Abstract. We construct a three-parameter deformation of the Hopf algebra $\text{LDIAG}$. This is the algebra that appears in an expansion in terms of Feynman-like diagrams of the product formula in a simplified version of Quantum Field Theory. This new algebra is a true Hopf deformation which reduces to $\text{LDIAG}$ for some parameter values and to the algebra of Matrix Quasi-Symmetric Functions ($\text{MQSym}$) for others, and thus relates $\text{LDIAG}$ to other Hopf algebras of contemporary physics. Moreover, there is an onto linear mapping preserving products from our algebra to the algebra of Euler-Zagier sums.

1. Introduction

The physics background to this mainly mathematical article is the following: In a recent publication[1] we showed that a basic quantum statistical boson model gives rise to a Hopf algebra structure in a natural and generic way. It is also known that a rather more complicated Hopf algebra is inherent in perturbative Quantum Field Theory (pQFT); for an elegant discussion of this approach see the book by Kreimer[2]. The question now naturally arises as to how the Hopf structure of the non-field theoretic model relates to that of pQFT. As the non-field model does not involve integrations over space and time, we do not, for example, expect the appearance of Riemann Zeta functions and their extensions, which arise from the evaluation of Feynman integrals in pQFT. The conjecture is that by suitably deforming the first, elementary Hopf structure, one may arrive at the more complex structure of the pQFT Hopf algebra. This article is an implementation of the deformations necessary to achieve this goal. And, surprisingly, the resulting Hopf structure is indeed related to the algebra of extensions of the Riemann Zeta functions (polyzeta functions or Euler-Zagier sums).

We now briefly describe the passage from the product formula, as described by Bender et al. [3], and the related Feynman-like diagrams, to the description of Hopf algebra structures [4] on the diagrams themselves compatible with their evaluations. First, C. M. Bender, D. C. Brody, and B. K. Meister [3] introduced a special field theory which proved to be particularly rich in combinatorial links and by-products. Second, the Feynman-like diagrams produced by this theory label monomials; these monomials combine in a manner compatible with the monomial multiplication and co-addition‡. This is the Hopf algebra DIAG.

Third, the natural noncommutative pull-back of this algebra, LDIAG, has a basis (the labeled diagrams) which is in one-to-one correspondence with that of the Matrix Quasi-Symmetric Functions (the packed matrices of MQSym), but their algebra and co-algebra structures are completely different. In particular, in this basis, the multiplication of MQSym implies a sort of shifted shuffle with overlappings reminiscent of Hoffmann’s shuffle used in the theory of of polyzeta functions[5]. The superpositions and overlappings involved there are not present in the (non-deformed) LDIAG and, moreover, the coproduct of LDIAG is co-commutative while that of MQSym is not.

The aim of this paper is to introduce a “parametric algebra” which mediates between the two Hopf algebras LDIAG and MQSym. The striking result is that when we introduce parameters which count the crossings and overlappings of the shifted shuffle, one notes that the resulting law is associative (graded with unit). We also show how to interpolate with a coproduct which at each stage makes our algebra a Hopf algebra. The result is thus a three-parameter Hopf algebra deformation which reduces to LDIAG at $(0,0,0)$ and to MQSym at $(1,1,1)$. Moreover it appears that, for one set of parameters, the multiplication rule of LDIAG recovers that of Euler-Zagier sums.

‡ i.e. the co-multiplication obtained by replacing each variable by the sum of two (independent) copies of it.
2. How and why these Feynman-like Diagrams arise

The beginning of the story was fully explained in [6, 7, 8, 9, 10, 11], and the Hopf algebra structure was made precise in [4, 12]. In this note we shall emphasize the latter part of the analysis, where the algebraic structure constructed on the diagrams themselves arise.

Our starting point is the formula \( \text{(product formula)} \) of Bender and al. [3], which can be considered as an expression of the Hadamard product for an exponential generating series. That is, using

\[
F(z) = \sum_{n \geq 0} a_n \frac{z^n}{n!}, \quad G(z) = \sum_{n \geq 0} b_n \frac{z^n}{n!}, \quad \mathcal{H}(F, G) := \sum_{n \geq 0} a_n b_n \frac{z^n}{n!}
\]  

one can check that

\[
\mathcal{H}(F, G) = F \left( z \frac{d}{dx} \right) G(x) \bigg|_{x=0}.
\]  

When \( F(0) \) and \( G(0) \) are not zero one can normalize the functions in this bilinear product so that \( F(0) = G(0) = 1 \). We wish to obtain compact and generic formulas. If we write the functions as

\[
F(z) = \exp \left( \sum_{n=1}^{\infty} L_n \frac{z^n}{n!} \right), \quad G(z) = \exp \left( \sum_{n=1}^{\infty} V_n \frac{z^n}{n!} \right).
\]  

that is, as free exponentials, then by using Bell polynomials in the sets of variables \( \mathbb{L}, \mathbb{V} \) (see [4, 13] for details), we obtain

\[
\mathcal{H}(F, G) = \sum_{n \geq 0} \frac{z^n}{n!} \sum_{P_1, P_2 \in UP_n} \mathbb{L}^{Type(P_1)} \mathbb{V}^{Type(P_2)}
\]  

where \( UP_n \) is the set of unordered partitions of \([1 \cdots n]\). An unordered partition \( P \) of a set \( X \) is a subset of \( P \subset \mathcal{P}(X) - \{\emptyset\} \) (that is an unordered collection of blocks, i.e. non-empty subsets of \( X \)) such that

- the union \( \bigcup_{Y \in P} Y = X \) (\( P \) is a covering)
- \( P \) consists of disjoint subsets, i.e.
  \[ Y_1, Y_2 \in P \text{ and } Y_1 \cap Y_2 \neq \emptyset \implies Y_1 = Y_2. \]

\( \mathbb{P}(X) \) is the set of subsets of \( X \) (this notation [14] is that of the former German school).
The type of $P \in U P_n$ (denoted above by $Type(P)$) is the multi-index $(\alpha_i)_{i \in \mathbb{N}^+}$ such that $\alpha_k$ is the number of $k$-blocks, that is the number of members of $P$ with cardinality $k$.

At this point the formula entangles and the diagrams of the theory arise.

Note particularly that

- the monomial $L^{Type(P_1)} \cap Type(P_2)$ needs much less information than that which is contained in the individual partitions $P_1, P_2$ (for example, one can relabel the elements without changing the monomial),
- two partitions have an incidence matrix from which it is still possible to recover the types of the partitions.

The construction now proceeds as follows.

(i) Take two unordered partitions of $[1 \cdots n]$, say $P_1, P_2$

(ii) Write down their incidence matrix $(\text{card}(Y \cap Z))_{(Y,Z) \in P_1 \times P_2}$

(iii) Construct the diagram representing the multiplicities of the incidence matrix: for each block of $P_1$ draw a black spot (resp. for each block of $P_2$ draw a white spot)

(iv) Draw lines between the black spot $Y \in P_1$ and the white spot $Z \in P_2$; there are $\text{card}(Y \cap Z)$ such.

(v) Remove the information of the blocks $Y, Z, \cdots$.

