Sulfur dioxide inhibits vascular smooth muscle cell proliferation via suppressing the Erk/MAP kinase pathway mediated by cAMP/PKA signaling

D Liu, Y Huang, D Bu, AD Liu, L Holmberg, Y Jia, C Tang, J Du and H Jin

The present study was designed to investigate the role of endogenous sulfur dioxide (SO2) in vascular smooth muscle cell (VSMC) proliferation, and explore the possible role of cross-talk between cyclic adenosine monophosphate (cAMP)/protein kinase A (PKA) and extracellular signal-regulated kinase (Erk)/mitogen-activated protein kinase (MAPK) pathways in this action. By cell counting, growth curve depict, flow cytometry and bromodeoxyuridine (BrdU) labeling assays, we found that SO2 inhibited VSMC proliferation by preventing cell cycle progression from G1 to S phase and by reducing DNA synthesis. SO2 synthase aspartate aminotransferase (AAT1 and AAT2) overexpression significantly inhibited serum-induced proliferating cell nuclear antigen (PCNA) protein expression in VSMCs, demonstrated by western blot analysis. Moreover, overexpression of AAT1 or AAT2 markedly reduced incorporation of BrdU in serum-treated VSMCs. By contrast, either AAT1 or AAT2 knockdown significantly exacerbated serum-stimulated VSMC proliferation. Thus, both exogenous- and endogenous-derived SO2 suppressed serum-induced VSMC proliferation. However, annexin V-propidium iodide (PI) staining and cell cycle analysis demonstrated that SO2 did not influence VSMC apoptosis in the serum-induced proliferation model. In a platelet-derived growth factor (PDGF)-BB-stimulated VSMC proliferation model, SO2 dephosphorylated the active sites of Erk1/2, MAPK kinase 1/2 and RAF proto-oncogene serine/threonine-protein kinase (c-Raf) induced by PDGF-BB. However, the inactivation of the three kinases of the Erk/MAPK pathway was not due to the separate interferences on them by SO2 simultaneously, but a consequence of the influence on the upstream activity of the c-Raf molecule. Hence, we examined the cAMP/PKA pathway, which could inhibit Erk/MAPK transduction in VSMCs. The results showed that SO2 could stimulate the cAMP/PKA pathway to block c-Raf activation, whereas the Ser259 site on c-Raf had an important role in SO2-induced suppression of Erk/MAPK pathway. The present study firstly demonstrated that SO2 exerted a negative regulation of VSMC proliferation via suppressing the Erk/MAPK pathway mediated by cAMP/PKA signaling.

Cell Death and Disease (2014) 5, e1251; doi:10.1038/cddis.2014.229; published online 22 May 2014

Subject Category: Experimental Medicine

Vascular smooth muscle cells (VSMCs), as the major component of tunica media, have an irreplaceable role in vascular morphogenesis and development during embryogenesis and in vascular diseases such as hypertension, diabetes, atherosclerosis and restenosis after rapid response to blood vessel injuries. When resting VSMCs get stimulated by growth factors, they become capable of proliferation, resulting in cell cycle suppression by inactivating MYT1, which restrains cell cycle progression, accelerating p27Kip1 degradation to activate cyclin E/Cdk2 and inducing cyclin D1 transcription to raise DNA synthesis by regulating Cdk4 and Cdk6. This will eventually lead to cell cycle progression.

The endogenous gaseous signaling molecules exert important function in the cardiovascular system. It was reported that the gasotransmitter hydrogen sulfide (H2S) could alleviate vascular remodeling in several blood vessel injury models, probably by inhibiting VSMC proliferation via Erk/MAPK pathway. Another gasotransmitter that shares the same substrates, sulfur-containing amino acids, with H2S is sulfur dioxide (SO2), which can also be...

endogenously generated. However, whether and how SO2 regulates VSMC proliferation has not yet been revealed.

Cyclic adenosine monophosphate (cAMP)/protein kinase A (PKA) can initiate apoptosis by inducing p53 and p21 transcriptions in the suppression of human aortic smooth muscle cells, and it can also prevent growth factor-stimulated Erk/MAPK from being activated in VSMCs. The target of cAMP/PKA signaling on the Erk/MAPK pathway is c-Raf kinase. PKA can phosphorylate the Ser43, Ser233, Ser259 and Ser621 sites in c-Raf, which blocks the Erk/MAPK cascade. The negative regulation in c-Raf activity mediated by Ser621 phosphorylation by PKA was only observed in in vitro experiment, whereas the other three sites played their negative roles in both in vivo and in vitro studies. Ser43 is located in a separate domain from Ser233 and Ser259, which means that these sites can work independently of each other to obstruct c-Raf activation by disturbing the interaction between c-Raf and ras.

It has been reported that the vasorelaxing effect of SO2 is correlated with the prostacyclin/adenylate cyclase (AC)/cAMP/PKA pathway, suggesting a potential connection between SO2 and the cAMP/PKA pathway. Therefore, the present study was undertaken to explore the role of SO2 in the regulation of VSMC proliferation and the signal-transduction pathways in its regulatory process.

