In this review we report the recent results of open charm decays and spectroscopy using the data collected with the Belle detector at the KEKB asymmetric-energy $e^+e^-$ collider.
1. Introduction

In this report an overview of the recent results of open charm decays and spectroscopy is presented based on the data, collected by the Belle experiment at the KEKB $e^+e^-$ asymmetric-energy collider [1]. Throughout this paper charge-conjugate modes are implied. The experiment took data at center-of-mass energies corresponding to several $\Upsilon(nS)$ resonances; the total data sample recorded exceeds 1 ab$^{-1}$.

The Belle detector is a large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Cherenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF), and an electromagnetic calorimeter comprised of CsI(Tl) crystals (ECL) located inside a super-conducting solenoid coil that provides a 1.5 T magnetic field. An iron flux-return located outside of the coil is instrumented to detect $K_L$ mesons and to identify muons (KLM). The detector is described in detail elsewhere [2, 3].

2. Analysis of $D^{*\ast}$ production

Orbitally excited states of the $D$ meson ($D^{*\ast}$ states) provide a good opportunity to test the heavy quark effective theory (HQET) [4] and QCD sum rule [5] predictions. Precise knowledge of the properties of the $D^{*\ast}$ state is important to reduce uncertainties in the measurements of the semileptonic decays and thus in the determination of the Cabibbo-Kobayashi-Maskawa matrix elements $|V_{cb}|$ and $|V_{ub}|$. Many $D^{*\ast}$ mesons have already been observed by B factories and LHCb [6]. In this analysis, we perform an amplitude analysis of the $B^0 \rightarrow D^{*\ast}\omega\pi^-$ decay to measure the decay fractions of $D^{*}\pi$ states and to study the $D^{*\ast}$ properties [7], using 711 fb$^{-1}$ of data collected at the $\Upsilon(4S)$ resonance.

The total signal yield is obtained from a binned $\chi^2$ fit to the $\Delta E = \sqrt{p_t^2 + m^2} - E_{beam}$ distribution, with a tight cut in the beam-constrained mass $M_{bc}$. The corresponding branching fraction is measured to be

$$\mathcal{B}(B^0 \rightarrow D^{*\ast}\omega\pi^-) = (2.31 \pm 0.11 \pm 0.14) \times 10^{-3}.$$  

Unless explicitly stated otherwise, whenever two uncertainties are quoted in this proceeding, the first is statistical and the second is systematic. The result is consistent with the values of CLEO [8] and BaBar [9] but with higher precision.

A six-dimensional amplitude analysis is performed using the method described in Ref. [10]. We define two sets of variables: $[M^2(\omega\pi), \cos \theta_1, \phi_1, \cos \beta_1, \psi_1, \cos \xi_1]$ and $[M^2(D^{*}\pi), \cos \theta_2, \phi_2, \cos \beta_2, \psi_2, \cos \xi_2]$, corresponding to the $\omega\pi$ and $D^{*\ast}$ production, respectively. The masses $M(\omega\pi)$ and $M(D^{*}\pi)$ are the invariant masses of the $\omega\pi$ and $D^{*}\pi$ combinations. The angular variables describing $\omega\pi$ production are defined in Fig. 1. The angular variables describing $D^{*\ast}$ production are defined in the same manner as angles for $\omega\pi$ production, but with the $D^{*}\pi$ flight direction instead of the $\omega$.

To describe all the features of the Dalitz plot, we use the following set of resonances: off-shell $\rho(770)^-$, $\rho(1450)^-$, $D_1(2430)^0$, $D_1(2420)^0$, $D_s(2460)^0$ and $b_1(1235)^-$. Figure 2 shows the projections of $M^2(\omega\pi)$ and $M^2(D^{*}\pi)$ distributions and the results are summarized in Table 1.

Figure 1: Kinematics of a $\bar{B}^0 \rightarrow D^{*+} \omega \pi^-$ decay mediated by an $\omega \pi^-$ intermediate resonance. The diagram in (a) defines two polar angles $\xi_1$ and $\beta_1$ and one azimuthal angle $\psi_1$. The diagram in (b) defines one polar angle $\theta_1$ and one azimuthal angle $\phi_1$. The direction $n_\omega$ in (b) corresponds to the vector normal to the $\omega$ decay plane.

Figure 2: Distributions of the variables (left) $M^2(\omega \pi)$ and (right) $M^2(D^* \pi)$.