In so doing, one obtains a bipartite graph with $p$ ( = $\text{card}(P_1)$) black spots, $q$ ( = $\text{card}(P_2)$) white spots, no isolated vertex and integer multiplicities. We denote the set of such diagrams by $\text{diag}$.

```
{1}   {2, 3, 4}     {5, 6, 7, 8, 9}{10, 11}
{2, 3, 5}{1, 4, 6, 7, 8}{9, 10, 11}
```

**Fig 1. — Diagram from $P_1, P_2$ (set partitions of $[1 \cdots 11]$).**

$P_1 = \{\{2, 3, 5\}, \{1, 4, 6, 7, 8\}, \{9, 10, 11\}\}$ and $P_2 = \{\{1\}, \{2, 3, 4\}, \{5, 6, 7, 8, 9\}, \{10, 11\}\}$ (respectively black spots for $P_1$ and white spots for $P_2$).

The incidence matrix corresponding to the diagram (as drawn) or these partitions is

$$
\begin{pmatrix}
0 & 2 & 1 & 0 \\
1 & 1 & 3 & 0 \\
0 & 0 & 1 & 2
\end{pmatrix}
$$

But, due to the fact that the defining partitions are unordered, one can permute the spots (black and white, between themselves) and, so, the lines and columns of this
matrix can be permuted. The diagram could be represented by the matrix
\[
\begin{pmatrix}
0 & 0 & 1 & 2 \\
0 & 2 & 1 & 0 \\
1 & 0 & 3 & 1
\end{pmatrix}
\]
as well.

The product formula now reads
\[
\mathcal{H}(F,G) = \sum_{n \geq 0} \frac{z^n}{n!} \sum_{d \in \text{diag}, |d| = n} \text{mult}(d) \mathbb{L}^{\alpha(d)} \mathbb{V}^{\beta(d)}
\]
where \(\alpha(d)\) (resp. \(\beta(d)\)) is the “white spots type” (resp. the “black spots type”) i.e. the multi-index \((\alpha_i)_{i \in \mathbb{N}^+}\) (resp. \((\beta_i)_{i \in \mathbb{N}^+}\)) such that \(\alpha_i\) (resp. \(\beta_i\)) is the number of white spots (resp. black spots) of degree \(i\) (\(i\) lines connected to the spot) and \(\text{mult}(d)\) is the number of pairs of unordered partitions of \([1 \cdots |d|]\) (here \(|d| = |\alpha(d)| = |\beta(d)|\) is the number of lines of \(d\)) with associated diagram \(d\).

Now one may naturally ask

\textbf{Q1) “Is there a (graphically) natural multiplicative structure on \text{diag} such that the arrow}
\[
d \mapsto \mathbb{L}^{\alpha(d)} \mathbb{V}^{\beta(d)}
\]
\textit{be a morphism ?”}

The answer is “yes”. The desired product just consists in concatenating the diagrams (the result, i.e. the diagram obtained in placing \(d_2\) at the right of \(d_1\), will be denoted by \([d_1|d_2]_D\)). One must check that this product is compatible with the equivalence of the permutation of white and black spots among themselves, which is rather straightforward (see [4]). We have

\textbf{Proposition 2.1} Let \text{diag} be the set of diagrams (including the empty one).

i) The law \((d_1, d_2) \mapsto [d_1|d_2]_D\) endows \text{diag} with the structure of a commutative monoid with the empty diagram as neutral element (this diagram will, therefore, be denoted by \(1_{\text{diag}}\)).

ii) The arrow \(d \mapsto \mathbb{L}^{\alpha(d)} \mathbb{V}^{\beta(d)}\) is a morphism of monoids, the codomain of this arrow being the monoid of (commutative) monomials in the alphabet \(\mathbb{L} \cup \mathbb{V}\) i.e.
\[
\text{MON}(\mathbb{L} \cup \mathbb{V}) = \{ \mathbb{L}^{\alpha} \mathbb{V}^{\beta} \}_{\alpha, \beta \in (\mathbb{N}^+)^{(n)}} = \bigcup_{n,m \geq 1} \{ L_1^{\alpha_1} L_2^{\alpha_2} \cdots L_n^{\alpha_n} V_1^{\beta_1} V_2^{\beta_2} \cdots V_m^{\beta_m} \}_{\alpha_i, \beta_j \in \mathbb{N}^+}
\]

iii) The monoid \((\text{diag}, [-|-], 1_{\text{diag}})\) is a free commutative monoid. Its letters are the connected (non-empty) diagrams.

\textbf{Remark 2.2} The reader who is not familiar with the algebraic structure of \(\text{MON}(X)\) can find rigorous definitions in paragraph (3.1) where this structure is needed for the proofs relating to deformations.
3. Non-commutative lifting (classical case)

The “classical” construction of the Hopf algebra LDIAG was given in [4]. We give the proofs below, using a coding through “lists of monomials” needed for the deformed (quantum) case. The entries of a list can be considered as “coordinate functions” for the diagrams (see introduction of section (4)).

3.1. Free monoids

We recall here the construction of the free and free-commutative monoids generated by a given set of variables (i.e. an alphabet) [15]. Let \( X \) be a set. We denote by \( X^\ast \) the set of lists of elements of \( X \), including the empty one. In many works, and in the sequel, the list \([x_1, x_2, \ldots, x_n]\) will be considered as a word \( x_1 x_2 \cdots x_n \) so that the concatenation of two lists \([x_1, x_2, \ldots, x_n], [y_1, y_2, \ldots, y_m]\) is just the word \( x_1 x_2 \cdots x_n y_1 y_2 \cdots y_m \). For this (associative) law, the empty list \([\ ]\) is the neutral element and will therefore be denoted by \( 1_{X^\ast} \).

Similarly, we denote by \( \mathbb{N}^{[X]} \) [16] the set of multisubsets of \( X \) (i.e. the set of - multiplicity - mappings with finite support \( X \mapsto \mathbb{N} \)). Every element \( \alpha \) of \( \mathbb{N}^{[X]} \) can be written multiplicatively, following the classical multi-index notation

\[
X^\alpha = \prod_{x \in X} x^{\alpha(x)}
\]

and the set \( \text{MON}(X) = \{X^\alpha\}_{\alpha \in \mathbb{N}^{[X]}} \) is exactly the set of (commutative) monomials with variables in \( X \). It is a monoid, indeed a (multiplicative) copy of \( \mathbb{N}^{[X]} \) as \( X^\alpha X^\beta = X^{\alpha+\beta} \). The subset of its non-unit elements is a semigroup which will be denoted by \( \text{MON}^+(X) \) (= \( \text{MON}(X) - \{X^0\} \)).

3.2. Labeling the nodes

There are (at least) two good reasons to look for non-commutative structures which may serve as a noncommutative pullback for \( \text{diag} \).

- Rows and Columns of matrices are usually (linearly) ordered and we have seen that a diagram is not represented by a matrix but by a class of matrices
- The complexity of \( \text{diag} \) and its algebra is not sufficient to relate it to other (non-commutative or non-cocommutative) algebras relevant to contemporary physics

The solution (of the non-deformed problem [4]) is simple and consists in labeling the nodes from left to right and from “1” to the desired number as follows.
The set of these graphs (i.e. bipartite graphs on some product \([1..p] \times [1..q]\) with no isolated vertex) will be denoted by \(\text{ldiag}\). The composition law is, as previously, concatenation in the obvious sense. Explicitly, if \(d_i, i = 1,2\) are two diagrams of dimension \([1..p_i] \times [1..q_i]\), one relabels the black (resp. white) spots of \(d_2\) from \(p_1 + 1\) to \(p_1 + p_2\) (resp. from \(q_1 + 1\) to \(q_1 + q_2\)) the result will be noted \([d_1|d_2]_L\). One has

**Proposition 3.1** Let \(\text{ldiag}\) be the set of labeled diagrams (including the empty one).

i) The law \((d_1,d_2) \mapsto [d_1|d_2]_L\) endows \(\text{ldiag}\) with the structure of a noncommutative monoid with the empty diagram \((p=q=0)\) as neutral element (which will, therefore, be denoted by \(1_{\text{ldiag}}\)).

ii) The arrow from \(\text{ldiag}\) to \(\text{diag}\), which implies “forgetting the labels of the vertices” is a morphism of monoids.

iii) The monoid \((\text{ldiag}, [\cdot|\cdot]_L, 1_{\text{ldiag}})\) is a free (noncommutative) monoid. Its letters are the irreducible diagrams (denoted from now on by \(\text{irr}(\text{ldiag})\)).