Results

SO2 derivatives inhibited serum-stimulated VSMC proliferation. The viability of VSMCs cultured in low-serum medium was not influenced by SO2 derivatives at concentrations of 5, 10, 15, 20, 50 and 100 μmol/l for 24 h, evaluated via CCK-8 assay (Figure 1a), whereas under serum-stimulated proliferation conditions, all of the doses of SO2 derivatives described above could significantly inhibit VSMC proliferation (all \( P < 0.01 \); Figure 1a). The latter was also confirmed by depicting the cell growth curve, which showed that SO2 derivative treatment could decrease serum-induced VSMC proliferation in a specific time course ranging from 0 to 72 h (Figure 1b).

Cell cycle analysis demonstrated that VSMCs in a quiescent state tended to stay in the G0/G1 phase (control group compared with fetal bovine serum (FBS) group, \( P < 0.01 \)); while compared with the FBS group, VSMCs in the SO2-treated groups tended to be in the G0/G1 phase accompanied with lowered proportions of cells in the G2/M and S phase (Figure 1c). Hence, SO2 prevented cell cycle progression from the G1 to the S phase in serum-induced VSMCs.

The incorporation of bromodeoxyuridine (BrDU) was increased PDGF-BB-induced cyclin D1 protein expression (\( P < 0.01 \)), whereas AAT1 or AAT2 silencing significantly exacerbated serum-induced VSMC proliferation (Figure 1d). Consistently, serum-enhanced protein expression of PCNA was confirmed in VSMCs transfected with AAT1 or AAT2 shRNA, as well as the incorporation of BrDU (Figures 3f and g). These data strongly support a significant role of endogenously derived SO2 in the regulation of VSMC proliferation.

SO2 overexpression suppressed serum-induced VSMC proliferation. SO2 could be produced endogenously from sulfur-containing amino-acid l-cysteine in mammals through transamination by aspartate aminotransferase (AAT). To further verify the inhibitory effect of endogenous SO2 on VSMC proliferation, we overexpressed two types of isoforms of AAT (AAT1 and AAT2) in VSMCs. Transfection of VSMCs with AAT1 plasmid or AAT2 plasmid at 2 μg markedly increased AAT1 or AAT2 mRNA and protein level compared with vehicle-transfected VSMCs (Figures 2a–d). Therefore, we used 2 μg in subsequent studies. Western blot analysis revealed that either AAT1 or AAT2 overexpression inhibited serum-induced proliferating cell nuclear antigen (PCNA) protein expression in VSMCs (Figure 2e). Similarly, over-expression of AAT1 or AAT2 significantly reduced incorporation of BrDU in serum-treated VSMCs (Figure 2f). Thus, both exogenous- and endogenous-derived SO2 suppressed serum-induced VSMC proliferation.

SO2 deficiency aggravated serum-stimulated VSMC proliferation. To further investigate the potential role of endogenous SO2 in VSMC proliferation, we knocked down AAT1 or AAT2 by shRNA. Specific knockdown of AAT1 or AAT2 was verified by both the mRNA and protein levels (Figures 3a–d). CCK-8 assay showed that either AAT1 or AAT2 silencing significantly exacerbated serum-induced VSMC proliferation (Figure 3e). Consistently, serum-enhanced protein expression of PCNA was suppressed in VSMCs transfected with AAT1 or AAT2 shRNA, as well as the incorporation of BrDU (Figures 3f and g). These data strongly support a significant role of endogenously derived SO2 in the regulation of VSMC proliferation.

Erk/MAPK pathway was involved in the inhibition of PDGF-BB-induced VSMC proliferation by SO2 derivatives. Another part of the BrDU incorporation assay demonstrated that pretreatment with SO2 derivatives at 15 μmol/l in 30 min could markedly lessen DNA synthesis in PDGF-BB-treated VSMCs within 24 h (\( P < 0.01 \); Figures 4a and b). Cyclin D1 protein level in VSMCs was elevated within 24 h after stimulation with PDGF-BB at 50 ng/ml (\( P < 0.01 \)), whereas pretreatment with SO2 derivatives at 15 μmol/l suppressed PDGF-BB-induced cyclin D1 protein expression (\( P < 0.01 \); Figure 4c). The inhibitory effect of SO2 derivatives on cyclin D1 was consistent with the reduced S-phase progression. To further confirm the effect of SO2 on cyclin D1 expression, we overexpressed or knocked down SO2 synthesize AAT1 or AAT2 and tested the level of cyclin D1 in VSMCs. As expected, AAT1 or AAT2 overexpression remarkably decreased PDGF-BB-enhanced cyclin D1 expression, whereas AAT1 or AAT2 silencing aggravated PDGF-BB-induced cyclin D1 level (Figures 4d and e). To determine the signal-transduction basis of cell cycle arrest induced by SO2, we evaluated the activity of Erk/MAPK pathway with the same stimulation method by PDGF-BB. Compared with control cells, cells treated with PDGF-BB displayed a significant increase in Erk1/2, MAPK kinase 1/2 (MEK1/2) and c-Raf activities (all \( P < 0.01 \)), but not in protein expression of these three signaling molecules (Figures 4f–k). In contrast, SO2 could dephosphorylate the active sites of

SO2 inhibits VSMC proliferation

D Liu et al
Erk1/2 on Thr202/Tyr204, MEK1/2 on Ser217/221 and c-Raf on Ser338 (P < 0.05, P < 0.05 and P < 0.01, respectively; Figures 4f–k). These findings implied that the inhibitory effect of SO₂ on VSMC proliferation might be mediated by the Erk/MAPK pathway.