3. Analysis of charmed baryon decays

3.1 First observation of the doubly Cabibbo-suppressed $\Lambda_c^+$ decay

Several doubly Cabibbo-suppressed (DCS) decays of charmed mesons have been observed [6]. Their measured branching ratios with respect to the corresponding Cabibbo-favored (CF) decays play an important role in constraining models of the decay of charmed hadrons and in the study of flavor- $SU(3)$ symmetry [11, 12]. On the other hand, because of the smaller production cross sec-
Table 1: Summary of the final results of the $B^0 \rightarrow D^{**} \omega \pi^-$ amplitude analysis. The first error is statistical, the second is systematic and the third is the model error.

tions for charmed baryons, DCS decays of charmed baryons have not yet been observed. Here we present the first observation of the DCS decay $\Lambda_c^+ \rightarrow pK^+ \pi^-$ and the measurement of its branching ratio with respect to the CF decay $\Lambda_c^+ \rightarrow pK^- \pi^+$, using 980 fb⁻¹ of data [13].

Figure 3: Distributions of (a) $M(pK^- \pi^+)$ and (b) $M(pK^+ \pi^-)$ and residuals of data with respect to the fitted combinatorial background. The solid curves indicate the full fit model and the dashed curves the combinatorial background.
Figure 3 shows invariant mass distributions of (a) $pK^-\pi^+$ (CF) and (b) $pK^+\pi^-$ (DCS) combinations. DCS decay events are clearly observed in $M(pK^+\pi^-)$. In order to obtain the signal yield, a binned least-$\chi^2$ fit is performed. From the mass fit, we extract $(1.452\pm0.015)\times10^6$ $\Lambda_c^+\rightarrow pK^-\pi^+$ events and $3587\pm380\Lambda_c^+\rightarrow pK^+\pi^-$ events. The latter has a peaking background from the single Cabibbo-suppressed (SCS) decay $\Lambda_c^+\rightarrow \Lambda(\rightarrow p\pi^-)K^+$, which has the same final-state topology. After subtracting the SCS contribution, we have $3379\pm380\pm78$ DCS events, where the first uncertainty is statistical and the second is the systematic due to SCS subtraction. The corresponding statistical significance is 9.4 standard deviations. We measure the branching ratio, $\mathcal{B}(\Lambda_c^+\rightarrow pK^+\pi^-) = (2.35\pm0.27\pm0.21)\times10^{-3}$, and the absolute branching fraction of the DCS decay, $\mathcal{B}(\Lambda_c^+\rightarrow pK^+\pi^-) = (1.61\pm0.23_{-0.08}^{+0.07})\times10^{-4}$. This measured branching ratio corresponds to $(0.82\pm0.21)\tan^4\theta_c$, where the uncertainty is the total, which suggests a slightly smaller decay width than the naive expectation [14]. After subtracting the contributions of $\Lambda^*(1520)$ and $\Delta$ isobar intermediates, which contribute only to the CF decay, the revised ratio, $\mathcal{B}(\Lambda_c^+\rightarrow pK^+\pi^-) = (1.10\pm0.17)\tan^4\theta_c$, is consistent with the naive expectation.

3.2 Study of excited $\Xi_c$ states decaying into $\Xi^0_c$ and $\Xi^+_c$ baryons

We present measurements of the masses of all members of the $\Xi_c^0$, $\Xi_c(2645)$, $\Xi_c(2790)$, $\Xi_c(2815)$ and $\Xi_c(2980)$ isodoublets, measurements of the intrinsic widths of those that decay strongly, and evidence of previously unknown transitions [15]. This analysis is based on $980$ fb$^{-1}$ of data. The following decay chains are used: $\Xi_c(2980)\rightarrow \Xi_c(2645)\pi \rightarrow \Xi_c\pi\pi$, $\Xi_c(2980)\rightarrow \Xi'_c\pi \rightarrow \Xi_c\gamma\pi$, $\Xi_c(2815)\rightarrow \Xi_c(2645)\pi \rightarrow \Xi_c\pi\pi$, $\Xi_c(2815)\rightarrow \Xi'_c\pi \rightarrow \Xi_c\gamma\pi$ and $\Xi_c(2980)\rightarrow \Xi'_c\pi \rightarrow \Xi_c\gamma\pi$. To obtain large statistics, we use many decay modes of the ground-state $\Xi^0_c$ and $\Xi^+_c$ baryons. Table 2 shows the results of the measurements of masses and widths of the five isodoublets. Of the eighteen measurements, five are of intrinsic widths of particles for which only limits existed previously. Of the remaining thirteen measurements, ten are within one standard deviation of the Particle Data Group [6] best-fit values. The three measurements that are in modest disagreement with previous results are in the $\Xi_c(2980)$ sector, where the previous measurements were dominated by decays into different final states and for which some measurements may have been prone to the existence of more than one resonance in the region, or biases from threshold effects. Measurements of the isospin splittings, give in Table 3 are in good agreement with predictions of non-relativistic quark model [16].