**Remark 3.2**

i) In a general monoid \((M, \ast, 1_M)\), the irreducible elements are the elements \(x \neq 1_M\) such that \(x = y \ast z \Rightarrow 1_M \in \{y, z\}\).

ii) It can happen that an irreducible of \(\text{ldiag}\) has an image in \(\text{diag}\) which splits, as shown by the simple example of the cross defined by the incidence matrix 
\[
\begin{pmatrix}
0 & 1 \\
1 & 0 \\
\end{pmatrix}
\]

### 3.3. Coding \(\text{ldiag}\) with “lists of monomials”

One can code every labelled diagram by a “list of (commutative) monomials” in the following way.

- Let \(X = \{x_i\}_{i \geq 1}\) be an infinite set of indeterminates and \(d \in \text{ldiag}_{p \times q}\) a diagram (\(\text{ldiag}_{p \times q}\) is the set of diagrams with \(p\) black spots and \(q\) white spots).
- Associate with \(d\) the multiplicity function \([1..p] \times [1..q] \rightarrow \mathbb{N}\) such that \(d(i, j)\) is the number of lines from the black spot \(i\) to the white spot \(j\).
- The code associated with \(d\) is \(\varphi_{lm}(d) = [m_1, m_2, \cdots, m_p]\) such that \(m_i = \prod_{j=1}^q x_j^{m(i,j)}\)
**Fig 3.** — Coding the diagram of fig 2 by a word of monomials. The code here is \([x_2^2 x_3, x_1 x_2 x_3^3, x_3 x_2^2]\)

As a data structure, the lists of monomials are elements of \((\mathcal{M} \mathcal{O} \mathcal{N}^+(X))^*\), the free monoid whose letters are \(\mathcal{M} \mathcal{O} \mathcal{N}^+(X) = \mathcal{M} \mathcal{O} \mathcal{N}(X) - \{X^0\}\), the semigroup of non-unit monomials over \(X\).

It is not difficult to see that, through this coding, concatenation is reflected in the following formula

\[
\varphi_{lm}(d_1 L \| d_2) = \varphi_{lm}(d_1) \ast T_{\text{max}}(\text{IndAlph}(\varphi_{lm}(l_1)))(\varphi_{lm}(d_2))
\]

where \(T_p\) is the translation operator which changes the variables according to \(T_p(x_i) = x_{i+p}\) (which corresponds to the relabelling of the white spots) and \(p_1\) is the number of black spots of \(d_1\).

For example, one has

\[
T_2([x_2 x_3, x_1 x_2 x_3^3, x_3 x_2^2]) = [x_2 x_4, x_3 x_4 x_5, x_5 x_6^2] ; T_6([x_1, x_2]) = [x_7, x_8]
\]

4. The Hopf algebra LDIAG (non-deformed case)

In [4], we defined a Hopf algebra structure on the space of diagrams LDIAG. The aim of this section is to give complete proofs and details for this construction through the use of the special space of coordinates constructed above (the complete vector of coordinates of a diagram being its code).

4.1. The monoid \((\mathcal{M} \mathcal{O} \mathcal{N}^+(X))^*\) and the submonoid of codes of diagrams

Formula (8) can be written using lists as

\[
l_1 \ast l_2 = l_1 \ast T_{\text{max}}(\text{IndAlph}(l_1))(l_2)
\]

which defines a monoid structure on \((\mathcal{M} \mathcal{O} \mathcal{N}^+(X))^*\) (the set of lists of non-unit monomials) with the empty list as neutral (i.e. \([\ ]\) which will, therefore, be denoted by \(1_{\mathcal{M} \mathcal{O} \mathcal{N}^+(X)}\) or simply “1” when the context is clear).

We will return to this construction (called shifting [17]) later.

The alphabet of a list is the set of variables occurring in the list. Formally

\[
\text{Alph}([m_1, m_2, \cdots, m_n]) = \bigcup_{1 \leq i \leq k} \text{Alph}(m_i)
\]
where, classically, for a monomial \( m = X^\alpha \), \( \text{Alph}(m) = \{ x_i \}_{\alpha(i) \neq 0} \).

Now, we can define the “compacting operator” on \( k(\mathfrak{MON}^+(X)) \) by its action on the lists. This operator actually removes the holes in the alphabet of a list by pushing to the left the indices which are at the right of a hole. For example (we denote by \( \text{cpt} \) the operator)

\[
\text{cpt}([x_2^2x_{10}, x_3x_4x_8^3, x_3x_4^2]) = [x_1^2x_5, x_2x_3x_4^3, x_2x_5^2].
\]  

(12)

The alphabet of the list on the LHS is \( \text{Alph}(l) = \text{Alph}([x_2^2x_{10}, x_3x_4x_8^3, x_3x_4^2]) = \{x_2, x_3, x_4, x_8, x_{10}\} \), its indices are \( \text{IndAlph}(l) = \{2, 3, 4, 8, 10\} \) and the re-indexing function is the unique strictly increasing mapping from \( \{2, 3, 4, 8, 10\} \) to \([5]\). Here the compacting operator is just the substitution

\[x_1 \leftarrow x_2; \quad x_2 \leftarrow x_3; \quad x_3 \leftarrow x_4; \quad x_4 \leftarrow x_8; \quad x_5 \leftarrow x_{10}\]

The formal definitions are the following

- \( \text{IndAlph}(l) = \{i \mid x_i \in \text{Alph}(l)\} \)
- \( l \) being given, let \( \phi_l \) be the unique increasing mapping from \( \text{IndAlph}(l) \) to \( [\text{card}(\text{IndAlph}(l))] \) (in fact, \( \text{card}(\text{IndAlph}(l)) = \text{card}(\text{Alph}(l)) \))
- let \( s_l \) be the substitution \( x_i \leftarrow x_{\phi_l(i)} \) in the monomials.
- Then, if \( l = [m_1, m_2, \cdots, m_n] \), \( \text{cpt}(l) = [s_l(m_1), s_l(m_2), \cdots, s_l(m_n)] \).

**Définition 4.1** The compacting operator \( \text{cpt} : k(\mathfrak{MON}^+(X)) \mapsto k(\mathfrak{MON}^+(X)) \) is the extension by linearity of the mapping \( \text{cpt} \) defined above.
It can be checked easily that, for \( l \in (\ MON^+(X))^* \), the following are equivalent

(i) \( \text{cpt}(l) = l \)
(ii) \( \text{IndAlph}(l) = [\text{card(IndAlph}(l))] \)
(iii) there is no hole in \( \text{Alph}(l) \); that is, there exists no \( i \geq 1 \) s.t. \( x_i \notin \text{Alph}(l) \) and \( x_{i+1} \in \text{Alph}(l) \)
(iv) \( l \) is the code of some (then unique) diagram \( d \).