SO₂ derivatives could not directly influence the activation of Erk1/2, MEK1/2 and c-Raf. We constructed three types of constitutively active (CA) MEK plasmids, breaking the stabilization of the inactive state of MEK. HEK293 cells exposed to CA-MEK plasmid transfection showed a sustained increased phosphorylation of Erk1/2 compared with that in the MEK wild-type group (all P < 0.05; Figure 5a). However, the pretreatment with SO₂ derivatives could not suppress the phosphorylation of Erk1/2 activated by mutant CA-MEK (Figure 5a), indicating that SO₂ derivatives were unable to inhibit the phosphorylation of Erk1/2 molecule directly. We inferred from the result that the inhibitory effect of SO₂ might result from upstream Erk1/2 molecules.

c-Raf kinase activity assay is based on the biochemical reaction using inactive recombinant MEK1 as a c-Raf substrate. After extracting cytoplasmic protein from normal cultured VSMCs, we added the total proteins (containing active c-Raf) and SO₂ derivatives at 5, 10, 15 and 20 μmol/l into the enzymatic reaction system. We found that there was no difference between the control group and the SO₂ derivative-treated groups (Figure 5b). To assess the effect of SO₂ on specific c-Raf kinase activity, we used the recombinant c-Raf protein purified from human HEK293 cells instead of extracting cytoplasmic protein. Similarly, the results showed that SO₂ did not change the phosphorylation of recombinant MEK1 (Figure 5c), which suggested that SO₂
derivatives could not directly interfere with the activation of the MEK1 molecule and neither could they reverse the active c-Raf to a silent state. Interestingly, however, if we pretreated the intact VSMCs with SO₂ derivatives and then stimulated c-Raf activity by PDGF-BB, the c-Raf extracted from those cells displayed lowered activity represented by decreased phosphorylation of the recombinant MEK1 compared with cells that were not pretreated with SO₂ derivatives (P < 0.01; Figure 5d). Thus, we should focus on the c-Raf molecule and its upstream signaling molecules to further investigate the mechanisms by which SO₂ could inhibit the Erk/MAPK pathway and VSMC proliferation.

The interaction of cAMP/PKA and Erk/MAPK pathways mediated SO₂ derivative-induced suppression of VSMC proliferation. To further determine the upstream signaling involved in the inhibition of Erk/MAPK by SO₂ derivatives, we first paid great attention to phosphorylating sites on c-Raf, including the active site Ser338 and the blocking sites Ser259 and Ser43, the targets of the cAMP/PKA pathway. The pretreatment with SO₂ derivatives reduced the phosphorylations of Erk1/2 on Thr202/Tyr204, MEK1/2 on Ser217/221 and c-Raf on Ser338 in VSMCs after short-term stimulation by PDGF-BB at 20 ng/ml (P < 0.05, P < 0.01 and P < 0.05, respectively; Figures 6a–c). Nevertheless, in

Figure 2  SO₂ overexpression inhibited serum-induced VSMC proliferation. (a and b) mRNA levels of AAT1 (a) and AAT2 (b) were quantified by real-time PCR. VSMCs were transfected by different amounts of AAT1 or AAT2 for 24 h. *P < 0.05. (c and d) Protein expression of AAT1 and AAT2 in VSMCs transfected with 2 μg AAT1, AAT2 plasmid or vehicle for 48 h. *P < 0.05. (e) Representative western blot and quantification of PCNA in VSMCs transfected with AAT1, AAT2 plasmid or vehicle before serum treatment. *P < 0.05 compared with vehicle and #P < 0.05 compared with the serum group. (f) Inhibitory effects of SO₂ overexpression on DNA synthesis in serum-induced VSMCs. Cells in coverslips were transfected with AAT1, AAT2 or vehicle before serum treatment for immunofluorescence assay of BrdU incorporation. Green fluorescence stands for cells with DNA synthesis, whereas red fluorescence stands for total cells. *P < 0.05 compared with the control group and #P < 0.05 compared with the serum group. Data are means ± S.D. of at least three independent experiments, each in triplicate.
contrast, SO2 derivative-pretreated cells displayed an increasing phosphorylation of c-Raf on Ser259 compared with PDGF-BB-treated cells (P < 0.05). Meanwhile, there was no difference in Ser43 phosphorylation between the two groups (Figure 6a). Furthermore, compared with resting cells, the cells treated only by SO2 derivatives for 30 min showed a high phosphorylating level both in Ser259 and Ser43 sites (both P < 0.05; Figure 6a). The findings illustrated that even though SO2 derivatives could stimulate c-Raf phosphorylation on both Ser259 and Ser43 sites, as for PDGF-BB treatment, the Ser259 site of c-Raf had an important role in the signaling crosstalk mechanism in which SO2 derivative-induced suppression of the Erk/MAPK pathway was involved.

