little from the mIAM. In particular, we have checked that in order to obtain a relative difference less than 10\% and 5\%, in the worst case, which is the $I = 2, J = 0$ wave, we have to be sure that our choice of subtraction point $z_0$ makes the ratio of $|s_4/(z_0 - s_2)| < 3\%$ and 2\%, respectively. Let us recall that an error of 5\% is a very precise result in this context, since it is much less than the uncertainties (mostly of systematic origin) of the existing data on meson-meson scattering. For instance, just the isospin violation effects, that are usually not taken into account by these experiments, can be estimated at the level of 2 or 3\%, and these are added to further statistical and very big systematic uncertainties.

In summary, the choice of subtraction constant has little relevance for the $z_0$IAM, as long as it lies in a place where the NLO chiral expansion of the inverse amplitude is a good approximation to the inverse itself. In such case, the $z_0$IAM results are very close to those of the mIAM, and therefore to those of the standard IAM in the physical region. This provides a strong check of the stability and robustness of the standard NLO IAM results.

We have also shown in the plots of Fig. 3 a line at $z_0 = s_{th}$, which is a very normal choice of subtraction point, since the subtraction constants can then be written in terms of threshold parameters, which are well studied in the literature. We see that, with this choice of $z_0$, in all cases we have a relative difference $\Delta$ which is less than 5\%. Actually, it is even smaller, as seen in Fig. 4 where we plot in detail the results for $\Delta$ subtracting at $z_0 = s_{th}$, and we see that for $\pi\pi$ we have a relative difference less than 1.5\% for all energies and less than 4\% for the $\pi K$ case.

### 7 Discussion and summary

In this work we have shown that it is possible to modify slightly the one-channel Inverse Amplitude Method (IAM) so that, also in the scalar channel, it provides a reliable description of the unitarized partial wave amplitudes below threshold. In particular, we have shown that it is possible to obtain a modified IAM that has the Adler zeros located in the same place as the Effective Chiral Expansion up to the desired order, that these zeros are single, and that the spurious poles below threshold that occur in the standard IAM are no longer present.

The IAM has been most frequently used at NLO, where the chiral expansion of a partial wave is written as $t(s) = t_2(s) + t_4(s) + \cdots$. For such a case the simplest modification to the IAM that we have found can be written as follows:

$$t^mIAM(s) = \frac{t_2(s)}{t_2(s) - t_4(s) + A^mIAM(s)} \quad (45)$$
Figure 3: Contour plots of the relative differences between the mIAM and the $z_0$IAM in the $(s, z_0)$ plane. We see that, as long as $z_0$ lies in the low energy region but sufficiently far from the the Adler zeros $s_A$ and $s_2$ (white lines) the differences become small for all partial waves. Note that for $z_0 = s_{th}$ (black line) the differences for all cases are less than 5%.
where

$$A^{mIAM}(s) = \frac{t_2(s_2)}{t_2^2(s_2)} \left[ \frac{t_4(s_2)}{(s - s_2)^2} - \frac{(s_2 - s_A)}{(s - s_2)(s - s_A)} \left( t_2'(s_2) - t_2'(s_2) + \frac{t_4(s_2) t_4'(s_2)}{t_2'(s_2)} \right) \right]$$

(46)

and in order to have the Adler zero exactly on its NLO position, we set $s_A \to s_2 + s_4$ where $s_2 = O(m^2)$ and $s_4 \simeq O(m^4/f^2)$ are the Adler zeros at LO and its NLO correction, respectively. That is, they are obtained from $t_2(s_2) = 0$ and $t_2(s_2 + s_4) + t_4(s_2 + s_4) = 0$. In general, $s_4$ should be calculated numerically. The above formula is valid both for the elastic scattering of equal and unequal meson masses. However, in most of the cases, like $\pi\pi$ scattering, the formula simplifies further since $t_2'(s_2) = 0$ and $t_2(s) = t'_2(s)(s - s_2)$. Note also that the $A^{mIAM}(s)$ piece counts as next to next to leading order (NNLO) in the chiral expansion, and for that reason it was neglected in the standard IAM derivation, which is recovered by setting $A^{mIAM}(s) \to 0$ and remains valid in the physical region, since $A^{mIAM}(s)$ is indeed negligible.