It follows from the preceding properties that \( \text{cpt} \) is a projector with range the subspace \( C_{\text{diag}} \) of \( k(\ MON^+(X)) \) generated by the codes of the diagrams. Formula (8) proves that \( C_{\text{diag}} \) is closed under the shifted concatenation defined by (10). More precisely

**Proposition 4.2** The algebra \( C_{\text{diag}} \) is a free algebra on the set of the codes of irreducible diagrams.

These codes are also the non-empty lists \( l \) which are compact (i.e. \( \text{cpt}(l) = l \)) and cannot be factorized into a product of two non-empty lists i.e. \( l = l_1 * l_2; \ l_i \neq [\ ] \) (one can check easily that, if \( l_1 * l_2 \) is compact, so are \( l_1 \) and \( l_2 \)).

### 4.2. The Hopf algebras \( C_{\text{diag}} \) and \( \text{LDIAG} \)

The algebra \( \text{LDIAG} \) is endowed with the structure of a bi-algebra by the comultiplication

\[
\Delta_{BS}(d) = \sum_{I+J=[1..p]} d[I] \otimes d[J] \tag{13}
\]

where \( p \) is the number of black spots and \( d[I] \) is the “restriction” of \( d \) to the black spots selected by the \( I \subset [1..p] \).

On the other hand, we have a standard Hopf algebra structure on the free algebra, expressed in terms of concatenation and subwords [18, 19]. Let \( A \) be an alphabet (a set of letters) and \( w \in A^* \) a word, if we write \( w \) a a sequence of letters \( w = a_1 a_2 \cdots a_n; \ a_i \in A \), the length \( |w| \) of \( w \) is \( n \) and if \( I = \{i_1, i_2, \cdots i_k\} \subset [1..n] \), the subword \( w[I] \) is \( a_{i_1} a_{i_2} \cdots a_{i_k} \) (this notation is slightly different from that of [19] where it is \( w|_I \)). Then, the free algebra \( k(A) \) is a Hopf algebra with comultiplication [19, 18],

\[
\Delta_{\text{LieHopf}}(w) = \sum_{I+J=[1..n]} w[I] \otimes w[J]. \tag{14}
\]

One has the following relation between restrictions of diagrams and subwords

\[
\varphi_{\text{lm}}(d[I]) = \text{cpt}(\varphi_{\text{lm}}(d)[I]) \tag{15}
\]

this suggests that the coproduct

\[
\Delta_{\text{int}}(l) = \sum_{I+J=[1..n]} \text{cpt}(l[I]) \otimes \text{cpt}(l[J]) \tag{16}
\]

could be a Hopf algebra comultiplication for the shifted algebra \((k(\ MON^+(X)), \bar{*}, [\ ]))

Unfortunately, this fails due to the lack of counit (i and ii of the following Theorem),
but the “ground subalgebra” \( C_{\text{diag}} \) is a genuine Hopf algebra (which is exactly what we do need here).

**Theorem 4.3** Let \( \mathcal{A} = (k\langle \text{MON}(X), \bar{\ast}, [\ ] \rangle) \) be the algebra of lists of (non-unit) monomials endowed with the shifted concatenation of formula (10). Then

i) \( \mathcal{A} \) is a free algebra.

ii) The coproduct \( \Delta_{\text{list}} \) (recalled below) is co-associative and a morphism of algebras \( \mathcal{A} \hookrightarrow \mathcal{A} \otimes \mathcal{A} \) (i.e. \( \mathcal{A} \) is a bi-algebra without counit).

\[
\Delta_{\text{list}}(l) = \sum_{I+J=[1..n]} \text{cpt}(l[I]) \otimes \text{cpt}(l[J])
\]  

(17)

iii) The algebra \( C_{\text{diag}} \) is a sub-algebra and coalgebra of \( \mathcal{A} \) which is a Hopf algebra for the following co-unit and antipode.

- **Counit**
  \[
  \varepsilon(l) = \delta_{L[1..t]}
  \]
  (Kronecker delta)

- **Antipode**
  \[
  S(l) = \sum_{r \geq 0} \sum_{_{0 < 0} I_j} (-1)^r \text{cpt}(l[I_1]) \text{cpt}(l[I_2]) \cdots \text{cpt}(l[I_r])
  \]

(18)

(19)

*Proof —* i) Throughout the proof, we will denote by \( \ast \) the concatenation between lists and \( \bar{\ast} \) the shifted concatenation defined by the formula (10). We first remark that, if \( l = l_1 \bar{\ast} l_2 \), then \( \max(\text{IndAlph}(l_1)) < \min(\text{IndAlph}(l_2)) \). This leads us to define, for a (non-shifted) factorization \( l = l_1 \ast l_2 = l[1..t] \ast l[t+1..p] \) (\( p = |l| \)), a gauge of the degree of overlapping of the intervals (of integers) \( [1..\max(\text{IndAlph}(l_1))] \) and \( [\min(\text{IndAlph}(l_2))..\infty[ \), thus the function

\[
\omega_l(t) = \text{card}\left([1..\max(\text{IndAlph}(l[1..t]))] \cap [\min(\text{IndAlph}(l[t+1..p]))..\infty[\right] = \left(\max(\text{IndAlph}(l[1..t])) - \min(\text{IndAlph}(l[t+1..p])) + 1\right)^+.
\]

(20)

(We recall that, for a real number \( x \), \( x^+ \) is its positive part \( x^+ = \max(x, 0) = \frac{1}{2}([x] + x) \) [33]). It can be easily checked that the points \( t \) where \( \omega_l(t) = 0 \) determine the (unique) factorisation of \( l \) in irreducibles. It follows that the monoid \( ((\text{MON}^+(X))^*, \bar{\ast}, [\ ]) \) is free and so is its algebra \( (k(\text{MON}^+(X)), \bar{\ast}, [\ ]) \).

ii) If we denote \( \Delta : \mathcal{A} \hookrightarrow \mathcal{A} \otimes \mathcal{A} \) the standard coproduct given, for a list \( l \) of length \( p \), by formula (14), one can remark that

\(\begin{align*}
(i) & \text{cpt}(l_1) \bar{\ast} \text{cpt}(l_2) = \text{cpt}(l_1 \bar{\ast} l_2) \\
(ii) & \Delta_{\text{list}} = (\text{cpt} \otimes \text{cpt}) \circ \Delta \\
(iii) & \Delta_{\text{list}} \circ \text{cpt} = \Delta_{\text{list}}
\end{align*}\)
(iv) \((\forall n \in \mathbb{N})(\text{cpt}(T_n(l)) = \text{cpt}(l))\)

(v) \((\forall n \in \mathbb{N})(\Delta \circ T_n = (T_n \otimes T_n) \circ \Delta)\).