Subsequently, we used Forskolin, an AC activator that could increase the intracellular cAMP concentration, and
H-89, a selective inhibitor of PKA, to determine the role of SO2 derivatives in the cAMP/PKA pathway. As the key of crosstalk between cAMP/PKA and Erk/MAPK pathways, the two sites, Ser259 and Ser43 of c-Raf as the targets of PKA signaling, showed high phosphorylations in both SO2 derivative- and Forskolin-treated groups (all \(P<0.05\); Figure 6d), accompanied with the same changing tendency in the activation of the PKA signal (both \(P<0.01\); Figure 6d). SO2 could not release the repressed activity of PKA pretreated with H-89 in advance, indicating that the stimulation step of cAMP/PKA pathway by SO2 derivatives might occur in the signaling pathway upstream of the PKA molecule. Fortunately, by examining the cAMP concentrations by the same interference method as above, we discovered that SO2 derivatives could elevate cAMP concentration no matter whether the cells were pretreated with H-89 or not (both \(P<0.01\); Figures 7a and b).

To complement this study, we also evaluated the proliferative status influenced by SO2 after interfering with both cAMP/PKA and Erk/MAPK pathways. As the key of crosstalk between cAMP/PKA and Erk/MAPK pathways, the two sites, Ser259 and Ser43 of c-Raf as the targets of PKA signaling, showed high phosphorylations in both SO2 derivative- and Forskolin-treated groups (all \(P<0.05\); Figure 6d), accompanied with the same changing tendency in the activation of the PKA signal (both \(P<0.01\); Figure 6d). SO2 could not release the repressed activity of PKA pretreated with H-89 in advance, indicating that the stimulation step of cAMP/PKA pathway by SO2 derivatives might occur in the signaling pathway upstream of the PKA molecule. Fortunately, by examining the cAMP concentrations by the same interference method as above, we discovered that SO2 derivatives could elevate cAMP concentration no matter whether the cells were pretreated with H-89 or not (both \(P<0.01\); Figures 7a and b).

To complement this study, we also evaluated the proliferative status influenced by SO2 after interfering with both
The results showed that SO2 could inhibit PDGF-BB-stimulated VSMC proliferation \((P<0.01)\), whereas H-89 reversed the SO2 derivative-induced suppression of proliferation by repressing PKA activity \((P<0.01; \text{Figure 7c})\). According to the above findings, we deduced that SO2 might inhibit VSMC proliferation by stimulating AC activity.

**Discussion**

Along with the recognition of H2S as a gaseous signaling molecule in the cardiovascular system, there has been increasing attention paid to the physiological and pathophysiological functions of SO2, as a novel gasotransmitter in cardiovascular regulation. L-Cysteine is the major precursor of endogenous SO2. It can be metabolized to L-cysteine sulfinate by cysteine dioxygenase (CDO). L-Cysteine sulfinate is then metabolized to \(\beta\)-sulfinylpyruvate via AAT.20,29 \(\beta\)-Sulfinylpyruvate degrades rapidly, producing pyruvate and SO2.20,29 Some of the endogenous SO2 is hydrated to sulfite, whereas the other part stays in the gaseous form.30,31 Our previous study demonstrated CDO and AAT expression in several tissues and organs in mammals accompanied with the generation of SO2.32 The plasma concentration of endogenous SO2 in Wistar rats is 15.44 ± 1.68 \(\mu\)mol/l, evaluated by high-performance liquid chromatography with fluorescence detection.33 The studies on hypoxic pulmonary hypertensive rats showed that SO2 might be involved in the pathogenesis.34 However, whether does SO2 regulate VSMC proliferation? If it does, what are the possible regulatory mechanisms? All the questions have no answer.

In their resting state, VSMCs in adults maintain their contractile phenotype. When vascular injury occurs, VSMCs can undergo phenotypic switching into the synthetic phenotype to repair the vasculature by their remarkable plasticity, representing migration and proliferation.1 Although this phenotypic modulation of VSMCs might derive from evolutionary self-repair ability, the consequences are mostly unsatisfying, resulting in conditions such as restenosis.35 In addition, several studies have found that this part of phenotypic switching VSMCs shows heterogeneity and might be from a monoclonal origin, similar to that of tumorigenesis.36–39 Therefore, if we could find a regulating procedure in VSMC proliferation, it will help preventing this excessive self-repairing.

The present research demonstrated that SO2 could bring about cell cycle arrest in both FBS- and PDGF-BB-treated VSMCs by downregulating DNA synthesis to delay the proliferation process. After recognizing PDGF receptors, PDGFs combine with their specific RTKs and activate ras to initiate MAPK signaling.40 As shown in this study, SO2 led to...
decreasing DNA synthesis and cyclin D1 protein expression in PDGF-BB-treated VSMCs simultaneously with the inactivation of Erk/MAPK pathway, implying that the Erk/MAPK cascade mediated the suppressing effect of the proliferation.

As the signal transduction of Erk/MAPK pathway is a series of kinase reactions in sequence, we need to clarify if the inactive Erk1/2, MEK1/2 and c-Raf are the result of separate targeting interferences of SO2 or from the inhibition of upstream signal transduction pathways. 