3.3 Studies of charmed strange baryons in the $\Lambda D$ final state

To date, all measurements of the excited $\Xi_c$ were performed using decays in which the charm quark is contained in the final state baryon. Measurements of final states in which the charm quark is part of the final state meson provide complementary information. Here we present the studies of $\Xi^+_c$ baryons decaying to $\Lambda D^+$ and $\Lambda D^0$ final states using $980$ fb$^{-1}$ of data [17].

Figures 4 (a) show the fit to the $\Lambda D^+$ invariant mass distribution. Peaks of $\Xi_c(3055)^+$ and $\Xi_c(3080)^+$ states with statistical significances of 11.7 and 4.8 standard deviations, respectively are seen in the $\Lambda D^+$ final state. These correspond to first observation of $\Xi_c(3055)^+\rightarrow \Lambda D^+$ and first evidence of $\Xi_c(3080)^+\rightarrow \Lambda D^+$ decays. The mass and width of the $\Xi_c(3055)^+$ are obtained to be $(3055.8\pm0.4\pm0.2)$ MeV/$c^2$ and $(7.0\pm1.2\pm1.5)$ MeV, respectively, and those for $\Xi_c(3080)^+$ are
Table 2: The results of the measurements of masses (in MeV/c²) and widths (in MeV) of the five isodoublets. In all cases, the first uncertainty is statistical, and the second is the systematic uncertainty associated with the individual measurement. All the masses have a final, asymmetric uncertainty, taken from the Particle Data Group [6], for the mass of the ground states, and the $\Xi_c(2790)$ have an extra uncertainty due to the uncertainty in the $M(\Xi_c^+)-M(\Xi_c^0)$ measurement.

| Particle     | Mass       | Width       |
|--------------|------------|-------------|
| $\Xi_c(2645)^+$ | 2645.58 ± 0.06 ± 0.07 +0.28 −0.40 | 2.06 ± 0.13 ± 0.13 |
| $\Xi_c(2645)^0$ | 2646.43 ± 0.07 ± 0.07 +0.28 −0.40 | 2.35 ± 0.18 ± 0.13 |
| $\Xi_c(2815)^+$ | 2816.73 ± 0.08 ± 0.06 +0.28 −0.40 | 2.43 ± 0.20 ± 0.17 |
| $\Xi_c(2815)^0$ | 2820.20 ± 0.08 ± 0.07 +0.28 −0.40 | 2.54 ± 0.18 ± 0.17 |
| $\Xi_c(2980)^+$ | 2966.0 ± 0.8 ± 0.2 +0.3 −0.4 | 28.1 ± 2.4 +1.0 −5.0 |
| $\Xi_c(2980)^0$ | 2970.8 ± 0.7 ± 0.2 +0.3 −0.4 | 30.3 ± 2.3 +1.0 −1.8 |
| $\Xi'_c$ | 2578.4 ± 0.1 ± 0.4 +0.3 −0.4 |
| $\Xi_c'$ | 2579.2 ± 0.1 ± 0.4 +0.3 −0.4 |
| $\Xi_c(2790)^+$ | 2791.6 ± 0.2 ± 0.1 +0.3 −0.4 | 8.9 ± 0.6 ± 0.8 |
| $\Xi_c(2790)^0$ | 2794.9 ± 0.3 ± 0.1 +0.3 −0.4 | 10.0 ± 0.7 ± 0.8 |

Table 3: Isospin splitting between the members of each isodoublet.

| Particle     | $M(\Xi_c^+) - M(\Xi_c^0)$ (MeV/c²) |
|--------------|-------------------------------------|
| $\Xi_c(2645)$ | −0.85 ± 0.09 ± 0.08 ± 0.48         |
| $\Xi_c(2815)$ | −3.47 ± 0.12 ± 0.05 ± 0.48         |
| $\Xi_c(2980)$ | −4.8 ± 0.1 ± 0.2 ± 0.5             |
| $\Xi_c'$     | −0.8 ± 0.1 ± 0.1 ± 0.5             |
| $\Xi_c(2790)$ | −3.3 ± 0.4 ± 0.1 ± 0.5             |