**Coassociativity of** \(\Delta_{\text{list}}\). —

One has

\[
(\Delta_{\text{list}} \otimes \text{Id}) \circ \Delta_{\text{list}} = (\Delta_{\text{list}} \otimes \text{Id}) \circ (\text{cpt} \otimes \text{cpt}) \circ \Delta =
\]

\[
((\Delta_{\text{list}} \circ \text{cpt}) \otimes \text{cpt}) \circ \Delta = (\Delta_{\text{list}} \otimes \text{cpt}) \circ \Delta =
\]

\[
(((\text{cpt} \otimes \text{cpt}) \circ \Delta) \otimes \text{cpt}) \circ \Delta =
\]

\[
(\text{cpt} \otimes (\text{ cpt} \otimes \text{cpt}) \circ \Delta) \circ \Delta = (\text{cpt} \otimes \Delta_{\text{list}}) \circ \Delta =
\]

\[
(\text{cpt} \otimes (\Delta_{\text{list}} \circ \text{cpt})) \circ \Delta =
\]

\[
(Id \otimes \Delta_{\text{list}}) \circ (\text{cpt} \otimes \text{cpt}) \circ \Delta = (Id \otimes \Delta_{\text{list}}) \circ \Delta_{\text{list}}
\]

(21)

\(\Delta_{\text{list}}\) **is a morphism.** —

For two lists \(u, v \in \), let us compute \(\Delta_{\text{list}}(u \ast v)\). With \(p = \text{max}(\text{IndAlph}(u))\), one has

\[
\Delta_{\text{list}}(u \ast v) = (\text{cpt} \otimes \text{cpt}) \circ \Delta(l_1 \ast T_p(v)) =
\]

\[
(\text{cpt} \otimes \text{cpt})(\Delta(u) \ast \mathcal{O}^2 \Delta(T_p(v))) =
\]

\[
(\text{cpt} \otimes \text{cpt})(\Delta(u) \ast \mathcal{O}^2 (T_p \otimes T_p)\Delta(v) =
\]

\[
(\text{cpt} \otimes \text{cpt})(\sum_{(1)(2)} u_{(1)} \otimes u_{(2)}) \ast \mathcal{O}^2 (T_p \otimes T_p)(\sum_{(3)(4)} v_{(3)} \otimes v_{(4)} =
\]

\[
(\text{cpt} \otimes \text{cpt})(\sum_{(1)(2)(3)(4)} u_{(1)} \ast T_{p_1}(T_{p-p_1}(v_{(3)})) \otimes u_{(2)} \ast T_{p_2}(T_{p-p_2}(v_{(4)})))
\]

(22)

with, for each term in the sum

\[
p_1 = \text{max}(\text{IndAlph}(u_{(1)})) \leq p ; p_2 = \text{max}(\text{IndAlph}(u_{(2)})) \leq p
\]

so, the quantity in (22) is

\[
(\text{cpt} \otimes \text{cpt})(\sum_{(1)(2)(3)(4)} u_{(1)} \ast (T_{p-p_1}(v_{(3)})) \otimes u_{(2)} \ast (T_{p-p_2}(v_{(4)})) =
\]

\[
\sum_{(1)(2)(3)(4)} \text{cpt}(u_{(1)})(T_{p-p_1}(v_{(3)})) \otimes \text{cpt}(u_{(2)})(T_{p-p_2}(v_{(4)})) =
\]

\[
\sum_{(1)(2)(3)(4)} (\text{cpt}(u_{(1)})) \ast \text{cpt}(T_{p-p_1}(v_{(3)})) \otimes (\text{cpt}(u_{(2)})) \ast \text{cpt}(T_{p-p_2}(v_{(4}))) =
\]

\[
\sum_{(1)(2)(3)(4)} (\text{cpt}(u_{(1)})) \ast \text{cpt}(v_{(3)}) \otimes (\text{cpt}(u_{(2)})) \ast \text{cpt}(v_{(4)}) =
\]

\[
\left(\sum_{(1)(2)} \text{cpt}(u_{(1)}) \otimes \text{cpt}(u_{(2)})\right) \ast \mathcal{O}^2 \left(\sum_{(3)(4)} \text{cpt}(v_{(3)}) \otimes \text{cpt}(v_{(4)})\right)
\]
\[ \Delta_{\text{list}}(u) \otimes^2 \Delta_{\text{list}}(v) \]  

(23)

iii) As \( C_{\text{diag}} \) is generated by the image of \( \text{cpt} \) it is clear that this space is a sub-coalgebra of \( \mathcal{A} \). Moreover, \( \text{cpt} \) is a (multiplicative) morphism \( \mathcal{A} \rightarrow \mathcal{A} \) and thus its image \( C_{\text{diag}} \) is a subalgebra of \( \mathcal{A} \). We now supply the missing ingredients to complete the proof of the Hopf algebra structure.

\( \varepsilon \) is a counit. —

Let \( l = \text{cpt}(l) \) be a compact list. We remark that, for any list \( u \), one has
\[ \text{cpt}(u) = [ \] \iff \[ u = [ \]. \]

Then, with \( \mu_l : k \otimes A \mapsto A \) the scaling operator

\[ \mu_l(\varepsilon \otimes \text{Id})\Delta_{\text{list}}(l) = \sum_{I+J=[1..n]} \varepsilon(\text{cpt}(l[I])\text{cpt}(l[J]) = \sum_{I+J=[1..n]} \varepsilon(\text{cpt}(l[I])\text{cpt}(l[J]) + \sum_{I+J=[1..n]} \varepsilon(\text{cpt}(l[1])\text{cpt}(l[J]) = \text{cpt}(l) + 0 = l \]  

(24)

the proof of the fact that \( \varepsilon \) is a left counit is similar.

\( S \) is the antipode. —

One has \( C_{\text{diag}} = k.1 \oplus \ker(\varepsilon) \), let us denote \( Id^+ \) the projection \( C_{\text{diag}} \mapsto \ker(\varepsilon) \) according to this decomposition.

Then, for every list \( l \),

\[ \sum_{r \geq 0} \sum_{I_1+I_2+...+I_r=[1..p]} (-1)^r \text{cpt}(l[I_1])\text{cpt}(l[I_2]) \cdots \text{cpt}(l[I_r]) \]

is well defined as the first sum is locally finite. Thus, the operator

\[ \sum_{r \geq 0} \sum_{I_1+I_2+...+I_r=[1..p]} (-1)^r (Id^+ \ast Id^+ \ast \cdots \ast Id^+) \quad r \text{ times} \]

is well defined and is the convolutional inverse of \( Id \).

4.3. Subalgebras of LDIAG

4.3.1. Graphic primitive elements  The problem of Graphic Primitive Elements (GPE) is the following.

Let \( \mathcal{H} \) be a Hopf algebra with (linear) basis \( G \), a set of graphs. The GPE are the primitive elements \( \Gamma \in G \) which are primitive i.e.

\[ \Gamma \text{ is a GPE } \iff \Gamma \in G \text{ and } \Delta(\Gamma) = \Gamma \otimes 1 + 1 \otimes \Gamma. \]  

(25)

It is not difficult to check that, in any case, the subalgebra \( \mathcal{H}^{\text{GPE}} \) generated by these elements is also a sub-coalgebra.

We make an extra hypothesis (which is often fulfilled)

\[ 1_\mathcal{H} \in G \text{ and } (\Gamma \in G - \{1_\mathcal{H}\} \implies \varepsilon(\Gamma) = 0). \]  

(26)
Then (if (26) is fulfilled) $\mathcal{H}^{\text{GPE}}$ is a sub-Hopf algebra as the antipode of the product $\Gamma_1\Gamma_2\cdots\Gamma_p$ of (GPE) is

$$S(\Gamma_1\Gamma_2\cdots\Gamma_p) = (-1)^p \Gamma_p\Gamma_{p-1}\cdots\Gamma_1.$$  (27)

The following proposition helps to determine $\text{LDIAG}^{\text{GPE}}$.

**Proposition 4.4** In $\text{LDIAG}$ (with basis $G = \text{l.diag}$), the following are equivalent
i) $d$ is a GPE
ii) $d$ has only one black spot.

Then, the Hopf algebra $\text{LDIAG}^{\text{GPE}}$ is generated by the product of “one-black-spot” diagrams.