**Figure 6** The crosstalk between cAMP/PKA and Erk/MAPK pathways mediated SO2-suppressed Erk/MAPK signaling. (a–c) Cells, starved for 24 h, were pretreated with or without Na2SO3/NaHSO3 at 15 μmol/l for 30 min and treated with or without PDGF-BB at 20 ng/ml for 30 min. Cellular proteins were extracted for western blotting to determine the phosphorylations of Erk1/2, MEK1/2 and c-Raf on Ser338, Ser259 and Ser43. *P<0.05 and **P<0.01 compared with the control group, and *P<0.05 and #P<0.01 compared with the PDGF-BB group (n=3, each containing triplicate). (d) Cells, starved for 24 h, were untreated or treated with Na2SO3/NaHSO3 at 15 μmol/l for 30 min, or treated with Forskolin at 30 μmol/l for 30 min, or treated with H-89 at 20 μmol/l for 20 min and then treated with Na2SO3/NaHSO3 at 15 μmol/l for 30 min. The phosphorolizations of c-Raf on Ser259 and Ser43 and PKA on Thr197 were estimated by western blotting analysis. *P<0.05 and **P<0.01 compared with the control group (n=3, each containing triplicate). Data are presented as mean ± S.D. of three independent experiments, each in triplicate.

**Figure 7** cAMP elevation in VSMCs by SO2 derivatives may mediate the inhibition of proliferation. (a and b) Cells, starved for 24 h, were untreated or treated with Na2SO3/NaHSO3 at 15 μmol/l for 30 min, or treated with Forskolin at 30 μmol/l for 30 min, or treated with H-89 at 20 μmol/l for 30 min, or pretreated with H-89 at 20 μmol/l for 20 min and then treated with Na2SO3/NaHSO3 at 15 μmol/l for 30 min. Samples of cellular extractions and culture supernatants were used for the measurement of cAMP concentrations. *P<0.05 and **P<0.01 compared with the control group, and #P>0.01 compared with the H-89 group (n=3, each containing triplicate). (c) Cells, starved for 24 h, and treated sequentially with H-89 at 20 μmol/l, Na2SO3/NaHSO3 at 15 μmol/l and PDGF-BB at 50 ng/ml. After 24 h, the proliferative rate was evaluated by Cell Counting Kit-8 (CCK-8) assay. **P<0.01 (n=6, each containing triplicate). Data are presented as mean ± S.D. of three to six independent experiments, each in triplicate.
transmission. Nevertheless, SO₂ could not impede activation of Erk1/2 by CA-MEK, or retard the enzymatic reaction catalyzed by c-Raf to produce activate MEK, both of which support that the negative effects of SO₂ on the Erk/MAPK pathway were mediated by upstream signals.

The activation of c-Raf needs the cooperation of several kinases, phosphatases and scaffolding proteins, which compose a complex surrounding c-Raf. As the center subunit, the phosphorylations of different sites on c-Raf decide the conformation of the complex, leading to an ‘active’ or ‘inactive’ structure. The phosphorylations of the four sites, Ser328, Tyr341, Thr491 and Ser494, are essential for c-Raf activation. However, in VSMCs, the cAMP/PKA pathway can target c-Raf by blocking its activation. PKA could stimulate Ser621, Ser43, Ser233 and Ser259 on c-Raf separately to inhibit c-Raf activation. Our present study corresponded with our present study in VSMCs.

The phosphorylation of Ser43 on c-Raf could directly hinder the ‘active’ conformation of the complex, whereas Ser233 and Ser259 manage to recruit 14-3-3 proteins to the N terminus of c-Raf to disturb ras binding. Our present study considered the Ser43 and Ser259 sites on c-Raf as subjects to seek for the interaction between the two signal pathways. The results showed that in quiescent VSMCs, Ser259 displayed mild phosphorylation, whereas PDGF-BB treatment did not change this status. However, if pretreated with SO₂ derivatives, PDGF-BB-induced VSMCs had a further increased quantity of Ser259 phosphorylation, lowered c-Raf kinase activity and increased PKA activation, suggesting that SO₂ derivatives might inhibit c-Raf activation by stimulating Ser259 phosphorylation on c-Raf by triggering PKA. Regarding the Ser43 site on c-Raf, we found that it stayed in a dephosphorylated state in resting VSMCs, and meanwhile, both PDGF-BB and SO₂ derivative treatment could elevate its phosphorylation level, respectively. The similar phosphorylation of Ser43 on c-Raf between the PDGF-BB group and the PDGF-BB + SO₂ derivative group implied that the antagonistic effect of SO₂ derivatives on PDGF-BB-stimulated c-Raf was not a result of the phosphorylation of Ser43 in VSMCs.

Until now, the underlying mechanism of the inactivation of c-Raf stimulated by PKA is still completely unrevealed, partly because of the complicated conformation of c-Raf and its scaffold proteins. Therefore, several models exist simultaneously. In resting cells, both Ser259 and Ser621 on c-Raf presented phosphorylation binding with 14-3-3 proteins to maintain the complex in a ‘closed’ state. Previous research testified that compared with Ser621, Ser259 was more important to modulate c-Raf complex conformation. The activation of ras could isolate 14-3-3 proteins from the CR2 domain in c-Raf, accompanied with dephosphorylation of Ser259, resulting in c-Raf activation and MEK coupling. When the PKA signal was agonized by high levels of cAMP-phosphorylated Ser43 and Ser233 on c-Raf, 14-3-3 proteins could find another binding site, Ser233, on c-Raf, and eventually c-Raf inactivation occurred. Other research groups discovered that in quiescent cells, merely 30% of the Ser259 sites on c-Raf showed phosphorylation and were coupled with 14-3-3 proteins, and cAMP could make Ser259 phosphorylation promoted by two- to threefold. This finding corresponded with our present study in VSMCs. The combination of 14-3-3 proteins and Ser259 could impede the recruitment of c-Raf to proximal cytomembrane for activation, whereas increasing cAMP could recruit c-Raf with dephosphorylated Ser259 to the cytomembrane area. Even though there are still controversies about those c-Raf complex models, just as the opposite effects of the cAMP/PKA pathway on the Erk/MAPK signaling in distinct cell types, the diversity of c-Raf sites’ phosphorylation in quiescent state or induced by PKA might be associated with species or tissue specificity. Therefore, our present study results are interesting, as they demonstrate that in PDGF-BB-stimulated rat VSMCs, the phosphorylation on Ser259 of c-Raf induced by SO₂-activated PKA might attribute to the inhibition of Erk/MAPK transmission.