Figure 4: Distributions of (a) $M(AD^+)$ and (b, c, d) $M(AD^0)$ for (b) $D^0 \to K^- \pi^+$, (c) $D^0 \to K^- \pi^+ \pi^+ \pi^-$ and (d) $D^0 \to K^- \pi^+ \pi^0$. Points with statistical error bars are data. Blue solid lines show the fit results. The red dashed, magenta dotted, and black dashed-dotted lines show the $\Xi_c(3055)$ signal, the $\Xi_c(3080)$ signal, and the background components, respectively.
(3079.6 ± 0.4 ± 0.1) MeV/c² and < 6.3 MeV at 90% confidence level, respectively. The measured values for Ξ_c(3055)⁺ are more accurate than the current world average values. Figure 4 (b, c, d) shows the simultaneous fit to the three different D⁰ decay modes of ΛD⁰ final state. We observe a clear peak of Ξ_c(3055)⁰ state with a statistical significance of 8.6 standard deviations. The peak for the Ξ_c(3080)⁰ is not statistically significant. The mass and width of Ξ_c(3055)⁰ are measured to be (3059.0 ± 0.5 ± 0.6) MeV/c² and (6.4 ± 2.1 ± 1.1) MeV, respectively. This is the first observation of the decay Ξ_c(3055)⁰ → ΛD⁰.

We perform a combined analysis of the Ξ_c(3055)⁺ and Ξ_c(3080)⁺ by comparing their decays into ΛD⁺ with those into Σ⁺K⁻ and Σ⁺⁺K⁻ final states. We measure the ratios of branching fractions \( \frac{\mathcal{B}(\Xi_c(3055)^+ \rightarrow \Lambda D^+)}{\mathcal{B}(\Xi_c(3080)^+ \rightarrow \Lambda D^+)} = 5.09 \pm 1.01 \pm 0.76 \), \( \frac{\mathcal{B}(\Xi_c(3080)^+ \rightarrow \Lambda D^+)}{\mathcal{B}(\Xi_c(3055)^+ \rightarrow \Lambda D^+)} = 1.29 \pm 0.30 \pm 0.15 \) and \( \frac{\mathcal{B}(\Xi_c(3080)^+ \rightarrow \Sigma^+ K^-)}{\mathcal{B}(\Xi_c(3055)^+ \rightarrow \Sigma^+ K^-)} = 1.07 \pm 0.27 \pm 0.04 \). These measurements are in contradictions with the chiral quark model predictions [18]. Further experimental and theoretical work is needed to understand the nature of these baryons. From the combined analysis we measure the widths of the state Ξ_c(3055)⁺ is (7.8 ± 1.2 ± 1.5) MeV and that of Ξ_c(3080)⁺ is (3.0 ± 0.7 ± 0.4) MeV.

4. Analysis of charmed meson decays

4.1 \( D^0 \rightarrow V\gamma \)

The radiative decays \( D^0 \rightarrow V\gamma \), where \( V (\phi, K^0, \rho^0) \) is a vector meson, are dominated by long-range contribution. They could be sensitive to NP via CP asymmetry [19, 20]. We present here the results of the measurement of the branching fractions and CP asymmetries in these decays based on 943 fb⁻¹ of data [21]. The candidate \( D^0 \) mesons are required to originate from the decay \( D^{*+} \rightarrow D^0 \pi^+_0 \) in order to identify the flavour of the \( D^0 \) and to suppress combinatorial background. The signal decays are reconstructed in the following sub-decay channels of the vector meson: \( \phi \rightarrow K^+ K^-, K^0 \rightarrow K^- \pi^+ \) and \( \rho^0 \rightarrow \pi^+ \pi^- \). The selection criteria are optimized to maximize the figure of merit \( N_{\text{sig}}/\sqrt{N_{\text{sig}} + N_{\text{bkg}}} \), where \( N_{\text{sig}} \) and \( N_{\text{bkg}} \) represent the number of signal and background events. Both the branching fractions \( \mathcal{B}(D^0 \rightarrow V\gamma) \) and CP asymmetries \( \mathcal{A}_{\text{CP}}(D^0 \rightarrow V\gamma) \) are obtained via normalization to other decay channels. The signal branching fraction \( \mathcal{B}_{\text{sig}} \) is given by

\[
\mathcal{B}_{\text{sig}} = \mathcal{B}_{\text{norm}} \times \frac{N_{\text{sig}}}{N_{\text{norm}}} \times \frac{\epsilon_{\text{norm}}}{\epsilon_{\text{sig}}},
\]