---

**Fig 4.** — Graphic Primitive Elements of $\text{LDIAG}$ have only one black spot and therefore are coded by the sequence of the ingoing degrees of their white spots (a composition). The first one here has code $[1, 2, 3, 1]$. The picture shows an element of the monoid generated by Graphic Primitive Elements (a linear basis of $\text{LDIAG}^{\text{GPE}}$) which is then coded by a list of compositions, here $[[1, 2, 3, 1], [2, 3, 1], [2, 1, 4]]$.

4.3.2. Level subalgebras

One can also impose limitations on the incoming degrees of the white spots in a way compatible with the coproduct. In this case, one defines an infinity of Hopf-subalgebras of $\text{LDIAG}$ which we will call “level subalgebras”.

More precisely, given an integer $l > 0$, one can ask for spaces generated by the diagrams $d$ for which every white spot has an incoming degree $\leq l$. This amounts to say that the “white spot type” of every diagram $d$ is of the form

$$\alpha(d) = (\alpha_1, \alpha_2, \cdots \alpha_k, 0, 0 \cdots 0, \cdots); \text{ (all the } \alpha_i \leq l \text{ for } i \leq k \text{ and } \alpha_i = 0 \text{ for } i > k)$$

We denote by $\text{LDIAG}^{\leq l}$ the subspace generated by these diagrams. One has a chain of Hopf algebras

$$\text{LDIAG}^{\leq 1} \subset \text{LDIAG}^{\leq 2} \subset \cdots \text{LDIAG}^{\leq l} \subset \text{LDIAG}^{\leq l+1} \subset \cdots \subset \text{LDIAG}$$  (28)
4.3.3. BELL and LBELL

The algebras BELL and LBELL were defined in [1].

The algebra LBELL is the intersection LDIAG$^{\leq 1} \cap$ LDIAG$^{gpe}$ and since they are subspaces generated by subsets of ldiag, LBELL is generated by diagrams that

- are concatenations of one-black-spot-diagrams
- such that the incoming degree of every white spot is one.

Let $d_k$ be the diagram with code $[x_1, x_2, \cdots x_k]$. LBELL is generated by concatenations of these diagrams. Indeed, the diagrams $d_k$ are a subalphabet of the free monoid ldiag so that they generate a free submonoid which we will denote here lbell.

**Fig 5.** — An element of lbell, concatenation $d_1d_3d_2$.

The algebras LDIAG and LBELL are both enveloping algebras. They are generated by their primitive elements which are in general linear combinations of diagrams and not pure diagrams. For an analysis of “graphic primitive elements” see section (4.3.1).

5. The algebra LDIAG($q_c, q_s, q_t$) (deformed case)

5.1. Counting crossings ($q_c$) and superpositions ($q_s$)

The preceding coding is particularly well adapted to the the deformation we want to construct here. The philosophy of the deformed product is expressed by the descriptive formula\|.

$$[d_1|d_2]_{L(q_c,q_s)} = \sum_{cs(?)\text{ all crossing and}} q_c^{nc\times weight} q_s^{weight\times weight} CS([d_1|d_2]_L)(29)$$

where

- $q_c, q_s \in \mathbb{C}$ or $q_c, q_s$ formal. These and other cases may be unified by considering the set of coefficients as belonging to a ring $K$.
- the exponent of $q_c^{nc\times weight}$ is the number of crossings of “what crosses” times its weight

\| Exact definition of the coefficient $q_c^{nc\times weight}q_s^{weight\times weight}$ is the result of crossing and shifting processes which will be detailed in paragraph (5.2).
• the exponent of \( q^{\text{weight} \times \text{weight}} \) is the product of the weights of "what is overlapped"
• \( cs() \) are the diagrams obtained from \([d_1|d_2]_L\) by the process of crossing and superposing the black spots of \(d_2\) on to those of \(d_1\), the order and distinguishability of the black spots of \(d_1\) (i.e. \(d_2\)) being preserved.

What is striking is that this law is associative. This result will be established after the following paragraph.

\[
* = + q_s^2 + q_c^2 + q_c q_s^6 + q_c^8
\]

Fig 5. — Counting crossings and superposings produces an associative law.

Fig 6. — Detail of the fourth monomial (with coefficient \(q_c^2 q_s^6\)), crossings (circles) and superposings (black squares) are counted the same way but with a different variable.

5.2. Modified laws

• Twisting

Proposition 5.1 Let \( A = (A_n)_{n \in \mathbb{N}} \) a graded semigroup and \( A^* \) the set of lists (denoted by \([a_1, a_2, \ldots, a_k]\)) with letters in \(A\).
For convenience we define the operator \( \ast \) (left append) \( A \times A^* \mapsto A^* \) by

\[
a \ast [b_1, b_2, \ldots, b_n] := [a, b_1, b_2, \ldots, b_n]
\]

(30)

Let \( q_c, q_s \in k \) be two elements in a ring \( k \). We define on \( k < A \geq k[A^*] \) a new law \( \uparrow \) by

\[
w \uparrow 1_{A^*} = 1_{A^*} \uparrow w = w
\]

\[
a \ast u \uparrow b \ast v = a \ast (u \uparrow b \ast v) + q_c^{u|v|a|b|c}b \ast (a \ast u \uparrow v) + q_s^{u|v|b|a|c}ab \ast (u \uparrow v)
\]

(31)

where the weights \((|x| = n \text{ if } x \in A_n)\) are extended additively to lists by

\[
|\{a_1, a_2, \ldots, a_k\}| = \sum_{i=1}^{k} |a_i|
\]

Then the new law \( \uparrow \) is graded, associative with \( 1_{A^*} \) as unit.

Proof — It suffices to prove the identity \( x \uparrow (y \uparrow z) = (x \uparrow y) \uparrow z \); \( x, y, z \) being lists (as the two members are trilinear). It is obviously true when one of the factors is the empty list. We show it when the three factors are non-empty (throughout the computation, the law \( \ast \) will have priority over other operators).

\[
(a \ast u \uparrow b \ast v) \uparrow c \ast w =
\]

\[
(a \ast (u \uparrow b \ast v) + q_c^{u|a|b|}b \ast (u \uparrow v) + q_s^{u|b|a|b|c}ab \ast (a \ast u \uparrow v)) \uparrow c \ast w =
\]

\[
[a \ast ((u \uparrow b \ast v) \uparrow c \ast w) + q_s^{u|b|a|b|c}ab \ast ((a \ast u \uparrow v) \uparrow w)]
\]

(32)
in the second expression, one gathers the three terms which we find first in the square brackets and we get

\[
\begin{align*}
a \ast (u \uparrow b \ast (v \uparrow cw)) + q^{[a\ast u][b\ast v]} & \ast (a \ast (u \uparrow b \ast (v \uparrow w))) + \\
q^{[b\ast v]} & \ast (u \uparrow c \ast (b \ast v \uparrow w)) = a \ast (u \uparrow b \ast v \uparrow c \ast w)
\end{align*}
\]  

(34)

in the first expression, one gathers the three terms which we find last in the square brackets and we get

\[
\begin{align*}
q^{([a\ast u]+[b\ast v])\ast c} & \ast (a \ast (u \uparrow b \ast v) \uparrow w) + \\
q^{[u][b]+([a\ast u]+[b\ast v])\ast c} & \ast ((ab) \ast (u \uparrow v)) \uparrow w) + \\
q^{[a\ast u][b]+([a\ast u]+[b\ast v])\ast c} & \ast (b \ast (a \ast u \uparrow v) \uparrow w) = \\
q^{([a\ast u]+[b\ast v])\ast c} & \ast (a \ast u \uparrow b \ast v \uparrow w)
\end{align*}
\]

(35)

and one finds the 7-term expression

\[
\begin{align*}
a \ast (u \uparrow b \ast v \uparrow c \ast w) + q^{[a\ast u]} & \ast (a \ast u \uparrow v \uparrow c \ast w) + \\
q^{[a\ast u]+[b\ast v]} & \ast (a \ast u \uparrow b \ast v \uparrow w) + q^{[u][b][a][c]} \ast (ab) \ast (u \uparrow v \uparrow c \ast w) + \\
q^{([u]+[b\ast v])\ast c} & \ast ((ac) \ast (u \uparrow b \ast v \uparrow w) + \\
q^{[u][c][b]+[a\ast u][b][c]} & \ast (bc) \ast (a \ast u \uparrow v \uparrow w) + \\
+q^{[v][c]+[u][c][b]} & \ast (abc) \ast (u \uparrow v \uparrow w)
\end{align*}
\]

(36)

The framework with diagrams will need another proposition on shifted laws.