For further exploration, we used a PKA inhibitor and an AC agonist to look for the target of SO₂ on the cAMP/PKA pathway by analyzing cAMP concentration and PKA activation. The results revealed that SO₂ could elevate cAMP production, no matter whether PKA was blocked or not. This implicates that SO₂ might enhance AC activity to increase cAMP generation and in this way facilitate the effect of PKA on Ser259 of c-Raf. In addition, according to CCK-8 assay, blocking PKA activity could prevent SO₂ from suppressing PDGF-BB-induced VSMC proliferation, meaning that SO₂ derivatives might inhibit VSMC proliferation via the interaction between the cAMP/PKA and the Erk/MAPK pathways (Figure 8).

In conclusion, the present study justified the inhibitory effect of SO₂ derivatives on rat VSMC proliferation by downregulating the activity of Erk/MAPK pathway. The underlying mechanism might involve elevating cellular cAMP production by SO₂ to activate the PKA signal, resulting in phosphorylation on Ser259 of c-Raf to block its activation. Eventually, this will contribute to the suppression of the Erk/MAPK signaling transduction.
Materials and Methods

Cell culture. Rat A7r5 VSMCs and HEK293 cells were both obtained from the American Type Culture Collection (Manassas, VA, USA). Cells were cultured in Dulbecco’s modified Eagle’s medium (DMEM) containing 10% FBS, 2 mmol/l glutamine and 20 mmol/l HEPES (pH 7.4) in an atmosphere of 5% CO2 at 37°C.

SO2 derivatives. SO2 is mainly derived from sulfite (SO32-) and bisulfite (HSO3-) generated after SO2 dissolves in cellular cytoplasm. SO2 can easily be hydrated to produce sulfurous acid, which subsequently dissociates to form its derivatives. SO32- and HSO3- (3:1 mole ratios in neutral fluids). Therefore, a combination of Na2SO3 and NaHSO3 (3:1 mole ratios; Sigma-Aldrich, St. Louis, MO, USA) was used as SO2 derivatives in the experiments.

Overexpression of AAT1 or AAT2 in VSMCs. The cDNA fragment encoding the full-length rat AAT1 (NM_012571.2) or AAT2 (NM_013177.2) was amplified by PCR and inserted into the pcRES2-EGFP vector, and the resultant plasmid pAAT1 or pAAT2 was verified by DNA sequencing. A7r5 VSMCs were then transfected with pAAT1, pAAT2 or vehicle plasmid using JetPEI reagent according to the manufacturer’s instructions (Polyplus Transfection, Illkirch, France).

Knockdown of AAT1 or AAT2 in VSMCs. Rat AAT1 shRNA and AAT2 shRNA were from OriGene Technologies (Rockville, MD, USA). A7r5 VSMCs were transfected with AAT1 shRNA, AAT2 shRNA or control shRNA using JetPEI reagent according to the manufacturer’s instructions.

Determination of AAT1 and AAT2 mRNA expressions by quantitative real-time polymerase chain reaction. Total RNA was extracted using the TriZol reagent and transcribed into cDNA using oligo (dt)15 primer and M-MLV reverse transcriptase. Quantitative real-time polymerase chain reaction (RT-PCR) was performed on an ABI PRISM 7300 instrument (Applied Biosystems, Foster, CA, USA). The amplification conditions for the cDNA for AAT1 and AAT2 were: denaturing at 94°C for 15 s, annealing at 60°C for 1 min and polymerizing at 72°C for 30 s for 40 cycles. Samples and standards were determined in duplicate. TaqMan probes were modified by 5′-FAM and 3′-TAMRA. The primers used for rat AAT1 were: 5′-CCAGGCGCTCTCGCATGCT-3′ (sense) and 5′-GCCATTGTTCTACGGTTTCT-3′ (antisense) and the expected product length was 79 base pairs. The primers for rat AAT2 were: 5′-GAGGGTCGGAGCCAGCTGAGCT-3′ (sense) and 5′-GTTTCCCCAGGAGTTGTG-3′ (antisense), and the expected product length was 82 base pairs. β-Actin was used for normalization. The 5′ and 3′ primers for β-actin were: 5′-ACCCCGAGTAACCTTCTT-3′ and 5′-TATGCTATCCATCGCAGACT-3′, respectively, and the expected product length was 80 base pairs.