(4.1)

where \( N \) is the extracted yield, \( \epsilon \) the reconstruction efficiency and \( \mathcal{B} \) the branching fraction for the corresponding mode. For \( \mathcal{B}_{\text{norm}} \) the world average value [6] is used. We use the decays \( D^0 \rightarrow K^+ K^-, D^0 \rightarrow K^- \pi^+ \) and \( D^0 \rightarrow \pi^+ \pi^- \) as the normalization channels for \( \phi \), \( K^0 \) and \( \rho^0 \) signal modes, respectively. The measured branching fractions are

\[
\mathcal{B}(D^0 \rightarrow \phi \gamma) = (2.76 \pm 0.19 \pm 0.10) \times 10^{-5},
\]

\[
\mathcal{B}(D^0 \rightarrow K^{0*} \gamma) = (4.66 \pm 0.21 \pm 0.21) \times 10^{-4},
\]

\[
\mathcal{B}(D^0 \rightarrow \rho^0 \gamma) = (1.77 \pm 0.30 \pm 0.07) \times 10^{-5}.
\]

The result of the \( \phi \) mode is improved compared to the previous Belle result [22] and is consistent with the world average value [6]. Our branching fraction for the \( K^{0*} \) mode is 3.3 \( \sigma \) higher than the BaBar result \( \mathcal{B}(D^0 \rightarrow K^{0*} \gamma) = (3.22 \pm 0.20 \pm 0.27) \times 10^{-4} \) [23]. For the \( \rho^0 \) mode, we report the
first observation of the decay with a significance of $5 \sigma$ including the systematic uncertainties. The fit results are shown in Fig. 5.

\textbf{Figure 5:} Distributions of the invariant masses and the cosine of the helicity angles of (left) $D^0 \rightarrow V\gamma$ and (right) $D^0 \rightarrow V\gamma$. Top row corresponds to $\phi$ mode, middle row the $\bar{K}^*0$ and the bottom row the $\rho^0$ mode.

The raw asymmetry is extracted using

$$A_{\text{raw}} = \frac{N(D^0) - N(D^0)}{N(D^0) + N(D^0)},$$

(4.2)

and has several contributions: $A_{\text{raw}} = A_{CP} + A_{FB} + A_{\pm}$. The forward-backward production asymmetry $A_{FB}$ and the asymmetry due to different reconstruction efficiencies for positively and negatively charged particles $A_{\pm}$ can be eliminated through a relative measurement of $A_{CP}$, if the charged final state particles are identical. It then follows

$$A_{CP}^{\text{sig}} = A_{\text{raw}}^{\text{sig}} - A_{\text{norm}} + A_{CP}^{\text{norm}},$$

(4.3)
where $A_{CP}^{norm}$ is the nominal value of CP asymmetry [6] of the normalization mode. We measure

$$A_{CP}(D^0 \to \phi \gamma) = -(0.094 \pm 0.066 \pm 0.001),$$
$$A_{CP}(D^0 \to \bar{K}^0 \gamma) = -(0.003 \pm 0.020 \pm 0.000),$$
$$A_{CP}(D^0 \to \rho^0 \gamma) = \ 0.056 \pm 0.152 \pm 0.006.$$

These are the first-ever $A_{CP}$ measurements for these decays and are consistent with no CP asymmetry in these modes.

4.2 $D^0 \to K^0_SK^0_S$

In this analysis, we report the preliminary result of a measurement of CP asymmetry in $D^0 \to K^0_SK^0_S$ decays, using 921 fb$^{-1}$ of data [24]. The CP asymmetry of the signal decay mode is given by

$$A_{CP}^{sig} = A_{raw}^{sig} - A_{raw}^{norm} + A_{CP}^{norm} + A^K_e. \quad (4.4)$$

The decay $D^0 \to K^0_SK^0_S$ is used as the normalization mode. Here $A^K_e$ is the asymmetry due to strong interaction of $K^0_S$ and $\bar{K}^0_S$ mesons with nucleons of the detector material. A simultaneous fit of the

$\Delta M$ for $D^{*+}$ and $D^{*-}$ is used to measure the raw asymmetry, shown in Fig. 6. We measure

$$A_{CP}(D^0 \to K^0_SK^0_S) = - (0.02 \pm 1.53 \pm 0.17)\%.$$

The result is consistent with no CP violation and with SM expectations [25, 26] and is a significant improvement compared to the previous measurements by CLEO [27] and LHCb [28].