- **Shifting**

We begin by the “shifting lemma”.

**Lemma 5.2** Let \( \mathcal{A} \) be an associative algebra (whose law will be denoted by \( \ast \)) and \( \mathcal{A} = \oplus_{n \in \mathbb{N}} \mathcal{A}_n \) a decomposition of \( \mathcal{A} \) in direct sum. Let \( T \in \text{End}(\mathcal{A}) \) be an endomorphism of the algebra \( \mathcal{A} \). We will denote by \( T^n = T \circ T \circ \cdots \circ T \) the \( n \)-th compositional power of \( T \). We suppose that the shifted law

\[
a \ast b = a \ast T^n(b)
\]

(37)

for \( a \in \mathcal{A}_n \) is graded for the decomposition \( \mathcal{A} = \oplus_{n \in \mathbb{N}} \mathcal{A}_n \).

Then, if the law \( \ast \) is associative so is the law \( \ast \).

**Remark 5.3** The hypothesis that the shifted law given by eq.(37) be graded is automatically satisfied if \( \mathcal{A} = \oplus_{n \in \mathbb{N}} \mathcal{A}_n \) is a graded algebra and if all the morphisms \( T_n \) are of degree 0.
This lemma will be applied to the decomposition given by $n = \sup(\text{Alph}(w))$ (the highest index of variables appearing in $w$) and the morphism given by $T(x_i) = x_{i+1}$.

What do these statements mean for us?

Here the graded semigroup is $\mathbb{MON}^+(X)$ and we do not forget the coding arrow $\varphi_{lm} : \text{l diag} \to (\mathbb{MON}^+(X))^*$. The image of $\varphi_{lm}$ is exactly the set of lists of monomials $w = [m_1, m_2, \ldots, m_k]$ such that the set of variables involved $\text{Alph}(w)$ is of the form $x_1 \cdots x_l$ (the labelling of the white spots is without hole). By abuse of language we will say that a list of monomials “is in $\text{l diag}$” in this case. It is not difficult to see, from formulas (31,37) that if $w_i, i = 1, 2$ are in $\text{l diag}$ so are all the factors of $\bar{w}_1 \uparrow \bar{w}_2$.

Proposition 5.4 Let $C_{\text{l diag}}$ be the subspace of $(K < \mathbb{MON}^+(X) >, \uparrow)$ generated by the codes of the diagrams (i.e. the lists $w \in \mathbb{MON}^+(X)$ such that $\text{Alph}(w)$ is without hole).

Then

i) $(C_{\text{l diag}}, \uparrow)$ is a unital subalgebra of $(K < \mathbb{MON}^+(X) >, \uparrow)$

ii) $(C_{\text{l diag}}, \uparrow)$ is a free algebra. More precisely, for any diagram decomposed in irreducibles $d = d_1.d_2 \cdots d_k$ let

$$B(d) := \varphi_{lm}(d_1) \uparrow \varphi_{lm}(d_2) \cdots \uparrow \varphi_{lm}(d_k)$$

then

$\alpha) (B(d))_{d \in \text{l diag}}$ is a basis of $C_{\text{l diag}}$

$\beta) B(d_1.d_2) = B(d_1) \uparrow B(d_2)$

As $k[\text{l diag}]$ is isomorphic to $C_{\text{l diag}}$ as a linear space, we denote $\text{LDIAG}(q_c, q_s)$ the new algebra structure of $k[\text{l diag}]$ inherited from $C_{\text{l diag}}$. one has

$$\text{LDIAG}(0,0) \simeq \text{LDIAG}; \text{LDIAG}(1,1) \simeq \text{MQSym}$$

6. Coproducts

We must now define a parametrized (say, by $q_t$) coproduct such that

$$(\text{LDIAG}(q_c, q_s), \uparrow, 1_{\text{l diag}}, \Delta_q, \varepsilon)$$

is a graded bialgebra (as in the non-deformed Hopf algebra of [4], the counit $\varepsilon$ is just the “constant term” linear form).

We will take advantage of the freeness of $\text{LDIAG}(q_c, q_s)$ through the following lemma.

Lemma 6.1 Let $\mathbb{Y}$ be an alphabet, $k$ a ring and $k < \mathbb{Y} > = k[\mathbb{Y}^*]$ be the free algebra constructed on $\mathbb{Y}$. For every mapping

$\Delta : A \to k < \mathbb{Y} > \otimes k < \mathbb{Y} >$, we denote $\bar{\Delta} : k < \mathbb{Y} > \mapsto k < \mathbb{Y} > \otimes k < \mathbb{Y} >$ its extension as a morphism of algebras ($k < \mathbb{Y} > \otimes k < \mathbb{Y} >$ being endowed with its non-twisted structure of tensor product of algebras). Then, in order to be coassociative, it is necessary and sufficient that

$$(\bar{\Delta} \otimes I) \circ \Delta and (I \otimes \bar{\Delta}) \circ \Delta$$

coincide on $\mathbb{Y}$. 
The preceding lemma expresses the fact that, for a free algebra, the variety of the possible coproducts is a linear subspace. This will be transparent in formula (43).

We now consider the structure constants of the coproduct of $\text{MQSym}$ expressed with respect to the family of free generators

$$\{\text{MS}_P\}_{P \in \mathcal{P} \mathcal{M}^c}$$

where $\mathcal{P} \mathcal{M}^c$ is the set of connex packed matrices (similarly, $\mathcal{P} \mathcal{M}$ is the set of packed matrices).

$$\Delta_{\text{MQSym}}(\text{MS}_P) = \sum_{Q, R \in \mathcal{P} \mathcal{M}} \alpha_{Q, R}^P \text{MS}_Q \otimes \text{MS}_R$$

(41)

For the irreducible diagram $d$, we set

$$\Delta_1(d) = \sum_{d_1, d_2 \in \text{irr}(\text{ldiag})} \alpha_{\varphi_1(d_1), \varphi_2(d_2)} d_1 \otimes d_2$$

(42)

and $\Delta_0(d) = \Delta_{\text{WS}}(d)$. Then proposition (6.1) proves that, for $q_t \in \{0, 1\}$

$$\Delta_t = (1 - q_t)\Delta_0 + q_t\Delta_1$$

(43)

is a coproduct of graded bialgebra for $(\text{LDIAG}(q_c, q_s), \uparrow, 1_{\text{ldiag}})$.

