The mechanistic/mammalian target of rapamycin complex-1 (mTORC1) integrates multiple signaling pathways and regulates various cellular processes. Tuberous sclerosis complex 1 (Tsc1) and complex 2 (Tsc2) are critical negative regulators of mTORC1. Mouse genetic studies, including ours, have revealed that inactivation of mTORC1 in undifferentiated mesenchymal cells and chondrocytes leads to severe skeletal abnormalities, indicating a pivotal role for mTORC1 in skeletogenesis. Here, we show that hyperactivation of mTORC1 influences skeletal development through its expression in undifferentiated mesenchymal cells at the embryonic stage. Inactivation of Tsc1 in undifferentiated mesenchymal cells by paired-related homeobox 1 (Prx1)-Cre-mediated recombination led to skeletal abnormalities in appendicular skeletons. In contrast, Tsc1 deletion in chondrocytes using collagen type II a1 (Col2a1)-Cre or in osteoprogenitors using Osterix (Oxs)-Cre did not result in skeletal defects in either appendicular or axial skeletons. These findings indicate that Tsc complex-mediated chronic overactivation of mTORC1 influences skeletal development at the embryonic stage through its expression in undifferentiated mesenchymal cells but not in chondrocytes or osteoprogenitors.

Key words skeletogenesis; undifferentiated mesenchymal cell; tuberous sclerosis complex 1; mechanistic/mammalian target of rapamycin complex-1 (mTORC1)

INTRODUCTION

During embryogenesis, skeletons are generated by two distinct ossification processes, designated intramembranous ossification and endochondral ossification in mammals.1) In the endochondral ossification process, mesenchymal stem cells undergo differentiation into chondrocytes to form a cartilaginous template, which is subsequently replaced with bone that contains bone-forming osteoblasts and bone-resorbing osteoclasts.2) In the intramembranous ossification process, mesenchymal stem cells directly differentiate into osteoblasts.3) The mechanistic/mammalian target of rapamycin (mTOR) is an evolutionarily conserved serine/threonine kinase that forms two different complexes designated mTOR complex-1 (mTORC1) and mTORC2.4) mTORC1 contains the regulatory-associated protein of mTOR (Raptor) subunit, and regulates various cellular processes, including growth, proliferation, differentiation, survival, and autophagy.5) Tuberous sclerosis complex 1 (Tsc1) and complex 2 (Tsc2), also known as hamartin and tuberin, negatively regulate mTORC1.6) Recent mouse genetic studies indicated that mTORC1 contributes to the pathogenesis of various diseases, including cancer, diabetes, aging, cardiac disease, and neurological diseases, as well as in a variety of physiological functions.7)

Using cell-specific disruption of the Raptor gene, we have recently demonstrated that expression of mTORC1 in undifferentiated mesenchymal cells and chondrocytes plays a critical role in skeletogenesis. For example, conditional ablation of the Raptor gene using paired-related homeobox 1 (Prx1)-Cre-mediated recombination, which occurred in undifferentiated mesenchymal cells, led to a severe impairment of appendicular skeletal formation.8) Moreover, chondrocyte-specific Raptor deficient embryos using collagen type II a1 (Col2a1)-Cre-dependent recombination displayed a very severe and generalized chondrodysplasia.9) Although several independent lines of evidence based on genetic strategies show that inactivation of mTORC1 signaling leads to abnormal skeletal development in vivo, the effect of sustained overactivation of mTORC1 on skeletal development is largely unknown.9,10) In this study, we generated and analyzed mutant embryos that harbor conditional deletion of the Tsc1 gene, a negative regulator of mTORC1, in undifferentiated mesenchymal cells, chondrocytes, or osteoprogenitors to further establish the role of mTORC1 in skeletal development.

MATERIALS AND METHODS

Mice Tsc1–/– mice were crossed with either Prx1-Cre, Col2a1-Cre, or Osterix (Oxs)-Cre mice.11–13) These mutant mice were backcrossed for more than five generations with C57BL/6J. Oxs-Cre mice were maintained in the absence of doxycycline. The study protocol meets the guidelines of the Japanese Pharmacological Society and was approved by the Committee for Ethical Use of Experimental Animals at Gifu University and Gifu Pharmaceutical University. Genotyping was performed by PCR with specific primers.

Skeletal Preparation and Histological Analyses Skeletal preparation was performed as described previously.14) In brief, embryos fixed with 95% ethanol were immersed in Alcian blue solution, and subsequently stained in Alizarin red solution. The skeletons were then cleaned with 1% KOH/20% glycerol. Mouse tibiae were fixed with 10% formalin, and subsequently embedded in paraffin, followed by section at a thickness of 5 µm. Sections were stained with hematoxylin & eosin, von Kossa, Safranin O, and Alcian blue.

Culture of Primary Chondrocytes and Immunoblotting

© 2020 The Pharmaceutical Society of Japan
Primary costal chondrocytes were prepared from newborn mice using a sequential enzymatic digestion method as described previously. Cells were solubilized in lysis buffer containing protease inhibitor cocktail, and then samples were subjected to immunoblotting assay. Antibodies were from the following companies: anti-β-tubulin was from Santa Cruz Biotechnology (Santa Cruz, CA, U.S.A.); anti-Tsc1 and anti-p-p70S6K1 were from Cell Signaling Technology (Danvers, MA, U.S.A.).