In Sect.3 we have given a “naive” formal derivation of $A^{mIAM}(s)$ by adding, in a rather ad hoc way, the pieces needed to fix the Adler zero and spurious pole problems without spoiling unitarity and the chiral symmetry expansion. However, in Sects. 4 and 5 we have shown that the mIAM formulae above can be derived by using the analytic properties of amplitudes in the form of dispersion relations and imposing elastic unitarity on the right cut. The use of the Chiral Effective Expansion is well justified to calculate the subtraction constants and pole contributions to the dispersion relations, and is also used to approximate contributions from other cuts. In particular the integral over the left cut is calculated to NLO, which is a good approximation in the low energy region that dominates the integral. Therefore, there are no model dependencies but just approximations within the effective theory up to a given order. This allows for a straightforward and systematic extension of the elastic IAM and modified IAM to higher orders.

A usual criticism to unitarization methods is their arbitrariness, but we have shown here that the IAM, modified or not, is not just unitarizing, but also imposing a stringent analytic structure on the amplitudes, something that leaves little room for such arbitrariness: the choice of the subtraction points. However, if the chiral effective expansion is to be used to calculate the amplitude at the subtraction points or pole positions, the subtraction points should lie, first of all, in the low energy region. But, in addition, since a dispersion relation is written for the inverse amplitude, that subtraction point should also lie far from the Adler zero. In this work, we have explicitly shown that as long as those two constraints are satisfied, the choice of subtraction point has a very small numerical effect on the resulting amplitude. Moreover, we have shown that the results of the standard IAM in the physical axis and resonance region in the complex plane remain unchanged when using the modified IAM and are extremely stable under different choices of subtraction points.

In summary, we have presented a slightly modified Inverse Amplitude Method for the elastic case, that has the Adler zeros in the correct position and of the correct order and no spurious poles in that region.
We have shown that the results already obtained with the standard IAM are robust in the physical region, where it can still be used safely, but the new modifications allow for the study of the subthreshold region that is of interest in problems like thermal restoration of chiral symmetry \[11\] or the quark mass dependence \[16\] of resonances in meson-meson scattering.

Research partially funded by Banco Santander/Complutense contract PR27/05-13955-BSCH and Spanish contracts FPA2007-29115-E, FPA2005-02327, FPA2004-02602, UCM-CAM 910309. J.R. Peláez research is partly funded by Spanish contract BFM2003-00856, and is part of the EU integrated infrastructure initiative HADRONPHYSICS PROJECT, under contract RI3-CT-2004-506078.

A Chiral counting of pole contributions

Next we will check by explicit calculation that the total pole contribution counts as $O(f^{-6})$ in the amplitude. We will do it for the more general case where $t''_2(s) \neq 0$. In particular, we only need to expand $PC(1/t)$. First note that

\[
t'(s_A) = t'_{2}(s_2 + s_4 + \cdots) + t'_{4}(s_2 + s_4 + \cdots) + O(f^{-6}) = t'_{2}(s_2) + t'_{4}(s_2)s_4 + t'_{4}(s_2) + O(f^{-6}).
\]

With this

\[
\frac{1}{t'(s_A)} = \frac{1}{t'_{2}(s_2)} - \frac{t'_{4}(s_2)^{2} + t'_{4}(s_2)t'_{4}(s_2)}{t'_{2}(s_2)^{3}} + O(f^{-2}).
\]

We also have to expand $1/(s - s_A)$:

\[
\frac{1}{s - s_A} = \frac{1}{s - s_2} - \frac{s_4}{(s - s_2)^2} + O(f^{-4}) = \frac{1}{s - s_2} - \frac{t'_{4}(s_2)}{t'_{2}(s_2)(s - s_2)^2} + O(f^{-4}),
\]

and similarly for $1/(z_0 - s_A)$, where we have taken into account that $t'_{4}(s_2)s_4 = -t_{4}(s_2) + O(f^{-6})$. Hence, we find that

\[
PC(1/t) = \frac{1}{t'(s_A)} \left( \frac{1}{s - s_A} - \frac{1}{s - s_2} \right) = \frac{1}{t'_{2}(s_2)} \left( \frac{1}{s - s_2} + \frac{1}{z_0 - s_2} \right) - \frac{t'_{4}(s_2)}{t'_{2}(s_2)^{2}} \left( \frac{1}{(s - s_2)^2} - \frac{1}{(z_0 - s_2)^2} \right)
\]

so the total pole contribution $PC(1/t) = PC(1/t_2) + PC(t_4^2/t_2^2) = O(f^{-2})$, which yields a $O(f^{-6})$ contribution to $t(s)$.