We sum up the results

**Proposition 6.2** i) With the operations defined above, $q_c, q_s$ complex or formal and $q_t$ boolean ($q_t \in \{0, 1\}$),

$\text{LDIAG}(q_c, q_s, q_t) := (\text{LDIAG}(q_c, q_s), \uparrow, 1_{\text{ldiag}}, \Delta_q, \varepsilon)$

is a Hopf algebra.

ii) At parameters $(0, 0, 0)$, one has $\text{LDIAG}(0, 0, 0) \simeq \text{LDIAG}$

iii) At parameters $(1, 1, 1)$, one has $\text{LDIAG}(1, 1, 1) \simeq \text{MQSym}$

7. More on LDIAG$(q_c, q_s, q_t)$ : structure, images and the link with Euler-Zagier sums

It has been proved recently that $\text{LDIAG}(q_c, q_s, q_t)$ is a tridendriform Hopf Algebra [21] and that $\text{LDIAG}(1, q_s, q_t)$ is a homomorphic image of the algebra of planar decorated trees of Foissy [22, 23]. Bidendriformity of the algebra $\text{LDIAG}(q_c, q_s)$ can also be established through a bi-word realization providing yet another (statistical) interpretation of the $(q_c, q_s)$ deformation [17].

We will now make clear the relations between the $(q_c, q_s)$ deformation and Euler-Zagier sums.

According the notation of [2], one has

$$\zeta(s_1, \ldots, s_n; \sigma_1, \ldots, \sigma_n) = \sum_{0 < i_1 < \cdots < i_n} \frac{\sigma_{i_1} \cdots \sigma_{i_n}}{i_{1}^{s_1} \cdots i_{n}^{s_n}}$$

(44)
\[\zeta(s_1, \ldots, s_n) = \sum_{0 < i_1 < \cdots < i_n} \frac{1}{i_1^{s_1} \cdots i_n^{s_n}}\]  

with \(\sigma_i \in \{-1, 1\}\) and \(s_i > 1\) if \(\sigma_i = 1\). Here we are more interested in the multiplication mechanism, so we extend the notation to formal variables and use, for indices, the bi-word notation. Hence

\[\zeta_{\text{FP}}\left(\frac{z_1 \cdots z_n}{s_1 \cdots s_n}\right) = \sum_{0 < i_1 < \cdots < i_n} \frac{z_1^{i_1} \cdots z_n^{i_n}}{i_1^{s_1} \cdots i_n^{s_n}}.\]  

We remark that the indices are taken as words (i.e. lists) with variables located in the semigroup \(\mathfrak{M}(Z) \times \mathbb{N}^+\) with \(Z = \{z_i\}_{i \geq 1}\). The set of these functions is closed under multiplication and will be called below \(FP(Z)\), \textit{formal polyzeta functions in the variables} \(Z\). Hence, the multiplication of these sums fits in the hypotheses of Proposition (5.1) with \(q_c = q_s = 1\) (quasi-shuffle in [24]). From this, we deduce an arrow

\[LDIAG(1, 1) \to FP(Z).\]  

More precisely, if \(d\) is a diagram with code \([m_1, m_2, \cdots, m_p]\) we make correspond

\[\zeta_{\text{FP}}\left(\frac{m_1 \cdots m_n}{\deg(m_1) \cdots \deg(m_n)}\right)\]  

where \(\deg(m_i)\) is the total degree of \(m_i\). We will denote \(\zeta_{D2\text{FP}}(d)\) this value (48). One has

\[\zeta_{D2\text{FP}}(d_1)\zeta_{D2\text{FP}}(d_2) = \zeta_{D2\text{FP}}(d_1 \uparrow_{11} d_2)\]  

the law \(\uparrow_{11}\) being unshifted and specialized to \((q_c, q_s) = (1, 1)\).

When restricted to “convergent” diagrams (i.e. diagrams with \(\deg(m_i) \geq 2\) which form a subalgebra of \(LDIAG_u(q_c, q_s)\)) and specializing all the variables to 1, we recover the “usual” Euler-Zagier sums by just counting the outgoing degrees of the black spots and the arrow of (47) becomes

\[d \to \zeta(\deg(m_1), \cdots, \deg(m_n))\]  

(usual Euler-Zagier sums). Denoting the last (50) value \(\zeta_{D2\text{EZ}}(d)\), one has

\[\zeta_{D2\text{EZ}}(d_1)\zeta_{D2\text{EZ}}(d_2) = \zeta_{D2\text{EZ}}(d_1 \uparrow_{11} d_2)\]  

8. Concluding remarks

For a diagram \(d\) with \(r\) black spots, the code \([m_1, m_2, \cdots, m_r]\) can be temporarily seen as a “vector of coordinates” for the given diagram, but we prefer to stick to the structure of lists as, firstly, the dimension of the vector varies with the diagram and secondly, we have to concatenate the codes. The coordinate functions of the diagram \(d\) are therefore the family \((a_i)_{i > 0}\) defined by \(a_i(d) = m_i\) for \(i \leq r\) and \(a_i(d) = 0\) for \(i > r\). From this perspective the “\(q_i\)” of our three parameter deformation is a quantization in the sense
of Moyal’s deformed products \cite{25} on the algebra of coordinate functions (but without the first order condition; see the introduction of \cite{26}), by the formula
\begin{equation}
a_{i_1} \ast a_{i_1} \cdots \ast a_{i_k} (d) = \mu (a_{i_1} \otimes a_{i_1} \otimes \cdots \otimes a_{i_k} ( \Delta_{q_{c}}^{|k|} (d)))
\end{equation}
where $\mu$ is the ordinary multiplication of polynomials.

The crossing parameter $q_{c}$ is also a quantization parameter as, for $q_{s} = 0$, one has
\begin{equation}
\text{code} (d_1 \ast d_2) = \text{code} (d_1) \sqcup q_{c} T (\text{code} (d_2))
\end{equation}
where $T$ is a suitable translation of the variables and $\sqcup q_{c}$ is the quantum shuffle \cite{27} for the braiding on $V = \mathbb{C}[x_{i}; i \geq 1]$ defined by
\begin{equation}
B (x_{i_1}^{\alpha_1} x_{i_2}^{\alpha_2} \cdots x_{i_k}^{\alpha_k} \otimes y_{j_1}^{\beta_1} y_{j_2}^{\beta_2} \cdots y_{j_l}^{\beta_l}) = q_{c}^{(\sum \alpha_i) (\sum \beta_j)} y_{j_1}^{\beta_1} y_{j_2}^{\beta_2} \cdots y_{j_l}^{\beta_l} \otimes x_{i_1}^{\alpha_1} x_{i_2}^{\alpha_2} \cdots x_{i_k}^{\alpha_k}
\end{equation}

Let us add that $q_{s}$ and $q_{c}$ are of different nature as $q_{s}$ is the coefficient of a perturbation of the shuffle product (better seen on the coproduct). This kind of perturbation occurs in various domains as: computer science by means of the infiltration product introduced by Ochsenschläger \cite{28} (see also \cite{29} and \cite{30}), algebra of the Euler-Zagier sums \cite{31} and noncommutative symmetric functions \cite{20}. The mathematics of this dual aspect is of geometrical nature and will be developed in \cite{32}.

Acknowledgements

The authors are pleased to acknowledge the hospitality of institutions in Paris, Cracow and New York. Special thanks are due to Catherine Borgen for having created a fertile atmosphere in Exeter (UK) where parts of this manuscript were prepared. This work was supported by the Agence Nationale de la Recherche (Paris, France) under Program No. ANR-08-BLAN-0243-2 and by PAN/CNRS Project PICS No.4339(2008-2010) as well as the Polish Ministry of Science and Higher Education Grant No.202 10732/2832. Finally, we are grateful to Loïc Foissy and Jim Stasheff for their reading of, and comments on, the manuscript.