Evaluation of the viability and proliferation of VSMCs. The viability and proliferation of VSMCs were evaluated using the CCK-8 assay (Dojindo Molecular Technologies, Kumamoto, Japan). Briefly, 1 × 103 cells per well were seeded in 96-well plates, starved in low-serum (0.5% FBS) medium for 24 h, treated with or without 10% FBS and Na2SO3/NaHSO3 (Sigma-Aldrich) at indicated concentrations for 24 h and incubated with CCK-8 solution for 1 h. The absorbance was then measured at 450 nm using a microplate reader (Bio-Rad, Richmond, CA, USA). VSMCs (1 × 103 per well) in 96-well plates were starved in low-serum medium for 24 h, and treated with H-89 (Cell Signaling Technology, Danvers, MA, USA) at 20 μmol/l, Na2SO3/NaHSO3 at 15 μmol/l and PDGF-BB (Peprotech, Rocky Hill, NJ, USA) at 50 ng/ml for 24 h. The proliferative levels were then assessed by CCK-8 assay.

Cell growth curve. Equal numbers (5 × 103) of VSMCs were plated into 24-well tissue culture dishes and cell numbers were determined by a TC-10 automated cell counter (Bio-Rad). Countings were made at 24, 48 and 72 h of cells with different doses of Na2SO3/NaHSO3 treatments. Triplicate plates were used for each time point.

Flow cytometry. VSMCs were starved in low-serum medium for 24 h, and then cultured in DMEM with 0.5% FBS, in medium with 10% FBS and/or treated with Na2SO3/NaHSO3 at indicated concentrations for 24 h. Samples were harvested and fixed in 70% ethanol overnight at −20°C. Before measurement, cells were incubated in PBS containing 100 μg/ml RNase A at 37°C for 30 min, stained with 50 μg/ml PI for 10 min and then analyzed by flow cytometry (Becton-Dickinson, Franklin Lakes, NJ, USA). Results are expressed as the percentage of cells in each cell cycle phase for cell cycle analysis.

BrdU incorporation assay. VSMCs were seeded on coverslips in 6-well plates to 60–70% confluences before they were made quiescent in DMEM containing 0.5% FBS for 24 h. Immunofluorescence assay was then used for the detection of BrdU incorporated into cellular DNA (BrdU Labeling and Detection Kit I, Roche, Penzberg, Germany). Then, cells were incubated in BrdU labeling reagent (final concentration 10 μmol/l) while cultured in: (1) medium with 0.5% FBS, medium with 10% FBS and with Na2SO3/NaHSO3 at 5, 10, 15 and 20 μmol/l for 24 h; and (2) medium with 0.5% FBS, medium with 0.5% FBS and with PDGF-BB at 50 ng/ml and medium with 0.5% FBS, PDGF-BB at 50 ng/ml and Na2SO3/NaHSO3 at 15 μmol/l for 24 h. The immunofluorescence detection was compiled with the manufacturer’s instructions. Total cellular nuclei were stained with PI. The results were reported as a percentage of BrdU-labelled cells to the total amount of cells.

In another model, A7r5 cells (5 × 103) were incubated in 6-well plates. When cells were grown to 60–70% confluences, they were transfected with 2 μg AAT1, AAT2 or vehicle plasmid using JetPEI reagent according to the manufacturer’s instructions. After 24 h, they were starved in DMEM containing 0.5% FBS for another 24 h. Then, cells were incubated in BrdU labeling reagent while cultured in medium with 0.5% FBS or medium with 10% FBS for 24 h. The immunofluorescence detection was described above.

Overexpression of MEK1 in HEK293 cells. MEK1 overexpression plasmids, wild-type and CA types, were constructed as described,51 using pIRE2-EGFP as the vector. After transfected with the vector, the MEK wild-type plasmid, CA-MEK S218E-S222D plasmid, CA-MEK N3 plasmid and the CA-MEK3 N3-S218E-S222D plasmid HEK293 cells in the experimental groups were treated with Na2SO3/NaHSO3 at 15 μmol/l for 24 h. The phosphorylation of Erk1/2 was evaluated by western blotting.

c-Raf kinase activity assay. VSMCs were cultured in DMEM with 10% FBS. Cytoplasmic proteins were then extracted in non-denaturing lysis buffer. The sample was divided evenly into six groups to estimate c-Raf (Raf-1) activity at different doses of Na2SO3/NaHSO3. Raf-1 Kinase Assay Kit with Chemiluminescence Detection (Millipore, Billerica, MA, USA) was used according to the manufacturer’s instructions. Na2SO3/NaHSO3 was added before adding inactive MEK1. c-Raf kinase activity was represented as the phosphorylation of recombinant inactive MEK1 after c-Raf kinase reaction by western blotting analysis.

Another part of c-Raf activity assay was on different reagents interfering whole VSMC. After 24 h low-serum starvation, cells were divided into four groups: (1) control; (2) with PDGF-BB 20 ng/ml for 30 min; (3) pretreated with Na2SO3/NaHSO3 at 15 μmol/l for 30 min and then with PDGF-BB 20 ng/ml for 30 min; and (4) with Na2SO3/NaHSO3 at 15 μmol/l for 30 min. Samples were lysed as described above and c-Raf activity was assessed technically conforming to the manufacturer’s protocol.

Western blotting analysis. A7r5 cells (5 × 103) were incubated in 6-well plates. When cells were grown to 60–70% confluences, they were starved in low-serum (0.5% FBS) medium for 24 h.

In the first series, cells were pretreated with or without Na2SO3/NaHSO3 at 15 μmol/l for 30 min, and then with PDGF-BB at 50 ng/ml for 24 h.