Data Analysis All results were expressed as the mean ± standard error of the mean. Statistical significance was determined using the two-tailed, unpaired Student’s t-test and one-way ANOVA with Bonferroni post hoc test.

RESULTS

Tsc1 Deficiency in Undifferentiated Mesenchymal Cells Leads to Skeletal Abnormalities To investigate whether mTORC1 hyperactivation could affect skeletal development in vivo, we first inactivated the Tsc1 gene in undifferentiated mesenchymal cells using Prx1-Cre transgenic mice. Staining of skeletal preparations from embryos at E18.5 with alci

Fig. 1. mTORC1 Activation in Undifferentiated Mesenchymal Cells Leads to Skeletal Abnormalities

(A) The whole and parts of skeleton of Prx1-Cre;Tsc1<sup>fl/fl</sup> embryos at E18.5. Embryos were double stained with alizarin red and alcian blue. Bar = 10 mm (a, b) and Bar = 1 mm (c–r). (B) Histological analyses of the tibiae at E18.5. Tibiae were stained with Hematoxylin and Eosin (H&E), von Kossa, safranin O, and alcian blue (a–h) Bar = 100 µm. Quantitative data of (C) length and (D) width of long bones of Prx1-Cre;Tsc1<sup>fl/fl</sup> embryos at E18.5 (n = 10–12). Representative images of skeletal preparations and histological analyses derived from more than 3 embryos from different litters are shown. *p < 0.05, significantly different from the value obtained in control embryos. (Color figure can be accessed in the online version.)
Cre;Tsc1<sup>fl/fl</sup> embryos and WT embryos at E18.5 (Figs. 2Aa, b). In addition, no marked skeletal abnormalities were observed in the long bones, calvaria, clavicle, or vertebrae of Col2a1-Cre;Tsc1<sup>fl/fl</sup> embryos at E18.5 (Figs. 2Ac–r). Histological analyses also revealed that both the length and width of these bones did not significantly differ between mutant and WT embryos (Figs. 2B, C). In the cultured chondrocytes of Col2a1-Cre;Tsc1<sup>fl/fl</sup> mice, Tsc1 expression was markedly abolished and the level of phosphorylated p70S6K was increased, indicating an increase in mTORC1 activity in chondrocytes (Fig. 2D).

Because the Osx-Cre transgene itself caused development defects in bones formed by the intramembranous ossification process, but not by the endochondral ossification process, Osx-Cre embryos were also used as a control for the effects of Osx-Cre recombination. In these structures of Osx-Cre;Tsc1<sup>fl/fl</sup> embryos when compared with Osx-Cre embryos (Figs. 2Ep–s, u, w).

Collectively, these results indicate that the hyperactivation of mTORC1 in chondrocytes or osteoprogenitors has a less significant impact on skeletal development at the embryonic stage.

**DISCUSSION**

Mouse genetic studies, including our own work, have recently revealed the critical role of mTORC1 in skeletal development during embryogenesis, including by disrupting the Raptor gene via Prxl-Cre or Col2a1-Cre to inactivate mTORC1 activity in undifferentiated mesenchymal cells or chondrocytes. Moreover, it has been shown that hyperactivation of mTORC1 in undifferentiated mesenchymal cells or chondrocytes mediates postnatal skeletal development. In that study, Prxl-Cre;Tsc1<sup>fl/fl</sup> mice displayed shorter and thicker long bones with increased bone volume, but decreased bone mineralization at the adolescent stage, suggesting that mTORC1 overactivation via Prxl-Cre-mediated recombination disrupted postnatal bone quality (size and mass). Further, Col2a1-Cre;Tsc1<sup>fl/fl</sup> mice showed severe growth retardation after birth, characterized by hypertrophy of growth plate chondrocytes, or
disorganization in the resting zone without affecting hypertrophy or proliferation, suggesting that mTORC1 overactivation via Col2al-Cre-mediated recombination disrupted postnatal bone development. However, to the best of our knowledge, this is the first study to demonstrate that hyperactivation of mTORC1 mediates skeletal development during embryogenesis through its expression in undifferentiated mesenchymal cells but not in chondrocytes or osteoprogenitor cells. Because Prxl-Cre targets the mesenchymal cells in the limb buds but not in the vertebrae, the skeletal abnormalities of Prxl-Cre;Tsc1fl/fl embryos were observed only in the long bones. Moreover, the fact that both the length and width of the long bones were significantly greater in Prxl-Cre;Tsc1fl/fl embryos indicates that the mutant embryos display an acceleration of endochondral ossification because endochondral ossification leads to growth in both length and width of long bones.

Inactivation of mTORC1 activity by conditional ablation of the Raport gene in undifferentiated mesenchymal cells or chondrocytes resulted in severe impairment of skeletal formation or severe chondrodysplasia at the embryonic stage. Together with these previous findings, our current study indicates that both inactivation and overactivation of mTORC1 lead to developmental abnormalities in some skeletal compartments, suggesting that a complex regulatory system may be required to control mTORC1 activity in undifferentiated mesenchymal cells for the maintenance of proper skeletal development during embryogenesis. Although further studies should be performed to reveal the precise mechanisms by which mTORC1 hyperactivation in undifferentiated mesenchymal cells influences skeletal development at the embryonic stage, our work contributes to an improved understanding of the molecular mechanisms underlying skeletal development. Further, these findings may aid in the future development of drugs targeting cartilage diseases associated with the abnormal activation or inactivation of mTORC1 signaling.