In the second series, cells were divided into four groups: (1) untreated; (2) with PDGF-BB 20 ng/ml for 30 min; (3) pretreated with Na2SO3/NaHSO3 at 15 μmol/l for 30 min and then with PDGF-BB 20 ng/ml for 30 min; and (4) with Na2SO3/NaHSO3 at 15 μmol/l for 30 min.

In the third series, cells were divided into five groups: (1) untreated; (2) treated with Na2SO3/NaHSO3 at 15 μmol/l for 30 min; (3) treated with Forskolin (Cell Signaling Technology) at 30 μmol/l for 30 min; (4) treated with H-89 at 20 μmol/l for 30 min; and (5) pretreated with H-89 at 20 μmol/l for 20 min followed by Na2SO3/NaHSO3 at 15 μmol/l for 30 min.

All samples were harvested and lysed in lysis buffer (0.5% mol/l EDTA, 10 mol/l Tris-HCl, pH 7.4, 0.3 mol/l sucrose and protease inhibitor cocktail) as described previously.54,55 Equal amounts of protein were resolved on SDS-PAGE gels and transferred onto nitrocellulose membranes. Nonspecific bindings were blocked by incubation in 5% milk blocking buffer. The primary antibodies anti-cyclin D1, anti-c-Raf, anti-phospho-c-Raf (Ser338), anti-phospho-c-Raf (Ser259), phosphor-MEK1/2 (Ser218/222), phosphor-Erk1/2 (Thr202/Tyr204) and anti-PKA and

SO2 inhibits VSMC proliferation D Liu et al

Cell Death and Disease
anti-phospho-PKA (Thr197) were all from Cell Signalling Technology; anti-phospho-
c-Raf (Ser43) was from Abcam (Cambridge, MA, USA); anti-Erk1/2 and anti-
GAPDH were from Kangcheng (Shanghai, China); and MEK1/2 and anti-
β-actin were from Santa Cruz Biotechnology (Santa Cruz, CA, USA). After incubation, each
primary antibody bound with their respective specific horseradish peroxidase-
conjugated secondary antibodies (Santa Cruz Biotechnology) and the bands were
visualized using Enhanced Chemiluminescence Detection Kit (Thermo Scientific,
Rockford, IL, USA). The densitometric analysis of the positive bands was performed
using AlphaEaseFC (Alpha Innotech Corporation, San Leandro, CA, USA).
A7r5 cells (5 × 10³) were incubated in 6-well plates. When cells were grown to
60–70% confluences, they were transfected with 2 μg of AAT1, AAT2 or vehicle
plasmid using jetPEI reagent according to the manufacturer’s instructions. After
24 h, they were starved in DMEM with 0.5% FBS before serum (10% FBS)
treatment for 24 h. Then, these samples were harvested and lysed in lysis buffer for
western blot analysis. The primary antibody dilutions were: 1: 500 for AAT1,
1: 5000 for AAT2 and 1: 2000 for PCNA, respectively.

Measurements of cAMP concentrations in VSMCs. A7r5 cells
(5 × 10³) were incubated in 6-well plates. When the cells were grown to 70–80%
confluences, they were starved in low-serum (0.5% FBS) medium for 24 h. cAMPs
were divided into five groups: (1) untreated; (2) treated with Na₂SO₃/NaHSO₃ at
15 μmol/l for 30 min; (3) treated with Forskolin at 30 μmol/l for 30 min; (4) treated
with H-89 at 20 μmol/l for 30 min; and (5) pretreated with H-89 at 20 μmol/l for
20 min, followed by Na₂SO₃/NaHSO₃ at 15 μmol/l for 30 min. Cells were
immediately lysed in 0.1 mol/l hydrochloric acid, while the culture medium could
also be treated with hydrochloric acid for sample preparation. The cAMP
concentrations were assessed using an ELISA-based assay (cAMP Enzyme
Immuonassay Kit, Direct; Sigma-Aldrich), according to the manufacturer’s
instructions. All standards and samples were run in duplicate and read in the
optical density at 405 nm with correction at 590 nm by an ELISA reader (Bio-Rad),
and the cAMP concentrations of samples (pmol/l) were calculated from the
standard curve.

Statistical analysis. Results were presented as mean ± S.D. Statistical
comparisons were performed with SPSS 13.0 software (SPSS, Chicago, IL, USA).
Comparison between two groups was performed using two-tailed independent
t-test. Comparisons among more than two groups involved one-way ANOVA
followed by the Student–Newman–Keuls test for post hoc comparison as
appropriate. Two-way ANOVA followed by the Bonferroni test for comparisons
between groups was performed in analyzing the effect of SO₂ derivatives at
different concentrations on serum-stimulated VSMC proliferation over time.
At least three different samples or independent experiments, each in triplicate,
were analyzed in each group. P < 0.05 was considered significant.

Conflict of Interest
The authors declare no conflict of interest.

Author contributions
DL and YH designed and performed the experiments, analyzed the data and
prepared the figures. DB, ADL and LH provided the VSMCs, constructed the
plasmids and contributed new analytical reagents and tools. YJ performed the
experiments, analyzed the data and prepared the figures. CT, JD and HJ obtained
funding, designed the study and wrote the manuscript. All authors read and
approved the final manuscript.
